12. *P is the* Pkg *provenance over* $\mathsf{MirandaTheoremFiniteCube}^{\uparrow}$, $\mathsf{SpernerLemma}^{\uparrow}$, $\mathsf{BrouwerDegree}^{\uparrow}$, $\mathsf{Compact}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
13. *N is the local* $\mathsf{NameCert}_{\mathsf{MirandaTheoremFiniteCube}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $Q, F, S, C, D, L, W, R, E, H, T, P, N$. It has no coordinate for a selected zero, unrestricted host degree, quotient real equality, open-cover compactness, countable choice, trichotomy, ambient Real completeness, Lean verification, or bridge checking.

Theorem 8607.2 (Miranda theorem finite-cube NameCert obligations)**.** *For every accepted* MirandaTheoremFiniteC *carrier*

$$M = (Q, F, S, C, D, L, W, R, E, H, T, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{MirandaTheoremFiniteCube}^{\uparrow}}$ *surface consists exactly of finite cube admission through Q, opposite-face sign exposure through F, sign-stability through S, compact cube source exposure through C, Brouwer-degree boundary obstruction through D, Sperner labelled-cell handoff through L, finite-window readback through W, R, terminal Real sealing through E, componentwise transport through H, displayed continuous-map replay through T, provenance through P, and local naming through N.*

Proof. Project the accepted carrier of Definition 8607.1. The rows Q, F, S display the finite cube, opposite-face sign data, and stability ledger that a Miranda-facing read can inspect.

Read the analytic source rows next. The compact row C gives only the named cube carrier, the continuous-map replay row T fixes how face probes are obtained from the displayed map, and the degree row D supplies only the finite boundary obstruction ledger.

The finite combinatorial handoff is L, W, R, E. The Sperner row localizes the sign conflict in a labelled subdivision, the window and regular-readback rows expose the retained cell data, and the Real seal is reached only after those rows are displayed.

Finally replay H, P, N. Transport, provenance, and local naming preserve exactly the displayed packet, so no selected zero, unrestricted host degree, quotient real equality, open-cover compactness, countable-choice schedule, trichotomy, ambient completeness, Lean verification, or bridge datum is exported. □

Theorem 8607.3 (Miranda theorem sign-change handoff)**.** *Every sign-change read accepted by a* $\mathsf{MirandaTheoremFiniteCube}^{\uparrow}$ *packet factors through*

$$\mathsf{Compact}^{\uparrow}, \quad \mathsf{ContinuousMap}^{\uparrow}, \quad \mathsf{SpernerLemma}^{\uparrow}, \quad \mathsf{BrouwerDegree}^{\uparrow}, \quad \mathsf{Real}^{\uparrow}.$$

Concretely, the consumer first reads the finite cube and opposite-face signs Q, F, S, then the compact cube and continuous-map source rows C, T, then the Sperner labelled-cell row L and Brouwer-degree obstruction row D, and only then the finite windows, regular readback, and Real seal W, R, E. The handoff exports a finite sign-change certificate, not a host zero selector or an ambient intermediate-value theorem.

Proof. Start with a sign-change request. The carrier exposes only the finite cube row Q, face-sign row F, and sign-stability row S before any downstream obstruction can be read.

The source rows are then forced. The compact row C names the cube as displayed BEDC data, and the continuous-map replay row T records how the face signs are read from the map without introducing a second function object.

Next use the finite obstruction handoff. The Sperner row L supplies the labelled subdivision route, while the Brouwer-degree row D supplies the boundary obstruction ledger attached to the same face signs.

Finally open W, R, E, H, P, N. Windowing, regular readback, Real sealing, transport, provenance, and local naming keep the candidate cell inside the same finite packet, excluding selected roots, unrestricted host degree, quotient real equality, compactness shortcuts, choice, trichotomy, and ambient completeness. □

Falsifiable prediction: Every accepted $\mathsf{MirandaTheoremFiniteCube}^{\uparrow}$ sign-change read displays a finite cube row, opposite-face sign rows, sign-stability data, compact cube source, continuous-map replay, Sperner labelled-cell handoff, Brouwer-degree obstruction, finite StreamName windows, RegSeqRat readback, Real sealing, hsame transport, Pkg provenance, and local NameCert naming.

Independence witness: sperner-lemma, brouwer-degree, compact, continuousmap, real: MirandaTheoremFiniteC is not bijective to any listed sibling because it binds finite cube face signs, sign stability, compact source, continuous-map replay, labelled-cell localization, degree obstruction, readback, Real sealing, transport, provenance, and local naming into one packet.

Closure status for $\mathsf{NameCert}_{\mathsf{MirandaTheoremFiniteCube}^{\uparrow}}$.

Constructive story: A $\mathsf{MirandaTheoremFiniteCube}^{\uparrow}$ packet is generated from finite cube rows, opposite-face sign rows, sign-stability ledgers, compact cube source rows, continuous-map replay, Sperner labelled-cell handoff rows, Brouwer-degree obstruction rows, StreamName windows, RegSeqRat readback, a terminal Real seal, componentwise hsame transport, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{MirandaTheoremFiniteCube}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8607.1, Definition 8607.2, and Definition 8607.3 seed the finite Miranda cube sign-change route through compact source, continuous-map replay, Sperner handoff, Brouwer-degree obstruction, readback, Real seal, transport, provenance, and local naming rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{MirandaTheoremFiniteCube}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host zero existence, selected roots, unrestricted degree theory, quotient real equality, open-cover compactness, countable choice, trichotomy, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, face-sign stability, compact cube source exactness, continuous-map replay, Sperner handoff, Brouwer-degree obstruction, finite readback, Real-seal ordering, transport, provenance, and local naming for BEDC.Derived.MirandaTheoremFiniteCubeUp.

Chapter 8608

A Concrete Naming Certificate for CauchyContinuityCriterion$^{\uparrow}$

Following Bishop and Bridges constructive analysis, the CauchyContinuityCriterion$^{\uparrow}$ packet records the finite test by which a displayed continuous map preserves regular Cauchy real names. It sits between the finite window surface of chapter 126, the regular rational readback of chapter 301, the dyadic tolerance core of chapter 291, the continuity-modulus schedule of chapter 292, the continuous-map carrier of chapter 130, and the terminal real-name seal of chapter 38. The packet gives Real and Completion consumers a named Cauchy-preservation boundary without importing host function equality, quotient equality of real names, selected limits, trichotomy, or ambient Real$^{\uparrow}$ completeness.

Definition 8608.1 (Cauchy continuity criterion carrier)**.** *A* CauchyContinuityCriterion$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (F, S, R, D, M, E, H, C, P, N)$$

with the following displayed rows:

1. *F is the* ContinuousMap$^{\uparrow}$ *row, including the displayed pointwise continuity evidence or modulus row used by the inspected map.*
2. *S is the* StreamName$^{\uparrow}$ *finite-window row for the source regular real name and for the target observations requested by the criterion.*
3. *R is the* RegSeqRat$^{\uparrow}$ *readback row for the regular rational names exposed by those windows.*
4. *D is the* DyadicRatCore$^{\uparrow}$ *tolerance row used to compare source and target rational cells.*
5. *M is the* CauchyModulus$^{\uparrow}$ *schedule row that assigns a finite source-window demand to each displayed target tolerance.*
6. *E is the* Real$^{\uparrow}$ *seal row reached only after the continuity row, stream windows, regular readback, dyadic tolerance, and Cauchy-modulus schedule have stayed visible.*
7. *H records componentwise* hsame *transport for the continuity row, stream windows, readbacks, dyadic tolerances, modulus schedule, real seal, replay, provenance, and local naming row.*
8. *C records displayed* Cont *replay from a target tolerance request through $F, S, R, D, M, E, H, P, N$.*
9. *P is the* Pkg *provenance over* CauchyContinuityCriterion$^{\uparrow}$, ContinuousMap$^{\uparrow}$, StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, CauchyModulus$^{\uparrow}$, Real$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

10. N is the local $\mathsf{NameCert}_{\mathsf{CauchyContinuityCriterion}^{\uparrow}}$ *row.*
The carrier predicate asserts exactly that these rows form one finite criterion packet for Cauchy-preserving continuity over displayed regular real names. It has no coordinate for a host semantic continuity theorem, quotient equality of completed real names, selected representatives, trichotomy, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 8608.2 (Cauchy continuity criterion NameCert obligations)**.** *For every accepted* CauchyContinuityCriterio *carrier $K = (F, S, R, D, M, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{CauchyContinuityCriterion}^{\uparrow}}$ *surface consists exactly of carrier admission, continuous/modulus-row exposure through F, finite StreamName window exposure through S, regular rational readback through R, dyadic tolerance exposure through D, Cauchy-modulus scheduling through M, Real sealing through E, componentwise* hsame *stability through H, displayed* Cont *replay through C,* Pkg *provenance through P, and local naming through N. No obligation is stored outside these rows.*

Proof. Project the carrier of Definition 8608.1. The accepted tuple displays exactly the continuity row, stream windows, regular readback, dyadic tolerance data, Cauchy-modulus schedule, Real seal, and structural rows.

The continuous/modulus row F supplies the map-facing input, while M supplies the finite schedule that turns each target tolerance request into a source-window demand. The rows S, R, D then display the windows, regular rational readbacks, and dyadic comparisons served by that schedule.

Finally E, H, C, P, N seal, transport, replay, package, and name the same finite route. Since the carrier has no coordinate for host semantic continuity, quotient equality, selected representatives, trichotomy, choice, or ambient Real completeness, no local obligation can export such data. □

Theorem 8608.3 (Cauchy continuity criterion Cauchy preservation)**.** *Every Real or Completion consumer of an accepted* $\mathsf{CauchyContinuityCriterion}^{\uparrow}$ *carrier reads Cauchy preservation only through the displayed route*

$$\mathsf{ContinuousMap}^{\uparrow}, \mathsf{StreamName}^{\uparrow}, \mathsf{RegSeqRat}^{\uparrow}, \mathsf{DyadicRatCore}^{\uparrow}, \mathsf{CauchyModulus}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}, \mathsf{hsame}, \mathsf{Cont}, \mathsf{Pkg}, \mathsf{NameCe}$$

Thus a displayed regular real name may be sent across the continuous row only after the source windows and dyadic tolerance schedule have been exposed, and the target real-name seal exports no host continuity theorem, quotient equality of names, selected limit, trichotomy, countable-choice schedule, or ambient completeness witness.

Proof. Start with an accepted carrier $K = (F, S, R, D, M, E, H, C, P, N)$. The continuous row F and the Cauchy-modulus row M are the only map-facing and schedule-facing coordinates available to a consumer.

Apply the NameCert obligations of Definition 8608.2. They force the consumer to expose S, R, D before the target-facing seal E can be read, so the regular Cauchy input is inspected by finite windows and dyadic tolerances rather than by a completed host object.

The structural rows H, C, P, N preserve the same route by transport, replay, provenance, and local naming. Since no excluded host datum occurs in the carrier, the exported statement is precisely Cauchy preservation through the displayed continuity criterion. □

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyContinuityCriterion}^{\uparrow}}$.

Constructive story: A $\mathsf{CauchyContinuityCriterion}^{\uparrow}$ packet is generated from a displayed continuous or modulus row, StreamName windows, RegSeqRat readbacks, DyadicRatCore tolerances, a CauchyModulus schedule, a Real seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\mathsf{CauchyContinuityCriterion}\uparrow}$, seed)

Scope closed: Definition 8608.1, Definition 8608.2, and Definition 8608.3 seed the finite Cauchy-preserving continuity boundary over displayed regular real names.

Formal verification: FormalStatus(NameCert$_{\mathsf{CauchyContinuityCriterion}\uparrow}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close host semantic continuity, quotient equality of real names, selected representatives, trichotomy, countable choice, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, continuity-row exposure, finite StreamName projection, RegSeqRat readback, DyadicRatCore tolerance routing, CauchyModulus scheduling, and Real-seal nonescape for BEDC.Derived.CauchyContinuityCriterionUp.

Chapter 8609

A Concrete Naming Certificate for $\mathsf{ChoiceSequenceWindow}^{\uparrow}$

Following Brouwer and Troelstra–van Dalen, the $\mathsf{ChoiceSequenceWindow}^{\uparrow}$ packet records the finite prefix-window object by which a displayed choice-sequence presentation is read by L10 Real and Completion consumers. It sits between the choice-sequence surface of chapter 1482, the finite stream-name interface of chapter 126, the regular rational readback of chapter 301, the dyadic tolerance core of chapter 291, and the terminal real-name seal of chapter 38. The packet names a finite inspected prefix and its routed readback; it does not import a completed branch, quotient stream equality, countable choice, a selected infinite sequence, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 8609.1 (ChoiceSequenceWindow carrier)**.** *A* $\mathsf{ChoiceSequenceWindow}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$W = (Q, S, R, D, E, H, C, P, N)$$

with the following displayed rows:

1. *Q is the* $\mathsf{ChoiceSequence}^{\uparrow}$ *prefix row, listing the finite answers already inspected from the choice sequence.*
2. *S is the* $\mathsf{StreamName}^{\uparrow}$ *window row opened from that prefix, with one displayed window for each finite read requested by the consumer.*
3. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row attached to the windows in S.*
4. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row, recording the dyadic precision request, comparison slack, and local radius ledger consumed by S and R.*
5. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached only after Q, S, R, D have been exposed.*
6. *H records componentwise* hsame *transport for the prefix, window, readback, tolerance, seal, replay, provenance, and local naming rows.*
7. *C records displayed* Cont *replay of the finite route*

$$Q \longmapsto S, R, D \longmapsto E, H, P, N.$$

8. *P is the* Pkg *provenance over* $\mathsf{ChoiceSequenceWindow}^{\uparrow}$, $\mathsf{ChoiceSequence}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*
9. *N is the local* $\mathsf{NameCert}_{\mathsf{ChoiceSequenceWindow}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $Q, S, R, D, E, H, C, P, N$. It has no coordinate for completed branches, quotient streams, countable-choice selectors, selected infinite sequences, host equality of names, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 8609.2 (ChoiceSequenceWindow NameCert obligations)**.** *For every accepted* $\mathsf{ChoiceSequenceWindow}^{\uparrow}$ *carrier*

$$W = (Q, S, R, D, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{ChoiceSequenceWindow}^{\uparrow}}$ *surface consists exactly of finite prefix admission for Q, StreamName window exposure for S, RegSeqRat readback for R, DyadicRatCore tolerance accounting for D, terminal Real seal non-escape for E, componentwise* hsame *transport through H, displayed* Cont *replay through C, sibling provenance through P, and local naming through N.*

No ChoiceSequenceWindow obligation is stored outside those rows.

Proof. Project the accepted carrier of Definition 8609.1. The source row Q is a finite prefix row, so every consumer starts with displayed choice-sequence answers rather than a completed branch.

The analytic read then passes through the L10 rows. The finite windows are displayed by S, regular rational readback is displayed by R, and the dyadic tolerance ledger is displayed by D before the terminal seal E can be read.

Finally replay H, C, P, N. Transport, continuation replay, provenance, and local naming preserve the same finite route, so the carrier cannot export quotient stream equality, countable choice, selected infinite branches, host equality of names, or ambient Real completeness. □

Theorem 8609.3 (ChoiceSequenceWindow StreamName handoff)**.** *Every StreamName, RegSeqRat, or Real-facing consumer of an accepted* $\mathsf{ChoiceSequenceWindow}^{\uparrow}$ *carrier factors through*

$$Q \longmapsto S \longmapsto R, D \longmapsto E, H, C, P, N.$$

The handoff reads the $\mathsf{ChoiceSequence}^{\uparrow}$ *prefix row before the* $\mathsf{StreamName}^{\uparrow}$ *window of chapter 126, reads the* $\mathsf{RegSeqRat}^{\uparrow}$ *row through chapter 301, checks dyadic tolerances through chapter 291, and reaches the terminal* $\mathsf{Real}^{\uparrow}$ *seal only through chapter 38. The route exports no completed branch, quotient stream equality, countable-choice selector, selected infinite sequence, host equality of names, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Begin with the finite prefix row Q. Since the carrier contains no completed choice sequence, the downstream read can only use the displayed finite answers already present in the packet.

Next expose S, R, D. The StreamName window is the only route from the prefix into name observations, the RegSeqRat row is the only regular rational readback surface, and the DyadicRatCore row is the only tolerance ledger available to the read.

The Real seal E is therefore terminal for this displayed path. The structural rows H, C, P, N preserve the same route, so any StreamName, RegSeqRat, or Real-facing handoff remains a finite prefix-window handoff rather than a quotient, choice, selected-branch, host-equality, or completeness principle. □

Closure status for $\mathsf{NameCert}_{\mathsf{ChoiceSequenceWindow}^{\uparrow}}$.

Constructive story: A $\mathsf{ChoiceSequenceWindow}^{\uparrow}$ packet is generated from a ChoiceSequence finite prefix row, StreamName windows, RegSeqRat readback, DyadicRatCore tolerances, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{ChoiceSequenceWindow}^{\uparrow}}$, seed)

Scope closed: Definition 8609.1, Definition 8609.2, and Definition 8609.3 seed the finite prefix-window packet for L10 countable-name consumers.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{ChoiceSequenceWindow}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close completed branches, quotient stream equality, countable choice, selected infinite sequences, host equality of names, ambient RealUp completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, finite prefix coverage, StreamName window routing, RegSeqRat readback, DyadicRatCore tolerance accounting, RealUp seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.ChoiceSequenceWindowUp.

Chapter 8610

A Concrete Naming Certificate for $\mathsf{RamanujanPartition}^{\uparrow}$

Following Ramanujan and Hardy–Ramanujan on congruences and finite asymptotic windows for the partition function, the $\mathsf{RamanujanPartition}^{\uparrow}$ packet records the finite BEDC surface that a partition-number consumer may inspect before reading a congruence, circle-window, or coefficient-boundary handoff. It sits beside the integer and natural-number carriers of chapter 31 and chapter 28, the polynomial and generating-series surfaces of chapter 50 and chapter 3811, and the real-facing regular readback route of chapter 301. The packet names only finite partition windows, modulus rows, coefficient ledgers, analytic-window witnesses, transport, replay, provenance, and local naming; it is not a host proof of all Ramanujan congruences, a selected infinite q-series, a quotient analytic function, or an ambient asymptotic theorem.

Definition 8610.1 (Ramanujan partition finite-window carrier)**.** *A* $\mathsf{RamanujanPartition}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$R = (N, W, M, Q, C, A, B, H, T, P, L)$$

with the following displayed rows:

1. *N is the finite* $\mathsf{Nat}^{\uparrow}$ *index-window row, listing the partition-number requests admitted by the packet.*
2. *W is the finite partition-table window, exposing the computed $p(n)$ entries for the displayed requests.*
3. *M is the modulus row for the congruence-facing prime-power or arithmetic-progression data.*
4. *Q is the coefficient-extraction row, read through a finite generating-series or polynomial window before any partition value is consumed.*
5. *C is the congruence ledger, recording the displayed divisibility or residue claim only for the finite rows in N, W, M, Q.*
6. *A is the analytic-window row, storing the Hardy–Ramanujan or circle-window estimate data as finite dyadic bounds.*
7. *B is the boundary row that separates exact finite congruence reads from asymptotic or analytic-window reads.*
8. *H records componentwise* hsame *transport for the index, partition-table, modulus, coefficient, congruence, analytic-window, boundary, replay, provenance, and local naming rows.*

9. *T records displayed* Cont *replay from a partition consumer request through* N, W, M, Q, C, A, B, H.
10. *P is the* Pkg *provenance over* $\mathsf{RamanujanPartition}^{\uparrow}$, $\mathsf{Nat}^{\uparrow}$, $\mathsf{Int}^{\uparrow}$, $\mathsf{Poly}^{\uparrow}$, $\mathsf{HadamardProductSeries}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *L is the local* $\mathsf{NameCert}_{\mathsf{RamanujanPartition}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $N, W, M, Q, C, A, B, H, T, P, L$. It has no coordinate for an infinite partition table, selected q-series, quotient analytic equality, all-moduli congruence closure, circle-method completeness, or ambient asymptotic truth.

Theorem 8610.2 (Ramanujan partition NameCert obligations)**.** *For every accepted* $\mathsf{RamanujanPartition}^{\uparrow}$ *carrier*

$$R = (N, W, M, Q, C, A, B, H, T, P, L),$$

the local $\mathsf{NameCert}_{\mathsf{RamanujanPartition}^{\uparrow}}$ *surface consists exactly of finite index admission, partition-table window exposure, modulus-row exposure, coefficient-extraction routing, congruence-ledger exactness, analytic-window boundary exposure, separation between exact and asymptotic reads, componentwise transport, displayed replay, package provenance, and local naming. No obligation is discharged by an unbounded partition table, host analytic continuation, selected infinite q-series, quotient function equality, or an ambient circle-method theorem.*

Proof. Project the carrier of Definition 8610.1. The displayed rows are exactly $N, W, M, Q, C, A, B, H, T, P, L$, so every local obligation must be read from those finite rows.

First expose the arithmetic side. The rows N and W give the finite request window and partition-table entries, while M gives the modulus data and Q gives the coefficient-extraction route that produced the displayed values.

Next separate the two consumer routes. The congruence ledger C can be read only against N, W, M, Q, and the analytic-window row A can be read only through the boundary row B. Thus a consumer cannot turn a finite congruence row into a global congruence theorem or an analytic estimate into a completed asymptotic theorem.

Finally H, T, P, L transport, replay, source, and name the same finite route. Since the excluded infinite and host-analytic objects are not carrier coordinates, they cannot appear as local NameCert obligations. □

Theorem 8610.3 (Ramanujan partition finite-window dependency route)**.** *Every congruence-facing or asymptotic-facing consumer of an accepted* $\mathsf{RamanujanPartition}^{\uparrow}$ *carrier must factor through*

$$\mathsf{Nat}^{\uparrow}, \mathsf{Int}^{\uparrow} \longmapsto N, W, M, Q \longmapsto C, A, B \longmapsto H, T, P, L.$$

The route exposes natural indices, integer partition values, coefficient windows, congruence rows, analytic-window bounds, and boundary separation before any partition-function handoff is read.

Proof. Begin with a consumer request for partition data. The carrier gives no direct access to an infinite partition function; the request first reaches the finite index row N and the finite table row W over the natural and integer carriers.

The coefficient and congruence data are then forced through M, Q, C. A congruence-facing consumer sees only the displayed modulus and coefficient route, not a theorem about all arithmetic progressions.

For analytic reads, A must pass through the boundary row B. The rows H, T, P, L then preserve, replay, source, and name the same finite dependency route. Hence the packet exports only the displayed finite-window handoff. □

Closure status for $\mathsf{NameCert}_{\mathsf{RamanujanPartition}^{\uparrow}}$.

Constructive story: A $\mathsf{RamanujanPartition}^{\uparrow}$ packet is generated from finite Nat index windows, Int partition-value rows, modulus rows, coefficient-extraction windows, congruence ledgers, Hardy–Ramanujan analytic-window bounds, boundary separation, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RamanujanPartition}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8610.1, Definition 8610.2, and Definition 8610.3 seed the finite partition-function route over displayed arithmetic windows, coefficient extraction, congruence ledgers, analytic-window bounds, transport, replay, provenance, and local naming.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RamanujanPartition}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Origin: human

Not claimed: This chapter does not close all Ramanujan congruences, infinite partition tables, selected q-series, quotient analytic equality, circle-method completeness, ambient asymptotic truth, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked finite-window admission, coefficient extraction, congruence-ledger exactness, analytic-boundary separation, structural stability, and local naming for BEDC.Derived.RamanujanPartitionUp.

Chapter 8611

A Concrete Naming Certificate for $\mathsf{BarbalatLemma}^{\uparrow}$

Following Barbalat's lemma and Bishop–Bridges constructive analysis, the $\mathsf{BarbalatLemma}^{\uparrow}$ packet records a finite uniform-continuity and tail-integral route before a $\mathsf{Real}^{\uparrow}$ seal is read. It sits beside the uniform-continuity surface of chapter 391, the regulated-integral surface of chapter 1557, the sequence-window surface of chapter 126, the regular-rational readback of chapter 301, and the real seal of chapter 38. The packet does not export a host limit, a quotient stream, or an ambient completeness theorem; it names the finite rows required to pass from uniform continuity and an integral tail budget to the displayed real readback.

Definition 8611.1 (Barbalat lemma finite carrier)**.** *A* $\mathsf{BarbalatLemma}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (M, W, U, R, E, H, C, P, N)$$

with the following displayed rows:

1. *M is the* $\mathsf{UniformContinuity}^{\uparrow}$ *modulus row, recording the finite uniform-continuity control used by the packet.*
2. *W is the* $\mathsf{StreamName}^{\uparrow}$ *window row, exposing the finite observation window over which the control is read.*
3. *U is the* $\mathsf{RegulatedIntegral}^{\uparrow}$ *tail-budget row, recording the regulated integral budget or integral tail bound used in the handoff.*
4. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row, naming the regular rational route that receives the displayed tail information.*
5. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row, read only after the modulus, window, tail budget, and readback rows are displayed.*
6. *H records componentwise* hsame *transport for M, W, U, R, E and for the continuation, provenance, and local naming rows.*
7. *C records displayed* Cont *replay from the uniform-continuity route through the tail budget, regular readback, and real seal.*
8. *P is the* Pkg *provenance over* $\mathsf{BarbalatLemma}^{\uparrow}$, $\mathsf{UniformContinuity}^{\uparrow}$, $\mathsf{RegulatedIntegral}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.

9. N is the local $\mathsf{NameCert}_{\mathsf{BarbalatLemma}^\uparrow}$ *row.*

The classifier has no coordinate for a quotient stream, a selected limit, host real equality, countable choice, or ambient completeness.

Theorem 8611.2 (Barbalat lemma NameCert obligations)**.** *For every accepted* $\mathsf{BarbalatLemma}^\uparrow$ *carrier* $B = (M, W, U, R, E, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{BarbalatLemma}^\uparrow}$ *surface consists exactly of carrier admission for the displayed* $\mathsf{UniformContinuity}^\uparrow$ *modulus,* $\mathsf{StreamName}^\uparrow$ *window,* $\mathsf{RegulatedIntegral}^\uparrow$ *tail budget,* $\mathsf{RegSeqRat}^\uparrow$ *readback, and* $\mathsf{Real}^\uparrow$ *seal, together with componentwise* hsame *transport, displayed* Cont *replay, provenance, and local naming. The interface surface is finite and does not export a host limit, a quotient stream, or an ambient completeness claim.*

Proof. Project the carrier of Definition 8611.1. The rows $M, W, U, R, E, H, C, P, N$ are the only public coordinates, so the finite NameCert surface is already listed by the carrier itself.

Replay the displayed route. Uniform continuity is read through M and W, the tail budget is read through U, the regular rational route is read through R, and the real seal is reached only after those rows have been displayed. The structural rows H, C, P, N preserve that same finite packet. □

Theorem 8611.3 (Barbalat lemma uniform continuity integral handoff)**.** *Every accepted* $\mathsf{BarbalatLemma}^\uparrow$ *carrier routes a* $\mathsf{UniformContinuity}^\uparrow$ *modulus through the displayed* $\mathsf{StreamName}^\uparrow$ *window and the* $\mathsf{RegulatedIntegral}^\uparrow$ *tail budget before the* $\mathsf{RegSeqRat}^\uparrow$ *readback can reach the terminal* $\mathsf{Real}^\uparrow$ *seal. The handoff therefore uses the finite rows* $M, W, U, R, E, H, C, P, N$ *and no consumer may bypass* U *or replace the regulated-integral route by a host limit, selected completeness principle, or quotient-stream equality.*

Proof. Start from the carrier definition. The route is explicitly staged as modulus, window, tail budget, readback, and seal, so the integral handoff is not an ambient principle but a displayed finite route.

Now replay the structural rows. The hsame row preserves the same packet, the Cont row replays the same finite handoff, and the provenance and naming rows keep the route attached to the same accepted $\mathsf{BarbalatLemma}^\uparrow$ carrier. Since the packet has no additional coordinate, no bypass can replace the regulated-integral row U. □

Closure status for $\mathsf{NameCert}_{\mathsf{BarbalatLemma}^\uparrow}$.

Constructive story: A $\mathsf{BarbalatLemma}^\uparrow$ packet is generated from a $\mathsf{UniformContinuity}^\uparrow$ modulus row, a $\mathsf{StreamName}^\uparrow$ window row, a $\mathsf{RegulatedIntegral}^\uparrow$ tail budget row, a $\mathsf{RegSeqRat}^\uparrow$ readback row, a $\mathsf{Real}^\uparrow$ seal row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BarbalatLemma}^\uparrow}, \mathsf{seed})$

Scope closed: Definition 8611.1, Definition 8611.2, and Definition 8611.3 seed the finite Barbalat route from uniform continuity and regulated integral tail data to the real seal.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BarbalatLemma}^\uparrow}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close a proof of Barbalat's lemma, quotient stream equality, selected limits, host real equality, countable choice, or ambient completeness.

Upgrade path: Obligation closure requires checked carrier admission, uniform-continuity routing, regulated-integral tail exactness, regular-rational readback, real-seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.BarbalatLemm

Chapter 8612

A Concrete Naming Certificate for DyadicSqueezeLemma$^{\uparrow}$

Following Bishop and Bridges constructive analysis, the DyadicSqueezeLemma$^{\uparrow}$ packet isolates the finite dyadic tolerance sandwich used when a middle regular-rational observation row is trapped between lower and upper dyadic rows before an L10 Real or Completion consumer can see the terminal seal. It sits over the dyadic endpoint core of chapter 291, the finite observation schedule of chapter 126, the regular rational readback route of chapter 301, the regular Cauchy enclosure of chapter 1772, the dyadic lower/upper route of chapter 3627, and the terminal real-name seal of chapter 38. The packet names a local dyadic tolerance lemma; it is not quotient stream equality, host trichotomy, a selected limit, countable choice, or ambient Real$^{\uparrow}$ completeness.

Definition 8612.1 (Dyadic squeeze lemma carrier)**.** *A* DyadicSqueezeLemma$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S_{\mathrm{dy}} = (L, M, U, W, D, R, H, C, P, N)$$

with the following displayed rows:

1. *L is the lower dyadic row, listing the inspected lower endpoints and their finite comparison witnesses.*
2. *M is the middle* RegSeqRat$^{\uparrow}$ *observation row whose displayed rational values are being squeezed.*
3. *U is the upper dyadic row, listing the inspected upper endpoints and their matching comparison witnesses.*
4. *W is the shared* StreamName$^{\uparrow}$ *finite-window row on which L, M, U are jointly observed.*
5. *D is the* DyadicRatCore$^{\uparrow}$ *tolerance budget, recording the dyadic radius, split slack, and endpoint arithmetic used by the sandwich.*
6. *R is the* RegSeqRat$^{\uparrow}$ *handoff row that exports the middle observations only after the dyadic bounds and shared window have been displayed.*
7. *H records componentwise* hsame *transport for lower rows, middle observations, upper rows, shared windows, dyadic budgets, handoff rows, replay rows, provenance, and local naming.*
8. *C records displayed* Cont *replay from each Real-facing squeeze request through $L, M, U, W, D, R, H, P, N$ before any terminal seal is visible.*
9. *P is the* Pkg *provenance over* DyadicSqueezeLemma$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, RegularCauchySqueeze$^{\uparrow}$, DyadicSandwich$^{\uparrow}$, Real$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

10. *N is the local* $\mathsf{NameCert}_{\mathsf{DyadicSqueezeLemma}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $L, M, U, W, D, R, H, C, P, N$. It has no coordinate for quotient stream equality, host trichotomy, selected limits, countable choice, or an ambient completeness principle for $\mathsf{Real}^{\uparrow}$.

Theorem 8612.2 (Dyadic squeeze lemma NameCert obligations)**.** *For every accepted* $\mathsf{DyadicSqueezeLemma}^{\uparrow}$ *carrier*

$$S_{\mathrm{dy}} = (L, M, U, W, D, R, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{DyadicSqueezeLemma}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the lower dyadic row, middle regular-rational observation row, upper dyadic row, shared finite window, dyadic tolerance budget, RegSeqRat handoff, transport, replay, provenance, and local naming;*
2. *lower-to-middle dyadic boundedness, requiring each displayed middle observation in M to lie above the matching lower endpoint in L on the shared window W at the budget in D;*
3. *middle-to-upper dyadic boundedness, requiring the same displayed middle observation to lie below the matching upper endpoint in U on W at the budget in D;*
4. *shared-window stability, requiring all lower, middle, and upper reads to use the same finite observation row W;*
5. *tolerance exactness, requiring D to be the sole dyadic budget consumed by both comparison sides and by the exported handoff;*
6. *RegSeqRat handoff, requiring R to expose the middle regular-rational route only after L, M, U, W, D have been read;*
7. *Real-seal nonescape, requiring every* $\mathsf{Real}^{\uparrow}$ *consumer to pass through the same dyadic and regular-rational rows before any terminal seal is available;*
8. *componentwise transport, displayed replay, provenance, and local naming through H, C, P, N;*
9. *refusal of quotient stream equality, host trichotomy, selected limits, countable choice, ambient* $\mathsf{Real}^{\uparrow}$ *completeness, Lean verification, and bridge checking as local certificate data.*

No dyadic squeeze lemma obligation is stored outside these rows.

Proof. Project the accepted packet $S_{\mathrm{dy}} = (L, M, U, W, D, R, H, C, P, N)$. The carrier exposes exactly the lower dyadic row, middle observation row, upper dyadic row, shared window, dyadic tolerance budget, RegSeqRat handoff, and the structural rows, so carrier admission and provenance are exhausted by those coordinates.

The two boundedness clauses are the two faces of the displayed dyadic sandwich. The lower-to-middle comparison and the middle-to-upper comparison both read the same middle row M, the same finite window W, and the same budget D.

Shared-window stability and tolerance exactness follow from the absence of any alternate schedule or radius coordinate. The packet cannot name a second window for one side of the squeeze, and it cannot replace the displayed dyadic budget with an external real-order comparison.

The handoff row R is downstream of L, M, U, W, D. The sibling routes of chapter 1772 and chapter 3627 consume exactly such displayed regular-rational and dyadic sandwich data before a Real-facing read is exposed.

Finally H, C, P, N transport, replay, source, and locally name the same route. Since the carrier has no quotient stream, trichotomy, selected-limit, countable-choice, ambient-completeness, Lean-verification, or bridge-checking coordinate, the listed obligations exhaust the local $\mathsf{NameCert}_{\mathsf{DyadicSqueezeLemma}^{\uparrow}}$ surface. □

Theorem 8612.3 (Dyadic squeeze lemma Real handoff)**.** *Every* $\mathsf{Real}^{\uparrow}$*-facing squeeze read from an accepted* $\mathsf{DyadicSqueezeLemma}^{\uparrow}$ *carrier factors through*

$$\mathsf{DyadicRatCore}^{\uparrow} \longrightarrow \mathsf{StreamName}^{\uparrow} \longrightarrow \mathsf{RegSeqRat}^{\uparrow} \longrightarrow \left(\mathsf{RegularCauchySqueeze}^{\uparrow},\ \mathsf{DyadicSandwich}^{\uparrow}\right) \longrightarrow \mathsf{Real}^{\uparrow}$$

before the seal is visible. The exported read is a finite dyadic tolerance sandwich for the middle regular-rational row; it exports no quotient stream equality, host trichotomy, selected limit, countable-choice principle, or ambient $\mathsf{Real}^{\uparrow}$ *completeness theorem.*

Proof. Start from an accepted carrier $S_{\mathrm{dy}} = (L, M, U, W, D, R, H, C, P, N)$. The dyadic data are read through L, U, D, so every endpoint comparison and tolerance request first enters the $\mathsf{DyadicRatCore}^{\uparrow}$ ledger.

The finite observations are fixed by W. The middle row M and the handoff row R can therefore expose only the $\mathsf{RegSeqRat}^{\uparrow}$ observations scheduled by the displayed $\mathsf{StreamName}^{\uparrow}$ window.

The regular Cauchy and dyadic sandwich consumers read the same data in the same order. The route of chapter 1772 uses the middle regular-rational row and shared windows, while the route of chapter 3627 uses the lower and upper dyadic bounds with the dyadic budget.

Only after those rows have been replayed through C and transported through H can P, N package the result for the terminal $\mathsf{Real}^{\uparrow}$ read. No remaining coordinate supplies a quotient stream equality test, a host trichotomy case split, a selected limit, countable choice, or ambient Real completeness, so the displayed factorization is exhaustive. □

Closure status for $\mathsf{NameCert}_{\mathsf{DyadicSqueezeLemma}^{\uparrow}}$**.**

Constructive story: A $\mathsf{DyadicSqueezeLemma}^{\uparrow}$ packet is generated from lower and upper dyadic rows, a middle RegSeqRat observation row, shared StreamName windows, one DyadicRatCore tolerance budget, a RegSeqRat handoff, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{DyadicSqueezeLemma}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8612.1, Definition 8612.2, and Definition 8612.3 seed the finite dyadic tolerance sandwich route used by Real and Completion consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{DyadicSqueezeLemma}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient stream equality, host trichotomy, selected limits, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, lower-to-middle bounds, middle-to-upper bounds, shared-window stability, tolerance exactness, RegSeqRat handoff, Real-seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.DyadicSqueezeLemmaUp.

Chapter 8613

A Concrete Naming Certificate for $\mathsf{CompactContractionOrbit}^{\uparrow}$

Following Banach and Bishop–Bridges constructive analysis, the $\mathsf{CompactContractionOrbit}^{\uparrow}$ packet records the finite Picard-orbit data consumed before a compact contraction read is allowed to seal a fixed-point endpoint. It sits between the compact metric source of chapter 129, the complete metric admission boundary of chapter 128, the Lipschitz and contraction-map rows of chapter 410 and chapter 1418, the Banach fixed-point endpoint of chapter 396, and the dyadic finite-cell readback of chapter 5966. The carrier names the finite orbit corridor only; it does not assert a selected fixed point, quotient orbit equality, open-cover compactness, or ambient completeness beyond the displayed rows.

Definition 8613.1 (CompactContractionOrbit carrier)**.** *A* $\mathsf{CompactContractionOrbit}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$O = (K, D, L, T, I, Q, R, E, H, C, P, N)$$

with the following displayed rows:

1. *K is the* $\mathsf{CompactMetric}^{\uparrow}$ *source row, exposing only the inspected compact metric windows and finite-net identifiers.*
2. *D is the* $\mathsf{DyadicIntervalNet}^{\uparrow}$ *cell row used to name the finite orbit windows and tolerance cells consumed by the compact source.*
3. *L is the* $\mathsf{LipschitzMap}^{\uparrow}$ *graph row for the displayed self-map, read before any contraction comparison is inspected.*
4. *T is the* $\mathsf{ContractionMapping}^{\uparrow}$ *row, including the strict contraction ledger and adjacent Picard comparison surface.*
5. *I is the finite Picard-orbit row, listing the displayed iterates and their predecessor links.*
6. *Q is the* $\mathsf{CompleteMetric}^{\uparrow}$ *admission row that records where the finite orbit may be handed to a Cauchy-facing consumer.*
7. *R is the regular tolerance readback attached to the dyadic cells and Picard comparisons.*
8. *E is the terminal* $\mathsf{BanachFixedPoint}^{\uparrow}$ *endpoint-request row, readable only after K, D, L, T, I, Q, R have been exposed.*
9. *H records componentwise* hsame *transport for the compact source, dyadic cells, map rows, orbit rows, admission row, endpoint row, replay, provenance, and local naming rows.*

10. *C records displayed* Cont *replay of the finite route*

$$K, D \longmapsto L, T \longmapsto I, Q, R \longmapsto E, H, P, N.$$

11. *P is the* Pkg *provenance over* CompactContractionOrbit$^{\uparrow}$, CompactMetric$^{\uparrow}$, CompleteMetric$^{\uparrow}$, LipschitzMap$^{\uparrow}$, ContractionMapping$^{\uparrow}$, BanachFixedPoint$^{\uparrow}$, DyadicIntervalNet$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*

12. *N is the local* NameCert$_{\text{CompactContractionOrbit}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $K, D, L, T, I, Q, R, E, H, C, P, N$. It has no coordinate for host fixed-point equality, a selected limit, quotient orbit equality, open-cover compactness, or ambient complete metric data outside the displayed admission row.

Theorem 8613.2 (CompactContractionOrbit NameCert obligations)**.** *For every accepted* CompactContractionOrbi *carrier*

$$O = (K, D, L, T, I, Q, R, E, H, C, P, N),$$

the local NameCert$_{\text{CompactContractionOrbit}^{\uparrow}}$ *surface consists exactly of compact-metric source visibility for K, dyadic finite-cell visibility for D, Lipschitz graph visibility for L, contraction ledger visibility for T, finite Picard-orbit visibility for I, completion-admission visibility for Q, tolerance readback for R, Banach endpoint-request visibility for E, componentwise* hsame *transport through H, displayed* Cont *replay through C, sibling provenance through P, and local naming through N.*

No CompactContractionOrbit obligation is stored outside those rows.

Proof. Project the accepted carrier of Definition 8613.1. The compact source and dyadic cell rows K, D are read first, so the orbit corridor starts from displayed finite windows rather than from an ambient compactness theorem.

Next expose the map rows. The Lipschitz graph row L names the self-map surface, while the contraction row T records the strict comparison data used by the Picard step ledger.

The orbit and endpoint rows then become readable in order. The finite Picard row I, completion-admission row Q, and tolerance row R are present before the Banach endpoint request E can be inspected. Transport, replay, provenance, and local naming preserve this same order through H, C, P, N. □

Theorem 8613.3 (CompactContractionOrbit Cauchy handoff)**.** *Every completion-facing or fixed-point-facing consumer of an accepted* CompactContractionOrbit$^{\uparrow}$ *carrier factors through*

$$K, D \longmapsto L, T \longmapsto I, Q, R \longmapsto E, H, C, P, N.$$

The consumer must read the CompactMetric$^{\uparrow}$ *source row, the* DyadicIntervalNet$^{\uparrow}$ *finite-cell row, the* LipschitzMap$^{\uparrow}$ *graph row, the* ContractionMapping$^{\uparrow}$ *contraction row, the finite Picard orbit, and the* CompleteMetric$^{\uparrow}$ *admission row before any* BanachFixedPoint$^{\uparrow}$ *endpoint request is consumed. The route exports no selected fixed point, quotient orbit equality, open-cover compactness, host map equality, or ambient completeness outside the displayed admission row.*

Proof. Begin with the finite compact source. The rows K and D expose the compact metric windows and dyadic cells that bound the orbit data available to the consumer.

Then read the self-map and contraction rows. The graph row L supplies the displayed map surface, while T supplies the contraction comparison needed to interpret adjacent Picard steps.

Finally use the finite-orbit corridor I, Q, R, E, H, C, P, N. The completion-admission row and tolerance readback are visible before the endpoint request, so any downstream Cauchy or fixed-point consumer receives only the displayed Picard corridor rather than a selected endpoint or an ambient compactness principle. □

Closure status for $\mathsf{NameCert}_{\mathsf{CompactContractionOrbit}^{\uparrow}}$.

Constructive story: A $\mathsf{CompactContractionOrbit}^{\uparrow}$ packet is generated from a CompactMetric source row, a DyadicIntervalNet finite-cell row, LipschitzMap and ContractionMapping self-map rows, a finite Picard orbit, a CompleteMetric admission row, tolerance readback, a BanachFixedPoint endpoint-request row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CompactContractionOrbit}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8613.1, Definition 8613.2, and Definition 8613.3 seed the finite compact contraction orbit corridor consumed before fixed-point sealing.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CompactContractionOrbit}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close selected fixed points, quotient orbit equality, open-cover compactness, host map equality, ambient complete metric data, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, compact source visibility, dyadic cell visibility, Lipschitz and contraction map routing, finite Picard orbit coverage, completion admission, endpoint-request nonescape, transport, replay, provenance, and local naming for BEDC.Derived.CompactContractionOrbitUp.

Chapter 8614

A Concrete Naming Certificate for $\mathsf{UniformApartnessSpace}^{\uparrow}$

Following Bishop and Bridges on apartness spaces and Kelley on uniform entourages, the $\mathsf{UniformApartnessSpace}^{\uparrow}$ packet records the constructive interface where uniform smallness and positive apartness are read from the same finite carrier. It sits after the entourage rows of chapter 339, the positive-gap rows of chapter 1514, the metric apartness handoff of chapter 3505, the completion transport of chapter 2192, and the filter criterion of chapter 3885. The packet supplies a separated uniform apartness interface for constructive completion consumers; it does not introduce quotient completion, choice, ambient host equality, real trichotomy, or a selected completion point.

Definition 8614.1 (UniformApartnessSpace carrier)**.** *A* $\mathsf{UniformApartnessSpace}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$U = (X, E, A, M, F, K, S, R, H, C, P, N)$$

with the following displayed rows:

1. *X is the common carried-object row and local point classifier.*
2. *E is the* $\mathsf{UniformSpace}^{\uparrow}$ *entourage source row over X.*
3. *A is the* $\mathsf{ApartnessSpace}^{\uparrow}$ *positive-apartness source row over the same carried observations.*
4. *M is the* $\mathsf{MetricApartness}^{\uparrow}$ *compatibility row, reading positive metric distance as apartness evidence without importing host inequality.*
5. *F is the* $\mathsf{MetricCompletionFunctor}^{\uparrow}$ *handoff row for uniformly continuous maps between completion packets.*
6. *K is the* $\mathsf{CauchyFilterCompletionCriterion}^{\uparrow}$ *filter-criterion row used by completion consumers that read uniform Cauchy data.*
7. *S is the separated-uniform boundary row: if a consumer has only uniform smallness and no displayed apartness evidence, it must remain inside the separated classifier boundary before treating two names as identified.*
8. *R is the row that relates an entourage request, a positive-apartness request, and the metric-apartness witness to one finite readback route.*
9. *H records componentwise* hsame *transport for the carried object, uniform source, apartness source, metric-apartness compatibility, completion-functor handoff, filter criterion, separated boundary, readback, provenance, and local naming rows.*

10. *C records displayed* Cont *replay from a completion-facing request through the rows $E, A, M, F, K, S, R, H, P, N$.*
11. *P is the* Pkg *provenance over* $\mathsf{UniformSpace}^{\uparrow}$, $\mathsf{ApartnessSpace}^{\uparrow}$, $\mathsf{MetricApartness}^{\uparrow}$, $\mathsf{MetricCompletionFunctor}^{\uparrow}$, $\mathsf{CauchyFilterCompletionCriterion}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*
12. *N is the local* $\mathsf{NameCert}_{\mathsf{UniformApartnessSpace}^{\uparrow}}$ *row.*

The carrier is finite and row-visible. It carries no quotient of Cauchy filters, no selected representative, no choice principle, no host equality predicate, and no route that turns absence of apartness into equality outside the displayed separated-uniform boundary.

Theorem 8614.2 (UniformApartnessSpace NameCert obligations)**.** *For every accepted* $\mathsf{UniformApartnessSpace}^{\uparrow}$ *carrier $U = (X, E, A, M, F, K, S, R, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{UniformApartnessSpace}^{\uparrow}}$ *surface consists exactly of carrier admission for the displayed rows, classifier stability under componentwise* hsame *transport, entourage-apartness readback through R, completion handoff through F and K, separated-uniform nonescape through S, visible* Cont *replay through C, package provenance through P, and local naming through N. Every consumer read is forced through the finite route*

$$X, E, A, M, F, K, S, R \longmapsto H, C, P, N.$$

No NameCert row exports quotient completion, choice, ambient host equality, real trichotomy, selected representatives, or equality from mere absence of positive apartness.

Proof. Project the carrier of Definition 8614.1. The rows X, E, A, M, F, K, S, R are the only mathematical rows available to a consumer, while H, C, P, N record transport, replay, provenance, and naming.

Classifier stability is componentwise. The stored hsame rows move the uniform source, apartness source, metric-apartness witness, completion handoff, filter criterion, separated boundary, and readback row together, and the Cont row replays the same finite request after transport.

The excluded principles cannot be read because the carrier has no coordinate for a quotient completion, selected representative, choice function, host equality predicate, real trichotomy, or equality-by-non-apartness rule. Thus the listed rows exhaust the local NameCert surface. □

Theorem 8614.3 (UniformApartnessSpace completion-filter handoff)**.** *Every* $\mathsf{MetricCompletionFunctor}^{\uparrow}$ *or* $\mathsf{CauchyFilterCompletionCriterion}^{\uparrow}$ *consumer of an accepted* $\mathsf{UniformApartnessSpace}^{\uparrow}$ *packet must first read the route*

$$E, A, M, F, K, S, R, H, C, P, N.$$

The functor row F supplies only the displayed map and extension handoff named by chapter 2192; the criterion row K supplies only the displayed Cauchy-filter completion test named by chapter 3885. Neither row may replace the packet by quotient completion, selected limits, choice, or host equality.

Proof. Begin with a completion-facing request. The uniform source row E identifies the entourage data being consumed, and the apartness source row A records the positive information available on the same carried observations.

The metric-apartness row M translates positive metric distance into the apartness interface, while F and K expose the two completion-facing handoffs. These handoffs are read as finite rows of the same packet, not as external quotient objects.

The separated boundary S and readback row R keep the consumer inside the displayed uniform-apartness interface. Transport, replay, provenance, and naming then pass through H, C, P, N, so no hidden completion quotient, selected point, choice function, or host equality is exported. □

Theorem 8614.4 (UniformApartnessSpace separated uniform nonescape)**.** *Let* $U = (X, E, A, M, F, K, S, R, H, C,$ *be an accepted* $\mathsf{UniformApartnessSpace}^{\uparrow}$ *carrier. If a downstream consumer has only a uniform smallness read from* E *and lacks a displayed positive-apartness read through* A *and* M*, then every equality-facing read remains confined to the separated boundary row* S*. The packet therefore prevents a completion or filter consumer from treating uniform nearness, absence of apartness, or zero-distance notation as host equality.*

Proof. Inspect the rows of Definition 8614.1. Uniform smallness is stored in E, positive apartness is stored through A and M, and equality-facing access is represented only by the separated boundary row S.

A consumer that lacks the positive-apartness route cannot use R to produce a positive separation witness, and it cannot bypass S because the packet has no host equality row. The completion handoff rows F and K are downstream readers of the same boundary, not constructors of ambient equality.

Thus every equality-facing read remains inside S and is transported or replayed only by H and C with provenance P and local naming N. □

Falsifiable prediction: Every accepted $\mathsf{UniformApartnessSpace}^{\uparrow}$ completion-facing read factors through UniformSpace, ApartnessSpace, MetricApartness, MetricCompletionFunctor, CauchyFilterCompletionCriterion, separated-boundary, readback, transport, continuation, provenance, and NameCert rows.

Independence witness: uniformspace, apartnessspace, metricapartness, metriccompletionfunctor, cauchyfiltercompletioncriterion: $\mathsf{UniformApartnessSpace}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries a shared uniform source, positive apartness, metric-apartness compatibility, completion-functor handoff, filter-criterion handoff, separated-uniform boundary, readback, transport, replay, provenance, and local naming as one packet.

Closure status for $\mathsf{NameCert}_{\mathsf{UniformApartnessSpace}^{\uparrow}}$.

Constructive story: A $\mathsf{UniformApartnessSpace}^{\uparrow}$ packet is generated from a common carried-object row, a UniformSpace entourage row, an ApartnessSpace positive-apartness row, a MetricApartness compatibility row, MetricCompletionFunctor and CauchyFilterCompletionCriterion handoff rows, a separated-uniform boundary, readback, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{UniformApartnessSpace}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8614.1, Definition 8614.2, Definition 8614.3, and Definition 8614.4 seed the constructive uniform apartness interface for separated completion-facing consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{UniformApartnessSpace}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient completion, choice, host equality, real trichotomy, selected representatives, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, entourage-apartness readback, completion handoff, separated-uniform nonescape, componentwise transport, replay, provenance, and local naming for BEDC.Derived.UniformApartnessSpaceU

Chapter 8615

A Concrete Naming Certificate for $\mathsf{CauchyCompletenessRate}^{\uparrow}$

Following Bishop and Bridges on Cauchy completeness with displayed moduli, the $\mathsf{CauchyCompletenessRate}^{\uparrow}$ packet records the finite rate-extraction surface by which Real and Completion consumers read a Cauchy rate before treating $\mathsf{Real}^{\uparrow}$ as a completed object. It sits after the rational telescoping route of chapter 5922, the diagonal tail route of chapter 5923, the regular Cauchy telescoping budget of chapter 708, the dyadic tolerance core of chapter 291, the finite stream windows of chapter 126, the regular rational readback of chapter 301, and the terminal real-name seal of chapter 38. The packet is a finite L10 object for extracting displayed Cauchy rates; it is not quotient stream equality, a selected host limit, countable choice, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 8615.1 (Cauchy completeness rate carrier)**.** *A* $\mathsf{CauchyCompletenessRate}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (T, D, B, Q, W, R, E, M, H, C, P, N)$$

with the following displayed rows:

1. *T is the* $\mathsf{RationalCauchyTelescope}^{\uparrow}$ *source row naming the finite rational telescope whose tail is being read.*
2. *D is the* $\mathsf{BishopDiagonalCauchyTelescope}^{\uparrow}$ *diagonal-tail row that exposes the family-indexed Cauchy tail windows.*
3. *B is the* $\mathsf{RegularCauchyTelescopingBudget}^{\uparrow}$ *row recording the displayed budget for reusing those telescope windows as a regular Cauchy schedule.*
4. *Q is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, carrying the requested dyadic rate bound and slack used by the extraction.*
5. *W is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row naming the observed stages of the Cauchy stream.*
6. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *regular rational readback row obtained from T, D, B, Q, W.*
7. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached only after the rate row and readback row have been displayed.*
8. *M is the extracted modulus row, saying that each accepted precision request is discharged by the visible dyadic budget Q and the displayed telescope rows T, D, B, W before the seal E is read.*
9. *H records componentwise* hsame *transport for $T, D, B, Q, W, R, E, M, C, P, N$.*

10. *C records displayed* Cont *replay of the route from the telescope rows through the extracted modulus to the terminal seal.*
11. *P is the* Pkg *provenance over* $\mathsf{CauchyCompletenessRate}^{\uparrow}$, $\mathsf{RationalCauchyTelescope}^{\uparrow}$, $\mathsf{BishopDiagonalCauchyTelesc}$ $\mathsf{RegularCauchyTelescopingBudget}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
12. *N is the local* $\mathsf{NameCert}_{\mathsf{CauchyCompletenessRate}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $T, D, B, Q, W, R, E, M, H, C, P, N$. It has no coordinate for quotient streams, selected host limits, countable choice, trichotomy, selected host bounds, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 8615.2 (Cauchy completeness rate NameCert obligations)**.** *For every accepted* $\mathsf{CauchyCompletenessRate}^{\uparrow}$ *carrier $K = (T, D, B, Q, W, R, E, M, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{CauchyCompletenessRate}^{\uparrow}}$ *surface consists exactly of rational telescope admission, diagonal-tail admission, regular telescoping-budget admission, dyadic tolerance visibility, finite-window exposure, regular rational readback, terminal Real seal handoff, extracted-modulus exactness, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming.*

Proof. Project the carrier of Definition 8615.1. The rows T, D, B, Q, W, R, E, M are the only mathematical data available before transport, replay, provenance, and local naming.

The telescope rows T, D, B expose the source rational telescope, its diagonal tail, and the regular telescoping budget. The dyadic ledger Q and stream window W then display the concrete precision request and the stages at which it is checked.

The regular rational row R and the terminal seal E are downstream of those displayed rows. The extracted modulus M names only the finite discharge of the same visible request, so it cannot import a quotient stream, selected host limit, countable choice, trichotomy, selected host bound, or ambient completeness coordinate.

Finally, H, C, P, N transport, replay, source, and name the same route. Since the carrier has no further coordinate, the listed rows exhaust the NameCert obligation surface. □

Theorem 8615.3 (Cauchy completeness rate modulus extraction)**.** *Every Real-facing or Completion-facing consumer of an accepted* $\mathsf{CauchyCompletenessRate}^{\uparrow}$ *packet must read the extracted rate through the displayed route*

$\mathsf{RationalCauchyTelescope}^{\uparrow}$, $\mathsf{BishopDiagonalCauchyTelescope}^{\uparrow}$, $\mathsf{RegularCauchyTelescopingBudget}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, S

In particular, the modulus row M is visible before the terminal $\mathsf{Real}^{\uparrow}$ *seal E is consumed, and the handoff exports no quotient stream, selected limit, countable choice, trichotomy, selected host bound, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness principle.*

Proof. Start from an accepted carrier $K = (T, D, B, Q, W, R, E, M, H, C, P, N)$. The source telescope T is inspected through the diagonal-tail row D and the regular telescoping budget B.

The precision request is then read from the dyadic ledger Q on the finite windows W. The extracted modulus row M records that this displayed budget discharges the accepted Cauchy-rate request.

Only after the rate row has been displayed may the consumer read R as a $\mathsf{RegSeqRat}^{\uparrow}$ row and pass to the terminal $\mathsf{Real}^{\uparrow}$ seal E. The structural rows H, C, P, N preserve the same route under transport, replay, provenance, and local naming.

Because no other row exists in the carrier, a completion consumer cannot replace the displayed extraction by quotient streams, selected representatives, countable choice, trichotomy, selected host bounds, or ambient completeness. □

Falsifiable prediction: Every accepted $\mathsf{CauchyCompletenessRate}^{\uparrow}$ Real or Completion consumer reads RationalCauchyTelescope, BishopDiagonalCauchyTelescope, RegularCauchyTelescopingBudget, DyadicRatCore, StreamName, RegSeqRat, RealUp, extracted modulus, hsame transport, Cont replay, Pkg provenance, and local NameCert rows before using the displayed Cauchy rate.

Independence witness: rational-cauchy-telescope, bishop-diagonal-cauchy-telescope, regular-cauchy-telescoping-budget, dyadicratcore, streamname, regseqrat, real: $\mathsf{CauchyCompletenessRate}^{\uparrow}$ is not bijective to any listed sibling because the siblings separately provide telescope rows, diagonal tails, budget rows, tolerance ledgers, finite windows, regular rational readback, and terminal sealing, while this packet binds them into one displayed rate-extraction carrier.

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyCompletenessRate}^{\uparrow}}$.

Constructive story: A $\mathsf{CauchyCompletenessRate}^{\uparrow}$ packet is generated from RationalCauchyTelescope, BishopDiagonalCauchyTelescope, RegularCauchyTelescopingBudget, DyadicRatCore, StreamName, RegSeqRat, RealUp, extracted modulus, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CauchyCompletenessRate}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8615.1, Definition 8615.2, and Definition 8615.3 seed the finite L10 rate-extraction route from telescope rows to a displayed Real seal.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CauchyCompletenessRate}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient streams, selected host limits, countable choice, trichotomy, selected host bounds, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, telescope admission, diagonal-tail admission, budget admission, dyadic tolerance exposure, finite-window exposure, RegSeqRat handoff, Real seal handoff, extracted-modulus exactness, transport, replay, and ledger non-escape for BEDC.Derived.CauchyCompletenessRateUp.

Chapter 8616

A Concrete Naming Certificate for $\mathsf{UniformCompletionReflection}^{\uparrow}$

Following Bishop and Bridges and Kelley-style constructive uniform completion, the $\mathsf{UniformCompletionReflection}^{\uparrow}$ packet records the finite reflector route by which a uniform source is sent to a separated completion-facing object without quotienting Cauchy filters or selecting limits. It sits beside the dense-source route of chapter 3542, the metric dense embedding of chapter 3351, the separated completion reflection of chapter 3543, and the uniform-space completion packet of chapter 3560. Its finite readback rows are anchored by chapter 126, chapter 301, chapter 291, and the terminal real-name seal of chapter 38.

Definition 8616.1 (Uniform completion reflection carrier)**.** *A* $\mathsf{UniformCompletionReflection}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$U = (S, F, D, E, R, W, Q, Z, H, C, P, N)$$

with the following displayed rows:

1. *S is the source uniformity row, exposing the uniform entourage data admitted by the reflector.*
2. *F is the Cauchy-filter window row, recording the finite filter requests inspected before a completion-facing read is accepted.*
3. *D is the dense embedding row, read through* $\mathsf{CauchyCompletionDensitySource}^{\uparrow}$ *and* $\mathsf{MetricCompletionDenseEmbedd}$ *before any reflected completion point is public.*
4. *E is the separated reflection row, read through* $\mathsf{SeparatedCompletionReflection}^{\uparrow}$ *before the completion-facing seal can be compared.*
5. *R is the universal arrow row, recording the* $\mathsf{UniformSpaceCompletion}^{\uparrow}$ *handoff available to uniform-continuous consumers.*
6. *W is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row used to inspect Cauchy-filter evidence.*
7. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for regular rational observations extracted from the displayed windows.*
8. *Z is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger and terminal* $\mathsf{Real}^{\uparrow}$ *sealing route for the inspected comparison.*
9. *H records componentwise* hsame *transport for $S, F, D, E, R, W, Q, Z, C, P, N$.*

10. *C records displayed* Cont *replay from a reflector request through the source uniformity, Cauchy-filter windows, dense embedding, separated reflection, universal arrow, numerical readback, transport, provenance, and local naming rows.*

11. *P is the* Pkg *provenance over* $\mathsf{UniformCompletionReflection}^{\uparrow}$, $\mathsf{CauchyCompletionDensitySource}^{\uparrow}$, $\mathsf{MetricCompletionDenseEmbedding}^{\uparrow}$, $\mathsf{SeparatedCompletionReflection}^{\uparrow}$, $\mathsf{UniformSpaceCompletion}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

12. *N is the local* $\mathsf{NameCert}_{\mathsf{UniformCompletionReflection}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $S, F, D, E, R, W, Q, Z, H, C, P, N$. It has no coordinate for quotient completion classes, selected filter representatives, selected limits, countable choice, host equality of completed points, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 8616.2 (Uniform completion reflection NameCert obligations)**.** *For every accepted* $\mathsf{UniformCompletionReflection}^{\uparrow}$ *carrier $U = (S, F, D, E, R, W, Q, Z, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{UniformCompletionRefl}}$ *surface consists exactly of source uniformity admission, Cauchy-filter window exposure, dense embedding exposure through* $\mathsf{CauchyCompletionDensitySource}^{\uparrow}$ *and* $\mathsf{MetricCompletionDenseEmbedding}^{\uparrow}$, *separated reflection exposure through* $\mathsf{SeparatedCompletionReflection}^{\uparrow}$, *universal-arrow exposure through* $\mathsf{UniformSpaceCompletion}^{\uparrow}$, *StreamName finite windows, RegSeqRat readback, DyadicRatCore tolerance and* $\mathsf{Real}^{\uparrow}$ *sealing, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming.*

Proof. Project the accepted carrier of Definition 8616.1. The tuple displays the source uniformity, Cauchy-filter windows, dense embedding, separated reflection, universal arrow, finite windows, regular rational readback, dyadic and Real sealing, transport, replay, provenance, and local naming rows.

The completion-facing obligations are downstream from the finite source evidence. A consumer first reads S and F, then the dense-source rows D, then the separated reflection row E, and only then the universal arrow row R.

The numerical and structural rows W, Q, Z, H, C, P, N preserve the same route. Since the packet contains no quotient class, selected representative, selected limit, countable-choice schedule, host equality, or ambient completeness coordinate, the NameCert surface is exhausted by the displayed rows. □

Theorem 8616.3 (Uniform completion reflection density route)**.** *Every density read exported by an accepted* $\mathsf{UniformCompletionReflection}^{\uparrow}$ *packet factors through* $\mathsf{CauchyCompletionDensitySource}^{\uparrow}$ *and* $\mathsf{MetricCompletionDenseEmbedding}^{\uparrow}$ *before the separated reflection or universal-arrow rows are consumed. The density route is carried by $S, F, D, W, Q, Z, H, C, P, N$ and remains a finite BEDC packet, not a quotient completion or selected representative.*

Proof. Read the source uniformity row S and Cauchy-filter window row F. These rows bound the request before any dense image can be inspected.

The dense embedding row D is then supplied by the dense-source and metric dense-embedding packets. Its readback still passes through the StreamName, RegSeqRat, DyadicRatCore, and Real rows W, Q, Z.

Transport, replay, provenance, and local naming keep the route within H, C, P, N. Thus density is exported only as displayed finite evidence, with no quotient completion class or selected representative available to the consumer. □

Theorem 8616.4 (Uniform completion reflection universal route)**.** *Every universal-arrow read from an accepted* $\mathsf{UniformCompletionReflection}^{\uparrow}$ *packet factors through*

$$S, F, D, E, W, Q, Z, H, C, P, N \longmapsto R.$$

The row R may be consumed by $\mathsf{UniformSpaceCompletion}^{\uparrow}$*-facing maps only after the source uniformity, Cauchy-filter window, dense embedding, separated reflection, numerical readback, transport, replay, provenance, and local naming rows remain visible in the same packet.*

Proof. Start with Definition 8616.2. It places the universal arrow after the source uniformity, Cauchy-filter windows, dense embedding, separated reflection, and numerical readback rows.

The density route of Definition 8616.3 supplies the source-to-completion side. The separated reflection row E then prevents the consumer from treating zero-distance evidence as host equality before the reflection boundary is displayed.

Finally project R through H, C, P, N. The universal route is therefore a replayable NameCert row for $\mathsf{UniformSpaceCompletion}^{\uparrow}$ consumers, not a selected-limit operator, quotient completion theorem, countable-choice principle, or ambient separated completion. □

Falsifiable prediction: Every accepted $\mathsf{UniformCompletionReflection}^{\uparrow}$ consumer that reaches the universal arrow while omitting source uniformity, Cauchy-filter windows, dense embedding, separated reflection, StreamName windows, RegSeqRat readback, DyadicRatCore tolerance, Real sealing, transport, replay, provenance, or local naming refutes the packet.

Independence witness: cauchy-completion-density-source, metric-completion-dense-embedding, separated-completion-reflection, uniform-space-completion, streamname, regseqrat, dyadicratcore, real: no listed sibling is bijective with $\mathsf{UniformCompletionReflection}^{\uparrow}$ because the packet jointly carries source uniformity, Cauchy-filter windows, dense embedding, separated reflection, universal-arrow routing, finite windows, regular rational readback, dyadic tolerance, Real sealing, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{UniformCompletionReflection}^{\uparrow}}$**.**

Constructive story: A $\mathsf{UniformCompletionReflection}^{\uparrow}$ packet is generated from a source uniformity row, Cauchy-filter windows, dense embedding rows, separated reflection rows, a universal-arrow row, StreamName windows, RegSeqRat readback, a DyadicRatCore tolerance ledger, a Real seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{UniformCompletionReflection}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8616.1, Definition 8616.2, Definition 8616.3, and Definition 8616.4 seed the constructive uniform-completion reflector route from source uniformity and Cauchy-filter windows through dense embedding, separated reflection, and universal-arrow rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{UniformCompletionReflection}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient completion, selected filter representatives, selected limits, countable choice, trichotomy, host equality of completed points, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, source-uniformity exactness, Cauchy-filter window exposure, dense embedding handoff, separated reflection non-escape, universal-arrow routing, finite numerical readback, transport, replay, provenance, and local naming for BEDC.Derived.UniformCompletionReflectionUp.

Chapter 8617

A Concrete Naming Certificate for $\mathsf{CantorNestedInterval}^{\uparrow}$

Following Cantor and Bishop, the $\mathsf{CantorNestedInterval}^{\uparrow}$ packet records the constructive nested-interval argument as finite NameCert data rather than as an ambient compactness or completeness theorem. It sits on the Phase Real and Completion frontier by reading dyadic rational endpoints from chapter 291, finite endpoint streams from chapter 126, regular rational readback from chapter 301, terminal real sealing from chapter 38, and limit uniqueness only through the already named boundary of chapter 5983.

Definition 8617.1 (Cantor nested interval carrier)**.** *A* $\mathsf{CantorNestedInterval}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$I = (L, U, D, W, R, E, H, C, P, N)$$

with the following displayed rows.

1. *L and U are finite endpoint histories whose entries are read through* $\mathsf{DyadicRatCore}^{\uparrow}$ *as lower and upper rational endpoints.*
2. *D is a dyadic diameter budget assigning each displayed index k a dyadic bound for the interval width.*
3. *W is the finite window in which the packet checks endpoint order and nesting for all displayed adjacent stages.*
4. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row that turns the endpoint windows into regular rational midpoint or endpoint reads.*
5. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal reached from those regular reads.*
6. *H, C, P, N are the componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local* $\mathsf{NameCert}_{\mathsf{CantorNestedInterval}^{\uparrow}}$ *rows.*

The carrier accepts only histories where each displayed interval is closed, rational, nested in the previous displayed interval, and bounded by the displayed dyadic diameter budget. It contains no coordinate for a selected point, a quotient real equality, trichotomy of endpoints, Heine–Borel compactness, or full real completeness.

Theorem 8617.2 (Cantor nested interval NameCert obligations)**.** *For every accepted* $\mathsf{CantorNestedInterval}^{\uparrow}$ *carrier*

$$I = (L, U, D, W, R, E, H, C, P, N),$$

the NameCert obligation surface consists exactly of carrier admission, finite closed-rational endpoint rows, displayed nesting, dyadic diameter decrease, $\mathsf{RegSeqRat}^{\uparrow}$ *handoff through* R*, terminal* $\mathsf{Real}^{\uparrow}$ *seal through* E*, componentwise* hsame *transport* H*, displayed* Cont *replay* C*,* Pkg *provenance* P*, and the local* $\mathsf{NameCert}_{\mathsf{CantorNestedInterval}^{\uparrow}}$ *row* N*. The packet exports no Heine–Borel principle, selected point operator, quotient real equality, endpoint trichotomy, or full completeness of* $\mathsf{Real}^{\uparrow}$*.*

Proof. Project the carrier of Definition 8617.1. The rows L, U, D, W display exactly the finite rational endpoint data, nesting checks, and dyadic diameter bounds; no external interval family is hidden outside those histories.

Use the real-frontier route named in the chapter introduction. The endpoint histories read through $\mathsf{DyadicRatCore}^{\uparrow}$ and $\mathsf{StreamName}^{\uparrow}$, the regular rational handoff is the row R, and the terminal real object is exposed only through the seal E.

The remaining rows are structural. Componentwise hsame transport H preserves the displayed endpoint and diameter rows, Cont replay C records the finite window used by a consumer, Pkg provenance P keeps the interval packet visible, and N names the local certificate. Since no row stores a selected point, quotient equality, trichotomy, compactness principle, or ambient completeness proof, the listed obligations are the entire certificate surface. □

Theorem 8617.3 (Cantor nested interval regular Cauchy seal)**.** *Every accepted* $\mathsf{CantorNestedInterval}^{\uparrow}$ *carrier whose displayed windows cover a requested precision* k *yields a regular Cauchy seal only by reading the finite endpoint window, dyadic diameter budget,* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff, and terminal* $\mathsf{Real}^{\uparrow}$ *row displayed in the carrier. The seal is a finite-window route from nested rational intervals to a regular rational readback; it is not an ambient completeness theorem and does not choose a point outside the displayed packet.*

Proof. Fix the requested precision k and open the displayed window W large enough for the dyadic budget row D at that precision. The nested endpoint rows L, U then give a finite closed rational interval whose diameter is bounded by the requested dyadic tolerance.

Read the chosen finite endpoint data through $\mathsf{DyadicRatCore}^{\uparrow}$ and the window interface through $\mathsf{StreamName}^{\uparrow}$. The regular rational readback row R supplies the Cauchy-stage comparison, while the terminal row E seals the read as a $\mathsf{Real}^{\uparrow}$ object.

The construction has used only the displayed finite rows of the carrier. Therefore the resulting seal is the regular Cauchy seal named by the packet and cannot be reinterpreted as a selected nested-intersection point, quotient real equality, Heine–Borel compactness, trichotomy, or full completeness of the real line. □

Closure status for $\mathsf{NameCert}_{\mathsf{CantorNestedInterval}^{\uparrow}}$**.**

Constructive story: A $\mathsf{CantorNestedInterval}^{\uparrow}$ packet is generated from finite lower and upper dyadic rational endpoint histories, a displayed dyadic diameter budget, a finite nesting window, RegSeqRat readback, a terminal Real seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{CantorNestedInterval}^{\uparrow}}$, seed)

Scope closed: The seed scope is the finite nested rational interval carrier, dyadic diameter budget, RegSeqRat handoff, terminal Real seal, and local NameCert obligation surface.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{CantorNestedInterval}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: The chapter does not close Heine–Borel compactness, selected intersection points, quotient real equality, endpoint trichotomy, or full Real completeness.

Upgrade path: Formalization should add BEDC.Derived.CantorNestedIntervalUp with the carrier, obligation theorem, and finite-window regular Cauchy seal.

Chapter 8618

A Concrete Naming Certificate for $\mathsf{ConstructiveCauchyRealLine}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{ConstructiveCauchyRealLine}^{\uparrow}$ packet records the real-line interface obtained from displayed regular Cauchy rational data, not from a selected quotient completion. It sits over the dyadic tolerance core of chapter 291, the finite stream-name surface of chapter 126, the regular rational readback of chapter 301, the terminal real-name seal of chapter 38, and the separability surface of chapter 1809. The packet names a finite Real and Completion interface for constructive Cauchy reals without importing quotient stream equality, a selected limit, countable choice, trichotomy, host real equality, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 8618.1 (Constructive Cauchy real line carrier)**.** *A* $\mathsf{ConstructiveCauchyRealLine}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (D, S, R, E, Q, H, C, P, N)$$

with the following displayed rows:

1. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger for comparison scales, slack witnesses, and refusal rows.*
2. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window schedule for the Cauchy-name observations consumed by the line interface.*
3. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row obtained from those displayed stream windows and dyadic tolerances.*
4. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal available only after D, S, R have been displayed.*
5. *Q is the* $\mathsf{RealSeparability}^{\uparrow}$ *countable-dense-source row used as a named separability witness for the same real-line packet.*
6. *H records componentwise* hsame *transport for the dyadic, stream, regular-rational, Real-seal, separability, continuation, provenance, and local naming rows.*
7. *C records displayed* Cont *replay from a real-line request through D, S, R, E, Q, H, P, N.*
8. *P is the* Pkg *provenance over* $\mathsf{ConstructiveCauchyRealLine}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{RealSeparability}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
9. *N is the local* $\mathsf{NameCert}_{\mathsf{ConstructiveCauchyRealLine}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these rows. It has no coordinate for quotient equality of Cauchy streams, selected representatives, countable-choice schedules, trichotomy, host real equality, or ambient completeness of $\mathsf{Real}^{\uparrow}$.

Theorem 8618.2 (Constructive Cauchy real line classifier route)**.** *For every accepted* $\mathsf{ConstructiveCauchyRealLine}^{\uparrow}$ *carrier* $L = (D, S, R, E, Q, H, C, P, N)$*, the classifier reads exactly the dyadic tolerance row, finite stream-window row, regular rational readback, terminal Real seal, separability source, componentwise transport, displayed replay, provenance, and local naming rows. Two packets with the same displayed rows are indistinguishable to the classifier, and no omitted quotient, selector, host equality, choice, trichotomy, or completeness datum can be recovered from the accepted packet.*

Proof. Project the carrier of Definition 8618.1. Its public rows are precisely $D, S, R, E, Q, H, C, P, N$, and the classifier is defined over those displayed coordinates.

The analytic route is staged by the same rows. Dyadic tolerances and stream windows are read before the regular rational row, the regular rational row is read before the terminal $\mathsf{Real}^{\uparrow}$ seal, and the separability row is named beside that seal.

The remaining rows only transport, replay, source, and name the packet. Since no coordinate stores a quotient representative, selector, host equality, countable-choice schedule, trichotomy oracle, or ambient completeness theorem, the classifier cannot export such data. □

Theorem 8618.3 (Constructive Cauchy real line NameCert obligations)**.** *The local* $\mathsf{NameCert}_{\mathsf{ConstructiveCauchyRealLine}}$ *surface consists exactly of carrier admission for* $D, S, R, E, Q, H, C, P, N$*, dyadic tolerance exposure, finite stream-window exposure, regular rational readback, terminal Real sealing, separability-source exposure, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming.*

Proof. Carrier admission supplies the packet $L = (D, S, R, E, Q, H, C, P, N)$. Each NameCert obligation is a projection of one displayed coordinate or of the ordered route among those coordinates.

The source obligations are D, S, R, E, Q. They expose the dyadic ledger, finite windows, regular rational readback, terminal seal, and separability source before a Real or Completion consumer can read the packet.

The structural obligations are H, C, P, N. They preserve the same finite route under transport, replay the request through displayed continuations, record sibling provenance, and provide the local name. No further NameCert row is available. □

Theorem 8618.4 (Constructive Cauchy real line source exactness)**.** *Every accepted* $\mathsf{ConstructiveCauchyRealLine}^{\uparrow}$ *read reaches its terminal* $\mathsf{Real}^{\uparrow}$ *seal only through*

$$\mathsf{DyadicRatCore}^{\uparrow}, \quad \mathsf{StreamName}^{\uparrow}, \quad \mathsf{RegSeqRat}^{\uparrow}, \quad \mathsf{Real}^{\uparrow}, \quad \mathsf{RealSeparability}^{\uparrow}.$$

The dyadic ledger D*, stream schedule* S*, regular rational row* R*, Real seal* E*, and separability source* Q *remain one finite source packet; none may be replaced by a host Cauchy sequence, quotient real, selected limit, or unrecorded dense subset.*

Proof. Use the classifier route of Definition 8618.2. It exposes D, S, R, E, Q as the only source rows available to a Real or Completion consumer.

The order of the read is forced by the carrier. Tolerances and finite windows are displayed before regular rational readback, the readback is displayed before the Real seal, and separability is named as a row of the same packet.

Transport and replay preserve this source packet through H and C, while P and N record provenance and naming only. Hence a consumer cannot substitute a host sequence, quotient real, selected limit, or unrecorded dense source for the displayed rows. □

Theorem 8618.5 (Constructive Cauchy real line transport stability)**.** *Let L_0 and L_1 be accepted* $\mathsf{ConstructiveCauchyRealLine}^{\uparrow}$ *carriers. If their dyadic tolerance rows, stream-window schedules, regular rational readbacks, Real seals, separability rows, replay rows, provenance rows, and local naming rows are componentwise* hsame*, then every Real or Completion read accepted for L_0 is accepted for L_1 with the transported finite route.*

Proof. Read the componentwise transport row H. It is scoped over the dyadic, stream, regular-rational, Real-seal, separability, replay, provenance, and local naming rows.

Use displayed replay through C. A consumer request for L_0 is replayed through the ordered rows D, S, R, E, Q, H, P, N, and the hsame route transports those rows componentwise to L_1.

Source exactness from Definition 8618.4 keeps the transported read inside the same finite route. The transported packet therefore exports no quotient equality, selector, choice schedule, trichotomy, host equality, or completeness datum. □

Theorem 8618.6 (Constructive Cauchy real line ledger exactness)**.** *Every comparison, readback, Real-seal, and separability read in an accepted* $\mathsf{ConstructiveCauchyRealLine}^{\uparrow}$ *carrier is ledgered by $D, S, R, E, Q, H, C, P, N$. The ledger records the dyadic tolerance budget, finite stream windows, regular rational observations, terminal Real seal, separability source, transport, replay, provenance, and local naming as one packet, and it records no selected representative, hidden quotient class, or countable-choice schedule.*

Proof. Start with the NameCert obligations of Definition 8618.3. They identify every admitted read as one of the displayed carrier rows.

The comparison and readback part is D, S, R. The Real-facing and separability part is E, Q. The structural part is H, C, P, N.

Together these rows form the whole ledger. Because the ledger has no selector, quotient representative, or countable-choice coordinate, an accepted read cannot hide one behind the Real seal or separability source. □

Theorem 8618.7 (Constructive Cauchy real line standard-bridge seed)**.** *The* $\mathsf{ConstructiveCauchyRealLine}^{\uparrow}$ *packet supplies a standard-bridge seed for the Real and Completion route: every candidate bridge must preserve the dyadic ledger D, finite stream schedule S, regular rational readback R, terminal* $\mathsf{Real}^{\uparrow}$ *seal E, separability row Q, componentwise transport H, displayed replay C, provenance P, and local naming N. The seed is not itself a checked bridge and does not assert ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Apply source exactness and transport stability. They force every Real or Completion read to pass through $D, S, R, E, Q, H, C, P, N$ and keep that route stable under componentwise hsame.

Use ledger exactness to identify the bridge payload. A bridge candidate that omits one of the displayed rows would no longer preserve the local NameCert surface of the packet.

The conclusion is only a seed obligation. Since the chapter provides no checked standard-bridge theorem and no completeness coordinate, ambient $\mathsf{Real}^{\uparrow}$ completeness and bridge checking remain outside the claim. □

Falsifiable prediction: Every accepted ConstructiveCauchyRealLineUp read displays DyadicRatCore, StreamName, RegSeqRat, Real, RealSeparability, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert rows before a Real or Completion consumer reads the packet.

Independence witness: dyadicratcore, streamname, regseqrat, real, real-separability: ConstructiveCauchyRealLin is not bijective to any listed sibling because it jointly carries dyadic tolerances, finite stream windows, regular rational readback, terminal Real sealing, separability source data, transport, replay, provenance, and local naming in one real-line packet.

Closure status for $\mathsf{NameCert}_{\mathsf{ConstructiveCauchyRealLine}^{\uparrow}}$.

Constructive story: A $\mathsf{ConstructiveCauchyRealLine}^{\uparrow}$ packet is generated from DyadicRatCore tolerances, StreamName finite windows, RegSeqRat readback, a Real seal, RealSeparability source data, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{ConstructiveCauchyRealLine}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8618.1, Definition 8618.2, Definition 8618.3, Definition 8618.4, and Definition 8618.7 seed the finite constructive Cauchy real-line route over DyadicRatCore, StreamName, RegSeqRat, Real, RealSeparability, BHist, hsame, Cont, Pkg, and NameCert rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{ConstructiveCauchyRealLine}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient stream equality, selected limits, countable choice, trichotomy, host real equality, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, classifier routing, dyadic tolerance exposure, finite stream-window exposure, regular rational readback, Real sealing, separability source exposure, transport stability, ledger exactness, standard-bridge seed obligations, provenance, and local naming for BEDC.Derived.ConstructiveCauchyRealLineUp.

Chapter 8619

A Concrete Naming Certificate for $\mathsf{DowkerSpace}^{\uparrow}$

Following Engelking and Kelley, the $\mathsf{DowkerSpace}^{\uparrow}$ packet records the standard topology boundary where normality is visible but countable paracompactness is obstructed by the interval product test. It sits over the topology carrier of chapter 88, the normal-space surface of chapter 1866, the paracompact comparison of chapter 1963, the locally finite cover boundary of chapter 7245, and the product-topology route of chapter 2000. The packet names the finite boundary data only; it does not import host powersets, selected open covers, open-cover compactness, or a choice principle.

Definition 8619.1 (Dowker space carrier)**.** *A* $\mathsf{DowkerSpace}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$D = (T, N, C, P, I, H, R, Q, Z)$$

with the following displayed rows:

1. *T is the* $\mathsf{Topology}^{\uparrow}$ *carrier row for the admitted point and open-set names.*
2. *N is the* $\mathsf{NormalSpace}^{\uparrow}$ *exposure row recording the displayed normal separation source.*
3. *C is the countable-paracompactness obstruction row; it records the finite refusal boundary rather than a selected countable cover.*
4. *P is the* $\mathsf{Paracompact}^{\uparrow}$ *comparison row, read only through the local obstruction and locally finite cover surfaces.*
5. *I is the interval and product-normality test row, routing the boundary through the product topology comparison.*
6. *H records componentwise* hsame *transport for topology, normality, obstruction, comparison, product test, replay, provenance, and local naming rows.*
7. *R records displayed* Cont *replay from a consumer request through the topology row, normal-source row, obstruction row, paracompact comparison, and interval-product test.*
8. *Q is the* Pkg *provenance over topology, normal space, paracompact comparison, locally finite cover, interval-product topology,* BHist, hsame, Cont, *and local naming rows.*
9. *Z is the local* $\mathsf{NameCert}_{\mathsf{DowkerSpace}^{\uparrow}}$ *row naming this boundary object.*

The carrier has no coordinate for a host powerset, a selected open cover, open-cover compactness, quotient equality of covers, or a choice-based paracompactness witness.

Theorem 8619.2 (Dowker space NameCert obligations)**.** *For every accepted* $\mathsf{DowkerSpace}^{\uparrow}$ *carrier* $D = (T, N, C, P, I, H, R, Q, Z)$*, the local NameCert surface consists of carrier admission for the nine displayed rows, normal-source exposure through* N*, countable-paracompact obstruction through* C*, product-normality boundary through* I*, componentwise transport through* H*, replay through* R*, provenance through* Q*, and local naming through* Z*. The paracompact comparison row* P *is readable only as a comparison against the displayed obstruction and does not supply a selected cover, a host powerset, open-cover compactness, or a global choice principle.*

Proof. Project the carrier of Definition 8619.1. The tuple displays exactly the topology carrier, normal source, countable-paracompact obstruction, paracompact comparison, interval-product test, transport, replay, provenance, and local naming rows.

The positive topological read starts with T and N. These rows expose the underlying topology and the normal-space source, but they do not create a paracompactness witness.

The boundary read is C, P, I. The obstruction row C records the countable-paracompactness refusal, P records only the comparison with paracompact and locally finite cover surfaces, and I records the interval-product normality test that consumes that same boundary.

The structural rows H, R, Q, Z transport, replay, source, and name the finite surface. Since the carrier omits host powersets, selected covers, open-cover compactness, and choice-based cover selectors, no consumer can extract those objects from the NameCert. □

Theorem 8619.3 (Dowker space normal-paracompact boundary)**.** *Every consumer of an accepted* $\mathsf{DowkerSpace}^{\uparrow}$ *packet that uses the normality row must keep* $\mathsf{NormalSpace}^{\uparrow}$*, the* $\mathsf{Paracompact}^{\uparrow}$ *and countably-paracompact comparison row, the* $\mathsf{Topology}^{\uparrow}$ *carrier row, and the interval/product topology row visible. The handoff may compare normality, paracompactness, locally finite covers, and product normality along the displayed rows* $T, N, C, P, I, H, R, Q, Z$*, but it cannot export host powersets, selected covers, selected refinements, open-cover compactness, or a global paracompactness witness.*

Proof. Start from the carrier of Definition 8619.1. A normality consumer reads N only after the topology carrier T has been displayed.

The comparison cannot bypass the obstruction row. The row C keeps the countable-paracompactness boundary visible, while P and I route any paracompact or product-normality request through the displayed comparison surface.

The locally finite cover and product-topology dependencies are read through provenance and replay. Rows R and Q point to the same finite route, and H preserves it componentwise under hsame.

Thus the consumer receives the normal-paracompact boundary as a finite NameCert surface. Host powersets, selected covers, selected refinements, open-cover compactness, and global paracompactness witnesses are absent from the carrier and cannot be exported. □

Closure status for $\mathsf{NameCert}_{\mathsf{DowkerSpace}^{\uparrow}}$**.**

Constructive story: A $\mathsf{DowkerSpace}^{\uparrow}$ packet is generated from finite BHist rows for topology, normality, countable-paracompact obstruction, paracompact comparison, interval-product testing, transport, replay, provenance, and local naming. The normal row is readable only with the obstruction and product-test rows still visible, so the packet records the standard normal/paracompact boundary without selected covers or host powersets.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{DowkerSpace}^{\uparrow}}, \mathsf{seed})$

Scope closed: This chapter binds the Dowker-space carrier, NameCert obligations, and normal-paracompact boundary for the displayed topology rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{DowkerSpace}^{\uparrow}}, \mathsf{unformalized})$

Lean target: `BEDC.Derived.DowkerSpaceUp`

Bridge status: none

Not claimed: It does not claim selected covers, host powersets, open-cover compactness, choice-based paracompactness, quotient cover equality, or a standard bridge.

Upgrade path: Obligation closure requires Lean encodings of carrier admission, normal-source exposure, obstruction preservation, product-normality boundary, and NameCert non-escape.

Chapter 8620

A Concrete Naming Certificate for $\mathsf{UniformEntourageCompletion}^{\uparrow}$

Following Kelley and Bourbaki on uniform spaces, the $\mathsf{UniformEntourageCompletion}^{\uparrow}$ packet records the L10 completion boundary where displayed entourage-Cauchy data are routed to a separated real-facing completion surface as finite BEDC rows. It sits after the uniform-space entourage discipline of chapter 339, the finite StreamName windows of chapter 126, the regular rational readback of chapter 301, the dyadic tolerance core of chapter 291, the terminal Real seal of chapter 38, and the separated-completion boundary of chapter 1612. The packet names an entourage-source completion handoff without quotient completion equality, selected representatives, countable choice, host equality of completed points, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 8620.1 (Uniform entourage completion carrier)**.** *A* $\mathsf{UniformEntourageCompletion}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (U, E, W, R, D, S, H, C, P, N)$$

with the following displayed rows:

1. *U is the* $\mathsf{UniformSpace}^{\uparrow}$ *source row, exposing the finite entourage requests and uniformity witnesses consumed before any completion-facing read.*
2. *E is the entourage-Cauchy row. It records the displayed entourage windows used to recognize Cauchy behavior inside the source uniformity.*
3. *W is the* $\mathsf{StreamName}^{\uparrow}$ *window row through which observed points, tails, and comparison requests are read.*
4. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row attached to the finite windows in W.*
5. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row, recording the dyadic radii and comparison budgets used by the Cauchy-window reads.*
6. *S is the separated* $\mathsf{Real}^{\uparrow}$ *and* $\mathsf{SeparatedCompletion}^{\uparrow}$ *handoff row. It is readable only after U, E, W, R, D have been displayed.*
7. *H records componentwise* hsame *transport for the uniform source, entourage-Cauchy, window, readback, tolerance, separated handoff, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay of the finite route*

$$U, E \longmapsto W, R, D \longmapsto S, H, P, N.$$

9. *P is the* Pkg *provenance over* $\mathsf{UniformEntourageCompletion}^{\uparrow}$, $\mathsf{UniformSpace}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{SeparatedCompletion}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{UniformEntourageCompletion}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $U, E, W, R, D, S, H, C, P, N$. It has no coordinate for quotient completion equality, quotient entourage filters, selected representatives, selected limits, countable-choice schedules, host equality, trichotomy, or ambient completeness.

Theorem 8620.2 (Uniform entourage completion NameCert obligations)**.** *For every accepted* $\mathsf{UniformEntourageCompletion}^{\uparrow}$ *carrier $K = (U, E, W, R, D, S, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{UniformEntourageCompletion}^{\uparrow}}$ *surface consists exactly of carrier admission for the uniform source row, entourage-Cauchy row, StreamName windows, RegSeqRat readback, DyadicRatCore tolerance rows, separated Real-completion handoff, componentwise transport, displayed replay, provenance, and local naming. Every completion-facing obligation is read through those rows before the separated handoff S is opened.*

Proof. Project the carrier of Definition 8620.1. The displayed tuple exposes $U, E, W, R, D, S, H, C, P, N$ and no other completion-facing coordinate.

The source and Cauchy evidence are read first. The uniform source row U supplies the entourage discipline, while E records the Cauchy-window rows inside that discipline.

The finite observation route is then forced through W, R, D. StreamName windows expose the observed tails, RegSeqRat rows read back the finite windows, and DyadicRatCore rows record the tolerance comparisons used by the Cauchy request.

Finally read S, H, C, P, N. The separated Real-completion handoff is downstream of the displayed source, window, readback, and tolerance rows, and the structural rows preserve only that route. Since the excluded quotient, selector, choice, host-equality, trichotomy, and ambient-completeness objects are not carrier coordinates, the listed rows exhaust the local NameCert surface. □

Theorem 8620.3 (Uniform entourage completion L10 handoff)**.** *Every L10 Real or Completion consumer of an accepted* $\mathsf{UniformEntourageCompletion}^{\uparrow}$ *carrier reads the finite route*

$$\mathsf{UniformSpace}^{\uparrow} \longmapsto E \longmapsto \mathsf{StreamName}^{\uparrow}, \mathsf{RegSeqRat}^{\uparrow}, \mathsf{DyadicRatCore}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}, \mathsf{SeparatedCompletion}^{\uparrow}.$$

In carrier notation, every such read factors through

$$U, E \longmapsto W, R, D \longmapsto S, H, C, P, N.$$

Thus the separated completion boundary is a displayed handoff from finite entourage-source Cauchy data, not a quotient completion equality, selected representative, countable-choice schedule, host equality, or ambient completeness premise.

Proof. Apply the NameCert obligation surface of Definition 8620.2. It confines every accepted completion-facing read to the carrier rows $U, E, W, R, D, S, H, C, P, N$.

Read the route in row order. The source row U and entourage-Cauchy row E precede the observation rows, so the consumer cannot start from a detached quotient filter or a selected completed point.

The finite observation rows W, R, D precede the separated handoff. They expose StreamName windows, regular rational readback, and dyadic tolerance budgets before the Real or separated-completion boundary in S is available.

The structural rows then replay the same route. Componentwise transport, displayed continuation, provenance, and local naming preserve the finite handoff, so no omitted quotient, selector,

choice, host-equality, trichotomy, or ambient-completeness coordinate can be introduced downstream. □

Falsifiable prediction: Every accepted $\mathsf{UniformEntourageCompletion}^{\uparrow}$ completion-facing read factors through $\mathsf{UniformSpace}^{\uparrow}$, entourage-Cauchy rows, $\mathsf{StreamName}^{\uparrow}$ windows, $\mathsf{RegSeqRat}^{\uparrow}$ readback, $\mathsf{DyadicRatCore}^{\uparrow}$ tolerances, a separated $\mathsf{Real}^{\uparrow}$ and $\mathsf{SeparatedCompletion}^{\uparrow}$ handoff, componentwise hsame, displayed Cont, Pkg, and local NameCert rows.

Independence witness: uniformspace, streamname, regseqrat, dyadicratcore, real, separated-completion: no listed sibling is bijective to $\mathsf{UniformEntourageCompletion}^{\uparrow}$ because this packet jointly carries the uniform source, entourage-Cauchy windows, finite readback, dyadic tolerances, separated handoff, transport, replay, provenance, and local naming as one completion boundary.

Closure status for $\mathsf{NameCert}_{\mathsf{UniformEntourageCompletion}^{\uparrow}}$.

Constructive story: A $\mathsf{UniformEntourageCompletion}^{\uparrow}$ packet is generated from UniformSpaceUp entourage rows, entourage-Cauchy window rows, StreamNameUp observations, RegSeqRatUp readback, DyadicRatCoreUp tolerances, RealUp and SeparatedCompletionUp handoff data, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{UniformEntourageCompletion}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8620.1, Definition 8620.2, and Definition 8620.3 seed the L10 entourage-source completion boundary over UniformSpaceUp, StreamNameUp, RegSeqRatUp, DyadicRatCoreUp, RealUp, SeparatedCompletionUp, BHist, hsame, Cont, Pkg, and NameCert rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{UniformEntourageCompletion}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close Lean verification, bridge checking, quotient completion equality, selected representatives, countable choice, host equality, trichotomy, or ambient RealUp completeness.

Upgrade path: Obligation closure requires checked carrier admission, entourage-Cauchy window routing, StreamName and RegSeqRat readback, DyadicRatCore tolerance ordering, separated Real-completion handoff, transport, replay, provenance, and local naming for BEDC.Derived.UniformEntourageCompletionUp.

Chapter 8621

A Concrete Naming Certificate for $\mathsf{BishopIntervalSearch}^{\uparrow}$

Following Bishop and Bridges on constructive analysis, the $\mathsf{BishopIntervalSearch}^{\uparrow}$ packet records the finite interval-search route by which a located predicate over a displayed closed real interval returns a certified subinterval and a regular Cauchy readback. It sits after the terminal real-name surface of chapter 38, the constructive real-line route of chapter 8618, the nested-interval source of chapter 8617, the dyadic tolerance core of chapter 291, the finite stream-name surface of chapter 126, and the regular rational readback of chapter 301. The packet names only a finite search certificate; it does not choose a completed point, quotient a Cauchy stream, decide a global order, or assert ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 8621.1 (Bishop interval search carrier)**.** *A* $\mathsf{BishopIntervalSearch}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$I = (L, D, G, R, W, H, C, P, N)$$

with the following displayed rows:

1. *L records located interval endpoints, endpoint-apartness evidence, and the closed interval boundary read through* $\mathsf{Real}^{\uparrow}$*.*
2. *D records the* $\mathsf{DyadicRatCore}^{\uparrow}$ *grid, mesh, midpoint, and refinement budget used by the search.*
3. *G records the finite dyadic grid and the chosen nested-refinement rows, including the parent-child containment witnesses for every inspected cell.*
4. *R records the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback rows obtained from the displayed endpoint and grid windows.*
5. *W records the result witness: the accepted subinterval, the located predicate side selected by the search, and the refusal rows for cells not selected.*
6. *H records componentwise* hsame *transport for the endpoint, dyadic-grid, refinement, regular-readback, result, replay, provenance, and local naming rows.*
7. *C records displayed* Cont *replay from an interval-search request through L, D, G, R, W, H, P, N.*
8. *P is the* Pkg *provenance over* $\mathsf{BishopIntervalSearch}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{ConstructiveCauchyRealLine}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
9. *N is the local* $\mathsf{NameCert}_{\mathsf{BishopIntervalSearch}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these displayed rows. It has no coordinate for a selected real point, quotient stream equality, host interval equality, omniscient case split, countable-choice schedule, or ambient completeness theorem.

Theorem 8621.2 (Bishop interval search NameCert obligations)**.** *The local* $\mathsf{NameCert}_{\mathsf{BishopIntervalSearch}^{\uparrow}}$ *surface consists exactly of carrier admission for* $L, D, G, R, W, H, C, P, N$*, located endpoint exposure, dyadic grid and refinement exposure, regular Cauchy readback, result-witness exposure, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming.*

Proof. Carrier admission supplies the packet $I = (L, D, G, R, W, H, C, P, N)$. The source obligations are projections of L, D, G, R, W: endpoints are located, the dyadic grid and refinement budget are displayed, the regular rational readback is visible, and the selected result interval is carried with its refusal rows.

The structural obligations are projections of H, C, P, N. Transport preserves the displayed rows componentwise, replay sends each request through the finite search route, provenance records the sibling Real and Completion sources, and the local certificate names the packet.

Since the carrier has no coordinate for a selected point, quotient stream equality, host interval equality, omniscient case split, countable-choice schedule, or ambient completeness theorem, no NameCert obligation can export one. □

Theorem 8621.3 (Bishop interval search located-net correctness)**.** *For every accepted* $\mathsf{BishopIntervalSearch}^{\uparrow}$ *carrier* $I = (L, D, G, R, W, H, C, P, N)$*, the result witness* W *is read only after the located endpoint row* L*, the dyadic grid budget* D*, the nested refinement row* G*, and the regular Cauchy readback* R *have been displayed. The selected subinterval is therefore a cell of the displayed finite net, and every refusal attached to a nonselected cell is ledgered by the same packet.*

Proof. Read the carrier route from Definition 8621.1. The result row W is not an independent search oracle; it is a row after the endpoint, dyadic-grid, refinement, and regular-readback rows.

The containment claim is a finite inspection of G. Each selected cell names its parent interval, mesh row, and endpoint witnesses, so the selected subinterval belongs to the displayed net rather than to an ambient interval object.

The refusal rows for nonselected cells are part of W and are replayed through C. Componentwise transport through H keeps the same refusals attached to the same endpoint, grid, refinement, and readback data. □

Theorem 8621.4 (Bishop interval search Cauchy stability)**.** *Let* I_0 *and* I_1 *be accepted* $\mathsf{BishopIntervalSearch}^{\uparrow}$ *carriers. If their located endpoint rows, dyadic grid budgets, nested refinement rows, regular Cauchy readbacks, result witnesses, replay rows, provenance rows, and local naming rows are componentwise* hsame*, then every interval-search read accepted for* I_0 *is accepted for* I_1 *with the transported finite result route.*

Proof. Use the transport row H. It is scoped over L, D, G, R, W, C, P, N, so each endpoint observation, grid budget, refinement cell, regular Cauchy readback, result witness, replay, provenance entry, and local name has a transported mate.

Apply displayed replay through C. A request accepted for I_0 is replayed through L, D, G, R, W, H, P, N, and the componentwise hsame route transports exactly those rows to I_1.

Located-net correctness from Definition 8621.3 keeps the transported result inside the displayed finite net. Thus Cauchy-stable search exports the same finite result route without selecting a completed point, quotienting streams, invoking choice, or using ambient $\mathsf{Real}^{\uparrow}$ completeness. □

Falsifiable prediction: Every accepted BishopIntervalSearchUp read displays located Real endpoints, DyadicRatCore grid rows, nested refinement rows, RegSeqRat readback, a result witness, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row before an interval-search consumer reads the packet.

Independence witness: real, constructive-cauchy-real-line, cantor-nested-interval, dyadicrat-core, streamname, regseqrat: $\mathsf{BishopIntervalSearch}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries located interval endpoints, dyadic grid and refinement rows, regular Cauchy readback, result witness data, transport, replay, provenance, and local naming in one interval-search packet.

Closure status for $\mathsf{NameCert}_{\mathsf{BishopIntervalSearch}^{\uparrow}}$.

Constructive story: A $\mathsf{BishopIntervalSearch}^{\uparrow}$ packet is generated from located Real endpoints, DyadicRatCore grid and refinement rows, RegSeqRat readback, a result witness, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BishopIntervalSearch}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8621.1, Definition 8621.2, Definition 8621.3, and Definition 8621.4 seed the finite constructive interval-search route over Real, constructive Cauchy real-line, dyadic grid, regular rational readback, BHist, hsame, Cont, Pkg, and NameCert rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BishopIntervalSearch}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close selected points, quotient stream equality, host interval equality, omniscient search, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, located endpoint exposure, dyadic grid and refinement exposure, regular Cauchy readback, result-witness correctness, transport stability, provenance, and local naming for BEDC.Derived.BishopIntervalSearchUp.

Chapter 8622

A Concrete Naming Certificate for $\mathsf{UniformCauchyMap}^{\uparrow}$

Following Bishop–Bridges constructive analysis, the $\mathsf{UniformCauchyMap}^{\uparrow}$ packet records the finite interface by which a uniformly Cauchy family of displayed maps is read before a $\mathsf{ContinuousMap}^{\uparrow}$ consumer receives any pointwise value or limiting seal. It sits between the displayed sequence-of-maps surface of chapter 8474, the uniform-tail ledger of chapter 3417, the finite stream windows of chapter 126, the regular rational readback route of chapter 301, the dyadic tolerance core of chapter 291, the terminal real-name seal of chapter 38, and the graph handoff of chapter 130. The packet names only displayed source windows, target readbacks, shared moduli, tolerances, seals, transport, replay, provenance, and local naming; it is not Real completeness, host function equality, a selected limit, quotient streams, trichotomy, or choice.

Definition 8622.1 (Uniform Cauchy map carrier)**.** *A* $\mathsf{UniformCauchyMap}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$U = (X, Y, F, W, R, M, D, E, H, C, P, N)$$

with the following visible rows:

1. *X is the source finite-window row, displaying the inspected argument windows and stage windows through* $\mathsf{StreamName}^{\uparrow}$*.*
2. *Y is the target carrier row, naming the displayed codomain read surface for each inspected value.*
3. *F is the displayed family row, routing inspected stage-and-argument pairs through* $\mathsf{FunctionSequence}^{\uparrow}$ *and* $\mathsf{ContinuousMap}^{\uparrow}$ *graph rows.*
4. *W is the finite window ledger that aligns the source windows with the inspected family stages.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for target values observed in those windows.*
6. *M is the shared uniform Cauchy modulus row. For every displayed dyadic tolerance request it records one threshold row used by every inspected source window in W.*
7. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, recording the requested dyadic radius, slack, and comparison rows.*
8. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row for value readback, available only after X, Y, F, W, R, M, D have been displayed.*

9. *H records componentwise* hsame *transport for the source windows, target row, family row, window ledger, readback, modulus, tolerance ledger, Real seal, replay, provenance, and local naming rows.*
10. *C records displayed* Cont *replay from a map-family Cauchy request through $X, Y, F, W, R, M, D, E, H, P, N$.*
11. *P is the* Pkg *provenance over* UniformCauchyMap$^\uparrow$, FunctionSequence$^\uparrow$, ContinuousMap$^\uparrow$, UniformConvergence$^\uparrow$, StreamName$^\uparrow$, RegSeqRat$^\uparrow$, DyadicRatCore$^\uparrow$, Real$^\uparrow$, BHist, hsame, Cont, *and* NameCert.
12. *N is the local* NameCert$_{\text{UniformCauchyMap}^\uparrow}$ *row.*

The classifier compares accepted carriers only through $X, Y, F, W, R, M, D, E, H, C, P, N$. It has no coordinate for ambient Real completeness, host function equality, selected limiting maps, quotient stream equality, trichotomy, or choice.

Theorem 8622.2 (Uniform Cauchy map NameCert obligations)**.** *For every accepted* UniformCauchyMap$^\uparrow$ *carrier $U = (X, Y, F, W, R, M, D, E, H, C, P, N)$, the local* NameCert$_{\text{UniformCauchyMap}^\uparrow}$ *surface consists exactly of carrier admission for the displayed source windows, target row, family row, finite window ledger,* RegSeqRat$^\uparrow$ *readback, shared uniform Cauchy modulus,* DyadicRatCore$^\uparrow$ *tolerance ledger, terminal* Real$^\uparrow$ *seal, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. Each tolerance request must read the same threshold row in M for every inspected source window before the target readback in R or the terminal seal E can be consumed.*

Proof. Project the carrier of Definition 8622.1. The analytic rows are X, Y, F, W, R, M, D, E, and the structural rows are H, C, P, N.

The uniform Cauchy condition is carried only by M and D. A requested dyadic tolerance first reads the radius and slack from D, then reads a single threshold row from M that is shared across the displayed source windows in W.

The target readback stays downstream. The row R records only regular rational observations of the inspected values, and the terminal Real$^\uparrow$ seal E appears only after the source windows, family graph rows, modulus row, and tolerance ledger have been displayed.

Transport and replay preserve the same rows through H and C, while P and N source and name the local packet. Since none of the refused principles is a carrier coordinate, the NameCert surface cannot use Real completeness, host function equality, selected limits, quotient streams, trichotomy, or choice. □

Theorem 8622.3 (Uniform Cauchy map ContinuousMap handoff)**.** *Every* ContinuousMap$^\uparrow$ *consumer of an accepted* UniformCauchyMap$^\uparrow$ *carrier must first read*

$$X, Y, F, W, R, M, D, E, H, C, P, N.$$

The handoff exposes source finite-window rows, target RegSeqRat$^\uparrow$ *readbacks, one shared uniform Cauchy modulus row,* DyadicRatCore$^\uparrow$ *tolerance rows, terminal* Real$^\uparrow$ *seals,* hsame *transport,* Cont *replay,* Pkg *provenance, and the local* NameCert *row before any continuous-map graph read is exported. It supplies a finite BEDC route for uniformly Cauchy map families, not Real completeness, host function equality, selected limits, quotient streams, trichotomy, or choice.*

Proof. Start with the NameCert obligations of Definition 8622.2. They force any consumer to expose the source windows, target row, family row, finite window ledger, regular rational readback, shared modulus, tolerance ledger, and terminal seal before the packet is named.

Read the sibling routes in order. The FunctionSequence$^\uparrow$ and ContinuousMap$^\uparrow$ rows expose the displayed map graph, StreamName$^\uparrow$ supplies the inspected source windows, RegSeqRat$^\uparrow$ supplies

the target readback, $\mathsf{DyadicRatCore}^{\uparrow}$ supplies the tolerance ledger, and $\mathsf{Real}^{\uparrow}$ supplies only the terminal seal reached through those rows.

Use the $\mathsf{UniformConvergence}^{\uparrow}$ sibling as the uniform-tail ledger. The shared row M gives a Cauchy threshold for every displayed source window, so the continuous-map consumer receives a finite map-family Cauchy route rather than a host function-space limit.

Finally H, C, P, N transport, replay, source, and name the same route. No quotient stream equality, selected limiting map, trichotomy oracle, countable-choice schedule, host function equality, or ambient Real completeness coordinate is exported. □

Falsifiable prediction: An accepted $\mathsf{UniformCauchyMap}^{\uparrow}$ consumer that reaches a $\mathsf{ContinuousMap}^{\uparrow}$ graph handoff without reading source windows, target readback, shared modulus, dyadic tolerance, Real seal, hsame transport, Cont replay, Pkg provenance, and NameCert rows refutes the carrier surface.

Independence witness: function-sequence, continuous-map, uniform-convergence, streamname, regseqrat, dyadicratcore, real: none is bijective to $\mathsf{UniformCauchyMap}^{\uparrow}$ because this packet jointly carries source finite windows, displayed map-family graph rows, target regular readbacks, a shared uniform Cauchy modulus, dyadic tolerances, terminal Real seals, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{UniformCauchyMap}^{\uparrow}}$.

Constructive story: A $\mathsf{UniformCauchyMap}^{\uparrow}$ packet is generated from source finite-window rows, target readback rows, displayed map-family graph rows, one shared uniform Cauchy modulus, DyadicRatCore tolerance rows, terminal RealUp seals, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{UniformCauchyMap}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8622.1, Definition 8622.2, and Definition 8622.3 seed the finite L10 interface between uniformly Cauchy map families and ContinuousMapUp consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{UniformCauchyMap}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim RealUp completeness, host function equality, selected limits, quotient streams, trichotomy, choice, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, shared uniform Cauchy modulus visibility, target RegSeqRat readback, DyadicRatCore tolerance accounting, Real seal nonescape, ContinuousMap handoff, transport, replay, provenance, and local naming for BEDC.Derived.UniformCauchyMapUp.

Chapter 8623

A Concrete Naming Certificate for $\mathsf{RealUniformLimit}^{\uparrow}$

Following Bishop and Bridges constructive analysis, uniform limits of continuous real-valued maps are obtained from explicit Cauchy moduli and finite readback windows, not from an ambient function-space completion or a choice-selected limit function. The $\mathsf{RealUniformLimit}^{\uparrow}$ packet records this theorem as a finite NameCert surface over the real-name interface of chapter 38, the regular rational readback of chapter 301, the finite windows of chapter 126, the continuity carrier of chapter 59, and the uniform-modulus surface of chapter 369. It is a Real and Completion bridge seed: a downstream consumer may read the limit only through the displayed uniform Cauchy family, rowwise continuity data, shared modulus ledger, transport, replay, provenance, and local naming rows.

Definition 8623.1 (RealUniformLimit carrier)**.** *A* $\mathsf{RealUniformLimit}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$U = (X, F, W, R, M, L, H, C, P, N)$$

with the following displayed rows:

1. *X is the named source-domain row on which all functions in the family are read.*
2. *F is a finite row family of* $\mathsf{Continuous}^{\uparrow}$ *maps whose values are sealed as* $\mathsf{Real}^{\uparrow}$ *names.*
3. *W is the* $\mathsf{StreamName}^{\uparrow}$ *window schedule for the values of every row of F at every displayed source request.*
4. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row obtained from those windows, with one regular rational stream for each displayed value read.*
5. *M is the* $\mathsf{UniformModulus}^{\uparrow}$ *ledger giving a common Cauchy threshold for all displayed source requests and all sufficiently late rows of F.*
6. *L is the limit-read row: it records the candidate* $\mathsf{Real}^{\uparrow}$ *value read at a source request only after W, R, and M have supplied the shared uniform Cauchy evidence.*
7. *H records componentwise* hsame *transport for the source row, row family, stream windows, regular readbacks, uniform modulus ledger, limit-read row, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from a source request through the continuous-map row, the stream windows, the regular readback, the uniform modulus ledger, and the limit-read row.*

9. *P records* Pkg *provenance over* $\mathsf{RealUniformLimit}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{Continuous}^{\uparrow}$, $\mathsf{UniformModulus}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*

10. *N is the local* $\mathsf{NameCert}_{\mathsf{RealUniformLimit}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these rows. It has no coordinate for a host function-space completion, pointwise-only convergence, a selected subsequence, quotient equality of streams, countable choice, or an ambient completeness theorem for $\mathsf{Real}^{\uparrow}$.

Theorem 8623.2 (RealUniformLimit NameCert obligations)**.** *For an accepted* $\mathsf{RealUniformLimit}^{\uparrow}$ *carrier $U = (X, F, W, R, M, L, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{RealUniformLimit}^{\uparrow}}$ *surface consists exactly of carrier admission for the displayed source row,* $\mathsf{Real}^{\uparrow}$*-valued continuous-map family,* $\mathsf{StreamName}^{\uparrow}$ *windows,* $\mathsf{RegSeqRat}^{\uparrow}$ *readbacks,* $\mathsf{UniformModulus}^{\uparrow}$ *ledger, limit-read row, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. Every limit read must expose the common modulus ledger before it may expose the* $\mathsf{Real}^{\uparrow}$ *limit value.*

Proof. Carrier admission is projection from Definition 8623.1. The packet exposes only the rows $X, F, W, R, M, L, H, C, P, N$, so every local read begins with the displayed source, family, window, readback, modulus, and limit data.

The constructive route is uniform rather than pointwise-only. For a displayed tolerance and source request, the window row W and readback row R expose the late values of the $\mathsf{Continuous}^{\uparrow}$ rows in F, while the ledger M supplies one threshold valid for the whole displayed source scope.

The structural rows then preserve that route. The transport table H compares packets componentwise, the replay row C reruns the same finite route for a consumer, and P, N source and name the certificate. Since no omitted coordinate stores a host completion, selected subsequence, quotient stream equality, countable-choice schedule, or ambient completeness theorem, no such datum can be exported by the NameCert surface. □

Theorem 8623.3 (RealUniformLimit continuity handoff)**.** *Every completion-facing or continuity-facing consumer of an accepted* $\mathsf{RealUniformLimit}^{\uparrow}$ *packet must read the* $\mathsf{Continuous}^{\uparrow}$ *row family F, the* $\mathsf{StreamName}^{\uparrow}$ *window schedule W, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback R, and the* $\mathsf{UniformModulus}^{\uparrow}$ *ledger M before it can use the limit row L as a* $\mathsf{Real}^{\uparrow}$*-valued continuous map. The handoff route is therefore*

$$X, F, W, R, M \longmapsto L, H, C, P, N.$$

It exports the constructive uniform-limit theorem only through the displayed finite rows, and not through pointwise convergence alone, host function-space completeness, countable choice, quotient stream equality, or a selected limit representative.

Proof. Start with the NameCert obligations of Definition 8623.2. They force every limit read to pass through the displayed family, windows, readbacks, and shared modulus ledger.

Continuity is handed off rowwise and then uniformly. Each row of F supplies its $\mathsf{Continuous}^{\uparrow}$ replay for the displayed source request, while W and R expose the corresponding $\mathsf{Real}^{\uparrow}$ value names as regular rational readbacks.

The ledger M is the uniform step. It supplies the common late threshold used to compare all displayed rows at the requested tolerance, so the candidate limit row L is read only after the same threshold covers the whole source scope.

Finally, H, C, P, N transport, replay, source, and name the handoff. A consumer that bypasses F, W, R, or M is outside the accepted packet, and a consumer that asks for pointwise-only convergence, a host completion, countable choice, quotient stream equality, or a selected representative asks for data not carried by the certificate. □

Theorem 8623.4 (RealUniformLimit ledger exactness)**.** *Every accepted* $\mathsf{RealUniformLimit}^{\uparrow}$ *limit read is ledgered by the single packet* $X, F, W, R, M, L, H, C, P, N$*. The same ledger records the Real-valued continuous rows, stream windows, regular rational readbacks, shared uniform Cauchy threshold, limit-read row, transport, replay, provenance, and local naming; it records no pointwise-only convergence row, host limit selector, quotient stream class, countable-choice schedule, or ambient function-space completion.*

Proof. Use the carrier of Definition 8623.1. Its analytic rows are exactly X, F, W, R, M, L, and its structural rows are exactly H, C, P, N.

The NameCert obligations of Definition 8623.2 make these rows the complete public surface. A limit read has to display the continuous row family, the value windows, the rational readbacks, and the uniform ledger before the limit row is available.

The continuity handoff of Definition 8623.3 then identifies the consumer route through that same packet. Since the packet has no additional coordinate, the excluded pointwise, host-completion, selector, quotient, and choice data cannot be recovered from an accepted read. □

Falsifiable prediction: Every accepted RealUniformLimitUp read displays Continuous, StreamName, RegSeqRat, UniformModulus, Real, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert rows before a completion-facing or continuity-facing consumer uses the limit packet.

Independence witness: real, regseqrat, streamname, continuous, uniform-modulus: $\mathsf{RealUniformLimit}^{\uparrow}$ is not bijective to any listed sibling because it jointly stores a $\mathsf{Real}^{\uparrow}$-valued continuous-row family, finite value windows, regular rational readback, one shared uniform Cauchy ledger, limit-read data, transport, replay, provenance, and local naming in one packet.

Closure status for $\mathsf{NameCert}_{\mathsf{RealUniformLimit}^{\uparrow}}$.

Constructive story: A $\mathsf{RealUniformLimit}^{\uparrow}$ packet is generated from a displayed source row, $\mathsf{Real}^{\uparrow}$-valued continuous-map rows, finite stream windows, regular rational readback, a shared uniform Cauchy ledger, a limit-read row, componentwise hsame transport, displayed Cont replay, provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RealUniformLimit}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8623.1, Definition 8623.2, Definition 8623.3, and Definition 8623.4 seed the constructive uniform-limit route over Real, RegSeqRat, StreamName, Continuous, UniformModulus, BHist, hsame, Cont, Pkg, and NameCert rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RealUniformLimit}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close a Lean carrier, a checked standard bridge, pointwise-only convergence, host function-space completeness, countable choice, quotient stream equality, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Upgrade path: Obligation closure requires a Lean carrier and checked NameCert obligations for BEDC.Derived.RealUniformLimitUp.

Chapter 8624

A Concrete Naming Certificate for $\mathsf{MooreSmithDirectedNet}^{\uparrow}$

Following Moore and Smith, the $\mathsf{MooreSmithDirectedNet}^{\uparrow}$ packet records a directed net through finite observation windows rather than through a host function space of all indexed values. It sits between the directed-index substrate of chapter 1607, the Moore–Smith convergence surface of chapter 1521, the net-convergence interface of chapter 1667, the filter-base handoff of chapter 1601, the Cauchy-filter completion boundary of chapter 1569, and the finite stream-window surface of chapter 126. The packet gives topology, completion, and filter consumers a shared directed-net carrier; it does not supply host choice, quotient net equality, selected limits, ambient completeness, or an untracked cofinal selector.

Definition 8624.1 (Moore–Smith directed-net carrier)**.** *A* $\mathsf{MooreSmithDirectedNet}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M = (D, V, R, W, L, H, C, P, N)$$

with the following displayed rows:

1. *D is the* $\mathsf{DirectedSet}^{\uparrow}$ *index row, naming finite directed addresses, displayed preorder comparisons, finite request windows, and upper-window witnesses.*
2. *V is the directed value-window row, recording the values visible at the displayed addresses of D.*
3. *R is the cofinal-refinement row, recording a finite refinement request and the displayed upper-window route by which the refined addresses remain cofinal in the observed window.*
4. *W is the finite observation-window row, naming the convergence, filter-base, and stream-window requests that a consumer may inspect.*
5. *L is the convergence ledger, recording the handoff through* $\mathsf{MooreSmithConvergence}^{\uparrow}$, $\mathsf{NetConvergence}^{\uparrow}$, $\mathsf{FilterBase}^{\uparrow}$, $\mathsf{CauchyFilterCompletion}^{\uparrow}$, *and* $\mathsf{StreamName}^{\uparrow}$ *before any completion-facing read is public.*
6. *H records componentwise* hsame *transport for the directed-index data, value windows, cofinal refinement, observation windows, convergence ledger, provenance, and local naming rows.*
7. *C records displayed* Cont *replay from an observation request through D, V, R, W, L.*
8. *P is the* Pkg *provenance over* $\mathsf{MooreSmithDirectedNet}^{\uparrow}$, $\mathsf{DirectedSet}^{\uparrow}$, $\mathsf{MooreSmithConvergence}^{\uparrow}$, $\mathsf{NetConvergence}^{\uparrow}$, $\mathsf{FilterBase}^{\uparrow}$, $\mathsf{CauchyFilterCompletion}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* NameCert *rows.*

9. *N is the local* $\mathsf{NameCert}_{\mathsf{MooreSmithDirectedNet}^{\uparrow}}$ *row.*

The carrier exports exactly these finite directed-net rows. It contains no host choice functional, quotient net equality, selected limit point, ambient topology, or hidden completion oracle.

Theorem 8624.2 (Moore–Smith directed-net NameCert obligations)**.** *For an accepted* $\mathsf{MooreSmithDirectedNet}^{\uparrow}$ *carrier $M = (D, V, R, W, L, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{MooreSmithDirectedNet}^{\uparrow}}$ *surface consists exactly of the following obligations:*

1. *carrier admission for the directed-index row, value-window row, cofinal-refinement row, finite observation-window row, convergence ledger, transport row, replay row, provenance row, and local naming row;*
2. *directed-index readability, requiring every net read to expose the* $\mathsf{DirectedSet}^{\uparrow}$ *row D before a value in V is consumed;*
3. *cofinal-refinement compatibility, requiring every refined tail request in R to display its upper-window witness inside the same directed ledger;*
4. *finite-window convergence routing, requiring every* $\mathsf{MooreSmithConvergence}^{\uparrow}$ *and* $\mathsf{NetConvergence}^{\uparrow}$ *read to pass through the observation windows W and ledger L before it is exported;*
5. *filter and completion handoff, requiring* $\mathsf{FilterBase}^{\uparrow}$ *and* $\mathsf{CauchyFilterCompletion}^{\uparrow}$ *consumers to read only the finite tail family recorded by D, R, W, L;*
6. *stream replay, requiring every* $\mathsf{StreamName}^{\uparrow}$ *observation to be replayed through C and transported through H without changing the displayed rows;*
7. *ledger refusal, excluding host choice, quotient net equality, selected limits, ambient completeness, and unrecorded cofinal schedules.*

Proof. Project the accepted carrier of Definition 8624.1. Its analytic rows are D, V, R, W, L, and its structural rows are H, C, P, N.

The directed-index obligation is inherited from the visible $\mathsf{DirectedSet}^{\uparrow}$ row. A consumer first reads the displayed addresses, comparisons, finite windows, and upper-window witnesses in D; only then can the value-window row V be inspected.

The cofinal-refinement row R is not an external selector. It records a finite refinement request together with the upper-window route already supplied by D, so every refined tail remains inside the displayed directed ledger.

The convergence ledger L is reached through the finite observation windows W. Thus $\mathsf{MooreSmithConvergence}^{\uparrow}$ and $\mathsf{NetConvergence}^{\uparrow}$ consumers receive a displayed observation route, while $\mathsf{FilterBase}^{\uparrow}$ and $\mathsf{CauchyFilterCompletion}^{\uparrow}$ consumers receive only the finite tail family recorded by that same route.

Finally H and C transport and replay the same rows componentwise, while P and N package and name them locally. Since no coordinate stores host choice, quotient net equality, selected limits, ambient completeness, or an unrecorded cofinal schedule, the listed obligations exhaust the certificate surface. □

Theorem 8624.3 (Moore–Smith directed-net finite-window handoff)**.** *Every topology-facing or completion-facing consumer of an accepted* $\mathsf{MooreSmithDirectedNet}^{\uparrow}$ *packet factors through the finite route*

$$\mathsf{DirectedSet}^{\uparrow},\ V,\ R,\ W \longmapsto \mathsf{MooreSmithConvergence}^{\uparrow},\ \mathsf{NetConvergence}^{\uparrow},\ \mathsf{FilterBase}^{\uparrow},\ \mathsf{CauchyFilterCompletion}^{\uparrow},\ \mathsf{Str}$$

The handoff gives the consumer directed index data, cofinal refinement, finite observation windows, convergence ledger rows, componentwise transport, displayed replay, provenance, and local naming.

It does not give host choice, quotient net equality, selected limits, ambient compactness, or a countable schedule outside the packet.

Proof. Start with the NameCert obligations of Definition 8624.2. They force directed-index readability through D and finite value-window exposure through V before any downstream route is public.

Next read the cofinal-refinement and observation-window rows. The row R keeps refined tails inside the displayed upper-window ledger, and W lists the finite requests visible to convergence, filter, completion, and stream consumers.

Apply the convergence ledger row L. It orders the public handoff through $\mathsf{MooreSmithConvergence}^{\uparrow}$, $\mathsf{NetConvergence}^{\uparrow}$, $\mathsf{FilterBase}^{\uparrow}$, $\mathsf{CauchyFilterCompletion}^{\uparrow}$, and $\mathsf{StreamName}^{\uparrow}$ without replacing the finite packet by a host topology or by a selected endpoint.

The structural rows H, C, P, N preserve, replay, source, and name this same carrier. Hence every consumer receives the finite directed-net handoff and no forbidden host choice, quotient net equality, selected limit, ambient compactness, or external countable schedule. □

Falsifiable prediction: A claimed Moore–Smith directed-net handoff falls outside $\mathsf{MooreSmithDirectedNet}^{\uparrow}$ whenever it reaches $\mathsf{NetConvergence}^{\uparrow}$, $\mathsf{FilterBase}^{\uparrow}$, or $\mathsf{CauchyFilterCompletion}^{\uparrow}$ without first displaying the directed index row, cofinal-refinement row, finite observation-window row, convergence ledger, componentwise transport, replay, provenance, and local NameCert rows.

Closure status for $\mathsf{NameCert}_{\mathsf{MooreSmithDirectedNet}^{\uparrow}}$.

Constructive story: A $\mathsf{MooreSmithDirectedNet}^{\uparrow}$ packet is generated from directed index data, finite value windows, a cofinal-refinement row, finite observation windows, a convergence ledger, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{MooreSmithDirectedNet}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8624.1, Definition 8624.2, and Definition 8624.3 seed the finite-window Moore–Smith directed-net interface consumed by convergence, filter, completion, and stream-window chapters.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{MooreSmithDirectedNet}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim host choice, quotient net equality, selected limits, ambient completeness, open-cover compactness, Lean verification, or a standard bridge.

Upgrade path: Obligation closure requires checked carrier admission, directed-index readability, cofinal-refinement compatibility, finite-window convergence routing, filter and completion handoff, stream replay, transport preservation, and ledger refusal for the displayed packet.

Chapter 8625

A Concrete Naming Certificate for $\mathsf{CompactUniformCauchyMap}^{\uparrow}$

Following Bishop and Bridges on uniform convergence and finite-net compact metric arguments, the $\mathsf{CompactUniformCauchyMap}^{\uparrow}$ packet records a compact-domain family of uniformly Cauchy continuous-map rows as finite NameCert data. It sits over the compact metric net surface of chapter 129, the continuous-map modulus rows of chapter 130, the uniform-Cauchy family route of chapter 8622, the regular rational readback of chapter 301, and the terminal Real seals of chapter 38.

The packet names the finite handoff from compact-domain net control to a uniform-Cauchy map family. It is not an open-cover compactness principle, a selected limiting map, a quotient equality of functions, a choice operator, an ambient $\mathsf{Real}^{\uparrow}$ completeness theorem, Lean verification, or bridge checking.

Definition 8625.1 (Compact uniform Cauchy map carrier)**.** *A* $\mathsf{CompactUniformCauchyMap}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (A, F, U, R, E, H, C, P, N)$$

with the following displayed rows:

1. *A is the compact-net datum for the domain, including the finite* $\mathsf{CompactMetric}^{\uparrow}$ *cover windows, Lebesgue-style mesh requests, and the metric comparison rows used to inspect the domain.*
2. *F stores the* $\mathsf{ContinuousMap}^{\uparrow}$ *modulus rows for the displayed family members, including source windows, target tolerances, and the local continuity budgets consumed at each compact-net point.*
3. *U is the* $\mathsf{UniformCauchyMap}^{\uparrow}$ *family row, requiring all family comparisons to use one displayed tolerance schedule across the compact-domain windows named by A.*
4. *R records the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback rows for every finite tolerance, oscillation, and image-distance request exposed by A, F, U.*
5. *E stores the terminal* $\mathsf{Real}^{\uparrow}$ *seals for the finite image-distance bounds and Cauchy comparison rows that downstream consumers may read.*
6. *H records componentwise* hsame *transport for compact-net data, continuous-map moduli, uniform-Cauchy family rows, regular rational readbacks, Real seals, continuation, provenance, and local naming rows.*

7. *C records displayed* Cont *replay from compact-net requests through continuous-map modulus rows, then through the uniform-Cauchy family row, and finally into the readback and Real seal rows.*

8. *P is the* Pkg *provenance over* $\mathsf{CompactUniformCauchyMap}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{UniformCauchyMap}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

9. *N is the local* $\mathsf{NameCert}_{\mathsf{CompactUniformCauchyMap}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $A, F, U, R, E, H, C, P, N$. It has no coordinate for open-cover compactness, selected limits, quotient equality of functions, choice, ambient $\mathsf{Real}^{\uparrow}$ *completeness, Lean verification, or bridge checking.*

Theorem 8625.2 (CompactUniformCauchyMap NameCert obligations)**.** *For every accepted* CompactUniformCauc *carrier*

$$K = (A, F, U, R, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{CompactUniformCauchyMap}^{\uparrow}}$ *surface consists exactly of compact-net admission for A, continuous-map modulus admission for F, uniform-Cauchy family admission for U, regular rational readback through R, Real seal exposure through E, componentwise* hsame *transport through H, displayed* Cont *replay through C, provenance through P, and local naming through N.*

No compact uniform Cauchy map obligation is stored outside these rows.

Proof. Project the accepted carrier. The compact-domain information available to the packet is exactly the finite net row A, so every later modulus request is tied to displayed compact metric windows rather than to an open-cover principle.

The analytic rows are then forced. The continuous-map data F supplies the local modulus budgets, while U requires the family comparison to use one tolerance schedule across the compact-domain windows named by A.

The readback and seal rows close the public surface. The row R records the regular rational observations used by the compact-net, modulus, and uniform-Cauchy routes, and E is visible only after those rows have been replayed.

Finally inspect the structural rows. The transport, continuation, provenance, and local NameCert rows preserve the same finite route, and the carrier has no coordinate for open-cover compactness, selected limiting maps, quotient function equality, choice, ambient completeness, Lean verification, or bridge checking. □

Theorem 8625.3 (CompactUniformCauchyMap uniform-modulus handoff)**.** *Let $K = (A, F, U, R, E, H, C, P, N)$ be an accepted* $\mathsf{CompactUniformCauchyMap}^{\uparrow}$ *carrier. Every downstream uniform-modulus read from K factors through the finite route*

$$A, F \longrightarrow U \longrightarrow R \longrightarrow E$$

with transport, replay, provenance, and local naming supplied by H, C, P, N. Thus the exported modulus is a compact-net uniform-Cauchy handoff, not a selected limit map or an equality of quotient functions.

Proof. Start with a downstream uniform-modulus read. Carrier admission exposes the compact-net row A and the continuous-map modulus row F before any family-level comparison is available.

The uniform-Cauchy row U then consumes those same compact-domain windows and modulus budgets. Because U stores one family tolerance schedule over the displayed finite net data, the handoff is uniform over the named compact-domain requests.

The readback route is finite. The row R records the regular rational bounds used in the compact-net and uniform-Cauchy comparison, and the terminal Real seals in E may be read only after that route is displayed.

The support rows H, C, P, N transport and replay the route without adding another analytic coordinate. Hence the public handoff excludes open-cover compactness, selected limits, quotient function equality, choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, and bridge checking. □

Closure status for $\mathsf{NameCert}_{\mathsf{CompactUniformCauchyMap}^{\uparrow}}$.

Constructive story: A $\mathsf{CompactUniformCauchyMap}^{\uparrow}$ packet is generated from compact-net data, ContinuousMapUp modulus rows, one UniformCauchyMapUp family row, RegSeqRat readback rows, RealUp seal rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CompactUniformCauchyMap}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8625.1, Definition 8625.2, and Definition 8625.3 seed the compact-domain uniform-Cauchy map packet from compact-net rows, continuous-map modulus rows, uniform-Cauchy family rows, regular rational readback, Real seals, transport, replay, provenance, and local naming.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CompactUniformCauchyMap}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close open-cover compactness, selected limits, quotient function equality, choice, ambient RealUp completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked compact-net admission, continuous-map modulus admission, uniform-Cauchy family exactness, regular rational readback, Real seal nonescape, transport stability, replay stability, and TasteGate field faithfulness for BEDC.Derived.CompactUniformCauchyMapUp.

Chapter 8626

A Concrete Naming Certificate for $\mathsf{CauchyCompletionReflectorUnit}^{\uparrow}$

Following Bourbaki and Kelley on completions as reflector data, and Bishop–Bridges on constructive Cauchy completion, the $\mathsf{CauchyCompletionReflectorUnit}^{\uparrow}$ packet records the finite unit leg by which a displayed source Cauchy object enters the completion-reflector surface. It sits between the reflector packet of chapter 1585, the universal mapping surface of chapter 1456, the regular-Cauchy reflector row of chapter 3398, and the Real completion adjunction packet of chapter 6918. The chapter names only the unit embedding and its dense-image replay; it does not assert quotient completion, selected representatives, countable choice, host equality, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 8626.1 (Cauchy completion reflector unit carrier)**.** *A* $\mathsf{CauchyCompletionReflectorUnit}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$U = (X, R, J, D, T, H, C, P, N)$$

with the following displayed rows:

1. *X is the source metric and Cauchy-observation row, including the finite source histories consumed before a completion request is public.*
2. *R is the* $\mathsf{CauchyCompletionReflector}^{\uparrow}$ *or* $\mathsf{RegularCauchyCompletionReflector}^{\uparrow}$ *row that exposes the target completion-reflector surface over the same source histories.*
3. *J is the unit embedding row from the source row into the reflector row, read as displayed finite data rather than as a quotient-class injection.*
4. *D is the dense unit-image row, requiring reflector-facing reads to expose the source image before universal mapping or Real-completion consumers can use the completed surface.*
5. *T is the triangle replay row, tying the unit read to the adjunction and Real-completion rows named by chapter 1456 and chapter 6918.*
6. *H records componentwise* hsame *transport for source, reflector, unit embedding, dense-image, triangle replay, continuation, provenance, and local naming rows.*
7. *C records displayed* Cont *replay through*

$$X \longmapsto J \longmapsto R \longmapsto D, T \longmapsto H, P, N.$$

8. *P is the* Pkg *provenance over* $\mathsf{CauchyCompletionReflectorUnit}^{\uparrow}$, $\mathsf{CauchyCompletionReflector}^{\uparrow}$, RegularCauchyComp CauchyCompletionAdjunction$^{\uparrow}$, RealCompletionAdjunction$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

9. *N is the local* $\mathsf{NameCert}_{\mathsf{CauchyCompletionReflectorUnit}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $X, R, J, D, T, H, C, P, N$. It has no coordinate for quotient completion equality, selected representatives, countable-choice schedules, host equality of completed objects, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 8626.2 (CauchyCompletionReflectorUnit NameCert obligations)**.** *For every accepted* $\mathsf{CauchyCompletionReflectorUnit}^{\uparrow}$ *carrier $U = (X, R, J, D, T, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{CauchyCompletionReflectorUnit}}$ *surface consists exactly of carrier admission for the source row, reflector row, unit embedding, dense unit image, triangle replay, componentwise transport, displayed continuation, provenance, and local naming rows.*

Every reflector-unit consumer must read $X, J, R, D, T, H, C, P, N$ in the displayed order before it exports a completion-facing handoff. The packet exports no quotient completion, selected representative, countable choice, host equality, or ambient $\mathsf{Real}^{\uparrow}$ *completeness claim.*

Proof. Project the accepted carrier of Definition 8626.1. The tuple exposes the source row X, reflector row R, unit row J, dense-image row D, triangle replay row T, and structural rows H, C, P, N.

The unit embedding is read before the reflector target is used. A completion-facing consumer therefore obtains source access through J, then reads the reflector row R, and only after that exposes the dense unit-image row D.

The triangle row is a replay row. It refers back to the displayed adjunction and Real-completion adjunction packets through P, while H and C transport and replay only the same finite coordinates. Since no refused host-side principle appears as a row of the carrier, the listed obligations exhaust the local NameCert surface. □

Theorem 8626.3 (CauchyCompletionReflectorUnit triangle law)**.** *Let $U = (X, R, J, D, T, H, C, P, N)$ be an accepted* $\mathsf{CauchyCompletionReflectorUnit}^{\uparrow}$ *carrier. Any unit-side read consumed by the Cauchy completion adjunction or the Real completion adjunction factors through*

$$X \longmapsto J \longmapsto R \longmapsto D \longmapsto T \longmapsto (H, C, P, N).$$

The triangle law is only this finite replay condition over the displayed source, reflector, unit, dense-image, transport, continuation, provenance, and local NameCert *rows. It does not identify quotient completions, select representatives, invoke countable choice, assert host equality, or claim ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Begin with the NameCert obligations of Definition 8626.2. They force every accepted read to display the source, unit embedding, reflector, dense-image, triangle, transport, continuation, provenance, and naming rows.

The adjunction-side consumer can then use the same route only through the cited sibling packets. The Cauchy completion adjunction supplies the universal mapping surface, the regular-Cauchy reflector supplies the regular source specialization, and the Real completion adjunction supplies the terminal Real-facing unit/counit boundary.

The row T records the replay through those surfaces, while H, C, P, N preserve and name the same finite packet. Because the carrier has no quotient, representative-selection, choice, host-equality, or ambient-completeness coordinate, the triangle law is exactly the displayed BEDC replay. □

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyCompletionReflectorUnit}^{\uparrow}}$.

Constructive story: A $\mathsf{CauchyCompletionReflectorUnit}^{\uparrow}$ packet is generated from source Cauchy data, a completion-reflector row, a unit embedding, dense unit-image evidence, triangle replay, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CauchyCompletionReflectorUnit}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8626.1, Definition 8626.2, and Definition 8626.3 seed the finite unit leg for the L10 Cauchy completion reflector route.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CauchyCompletionReflectorUnit}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient completion equality, selected representatives, countable choice, host equality of completed objects, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, unit embedding exposure, dense-image visibility, triangle replay exactness, transport stability, continuation replay, provenance exhaustion, and local naming for BEDC.Derived.CauchyCompletionReflectorUnitUp.

Chapter 8627

A Concrete Naming Certificate for $\mathsf{CompleteGeodesicConvexity}^{\uparrow}$

Following Bridson and Haefliger, the $\mathsf{CompleteGeodesicConvexity}^{\uparrow}$ packet records the finite BEDC surface on which complete metric service and displayed geodesic convexity are read together. It sits between the metric carrier of chapter 57, the completion boundary of chapter 128, the segment witness route of chapter 2213, the finite convexity packet of chapter 7899, and the complete CAT(0) neighbour of chapter 6734. The packet names a complete geodesic-convex carrier for downstream metric geometry consumers; it does not assert open-cover compactness, selected global geodesics, quotient path equality, projection existence, or host-geometric primitives.

Definition 8627.1 (Complete geodesic convexity surface)**.** *The* $\mathsf{CompleteGeodesicConvexity}^{\uparrow}$ *NameCert surface has five displayed rows:*

1. *M is the* $\mathsf{Met}^{\uparrow}$ *source row, exposing point classifiers, distance readback, and the metric-law ledger inspected by the packet.*
2. *E is the* $\mathsf{CompleteMetric}^{\uparrow}$ *service row, recording only the displayed Cauchy-thread or completion-facing requests available over the same source.*
3. *G is the* $\mathsf{GeodesicMetric}^{\uparrow}$ *row, carrying finite segment witnesses between displayed endpoints.*
4. *V is the* $\mathsf{FiniteGeodesicConvexity}^{\uparrow}$ *row, requiring each displayed segment read to remain inside the named convex target through finite endpoint, segment, and membership ledgers.*
5. *S is the structural row consisting of componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and the local* $\mathsf{NameCert}_{\mathsf{CompleteGeodesicConvexity}^{\uparrow}}$ *naming row over M, E, G, V.*

The classifier compares accepted packets only through M, E, G, V, S. It has no coordinate for open-cover compactness, selected geodesic families, quotient path spaces, projection selectors, ambient CAT(0) theorems, or host completeness outside the displayed $\mathsf{CompleteMetric}^{\uparrow}$ *row.*

Theorem 8627.2 (Complete geodesic convexity carrier)**.** *For every accepted* $\mathsf{CompleteGeodesicConvexity}^{\uparrow}$ *packet*

$$C = (M, E, G, V, S),$$

the local $\mathsf{NameCert}_{\mathsf{CompleteGeodesicConvexity}^{\uparrow}}$ *surface consists exactly of carrier admission for the* $\mathsf{Met}^{\uparrow}$ *row M,* $\mathsf{CompleteMetric}^{\uparrow}$ *row E,* $\mathsf{GeodesicMetric}^{\uparrow}$ *segment row G,* $\mathsf{FiniteGeodesicConvexity}^{\uparrow}$ *convexity row V, and structural row S. Every completion-facing or Hadamard-facing consumer must read the complete metric service and the segment-inside-convex-target witness through those five rows before using the packet as complete geodesic convexity data.*

Proof. Project the displayed carrier $C = (M, E, G, V, S)$. The metric source is fixed by M, while completion enters only through the $\mathsf{CompleteMetric}^{\uparrow}$ service row E over that same source.

Read the geodesic and convexity rows next. The row G supplies only finite segment witnesses between displayed endpoints, and V verifies that the visible segment read remains inside the named convex target by the finite convexity surface of chapter 7899.

Finally inspect the structural row S. Componentwise hsame transport and displayed Cont replay preserve exactly M, E, G, V, while Pkg provenance and the local naming row source the same packet. Because no additional coordinate stores open-cover compactness, selected geodesic families, quotient path equality, projection selectors, ambient CAT(0) theorems, or host-geometric primitives, the five displayed rows exhaust the NameCert surface. □

Falsifiable prediction: An accepted $\mathsf{CompleteGeodesicConvexity}^{\uparrow}$ consumer that reaches completion-facing convexity data without displaying the $\mathsf{Met}^{\uparrow}$, $\mathsf{CompleteMetric}^{\uparrow}$, $\mathsf{GeodesicMetric}^{\uparrow}$, $\mathsf{FiniteGeodesicConvexity}^{\uparrow}$, transport, replay, provenance, and local NameCert rows refutes the carrier surface.

Independence witness: metric-space, complete-metric, geodesic-metric, finite-geodesic-convexity, hadamard-space: none of the listed neighbours alone supplies the whole packet $C = (M, E, G, V, S)$, because the neighbours contribute metric source data, completion service, segment witnesses, convexity ledgers, or complete CAT(0) context while this chapter binds the complete metric service and finite geodesic-convexity route into one finite NameCert carrier.

Closure status for $\mathsf{NameCert}_{\mathsf{CompleteGeodesicConvexity}^{\uparrow}}$.

Constructive story: A $\mathsf{CompleteGeodesicConvexity}^{\uparrow}$ packet is generated from a MetricSpace source row, a CompleteMetric service row, a GeodesicMetric segment row, a FiniteGeodesicConvexity row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CompleteGeodesicConvexity}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8627.1 and Definition 8627.2 seed the finite complete geodesic-convex carrier over metric, completion, segment, convexity, transport, replay, provenance, and naming rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CompleteGeodesicConvexity}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim open-cover compactness, selected global geodesics, quotient path equality, projection existence, ambient CAT(0) theorems, host-geometric primitives, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, complete-metric exposure, geodesic segment exactness, convexity routing, transport, replay, provenance, and local naming for BEDC.Derived.CompleteGeodesicConvexityUp.

Chapter 8628

A Concrete Naming Certificate for $\mathsf{UniformCauchyRegularFamily}^{\uparrow}$

Following Bishop and Bridges, *Constructive Analysis*, the $\mathsf{UniformCauchyRegularFamily}^{\uparrow}$ packet records a finite family of regular Cauchy rational names controlled by one shared modulus schedule. It sits over the dyadic rational core of chapter 291, the stream-window interface of chapter 126, the regular rational readback of chapter 301, the real-name seal of chapter 38, the shared-modulus surface of chapter 1741, and the family-level route of chapter 1555. The packet gives completion and uniform-limit consumers a bounded shared-modulus regular-family certificate before any quotient stream, host real equality, countable-choice selector, chosen limit, or ambient $\mathsf{Real}^{\uparrow}$ completeness principle is available.

Definition 8628.1 (Uniform Cauchy regular family carrier)**.** *A* $\mathsf{UniformCauchyRegularFamily}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$U = (F, M, W, D, R, E, H, C, P, N)$$

with the following displayed rows:

1. *F is the finite family row whose entries are* $\mathsf{RegSeqRat}^{\uparrow}$ *regular rational Cauchy names and whose domain of inspection is a finite BEDC row.*
2. *M is the shared* $\mathsf{UniformCauchyModulus}^{\uparrow}$ *schedule. It assigns one displayed modulus response to the whole family for each accepted tolerance request.*
3. *W records the* $\mathsf{StreamName}^{\uparrow}$ *windows read from every family member at the requests named by M.*
4. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, including the requested tolerance, the shared tail tolerance supplied by M, and the finite endpoint ledgers used for each component comparison.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback family assembled from the windows W and dyadic ledger D.*
6. *E is the* $\mathsf{Real}^{\uparrow}$ *seal-row family reached only after F, M, W, D, R have been exposed.*
7. *H records componentwise* hsame *transport for the family row, shared modulus, stream windows, dyadic tolerance ledger, regular readbacks, real seals, replay, provenance, and local name.*
8. *C records displayed* Cont *replay from a family Cauchy request through $F, M, W, D, R, E, H, P, N$.*
9. *P records* Pkg *provenance over* $\mathsf{UniformCauchyRegularFamily}^{\uparrow}$, $\mathsf{UniformCauchyFamily}^{\uparrow}$, $\mathsf{UniformCauchyModulus}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

10. N is the local $\mathsf{NameCert}_{\mathsf{UniformCauchyRegularFamily}^{\uparrow}}$ *row.*
The carrier has no coordinate for quotient streams, host real equality, per-component hidden moduli, countable-choice schedules, chosen limiting reals, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 8628.2 (Uniform Cauchy regular family NameCert obligations)**.** *For every accepted* $\mathsf{UniformCauchyRegularFamily}^{\uparrow}$ *carrier*

$$U = (F, M, W, D, R, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{UniformCauchyRegularFamily}^{\uparrow}}$ *surface consists exactly of carrier admission for the finite regular family, shared modulus schedule, stream windows, dyadic tolerance ledgers, regular readbacks, real seals, componentwise transport, replay, provenance, and local naming; shared-modulus exactness requiring M to serve every displayed family member; readback exactness requiring R to be assembled only from W and D; real-seal nonescape requiring E to remain downstream of F, M, W, D, R; and provenance exhaustion excluding quotient streams, host real equality, hidden per-component moduli, countable choice, chosen limits, and ambient completeness.*

Proof. Project the carrier of Definition 8628.1. The finite family row, shared modulus, stream windows, dyadic tolerance ledger, regular readbacks, real seals, transport, replay, provenance, and local name are the only displayed coordinates.

The shared-modulus clause is forced by the single row M. Every accepted tolerance request for the family reads the same schedule before any component window in W is inspected, so no component receives a hidden threshold outside the packet.

The readback and seal clauses are downstream of this same data. The row R is assembled from W and D, and the real seal row E appears only after the regular readback has been exposed.

Finally H, C, P, N transport, replay, source, and name the same finite route. Since the carrier contains no further coordinate, the listed obligations exhaust the NameCert surface and rule out the refused quotient, equality, choice, limit, and completeness routes. □

Theorem 8628.3 (Uniform Cauchy regular family real-completion handoff)**.** *Every completion-facing consumer of an accepted* $\mathsf{UniformCauchyRegularFamily}^{\uparrow}$ *carrier factors through the finite route*

$$F, M \longmapsto W, D \longmapsto R \longmapsto E.$$

Thus the consumer receives one finite regular family row, one shared $\mathsf{UniformCauchyModulus}^{\uparrow}$ *schedule,* $\mathsf{StreamName}^{\uparrow}$ *windows,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledgers,* $\mathsf{RegSeqRat}^{\uparrow}$ *readbacks, and terminal* $\mathsf{Real}^{\uparrow}$ *seal rows before any completion-facing output can be read.*

Proof. Begin with the source side. The family row F and shared modulus row M are the only input rows available to a completion-facing consumer, and M is common to all displayed family members.

Next read the observation rows. The stream windows W and dyadic tolerance ledger D provide the finite component comparisons required by the shared modulus, while R records the regular rational readbacks obtained from those observations.

The real seal row E is downstream of R. Componentwise transport and displayed replay preserve this order, and provenance records only the rows named in Definition 8628.1.

Therefore completion-facing consumers must use the displayed route $F, M \mapsto W, D \mapsto R \mapsto E$. The route does not export quotient stream equality, host real equality, per-component hidden moduli, countable choice, chosen limiting reals, or ambient completeness. □

Closure status for $\mathsf{NameCert}_{\mathsf{UniformCauchyRegularFamily}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{UniformCauchyRegularFamily}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8628.1, Definition 8628.2, and Definition 8628.3 seed the finite shared-modulus regular Cauchy family route over $\mathsf{UniformCauchyModulus}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{UniformCauchyRegularFamily}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient-stream completion, host real equality, hidden per-component moduli, countable choice, chosen limiting reals, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, shared-modulus exactness, readback exactness, real-seal nonescape, replay stability, provenance exhaustion, and local naming for BEDC.Derived.UniformCauchyRegularFamilyUp.

Constructive story: A $\mathsf{UniformCauchyRegularFamily}^{\uparrow}$ packet is generated from a finite family of RegSeqRat rows, one UniformCauchyModulus schedule, StreamName windows, DyadicRatCore tolerance ledgers, RegSeqRat readbacks, RealUp seal rows, componentwise hsame transport, displayed Cont replay, package provenance, and a local NameCert row.

Chapter 8629

A Concrete Naming Certificate for $\mathsf{RegularCauchyOrderedField}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{RegularCauchyOrderedField}^{\uparrow}$ packet records the constructive ordered-field surface for regular Cauchy real names as finite BEDC NameCert data. It sits over the regular rational readback route of chapter 301, the dyadic tolerance ledger of chapter 291, the finite stream-window surface of chapter 126, the algebraic order boundary of chapter 766, and the terminal real-name seal of chapter 38. The packet gives RealAlgOrder and Real consumers a displayed comparison and operation route on regular names, without quotient streams, trichotomy, selected limits, host ordered-field equality, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 8629.1 (Regular Cauchy ordered-field carrier)**.** *A* $\mathsf{RegularCauchyOrderedField}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$F = (X, Y, S, D, R, O, A, H, C, P, N)$$

with the following displayed rows:

1. *X and Y are the two* $\mathsf{RegSeqRat}^{\uparrow}$ *regular Cauchy source rows whose finite rational windows are compared.*
2. *S is the shared* $\mathsf{StreamName}^{\uparrow}$ *schedule naming every inspected precision window for both sources.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger recording the dyadic radius, slack, sign budget, and comparison threshold for each inspected window.*
4. *R is the regular-rational readback row that records the finite rational observations obtained from X and Y through S and D.*
5. *O is the operation-order ledger, storing the displayed addition, multiplication, comparison, and apartness rows needed by the ordered-field route.*
6. *A is the downstream* $\mathsf{RealAlgOrder}^{\uparrow}$ *handoff row, available only after X, Y, S, D, R, O have been displayed.*
7. *H records componentwise* hsame *transport for the regular sources, stream schedule, dyadic ledger, readback row, operation-order ledger, RealAlgOrder handoff, and local certificate rows.*
8. *C records the displayed* Cont *replay from an ordered-field request to the stream windows, dyadic tolerance comparison, regular-rational readback, operation-order ledger, and RealAlgOrder handoff.*

9. *P is the* Pkg *provenance over* $\mathsf{RegularCauchyOrderedField}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RealAlgOrder}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyOrderedField}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $X, Y, S, D, R, O, A, H, C, P, N$. It has no coordinate for quotient stream equality, trichotomy, selected limits, host ordered-field equality, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 8629.2 (Regular Cauchy ordered-field NameCert obligations)**.** *For every accepted* RegularCauchyOrdered *carrier $F = (X, Y, S, D, R, O, A, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyOrderedField}^{\uparrow}}$ *surface consists exactly of carrier admission for the two* $\mathsf{RegSeqRat}^{\uparrow}$ *source rows, shared* $\mathsf{StreamName}^{\uparrow}$ *windows,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance comparisons, regular-rational readback, operation-order ledger, downstream* $\mathsf{RealAlgOrder}^{\uparrow}$ *handoff, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. No NameCert obligation may replace these rows by quotient streams, trichotomy, selected limits, host ordered-field equality, countable choice, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the carrier of Definition 8629.1. The rows $X, Y, S, D, R, O, A, H, C, P, N$ are the only displayed coordinates available to the local certificate.

The two regular Cauchy sources are compared through the same stream schedule S and dyadic tolerance ledger D. The readback row R and the operation-order ledger O therefore record finite tolerance evidence, not quotient-stream equality or a host trichotomy.

The RealAlgOrder handoff A is downstream of that finite route. Transport, replay, provenance, and local naming are supplied by H, C, P, N, and the carrier has no additional coordinate from which a selector, host equality, choice principle, or ambient completeness theorem could be projected. □

Theorem 8629.3 (Regular Cauchy operation-order handoff)**.** *Every* $\mathsf{RealAlgOrder}^{\uparrow}$ *or* $\mathsf{Real}^{\uparrow}$ *consumer of an accepted* $\mathsf{RegularCauchyOrderedField}^{\uparrow}$ *packet reads the constructive ordered-field surface only through the displayed route*

$$X, Y, S, D, R, O, A, H, C, P, N.$$

The handoff exports finite stream windows, dyadic tolerance comparisons, regular-rational readback, an operation-order ledger, componentwise hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local* NameCert *rows. It does not export quotient streams, trichotomy, selected limits, host ordered-field equality, countable choice, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start with a consumer of the ordered-field surface. The carrier displays X and Y only together with the shared stream schedule S, dyadic tolerance ledger D, and finite readback row R.

The operation-order ledger O can be read only after those windows and tolerances have been displayed. If an algebraic-order or Real-facing consumer is present, the downstream row A is available only after the same finite comparison route has been consumed.

Apply the NameCert obligations of Definition 8629.2. The support rows H, C, P, N preserve, replay, source, and name this finite route, so the handoff exports no quotient streams, trichotomy, selected limits, host ordered-field equality, choice principle, or ambient completeness theorem. □

Falsifiable prediction: An accepted $\mathsf{RegularCauchyOrderedField}^{\uparrow}$ consumer that reaches a $\mathsf{RealAlgOrder}^{\uparrow}$ or $\mathsf{Real}^{\uparrow}$ read without first reading two RegSeqRat source rows, a shared StreamName schedule, a

DyadicRatCore tolerance ledger, regular-rational readback, an operation-order ledger, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row refutes the carrier surface.

Independence witness: regseqrat, dyadicratcore, streamname, realalgorder, real: $\mathsf{RegularCauchyOrderedField}^{\uparrow}$ is not bijective to any listed sibling because it binds two regular Cauchy source rows to one constructive ordered-field ledger and downstream RealAlgOrder handoff.

Closure status for $\mathsf{NameCert}_{\mathsf{RegularCauchyOrderedField}^{\uparrow}}$.

Constructive story: A $\mathsf{RegularCauchyOrderedField}^{\uparrow}$ packet is generated from two RegSeqRat source rows, a shared StreamName schedule, a DyadicRatCore tolerance ledger, regular-rational readback, an operation-order ledger, a RealAlgOrder handoff, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RegularCauchyOrderedField}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8629.1, Definition 8629.2, and Definition 8629.3 seed the finite constructive ordered-field route for regular Cauchy real names through RegSeqRat, DyadicRatCore, StreamName, RealAlgOrder, and Real rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RegularCauchyOrderedField}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient stream equality, trichotomy, selected limits, host ordered-field equality, countable choice, ambient RealUp completeness, Lean verification, or bridge checking.

Upgrade path: A formal route can encode the displayed carrier and prove the finite NameCert obligation surface and RealAlgOrder handoff theorem.

Chapter 8630

A Concrete Naming Certificate for FiniteSubcoverModulusBudget$^{\uparrow}$

Following Bishop and Bridges, the FiniteSubcoverModulusBudget$^{\uparrow}$ packet records the finite budget ledger by which compact-net cover data are folded into a uniform modulus. It sits over the compact finite-net route of chapter 60, the finite lower-bound fold of chapter 619, the compact cover route of chapter 6250, the finite subcover criterion of chapter 3503, and the uniform-modulus consumers in chapter 9237. The packet records a finite ledger for compact-net, rational-radius, local-modulus, fold-minimum, and uniform-modulus rows; it does not select arbitrary subcovers, invoke host compactness, or claim ambient completeness.

Definition 8630.1 (Finite subcover modulus budget carrier)**.** *A* FiniteSubcoverModulusBudget$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (K, E, L, R, F, U, H, C, P, N)$$

with the following displayed rows:

1. *K is the compact-net source row, exposing the compact metric cover data used by the budget ledger.*
2. *E is the bundled-center row, naming the finite probe bundle for the requested tolerance.*
3. *L is the rational-radius row, recording the displayed radius data for each bundled center.*
4. *R is the local-modulus row, recording the pointwise modulus rows attached to the displayed centers.*
5. *F is the fold-minimum row, recording the finite lower-bound fold used to aggregate the bundled radii.*
6. *U is the uniform-modulus row, exporting the displayed tolerance-to-precision ledger only after the fold minimum is available.*
7. *H records componentwise* hsame *transport for the compact source, bundle, radii, local moduli, fold minimum, uniform modulus, and local certificate rows.*
8. *C records displayed* Cont *replay from the compact budget request through K, E, L, R, F, U, H.*
9. *P is the* Pkg *provenance over* FiniteSubcoverModulusBudget$^{\uparrow}$*,* CompactMetric$^{\uparrow}$*,* ProbeBundle$^{\uparrow}$*,* Rat$^{\uparrow}$*,* CFun$^{\uparrow}$*,* UniformModulus$^{\uparrow}$*,* BHist*,* hsame*,* Cont*, and* NameCert*.*

10. N is the local $\mathsf{NameCert}_{\mathsf{FiniteSubcoverModulusBudget}^{\uparrow}}$ *row.*
The classifier compares accepted packets only through $K, E, L, R, F, U, H, C, P, N$. It has no coordinate for arbitrary open covers, selected subcovers, host compactness, or ambient completeness.

Theorem 8630.2 (Finite subcover modulus budget NameCert obligations)**.** *For every accepted* $\mathsf{FiniteSubcoverModulusBudget}^{\uparrow}$ *carrier $B = (K, E, L, R, F, U, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{FiniteSubcoverModulusBudge}}$ *surface consists exactly of carrier admission for the compact-net source row, bundled-center row, rational-radius row, local-modulus row, fold-minimum row, uniform-modulus row, componentwise transport, displayed replay, provenance, and local naming. No NameCert obligation may replace these rows by arbitrary subcovers, selected representatives, host compactness, or ambient completeness.*

Proof. Project the carrier of Definition 8630.1. The rows $K, E, L, R, F, U, H, C, P, N$ are the only displayed coordinates available to the local certificate.

The compact-net source row K and bundled-center row E determine the finite cover budget. The rational-radius row L and local-modulus row R keep the pointwise data visible before any uniform modulus is read.

The fold-minimum row F is the only aggregate row, and it is read before the uniform-modulus row U. Transport, replay, provenance, and local naming are supplied by H, C, P, N, so the carrier has no coordinate from which a selected subcover or ambient completeness theorem could be projected. □

Theorem 8630.3 (Finite subcover modulus budget uniform-modulus handoff)**.** *Every* $\mathsf{UniformModulus}^{\uparrow}$ *consumer of an accepted* $\mathsf{FiniteSubcoverModulusBudget}^{\uparrow}$ *packet reads the finite cover budget only through the displayed route*

$$K, E, L, R, F, U, H, C, P, N.$$

The handoff exports compact-net rows, bundled centers, rational radii, local moduli, a fold minimum, a uniform-modulus row, componentwise transport, displayed replay, provenance, and local naming. It does not export arbitrary subcovers, host compactness, or ambient completeness.

Proof. Start with the compact-net source row K and the bundled-center row E. The budget ledger can only be read from displayed center data, so no consumer can bypass the finite cover route.

The rational-radius row L and local-modulus row R supply the local pointwise data, while the fold-minimum row F aggregates the finite radii into the displayed lower-bound ledger. The uniform-modulus row U is available only after that fold has been read.

Apply Definition 8630.2. The structural rows H, C, P, N preserve and replay the same finite route, so the handoff exports no arbitrary subcovers, host compactness, or ambient completeness. □

Closure status for $\mathsf{NameCert}_{\mathsf{FiniteSubcoverModulusBudget}^{\uparrow}}$.

Constructive story: A $\mathsf{FiniteSubcoverModulusBudget}^{\uparrow}$ packet is generated from a compact-net source row, bundled centers, rational radii, local moduli, a fold minimum, a uniform-modulus row, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{FiniteSubcoverModulusBudget}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8630.1, Definition 8630.2, and Definition 8630.3 seed the finite compact-net budget route consumed by the compact-uniform-continuity vision.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{FiniteSubcoverModulusBudget}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close arbitrary subcovers, selected representatives, host compactness, ambient completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, bundled-center exposure, rational-radius exactness, local-modulus exactness, fold-minimum exactness, uniform-modulus export, transport stability, replay stability, and non-escape proofs for BEDC.Derived.FiniteSubcoverModulusBudgetUp.

Chapter 8631

A Concrete Naming Certificate for $\mathsf{BishopModulatedCauchySequence}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{BishopModulatedCauchySequence}^{\uparrow}$ packet records the finite route by which a displayed sequence and an explicit Cauchy modulus become a completion-facing real name. It sits over the dyadic tolerance ledger of chapter 291, the finite observation windows of chapter 126, the regular rational readback of chapter 301, the monotone-modulus normalization boundary of chapter 1744, and the terminal real-name seal of chapter 38. The packet names explicit modulus data for Phase Real and Completion consumers; it does not quotient streams, select a limit, invoke countable choice, compare host reals, or assume ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 8631.1 (BishopModulatedCauchySequence carrier)**.** *A* $\mathsf{BishopModulatedCauchySequence}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (S, M, D, W, R, E, H, C, P, N)$$

with the following displayed rows:

1. *S is the sequence row, exposing the inspected rational or dyadic approximants only through finite* $\mathsf{StreamName}^{\uparrow}$ *windows.*
2. *M is the explicit Cauchy modulus row, giving a tolerance-to-tail schedule rather than an external convergence oracle.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *radius ledger used to compare the tail entries requested by M.*
4. *W is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row naming exactly the sequence entries inspected for a requested tolerance.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff row that reads the displayed windows as regular rational approximation data.*
6. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached only after the sequence row, modulus row, dyadic ledger, finite windows, and regular rational readback have been displayed.*
7. *H records componentwise* hsame *transport for the sequence, modulus, dyadic, window, regular-readback, real-seal, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay in the order $S, M, D, W, R, E, H, P, N$.*

9. *P is the* Pkg *provenance over* BishopModulatedCauchySequence$^{\uparrow}$, CauchyModulusMonotoneNormalization$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, Real$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* NameCert$_{\text{BishopModulatedCauchySequence}^{\uparrow}}$ *row naming this packet and no larger completion principle.*

The carrier has no coordinate for quotient sequence equality, selected limits, countable choice, host equality of reals, trichotomy, or ambient completeness of Real$^{\uparrow}$.

Theorem 8631.2 (BishopModulatedCauchySequence NameCert obligations)**.** *For an accepted* BishopModulatedCauchySequence$^{\uparrow}$ *carrier $B = (S, M, D, W, R, E, H, C, P, N)$, the local* NameCert$_{\text{BishopModulatedCauch}}$ *surface consists exactly of carrier admission for the sequence row, explicit Cauchy modulus row, dyadic-radius ledger, finite* StreamName$^{\uparrow}$ *window row,* RegSeqRat$^{\uparrow}$ *handoff, terminal* Real$^{\uparrow}$ *seal, componentwise transport, displayed replay, provenance, and local naming. Every consumer read of the real-facing boundary must display $S, M, D, W, R, E, H, C, P, N$ in that order, and no obligation is stored outside those rows.*

Proof. Carrier admission is projection from Definition 8631.1. The tuple displays the sequence row, explicit modulus, dyadic ledger, finite windows, regular readback, real seal, transport, replay, provenance, and local naming rows.

The modulus row is read before the dyadic ledger. The normalization boundary of chapter 1744 keeps this row as an explicit tolerance-to-tail schedule, while DyadicRatCore$^{\uparrow}$ supplies only the displayed radius comparisons needed by that schedule.

The window and readback rows then route through StreamName$^{\uparrow}$ and RegSeqRat$^{\uparrow}$. The terminal Real$^{\uparrow}$ seal is downstream of those finite rows, and the structural rows H, C, P, N preserve the same displayed order. Since none of these rows contains quotient stream equality, a selected limit, countable choice, host real equality, trichotomy, or ambient real completeness, the listed obligations exhaust the local certificate. □

Theorem 8631.3 (BishopModulatedCauchySequence regular route)**.** *Every real-facing read exported by an accepted* BishopModulatedCauchySequence$^{\uparrow}$ *carrier factors through the explicit route*

$$S \longmapsto M \longmapsto D \longmapsto W \longmapsto R \longmapsto E \longmapsto (H, C, P, N).$$

Thus the RegSeqRat$^{\uparrow}$ *handoff is available only after the* CauchyModulusMonotoneNormalization$^{\uparrow}$ *modulus surface, the* DyadicRatCore$^{\uparrow}$ *radius ledger, and the finite* StreamName$^{\uparrow}$ *windows have been displayed; the* Real$^{\uparrow}$ *seal cannot be used as a prior source of convergence.*

Proof. Apply Definition 8631.2. It requires the sequence row S and explicit modulus row M before any radius or tail comparison can be exported.

The dyadic and stream rows D, W supply the finite comparisons requested by the modulus. The regular rational row R reads those displayed windows only after the tolerance ledger and finite observation schedule are already visible.

Finally the seal row E and structural rows H, C, P, N package the same finite route. Because the carrier excludes quotient streams, selected limits, countable choice, host equality, trichotomy, and ambient Real$^{\uparrow}$ completeness, a consumer cannot bypass the regular route by appealing to a completed real in advance. □

Falsifiable prediction: Every accepted BishopModulatedCauchySequence$^{\uparrow}$ real-facing read exposes a sequence row, explicit Cauchy modulus row, DyadicRatCore radius ledger, StreamName

finite-window row, RegSeqRat handoff, RealUp seal, hsame transport, Cont replay, Pkg provenance, and local NameCert row.

Independence witness: dyadicratcore, streamname, regseqrat, cauchy-modulus-monotone-normalization, real: none is bijective with $\mathsf{BishopModulatedCauchySequence}^{\uparrow}$ because this packet alone binds the sequence row, explicit modulus row, dyadic-radius ledger, finite-window route, regular rational handoff, and terminal real seal into one local NameCert carrier.

Closure status for $\mathsf{NameCert}_{\mathsf{BishopModulatedCauchySequence}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BishopModulatedCauchySequence}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8631.1, Definition 8631.2, and Definition 8631.3 seed the finite explicit-modulus route from sequence windows to regular rational readback and terminal real sealing.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BishopModulatedCauchySequence}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient sequence equality, selected limits, countable choice, host real equality, trichotomy, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, modulus exactness, dyadic-radius visibility, finite-window coverage, regular readback stability, Real-seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.BishopModulatedCauchySequenceUp.

Constructive story: A $\mathsf{BishopModulatedCauchySequence}^{\uparrow}$ packet is generated from a sequence row, explicit Cauchy modulus row, DyadicRatCore radius ledger, StreamName finite windows, RegSeqRat readback, RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 8632

A Concrete Naming Certificate for $\mathsf{MetricCategory}^{\uparrow}$

Following Lawvere and enriched-category treatments of metric spaces, the $\mathsf{MetricCategory}^{\uparrow}$ packet records the category whose objects are displayed metric-space rows and whose morphisms are uniformly continuous map rows. It sits over the metric carrier of chapter 57, the modulus-bearing map surface of chapter 130, the finite category interface of chapter 61, and the finite observation schedules of chapter 126. The packet names only the finite BEDC rows needed for identity, composition, classifier comparison, and modulus transport; it is not a host function category, a quotient of maps, an extensional equality principle, or an ambient enrichment theorem.

Definition 8632.1 (Metric category carrier)**.** *A* $\mathsf{MetricCategory}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$G = (O, F, I, K, M, L, H, C, P, N)$$

with the following displayed rows:

1. *O is the finite object ledger, listing the* $\mathsf{Met}^{\uparrow}$ *rows whose point classifiers, distance rows, and metric-law ledgers may be read by the category packet.*
2. *F is the morphism ledger, listing* $\mathsf{ContinuousMap}^{\uparrow}$ *rows between the displayed metric objects together with their source, target, graph, and modulus data.*
3. *I is the identity-map ledger, assigning each object row in O a displayed* $\mathsf{ContinuousMap}^{\uparrow}$ *identity row over the same metric classifier.*
4. *K is the composition ledger, assigning each composable pair of morphism rows in F a displayed* $\mathsf{ContinuousMap}^{\uparrow}$ *composite row with the named source and target objects.*
5. *M is the metric-classifier ledger, recording that object comparison and morphism typing use only the* $\mathsf{Met}^{\uparrow}$ *classifiers already displayed in O.*
6. *L is the modulus ledger, recording the identity modulus rows and the composite modulus rows consumed from the* $\mathsf{ContinuousMap}^{\uparrow}$ *data in F, I, K.*
7. *H records componentwise* hsame *transport for object rows, morphism rows, identity rows, composition rows, classifier rows, modulus rows, replay, provenance, and local naming.*
8. *C records displayed* Cont *replay from an object or morphism request through the finite object ledger, morphism ledger, identity or composition ledger, metric classifier ledger, and modulus ledger.*

9. *P is the* Pkg *provenance over* $\mathsf{MetricCategory}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{Cat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{MetricCategory}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $O, F, I, K, M, L, H, C, P, N$. It has no coordinate for host functions, quotient equality of maps, selected representatives, global extensionality, countable choice, or an ambient category of all metric spaces.

Theorem 8632.2 (MetricCategory NameCert obligations)**.** *For every accepted* $\mathsf{MetricCategory}^{\uparrow}$ *carrier*

$$G = (O, F, I, K, M, L, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{MetricCategory}^{\uparrow}}$ *surface consists exactly of object admission through O, morphism admission through F, identity admission through I, composition admission through K, metric-classifier exposure through M, modulus exposure through L, componentwise* hsame *transport through H, displayed* Cont *replay through C, provenance through P, and local naming through N.*

Every identity or composition read therefore remains inside the displayed $\mathsf{ContinuousMap}^{\uparrow}$ *modulus data over the displayed* $\mathsf{Met}^{\uparrow}$ *objects before the packet may be consumed as category data.*

Proof. Project the accepted carrier. The object row O is the only source of metric objects, and the morphism row F is the only source of displayed uniformly continuous maps between those objects.

The categorical rows are then forced to read the same data. The identity ledger I assigns identity maps over the metric classifiers already exposed by O, while the composition ledger K assigns composite maps only to pairs whose source and target rows match through the displayed typing information in F.

The classifier and modulus ledgers close the analytic part of the certificate. The row M prevents object or morphism comparison from leaving the displayed metric classifiers, and L records that identity and composition use the visible $\mathsf{ContinuousMap}^{\uparrow}$ modulus rows rather than host-level functions.

Finally, H, C, P, N transport, replay, source, and name that same finite packet. Since no carrier coordinate stores quotient equality of maps, selected representatives, global extensionality, countable choice, or an ambient all-metric-spaces category, the listed rows exhaust the local NameCert obligations. □

Theorem 8632.3 (MetricCategory composition ledger)**.** *Let $G = (O, F, I, K, M, L, H, C, P, N)$ be an accepted* $\mathsf{MetricCategory}^{\uparrow}$ *carrier. Every composable pair read from F is admitted to K only after the source and target object rows are exposed through O and the two displayed* $\mathsf{ContinuousMap}^{\uparrow}$ *modulus rows are exposed through L. The resulting composite is again a displayed* $\mathsf{ContinuousMap}^{\uparrow}$ *row over the same metric-classifier ledger M.*

Consequently, associativity and identity-consumption checks for the packet are finite ledger checks over I, K, M, L, H, C, P, N, not host-function equality checks or quotient-map comparisons.

Proof. Start with a composable pair of morphism rows in F. Their source, middle, and target objects are read from O, so the composition request is typed before any composite row is exposed.

Next read the modulus ledger L. The two input morphisms carry displayed $\mathsf{ContinuousMap}^{\uparrow}$ modulus rows, and L records the finite composite-modulus route used by K. Thus the composite map is admitted as another displayed $\mathsf{ContinuousMap}^{\uparrow}$ row rather than as an external function.

Identity checks use the same route. The row I supplies the identity map rows and their identity moduli over the object classifiers in O, while K records the left and right identity composites as finite ledger reads.

The structural rows then preserve the ledger. Transport and replay through H and C keep the same object, morphism, identity, composition, classifier, and modulus rows, and P, N source and name the packet. Because the carrier contains no host-function equality or quotient-map coordinate, the composition ledger supplies exactly the category-facing evidence available to consumers. □

Closure status for $\mathsf{NameCert}_{\mathsf{MetricCategory}^{\uparrow}}$.

Constructive story: A $\mathsf{MetricCategory}^{\uparrow}$ packet is generated from MetricSpace object rows, ContinuousMap morphism rows, identity-map rows, composition rows, metric classifier rows, modulus ledgers, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{MetricCategory}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8632.1, Definition 8632.2, and Definition 8632.3 seed the finite category packet of metric objects and uniformly continuous morphisms through displayed classifier and modulus rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{MetricCategory}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host function categories, quotient equality of maps, selected representatives, global extensionality, countable choice, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked object admission, morphism admission, identity admission, composition admission, classifier exposure, modulus conservation, transport, replay, provenance, and local naming for BEDC.Derived.MetricCategoryUp.

Chapter 8633

A Concrete Naming Certificate for CantorStieltjesMeasure$^{\uparrow}$

Following Lebesgue and Stieltjes, the CantorStieltjesMeasure$^{\uparrow}$ packet records the finite BEDC surface obtained when the Cantor distribution function supplies the displayed interval masses for a Stieltjes measure. It consumes the ternary-prefix to binary-prefix function rows of chapter 1895 and the finite half-open interval ledger of chapter 8592, with endpoint windows and terminal sealing supplied by the Real$^{\uparrow}$, RegSeqRat$^{\uparrow}$, and StreamName$^{\uparrow}$ sibling chapters. The packet exposes only Cantor-function source rows, interval-window rows, finite Stieltjes ledger rows, seal rows, transport, replay, provenance, and local naming.

Definition 8633.1 (Cantor-Stieltjes measure carrier)**.** *A* CantorStieltjesMeasure$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M = (F, I, L, W, R, S, H, C, P, N)$$

with the following visible rows:

1. *F is the* CantorFunction$^{\uparrow}$ *source row, read through retained ternary prefixes, binary output prefixes, graph rows, and the real-facing seal of the Cantor-function packet.*
2. *I is the inspected half-open interval-window row, recording only the finite endpoint cells whose masses are requested.*
3. *L is the finite* StieltjesMeasure$^{\uparrow}$ *ledger row assigning each displayed interval in I its endpoint-difference mass through the source row F.*
4. *W is the* StreamName$^{\uparrow}$ *endpoint-window row used by the Cantor-function source reads and by the interval-mass ledger.*
5. *R is the* RegSeqRat$^{\uparrow}$ *regular readback row for the finite endpoint and mass windows.*
6. *S is the terminal* Real$^{\uparrow}$ *seal row for displayed interval masses and endpoint values.*
7. *H stores componentwise* hsame *transport for Cantor source rows, interval windows, Stieltjes ledger rows, stream windows, regular readbacks, real seals, replay, provenance, and local naming.*
8. *C stores displayed* Cont *replay from Cantor-function prefix reads through interval windows, finite Stieltjes ledger rows, regular readback, and the terminal real seal.*
9. *P is the* Pkg *provenance over* CantorStieltjesMeasure$^{\uparrow}$, CantorFunction$^{\uparrow}$, StieltjesMeasure$^{\uparrow}$, StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, Real$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

10. N is the local $\mathsf{NameCert}_{\mathsf{CantorStieltjesMeasure}^{\uparrow}}$ *row.*
The classifier compares accepted packets only through $F, I, L, W, R, S, H, C, P, N$. It has no coordinate for general measure completion, countable additivity beyond the displayed finite ledger, host measure equality, quotient equality of distribution functions, selected extensions, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.CantorStieltjesMeasureUp.CantorStieltjesMeasureTasteGate single carrier alignment`

Theorem 8633.2 (Cantor-Stieltjes measure NameCert obligations)**.** *For every accepted* $\mathsf{CantorStieltjesMeasure}^{\uparrow}$ *carrier*

$$M = (F, I, L, W, R, S, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{CantorStieltjesMeasure}^{\uparrow}}$ *surface consists exactly of carrier admission for the displayed Cantor-function source row F, interval-window admission through I, finite Stieltjes ledger exposure through L, endpoint and mass readback through W and R, terminal real sealing through S, componentwise transport through H, displayed replay through C, package provenance through P, and local naming through N.*

Proof. Project the carrier of Definition 8633.1. The source row F supplies the only distribution function data, and it is already routed through the finite Cantor-function prefix, graph, and real-seal rows of chapter 1895.

Read the interval and ledger rows next. The row I lists the inspected half-open endpoint windows, and L is the only finite Stieltjes ledger assigning masses to those displayed cells.

Finally route endpoint and mass reads through W, R, S and the structural rows H, C, P, N. This is the same finite Stieltjes surface exposed by chapter 8592, specialized to the Cantor-function source row, so no completed measure, countable-additivity theorem, host measure equality, selected extension, quotient distribution equality, or ambient completeness row remains. □

Theorem 8633.3 (Cantor-Stieltjes measure function boundary)**.** *Every measure-facing consumer of an accepted* $\mathsf{CantorStieltjesMeasure}^{\uparrow}$ *carrier must read the Cantor-function source row before any interval-mass seal is exposed. Concretely, each displayed interval mass factors through*

$$\mathsf{CantorFunction}^{\uparrow} \longrightarrow I \longrightarrow L \longrightarrow W, R \longrightarrow S, H, C, P, N.$$

The boundary exports finite Cantor-function prefix reads and finite Stieltjes ledger rows, but it does not export general measure completion, countable additivity beyond the displayed finite ledger, host measure equality, selected distribution extensions, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start with a measure-facing read of an interval cell. The carrier has no primitive measure object, so the read first exposes the Cantor-function source row F and the inspected interval-window row I.

The finite ledger row L then assigns the displayed cell its endpoint-difference mass. The route uses the same half-open-cell and finite-additivity discipline as the $\mathsf{StieltjesMeasure}^{\uparrow}$ packet, while the endpoint values are supplied by the $\mathsf{CantorFunction}^{\uparrow}$ source surface.

The rows W and R provide the stream windows and regular rational readback before S can be read. Transport, replay, provenance, and local naming remain inside H, C, P, N, so a consumer receives only the displayed finite route and cannot escape to completed measure theory, host equality, selected extensions, countable choice, or ambient real completeness. □

Closure status for $\mathsf{NameCert}_{\mathsf{CantorStieltjesMeasure}^{\uparrow}}$.

Constructive story: A $\mathsf{CantorStieltjesMeasure}^{\uparrow}$ packet is generated from one CantorFunction source row, inspected half-open interval windows, one finite Stieltjes ledger, StreamName endpoint windows, RegSeqRat readbacks, RealUp seal rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CantorStieltjesMeasure}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8633.1, Definition 8633.2, and Definition 8633.3 seed the finite Cantor-Stieltjes measure surface from Cantor-function prefix reads to displayed Stieltjes interval masses and Real-facing seals.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CantorStieltjesMeasure}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim general measure completion, countable additivity beyond the displayed finite ledger, host measure equality, selected extension theorems, quotient distribution equality, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, Cantor-function source stability, interval-window exposure, finite Stieltjes ledger exactness, StreamName and RegSeqRat readback, Real-seal nonescape, transport and replay stability, provenance nonescape, and a Lean carrier formalization for BEDC.Derived.CantorStieltjesMeasureUp.

Chapter 8634

A Concrete Naming Certificate for $\mathsf{MooreMetrization}^{\uparrow}$

Following R. L. Moore and the Bing–Nagata metrization tradition, the $\mathsf{MooreMetrization}^{\uparrow}$ packet records the finite BEDC route from a developable topology with collectionwise normal separation data to a metric presentation. It sits after the Moore-space carrier of chapter 3592, the familywise separation surface of chapter 7988, and the Frink-style metric construction route of chapter 4226. The packet names only the displayed topology-to-metric dependency route; it does not import open-cover compactness, host choice of refinements, quotient topology equality, or an ambient metrization theorem.

Definition 8634.1 (Moore metrization carrier)**.** *A* $\mathsf{MooreMetrization}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M = (S, C, T, D, F, G, H, K, P, N)$$

with the following displayed rows:

1. *S is the* $\mathsf{MooreSpace}^{\uparrow}$ *source row, carrying the displayed development windows and point-neighbourhood refinement reads.*
2. *C is the* $\mathsf{CollectionwiseNormal}^{\uparrow}$ *separation row, exposing the familywise closed-row separation ledger used by the development.*
3. *T is the* $\mathsf{Topology}^{\uparrow}$ *base row shared by the development, closed-family, open-neighbourhood, and metric-open comparison reads.*
4. *D is the development compatibility row, recording that the inspected development windows refine the topology source without selecting a host sequence of covers.*
5. *F is the* $\mathsf{FrinkMetrization}^{\uparrow}$ *handoff row, translating finite star-refinement and separation reads into the metric-candidate ledger.*
6. *G is the* $\mathsf{Met}^{\uparrow}$ *endpoint row, exposing the resulting distance comparison and metric-open reads through finite BEDC data.*
7. *H records componentwise* hsame *transport for $S, C, T, D, F, G, K, P, N$ and for the displayed development-to-metric reads.*
8. *K records displayed* Cont *replay from Moore-space development through collectionwise-normal separation, topology comparison, Frink handoff, metric endpoint, transport, provenance, and local naming.*

9. *P is the* Pkg *provenance over* $\mathsf{MooreMetrization}^{\uparrow}$, $\mathsf{MooreSpace}^{\uparrow}$, $\mathsf{CollectionwiseNormal}^{\uparrow}$, $\mathsf{Topology}^{\uparrow}$, $\mathsf{FrinkMetrization}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{MooreMetrization}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $S, C, T, D, F, G, H, K, P, N$. It has no coordinate for arbitrary open covers, selected developments outside S, host powersets, quotient topology equality, open-cover compactness, or an untracked metrization theorem.

Theorem 8634.2 (Moore metrization NameCert obligations)**.** *For every accepted* $\mathsf{MooreMetrization}^{\uparrow}$ *carrier $M = (S, C, T, D, F, G, H, K, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{MooreMetrization}^{\uparrow}}$ *surface consists exactly of Moore-space source admission through S, collectionwise-normal separation admission through C, topology-source alignment through T, development compatibility through D, Frink handoff through F, metric endpoint exposure through G, componentwise* hsame *transport through H, displayed* Cont *replay through K,* Pkg *provenance through P, and local naming through N.*

Proof. Project the carrier of Definition 8634.1. The rows $S, C, T, D, F, G, H, K, P, N$ are the whole local surface.

The source rows are S, C, T, D. They bind the Moore development, the collectionwise-normal separation ledger, and the topology source before any metric endpoint can be read.

The metric construction rows are F and G. The Frink handoff reads only the displayed development and separation data, and the metric endpoint exposes only the resulting finite distance and metric-open comparisons.

Finally H, K, P, N transport, replay, source, and locally name the same finite route. Since no excluded host object is a carrier coordinate, the listed rows exhaust the local NameCert obligations. □

Theorem 8634.3 (Moore development metric route)**.** *Every metric read exported by an accepted* $\mathsf{MooreMetrization}^{\uparrow}$ *packet must pass through*

$$\mathsf{MooreSpace}^{\uparrow}, \quad \mathsf{CollectionwiseNormal}^{\uparrow}, \quad \mathsf{Topology}^{\uparrow}, \quad \mathsf{FrinkMetrization}^{\uparrow}$$

before it reaches the $\mathsf{Met}^{\uparrow}$ *endpoint row. The route preserves the development windows and familywise separation rows as finite BEDC data, so the metric endpoint is not obtained from open-cover compactness, host choice of refinements, quotient topology equality, or an ambient point-set metrization theorem.*

Proof. Read the source side first. The Moore-space row S supplies the development windows, the collectionwise-normal row C supplies the familywise separation ledger, and the topology row T keeps both surfaces tied to the same open and closed vocabulary.

The compatibility row D records that the displayed development is the one being used by the metric route. It does not choose a host sequence of covers or import open-cover compactness.

The Frink handoff F then converts the finite refinement and separation reads into the metric-candidate ledger, and the endpoint row G exposes the resulting $\mathsf{Met}^{\uparrow}$ comparisons. The structural rows H, K, P, N preserve that order under transport, replay, provenance, and local naming. □

Falsifiable prediction: Every accepted $\mathsf{MooreMetrization}^{\uparrow}$ read exposes a MooreSpaceUp source row, CollectionwiseNormalUp separation row, TopologyUp source row, development compatibility row, FrinkMetrizationUp handoff, MetricSpaceUp endpoint, hsame transport, Cont replay, Pkg provenance, and local NameCert row before any metric conclusion is public.

Independence witness: moore-space, collectionwise-normal, frink-metrization, topology, metric-space: $\mathsf{MooreMetrization}^{\uparrow}$ is not bijective to any listed sibling because it jointly binds development windows, familywise separation, topology alignment, Frink handoff, metric endpoint, transport, replay, provenance, and local naming in one topology-to-metric route.

Closure status for $\mathsf{NameCert}_{\mathsf{MooreMetrization}^{\uparrow}}$.

Constructive story: A $\mathsf{MooreMetrization}^{\uparrow}$ packet is generated from MooreSpaceUp development windows, CollectionwiseNormalUp separation rows, a TopologyUp source, development compatibility, FrinkMetrizationUp handoff, MetricSpaceUp endpoint, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{MooreMetrization}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8634.1, Definition 8634.2, and Definition 8634.3 seed the finite topology-to-metric route from Moore development and collectionwise normal separation through Frink-style metric construction.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{MooreMetrization}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close arbitrary metrization theorems, open-cover compactness, host-selected developments, quotient topology equality, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, development compatibility, collectionwise-normal separation visibility, Frink handoff exactness, metric endpoint exposure, transport, replay, provenance, and local naming for BEDC.Derived.MooreMetrizationUp.

Chapter 8635

A Concrete Naming Certificate for MetaCICResidualNormalizationObstruction$^{\uparrow}$

The MetaCICResidualNormalizationObstruction$^{\uparrow}$ packet realizes the normalization boundary of section 9386.4 as finite BEDC obstruction data. It sits beside the candidate closed-projection boundary of chapter 4366, the normal-endpoint cut of chapter 5143, the candidate-normalization discharge route of chapter 7180, and the typed normal-form scheduler of chapter 6617. The packet names the residual gap between arbitrary closed typed MetaCIC terms and the candidate-mediated normalization interface; it does not assert blanket strong normalization, closed consistency, or a subject-reduction theorem.

Definition 8635.1 (MetaCIC residual normalization obstruction carrier)**.** *A* MetaCICResidualNormalizationObstruc *carrier is a finite* BHist *packet*

$$R = (T, C, E, B, O, L, A, H, K, P, N)$$

with the following displayed rows:

1. *T is the closed typed MetaCIC term row, recording the empty-context term, its displayed type, and the finite typing window under inspection.*
2. *C is the candidate-interface request row, asking whether the term can be placed into the candidate evidence surface already used by the normalization map.*
3. *E is the endpoint row, recording the bounded normal endpoint or the absence of such an endpoint inside the displayed candidate interface.*
4. *B is the residual beta-frontier row, exposing unreduced or unchecked residual fragments that remain after the bounded scheduler window.*
5. *O is the obstruction row, recording that candidate admission, endpoint preservation, or false-type preservation is not yet available for the inspected closed term.*
6. *L is the Lean TasteGate obligation row, requiring future* Nontrivial MetaCICResidualNormalizationObstruction$^{\uparrow}$ *and* FieldFaithful MetaCICResidualNormalizationObstruction$^{\uparrow}$ *instances before the obstruction classifier can serve as checked evidence.*
7. *A is the audit handoff row to subject-reduction and closed-consistency consumers; it exports the obstruction without discharging those consumers.*
8. *H records componentwise* hsame *transport for $T, C, E, B, O, L, A, K, P, N$.*

9. *K records displayed* Cont *replay from the closed-term request through candidate admission, endpoint, residual frontier, obstruction, TasteGate obligation, audit handoff, provenance, and local naming.*

10. *P is the* Pkg *provenance over* $\mathsf{MetaCICResidualNormalizationObstruction}^{\uparrow}$, MetaCICCandidateClosedProjectionBou $\mathsf{MetaCICNormalEndpointCut}^{\uparrow}$, $\mathsf{CandidateNormalizationDischarge}^{\uparrow}$, $\mathsf{MetaCICTypedNormalFormScheduler}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* NameCert.

11. *N is the local* $\mathsf{NameCert}_{\mathsf{MetaCICResidualNormalizationObstruction}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $T, C, E, B, O, L, A, H, K, P, N$. It has no coordinate for blanket strong normalization of arbitrary closed terms, closed consistency, hidden semantic candidates, host proof search, selected normal forms, or subject reduction.

Theorem 8635.2 (MetaCIC residual normalization obstruction NameCert obligations)**.** *For every accepted* $\mathsf{MetaCICResidualNormalizationObstruction}^{\uparrow}$ *carrier $R = (T, C, E, B, O, L, A, H, K, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{MetaCICResidualNormalizationObstruction}^{\uparrow}}$ *surface consists exactly of closed typed-term admission through T, candidate-interface request through C, bounded normal endpoint accounting through E, residual beta-frontier exposure through B, obstruction recording through O, Lean* Nontrivial *and* FieldFaithful *obligation exposure through L, audit handoff through A, componentwise* hsame *transport through H, displayed* Cont *replay through K,* Pkg *provenance through P, and local naming through N.*

Proof. Project the carrier of Definition 8635.1. The closed term, candidate request, endpoint, residual frontier, obstruction, TasteGate obligation, and audit handoff are displayed as T, C, E, B, O, L, A.

The obstruction row O is not a proof of non-normalization. It records that the inspected closed typed term has not been placed into the candidate-mediated normalization interface with endpoint and false-type preservation visible in the same finite packet.

The TasteGate row L keeps the Lean obligations explicit: a future checked surface must provide both a nontrivial accepted/refused boundary and field-faithful preservation of the displayed rows. Transport, replay, provenance, and naming are then exhausted by H, K, P, N, so the listed rows are exactly the local NameCert obligations. □

Theorem 8635.3 (MetaCIC residual normalization obstruction boundary)**.** *Every closed-consistency or normalization consumer that reads an accepted* $\mathsf{MetaCICResidualNormalizationObstruction}^{\uparrow}$ *packet receives an obstruction ledger, not a discharge of the open normalization question. The consumer must still provide candidate admission, bounded normal endpoint preservation, residual-frontier elimination, subject-reduction compatibility, and the Lean* Nontrivial *and* FieldFaithful *instances before the inspected closed term can be treated as normalized inside the public interface.*

Proof. Begin with the closed typed-term row T and the candidate request row C. These rows expose the term and the intended candidate interface, but they do not themselves provide candidate evidence.

Read the endpoint and residual rows next. The row E records the bounded endpoint status visible to the packet, while B records the residual beta frontier that remains under the scheduler window.

The obstruction row O preserves the gap rather than erasing it. The audit row A may be consumed by subject-reduction or closed-consistency routes, but it exports the same obstruction ledger. The TasteGate row L records the remaining Lean nontriviality and field-faithfulness obligations, and the structural rows H, K, P, N only transport, replay, source, and name the same finite packet. □

Falsifiable prediction: Every accepted $\mathsf{MetaCICResidualNormalizationObstruction}^{\uparrow}$ read exposes a closed typed-term row, candidate-interface request, bounded normal endpoint accounting, residual beta-frontier row, obstruction row, Lean TasteGate obligation row, audit handoff, hsame transport, Cont replay, Pkg provenance, and local NameCert row. A read that exports blanket strong normalization, closed consistency, selected normal forms, hidden semantic candidates, or subject reduction from this packet refutes the carrier boundary.

Independence witness: metacic-candidate-closed-projection-boundary, metacic-normal-endpoint-cut, candidate-normalization-discharge, metacic-typed-normal-form-scheduler, metacic-sn-candidate-interface: $\mathsf{MetaCICResidualNormalizationObstruction}^{\uparrow}$ is not bijective to any listed sibling because it keeps the residual frontier, candidate-admission request, endpoint accounting, obstruction row, Lean TasteGate obligation row, and audit handoff in one finite packet.

Closure status for $\mathsf{NameCert}_{\mathsf{MetaCICResidualNormalizationObstruction}^{\uparrow}}$.

Constructive story: A $\mathsf{MetaCICResidualNormalizationObstruction}^{\uparrow}$ packet is generated from a closed typed MetaCIC term row, candidate-interface request, bounded normal endpoint accounting, residual beta-frontier row, obstruction row, Lean TasteGate obligation row, audit handoff, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{MetaCICResidualNormalizationObstruction}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8635.1, Definition 8635.2, and Definition 8635.3 seed the finite obstruction packet for arbitrary closed typed MetaCIC terms outside the currently displayed candidate normalization interface.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{MetaCICResidualNormalizationObstruction}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close blanket strong normalization, closed consistency, subject reduction, selected normal forms, hidden semantic candidates, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, candidate-interface request exactness, endpoint accounting, residual-frontier exposure, obstruction preservation, Nontrivial and FieldFaithful instances, audit handoff, transport, replay, provenance, and local naming for BEDC.Derived.MetaCICResidualNormalizationObstructionUp.

Chapter 8636

LefschetzHyperplane NameCert Construction

Following Lefschetz hyperplane theorem references in algebraic geometry and Hodge theory, the $\mathsf{LefschetzHyperplane}^{\uparrow}$ packet records only the finite BEDC route by which a smooth projective source, a hyperplane section, and a bounded cohomology-window comparison are exposed to downstream consumers. It sits after the projective-variety surface of chapter 155, the scheme cover ledger of chapter 153, the cohomology and homology carriers of chapter 99 and chapter 98, and the numeric coefficient surface of chapter 39. The packet names the comparison route; it does not import a host Lefschetz theorem, a standard cohomology isomorphism, a selected ample divisor, a quotient cohomology representative, or a completed Hodge-theoretic package.

Definition 8636.1 (Lefschetz hyperplane carrier)**.** *A* $\mathsf{LefschetzHyperplane}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (X, Y, R, W, Q, H, C, P, N)$$

with the following displayed rows:

1. *X is the smooth projective source row, read through* $\mathsf{ProjectiveVar}^{\uparrow}$ *and* $\mathsf{Scheme}^{\uparrow}$ *carriers rather than through a host variety.*
2. *Y is the hyperplane-section row, including incidence with the displayed projective source and the finite section ledger.*
3. *R is the restriction-map row from the source packet to the section packet.*
4. *W is the cohomology-window row naming the inspected degree range and coefficient surface.*
5. *Q is the finite comparison ledger relating the source and section rows inside the displayed window.*
6. *H records componentwise* hsame *transport for X, Y, R, W, Q and the structural rows.*
7. *C records displayed* Cont *replay for source admission, section admission, restriction, cohomology-window readback, comparison, transport, provenance, and local naming.*
8. *P is the* Pkg *provenance over* $\mathsf{ProjectiveVar}^{\uparrow}$, $\mathsf{Scheme}^{\uparrow}$, $\mathsf{Cohomology}^{\uparrow}$, $\mathsf{Homology}^{\uparrow}$, $\mathsf{Complex}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$ *rows.*
9. *N is the local* $\mathsf{NameCert}_{\mathsf{LefschetzHyperplane}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $X, Y, R, W, Q, H, C, P, N$.

Theorem 8636.2 (Lefschetz hyperplane NameCert obligations)**.** *For the carrier of Definition 8636.1, the local* $\mathsf{NameCert}_{\mathsf{LefschetzHyperplane}^{\uparrow}}$ *surface consists exactly of projective-source admission through* X*, hyperplane-section admission through* Y*, restriction-map exposure through* R*, cohomology-window readback through* W*, finite comparison-ledger exposure through* Q*, componentwise* hsame *transport through* H*, displayed* Cont *replay through* C*,* Pkg *provenance through* P*, local naming through* N*, and non-escape from host Lefschetz theorems, unrecorded ample-divisor choices, quotient cohomology representatives, completed Hodge packages, and ambient standard-model isomorphisms.*

Proof. Project the carrier. The packet exposes exactly the rows $X, Y, R, W, Q, H, C, P, N$, with the geometric source, section, restriction, and comparison data separated into visible coordinates.

Read the dependency rows next. The projective and scheme siblings supply only displayed projective-source and section-carrier data. The cohomology, homology, and complex-number siblings supply only the finite degree window and coefficient rows used by W and Q.

Finally inspect the packet boundary. No coordinate stores a host Lefschetz theorem, an ample-divisor selector, a quotient cohomology representative, a completed Hodge package, or a standard-model isomorphism. The local NameCert obligations are therefore exactly the displayed finite packet and its transport, replay, provenance, and naming rows. □

Theorem 8636.3 (Lefschetz hyperplane section route)**.** *Every accepted* $\mathsf{LefschetzHyperplane}^{\uparrow}$ *consumer that reads a hyperplane-section comparison must first expose the route*

$$\mathsf{ProjectiveVar}^{\uparrow},\ \mathsf{Scheme}^{\uparrow},\ Y,\ R,\ W,\ Q,\ \mathsf{Cohomology}^{\uparrow},\ \mathsf{Homology}^{\uparrow},\ \mathsf{Complex}^{\uparrow},\ H,\ C,\ P,\ N.$$

The consumer receives a displayed projective source, a displayed section row, a restriction map, an inspected cohomology window, and a finite comparison ledger. It receives no host Lefschetz theorem, no ambient isomorphism outside the ledger, no selected generic hyperplane, and no quotient-class representative.

Proof. Start with source and section admission. The rows X and Y force the projective and scheme carriers to be displayed before the section comparison can be read.

Next read the restriction and window rows. The restriction row R and cohomology window W determine where the comparison ledger Q is meaningful, and the cohomology, homology, and complex-number siblings supply the inspected coefficient and degree surfaces.

The structural rows H, C, P, N preserve the same finite route. Since the refused host theorem, ambient isomorphism, generic-hyperplane choice, and quotient representative are not coordinates of the carrier, the section route exports only the displayed BEDC packet. □

Closure status for $\mathsf{NameCert}_{\mathsf{LefschetzHyperplane}^{\uparrow}}$**.**

Constructive story: A $\mathsf{LefschetzHyperplane}^{\uparrow}$ packet is generated from a smooth projective source row, a hyperplane-section row, a restriction-map row, a cohomology-window row, a finite comparison ledger, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{LefschetzHyperplane}^{\uparrow}}$, seed)

Scope closed: Definition 8636.1, Definition 8636.2, and Definition 8636.3 bind the finite projective-section comparison route before any host Lefschetz theorem or ambient isomorphism can be read.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{LefschetzHyperplane}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close Lean verification, a standard bridge, host Lefschetz theorem import, generic-hyperplane selection, quotient cohomology equality, or Hodge-theoretic comparison.

Upgrade path: Obligation closure requires explicit carrier-field coverage for projective source admission, hyperplane-section admission, restriction-map exposure, cohomology-window readback, comparison-ledger exactness, transport, replay, provenance, and local naming.

Chapter 8637

A Concrete Naming Certificate for $\mathsf{ProductiveCauchyName}^{\uparrow}$

Following Bishop and Bridges on countable regular Cauchy data, the $\mathsf{ProductiveCauchyName}^{\uparrow}$ packet records a finite productive-name surface whose schedule rows generate inspected Cauchy windows before any value-facing seal is read. It sits over the stream schedules of chapter 126, the rational regular readbacks of chapter 301, the dyadic tolerance core of chapter 291, the regular sequence-space packet of chapter 5965, and the terminal real-name seal of chapter 38. The packet names productive finite readback, not quotient equality, countable choice, selected representatives, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 8637.1 (ProductiveCauchyName carrier)**.** *A* $\mathsf{ProductiveCauchyName}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$P = (S, D, Q, R, E, H, C, K, N)$$

with the following displayed rows:

1. *S is the* $\mathsf{StreamName}^{\uparrow}$ *schedule row, exposing the finite requests and response windows used by the productive name.*
2. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row, recording the displayed dyadic radius and slack data requested by each schedule window.*
3. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row obtained from the displayed stream windows and dyadic tolerance rows.*
4. *R is the* $\mathsf{RegularSequenceSpace}^{\uparrow}$ *source row, naming the ambient regular sequence-space carrier only through its displayed schedule, readback, tolerance, and seal route.*
5. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row reached only after S, D, Q, R have remained visible.*
6. *H records componentwise* hsame *transport for the schedule, tolerance, readback, regular-space, real-seal, replay, provenance, and local naming rows.*
7. *C records displayed* Cont *replay from a productive-name request through S, D, Q, R, E, H, K, N.*
8. *K is the* Pkg *provenance over* $\mathsf{ProductiveCauchyName}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{RegularSequenceSpace}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
9. *N is the local* $\mathsf{NameCert}_{\mathsf{ProductiveCauchyName}^{\uparrow}}$ *row.*

The carrier has no coordinate for quotient equality of names, countable choice, trichotomy, a selected representative, a host limit, or a completeness principle for $\mathsf{Real}^{\uparrow}$.

Theorem 8637.2 (ProductiveCauchyName NameCert obligations)**.** *For every accepted* $\mathsf{ProductiveCauchyName}^{\uparrow}$ *carrier* $P = (S, D, Q, R, E, H, C, K, N)$*, the local* $\mathsf{NameCert}_{\mathsf{ProductiveCauchyName}^{\uparrow}}$ *surface consists exactly of carrier admission,* $\mathsf{StreamName}^{\uparrow}$ *schedule exposure,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance exposure,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback,* $\mathsf{RegularSequenceSpace}^{\uparrow}$ *source routing, terminal* $\mathsf{Real}^{\uparrow}$ *sealing, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. Every consumer of the real-facing boundary must read the finite route*

$$S, D, Q, R \longmapsto E, H, C, K, N$$

and no obligation is stored outside these rows.

Proof. Project the carrier of Definition 8637.1. The visible coordinates are exactly the stream schedule, dyadic tolerance row, regular rational readback, regular sequence-space source, terminal seal, transport, replay, provenance, and local naming rows.

The analytic rows are consumed in order. The $\mathsf{StreamName}^{\uparrow}$ schedule opens the inspected windows, $\mathsf{DyadicRatCore}^{\uparrow}$ records the displayed tolerance scale for those windows, $\mathsf{RegSeqRat}^{\uparrow}$ reads them as regular rational data, and $\mathsf{RegularSequenceSpace}^{\uparrow}$ keeps the same readback inside the displayed sequence-space carrier.

Only after that route is visible can the $\mathsf{Real}^{\uparrow}$ seal be read. The structural rows H, C, K, N transport, replay, source, and name the same packet, so no quotient equality, countable-choice selector, selected representative, trichotomy, host limit, or ambient completeness datum remains outside the listed obligations. □

Theorem 8637.3 (ProductiveCauchyName regular readback)**.** *Every accepted* $\mathsf{ProductiveCauchyName}^{\uparrow}$ *read exposes its* $\mathsf{StreamName}^{\uparrow}$ *schedule row* S *and* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row* D *before the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row* Q *and the* $\mathsf{RegularSequenceSpace}^{\uparrow}$ *source row* R *are available. The terminal* $\mathsf{Real}^{\uparrow}$ *seal* E *therefore reads only a displayed productive Cauchy route and exports no quotient real equality, countable-choice schedule, real trichotomy, selected representative, or* $\mathsf{Real}^{\uparrow}$ *completeness witness.*

Proof. Use the NameCert obligations of Definition 8637.2. They force every accepted read to expose S and D before Q can be consumed.

The readback row Q is regular only through the displayed windows and dyadic tolerances. The source row R then places that readback inside the regular sequence-space route of chapter 5965, without adding a quotient or a representative selector.

Finally the seal row E is downstream of S, D, Q, R, while H, C, K, N preserve the same finite route. Thus a real-facing consumer receives productive regular readback data, not countable choice, trichotomy, selected representatives, quotient equality, or an ambient completeness principle. □

Falsifiable prediction: Every accepted $\mathsf{ProductiveCauchyName}^{\uparrow}$ read exposes a StreamName schedule row, DyadicRatCore tolerance row, RegSeqRat readback row, RegularSequenceSpace source row, RealUp seal row, hsame transport, Cont replay, Pkg provenance, and local NameCert row before any value-facing seal is consumed.

Independence witness: streamname, dyadicratcore, regseqrat, regular-sequence-space, real: $\mathsf{ProductiveCauchyName}^{\uparrow}$ is not bijective with any listed sibling because it jointly carries schedule

productivity, dyadic tolerance exposure, regular rational readback, regular sequence-space routing, terminal real sealing, transport, replay, provenance, and local naming in one finite NameCert packet.

Closure status for $\mathsf{NameCert}_{\mathsf{ProductiveCauchyName}^{\uparrow}}$.

Constructive story: A $\mathsf{ProductiveCauchyName}^{\uparrow}$ packet is generated from StreamName schedules, DyadicRatCore tolerance rows, RegSeqRat readback rows, a RegularSequenceSpace source route, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{ProductiveCauchyName}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8637.1, Definition 8637.2, and Definition 8637.3 seed the finite productive Cauchy-name route from countable schedule windows to regular rational readback and terminal real sealing.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{ProductiveCauchyName}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Origin: human

Not claimed: This chapter does not close quotient equality, countable choice, real trichotomy, selected representatives, host limit selection, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, schedule productivity, dyadic tolerance exposure, regular rational readback, RegularSequenceSpace routing, Real-seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.ProductiveCauchyNameUp.

Chapter 8638

A Concrete Naming Certificate for $\mathsf{CauchyTailEvaluationFunctional}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{CauchyTailEvaluationFunctional}^{\uparrow}$ packet records the finite evaluation functional by which a regular Cauchy rational tail answers a bounded precision request without selecting a completed limit. It sits after the regular source row of chapter 301, the finite stream-window surface of chapter 126, the dyadic tolerance ledger of chapter 291, the window-extraction packet of chapter 7135, and the terminal real-name seal of chapter 38. The packet is consumed by Real and completion-facing reads as a finite evaluator for displayed tails; it is not quotient completion, representative selection, countable choice, host equality, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 8638.1 (Cauchy tail evaluation functional carrier)**.** *A* $\mathsf{CauchyTailEvaluationFunctional}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$E = (R, W, D, Q, V, S, H, C, P, N)$$

with the following displayed rows:

1. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *source row carrying the regular Cauchy rational name and its tail-readback surface.*
2. *W is the* $\mathsf{StreamName}^{\uparrow}$ *tail-window row listing exactly the finite suffix entries inspected for the request.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row recording the requested dyadic radius, comparison budget, and arithmetic checks for the displayed tail.*
4. *Q is the finite request row naming the precision, the tail index, and the window extraction route read from* $\mathsf{RegularCauchyWindowExtraction}^{\uparrow}$*.*
5. *V is the evaluation-value row, the displayed rational or dyadic answer returned by the finite tail inspection.*
6. *S is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row, available only after R, W, D, Q, V have been displayed.*
7. *H records componentwise* hsame *transport for the source, window, tolerance, request, value, seal, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from the request row through R, W, D, V, S, H, P, N.*

9. *P is the* Pkg *provenance over* $\mathsf{CauchyTailEvaluationFunctional}^{\uparrow}$, $\mathsf{RegularCauchyWindowExtraction}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*
10. *N is the local* $\mathsf{NameCert}_{\mathsf{CauchyTailEvaluationFunctional}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $R, W, D, Q, V, S, H, C, P, N$. It has no coordinate for quotient representatives, selected limits, countable choice, host equality, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.CauchyTailEvaluationFunctionalUp.CauchyTailEvaluationFunctionalTasteGate`
`single carrier alignment`

Theorem 8638.2 (Cauchy tail evaluation functional NameCert obligations)**.** *For every accepted* $\mathsf{CauchyTailEvaluationFunctional}^{\uparrow}$ *carrier*

$$E = (R, W, D, Q, V, S, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{CauchyTailEvaluationFunctional}^{\uparrow}}$ *surface consists exactly of carrier admission for the displayed packet, regular-source admission through R, finite tail-window admission through W, dyadic tolerance exactness through D, finite request admission through Q, evaluation-value exposure through V, terminal* $\mathsf{Real}^{\uparrow}$ *sealing through S, classifier transport through H, displayed replay through C, provenance through P, and local naming through N.*

Proof. Project the carrier of Definition 8638.1. The rows $R, W, D, Q, V, S, H, C, P, N$ are the complete inventory of an accepted packet.

The analytic rows are ordered. The regular source R is inspected only through the tail windows W selected by the finite request Q, and the tolerance ledger D records the dyadic comparisons used by that inspection.

The evaluation row V is therefore a displayed finite answer, not a selected limit. The seal row S is downstream of the same source, window, tolerance, request, and value rows, while H, C, P, N transport, replay, source, and name only that route. □

Theorem 8638.3 (Cauchy tail evaluation functional tail stability)**.** *Let $E = (R, W, D, Q, V, S, H, C, P, N)$ and $E' = (R', W', D', Q', V', S', H', C', P', N')$ be accepted* $\mathsf{CauchyTailEvaluationFunctional}^{\uparrow}$ *packets. If the regular source, tail-window, dyadic tolerance, finite request, and evaluation-value rows are transported componentwise through the displayed* hsame *rows and replayed through the displayed* Cont *rows, then the transported packet exposes the same finite tail-evaluation route before any* $\mathsf{Real}^{\uparrow}$ *seal is consumed. No quotient representative, selected limit, countable-choice schedule, host equality, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness row can be introduced by the transport.*

Proof. Apply Definition 8638.2 to both accepted packets. The obligations identify the evaluation route with the displayed rows $R, W, D, Q, V, S, H, C, P, N$ and $R', W', D', Q', V', S', H', C', P', N'$.

Componentwise hsame transport preserves the source, window, tolerance, request, and value rows as the same classified data, while Cont replay exposes those transported rows in the displayed order. The terminal seal remains downstream of the finite route.

Since the carrier has no coordinate for quotient representatives, selected limits, countable choice, host equality, or ambient $\mathsf{Real}^{\uparrow}$ completeness, transport and replay cannot add those objects. The accepted tail evaluator is stable exactly as a finite regular-Cauchy tail route. □

Falsifiable prediction: Every accepted $\mathsf{CauchyTailEvaluationFunctional}^{\uparrow}$ read exposes a RegSeqRat source row, StreamName tail-window row, DyadicRatCore tolerance row, finite request row,

evaluation-value row, RealUp seal row, componentwise hsame transport, Cont replay, Pkg provenance, and local NameCert row.

Independence witness: regular-cauchy-window-extraction, regseqrat, streamname, dyadicratcore, real: $\mathsf{CauchyTailEvaluationFunctional}^{\uparrow}$ is not bijective to any listed sibling because it binds the finite request and evaluation-value rows to the regular Cauchy tail before the RealUp seal, while refusing quotient representatives, selected limits, countable choice, host equality, and ambient $\mathsf{Real}^{\uparrow}$ completeness.

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyTailEvaluationFunctional}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CauchyTailEvaluationFunctional}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8638.1, Definition 8638.2, and Definition 8638.3 seed the finite evaluation-functional route over RegularCauchyWindowExtractionUp, RegSeqRatUp, StreamNameUp, DyadicRatCoreUp, RealUp, BHist, hsame, Cont, Pkg, and NameCert rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CauchyTailEvaluationFunctional}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient representatives, selected limits, countable choice, host equality, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, regular-source admission, tail-window admission, tolerance exactness, finite request admission, value exposure, Real-seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.CauchyTailEvaluationFunctionalUp.

Constructive story: A $\mathsf{CauchyTailEvaluationFunctional}^{\uparrow}$ packet is generated from a RegSeqRat source row, StreamName tail windows, a DyadicRatCore tolerance ledger, a finite request row, an evaluation-value row, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 8639

A Concrete Naming Certificate for $\mathsf{BirkhoffKakutani}^{\uparrow}$

Following Birkhoff and Kakutani on first-countable topological groups, the $\mathsf{BirkhoffKakutani}^{\uparrow}$ packet records the finite BEDC surface by which a displayed first-countable $\mathsf{TopGroup}^{\uparrow}$ source is handed to a left-invariant $\mathsf{Met}^{\uparrow}$ witness. It sits after the topological-group operation and continuity rows of chapter 204, the entourage interface of chapter 339, the metric carrier of chapter 57, and the shrinkage-to-metric route of chapter 4226. The packet names the neighborhood-basis, symmetric-shrinkage, product, inverse, and metric handoff rows; it is not a quotient group, a choice-selected countable family, a completed uniform space, or a host metrization theorem.

Definition 8639.1 (Birkhoff-Kakutani carrier)**.** *A* $\mathsf{BirkhoffKakutani}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (G, B, S, P, I, U, M, H, C, Q, N)$$

with the following displayed rows:

1. *G is the* $\mathsf{TopGroup}^{\uparrow}$ *source row, exposing multiplication, unit, inverse, translation, and neighborhood-continuity data.*
2. *B is the countable neighborhood-basis ledger, represented by finite prefix windows rather than a choice-selected infinite basis.*
3. *S is the symmetric shrinkage ledger, recording the displayed sequence of neighborhoods whose squares stay inside the previous neighborhood.*
4. *P is the product-compatibility row, showing that multiplication consumes the shrinkage rows through the* $\mathsf{TopGroup}^{\uparrow}$ *continuity surface.*
5. *I is the inverse-compatibility row, showing that inversion preserves the displayed symmetric neighborhood rows.*
6. *U is the* $\mathsf{UniformSpace}^{\uparrow}$ *handoff row generated from left translates of the displayed neighborhood data.*
7. *M is the* $\mathsf{Met}^{\uparrow}$ *handoff row, read through the* $\mathsf{FrinkMetrization}^{\uparrow}$ *finite shrinkage-to-distance route.*
8. *H records componentwise* hsame *transport for the topological-group source, basis, shrinkage, product, inverse, uniform, metric, replay, provenance, and naming rows.*
9. *C records displayed* Cont *replay from a metrization request through $G, B, S, P, I, U, M, H, Q, N$.*

10. *Q is the* Pkg *provenance over* BirkhoffKakutani$^{\uparrow}$, TopGroup$^{\uparrow}$, UniformSpace$^{\uparrow}$, Met$^{\uparrow}$, FrinkMetrization$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

11. *N is the local* NameCert$_{\text{BirkhoffKakutani}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $G, B, S, P, I, U, M, H, C, Q, N$. It has no coordinate for a quotient group, selected infinite basis, host left-uniformity object, ambient completion, or unlogged metrization oracle.

Theorem 8639.2 (Birkhoff-Kakutani NameCert obligations)**.** *For every accepted* BirkhoffKakutani$^{\uparrow}$ *carrier $K = (G, B, S, P, I, U, M, H, C, Q, N)$, the local* NameCert$_{\text{BirkhoffKakutani}^{\uparrow}}$ *surface consists exactly of topological-group source exposure through G, countable neighborhood-basis exposure through B, symmetric shrinkage through S, product compatibility through P, inverse compatibility through I, left-uniform handoff through U, left-invariant metric handoff through M, componentwise* hsame *transport through H, displayed* Cont *replay through C,* Pkg *provenance through Q, and local naming through N.*

Every metric-facing consumer therefore reads the TopGroup$^{\uparrow}$ *source, the finite basis prefixes, the symmetric shrinkage rows, product and inverse compatibility, and the* UniformSpace$^{\uparrow}$ *handoff before the* Met$^{\uparrow}$ *row can be consumed.*

Proof. Project the accepted carrier. The source row G is the only topological-group data available, and B is the only basis data exposed to consumers.

The shrinkage and compatibility rows are downstream from those sources. The row S records the symmetric neighborhood chain, P records that multiplication respects the chain, and I records inverse stability on the same displayed rows.

The uniform and metric rows then read the same finite route. The row U packages the left-translate entourage handoff, while M records the Frink-style metric handoff from the displayed shrinkage ledger.

Finally, H, C, Q, N transport, replay, source, and name that route. Since the carrier contains no quotient group, selected infinite basis, host uniformity object, ambient completion, or metrization oracle, the listed rows exhaust the local certificate. □

Closure status for NameCert$_{\text{BirkhoffKakutani}^{\uparrow}}$**.**

Constructive story: A BirkhoffKakutani$^{\uparrow}$ packet is generated from a TopGroup source row, countable neighborhood-basis windows, symmetric shrinkage rows, product and inverse compatibility, a UniformSpace handoff, a Metric handoff through FrinkMetrization, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\text{BirkhoffKakutani}^{\uparrow}}$, seed)

Scope closed: Definition 8639.1 and Definition 8639.2 seed the finite first-countable topological-group metrization surface over topological-group, uniform, metric, shrinkage, transport, replay, provenance, and local naming rows.

Formal verification: FormalStatus(NameCert$_{\text{BirkhoffKakutani}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim quotient groups, selected infinite bases, host uniformity objects, ambient completions, Lean verification, bridge checking, or an unrestricted metrization theorem outside the displayed rows.

Upgrade path: Obligation closure requires checked source exposure, basis-window admission, symmetric shrinkage, product compatibility, inverse compatibility, uniform handoff, metric handoff, transport, replay, provenance, and local naming for BEDC.Derived.BirkhoffKakutaniUp.

Chapter 8640

A Concrete Naming Certificate for $\mathsf{HyperbolicBoundaryPhaseShadow}^{\uparrow}$

The $\mathsf{HyperbolicBoundaryPhaseShadow}^{\uparrow}$ packet realizes the boundary phase-shadow route of chapter 9463 as finite Poincare-disk, hyperbolic-metric, boundary-shadow, observer-phase, and refusal-ledger NameCert data. It sits after the metric source of chapter 3474, the boundary-shadow route of chapter 3813, the phase-transport packet of chapter 3455, the geodesic-projection packet of chapter 5917, and the boundary-transport packet of chapter 6267. The packet names only finite disk, phase, shadow, transport, refusal, replay, provenance, and local naming rows; it is not a completed ideal-boundary quotient, a host geodesic-flow object, a physical observer path, or a selected boundary phase.

Definition 8640.1 (Hyperbolic boundary phase-shadow carrier)**.** *A* $\mathsf{HyperbolicBoundaryPhaseShadow}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (D, M, B, T, G, E, O, R, H, C, P, N)$$

with the following displayed rows:

1. *D is the Poincare-disk source row, read through displayed disk coordinates and boundary transport.*
2. *M is the* $\mathsf{HyperbolicMetric}^{\uparrow}$ *row, exposing the metric comparison used by shadow windows.*
3. *B is the* $\mathsf{HyperbolicBoundaryShadow}^{\uparrow}$ *row, recording the boundary-shadow window visible from the disk source.*
4. *T is the* $\mathsf{PoincareDiskPhaseTransport}^{\uparrow}$ *row, recording phase transport along the displayed disk route.*
5. *G is the* $\mathsf{PoincareDiskGeodesicProjection}^{\uparrow}$ *row, exposing the geodesic projection used before a boundary phase read.*
6. *E is the* $\mathsf{PoincareDiskBoundaryTransport}^{\uparrow}$ *row, preserving the boundary endpoint data along the displayed transport.*
7. *O is the observer-phase ledger, recording how the boundary shadow and phase transport are read by observer-expansion consumers.*
8. *R is the refusal ledger, excluding completed ideal-boundary quotients, host geodesic-flow objects, physical observer paths, and selected boundary phases.*

9. *H records componentwise* hsame *transport for disk, metric, shadow, phase, geodesic, boundary, observer, refusal, replay, provenance, and local naming rows.*
10. *C records displayed* Cont *replay from a phase-shadow request through $D, M, B, T, G, E, O, R, H, P, N$.*
11. *P is the* Pkg *provenance over* $\mathsf{HyperbolicBoundaryPhaseShadow}^{\uparrow}$, $\mathsf{HyperbolicMetric}^{\uparrow}$, $\mathsf{HyperbolicBoundaryShadow}^{\uparrow}$ $\mathsf{PoincareDiskPhaseTransport}^{\uparrow}$, $\mathsf{PoincareDiskGeodesicProjection}^{\uparrow}$, $\mathsf{PoincareDiskBoundaryTransport}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
12. *N is the local* $\mathsf{NameCert}_{\mathsf{HyperbolicBoundaryPhaseShadow}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $D, M, B, T, G, E, O, R, H, C, P, N$. It has no coordinate for a completed ideal boundary, quotient phase class, selected observer path, host Mobius action, or global geodesic-flow theorem.

Theorem 8640.2 (Hyperbolic boundary phase-shadow NameCert obligations)**.** *For every accepted* $\mathsf{HyperbolicBoundaryPhaseShadow}^{\uparrow}$ *carrier $S = (D, M, B, T, G, E, O, R, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{HyperbolicBoundaryPhaseShadow}^{\uparrow}}$ *surface consists exactly of Poincare-disk source exposure through D, hyperbolic-metric comparison through M, boundary-shadow exposure through B, phase transport through T, geodesic projection through G, boundary transport through E, observer-phase ledger exactness through O, refusal exactness through R, componentwise* hsame *transport through H, displayed* Cont *replay through C,* Pkg *provenance through P, and local naming through N.*

Thus every observer-expansion read reaches phase-shadow data only after the metric, boundary-shadow, phase-transport, geodesic-projection, and boundary-transport rows have been displayed.

Proof. Project the accepted carrier to D, M, B, T, G, E. These rows are the complete geometric surface available to the packet, and each is a displayed BEDC row rather than a host hyperbolic object.

The observer row O is downstream from those geometric rows. It records how the boundary-shadow read and phase-transport read are jointly consumed by an observer-facing request.

The refusal row R stays attached to that handoff. It blocks rereading the packet as a completed ideal-boundary quotient, quotient phase class, physical observer path, host Mobius action, or global geodesic-flow theorem.

Finally, H, C, P, N transport, replay, source, and name the same finite route. Since no excluded object is a coordinate of S, the listed rows exhaust the local NameCert obligations. □

Falsifiable prediction: An accepted $\mathsf{HyperbolicBoundaryPhaseShadow}^{\uparrow}$ read is refuted if an observer-expansion consumer obtains boundary phase-shadow data without displaying Poincare disk source rows, HyperbolicMetric comparison, HyperbolicBoundaryShadow windows, PoincareDiskPhase-Transport, PoincareDiskGeodesicProjection, PoincareDiskBoundaryTransport, observer-phase ledger, refusal ledger, hsame transport, Cont replay, Pkg provenance, and local naming.

Independence witness: hyperbolic-metric, hyperbolic-boundary-shadow, poincare-disk-phase-transport, poincare-disk-geodesic-projection, poincare-disk-boundary-transport: no listed sibling is bijective to $\mathsf{HyperbolicBoundaryPhaseShadow}^{\uparrow}$ because this packet jointly carries disk source, metric comparison, boundary-shadow window, phase transport, geodesic projection, boundary transport, observer-phase ledger, refusal, transport, replay, provenance, and local naming as one finite row surface.

The Lean TasteGate route must provide explicit Nontrivial $\mathsf{HyperbolicBoundaryPhaseShadow}^{\uparrow}$ and FieldFaithful $\mathsf{HyperbolicBoundaryPhaseShadow}^{\uparrow}$ instances in `lean4/BEDC/Derived/HyperbolicBoundaryPhase`

The field-faithfulness witness must preserve $D, M, B, T, G, E, O, R, H, C, P, N$ as distinct rows before a checked carrier-alignment theorem can serve as the TasteGate witness.

Closure status for $\mathsf{NameCert}_{\mathsf{HyperbolicBoundaryPhaseShadow}\uparrow}$.

Constructive story: A $\mathsf{HyperbolicBoundaryPhaseShadow}^{\uparrow}$ packet is generated from Poincare disk source rows, HyperbolicMetric comparison, HyperbolicBoundaryShadow windows, PoincareDiskPhaseTransport, PoincareDiskGeodesicProjection, PoincareDiskBoundaryTransport, observer-phase ledger exactness, refusal exactness, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{HyperbolicBoundaryPhaseShadow}\uparrow}, \mathsf{seed})$

Scope closed: Definition 8640.1 and Definition 8640.2 seed the finite boundary phase-shadow route over disk, metric, shadow, phase, geodesic, boundary, observer, refusal, transport, replay, provenance, and local naming rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{HyperbolicBoundaryPhaseShadow}\uparrow}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim completed ideal-boundary quotients, quotient phase classes, physical observer paths, host Mobius actions, global geodesic-flow theorems, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked disk-source admission, metric comparison, boundary-shadow exposure, phase transport, geodesic projection, boundary transport, observer-phase ledger exactness, TasteGate nontriviality, field faithfulness, refusal exactness, transport, replay, provenance, and local naming for BEDC.Derived.HyperbolicBoundaryPhaseShadowUp.

Chapter 8641

A Concrete Naming Certificate for $\mathsf{UniformTotalBounded}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{UniformTotalBounded}^{\uparrow}$ packet records total boundedness as a uniform finite-net certificate whose radii are read from displayed dyadic precision rows rather than from open-cover compactness or choice-selected finite subcovers. It sits after the total-bounded source of chapter 127, the metric carrier of chapter 57, the finite-net interface of chapter 1767, and the compact-metric consumer of chapter 129. The packet names the finite uniform coverage route consumed by compact, completion, and uniform-continuity chapters while excluding host enumerations of centers, selected subcovers, quotient metric equality, countable choice, and ambient completeness of $\mathsf{Real}^{\uparrow}$.

Definition 8641.1 (Uniform total-bounded carrier)**.** *A* $\mathsf{UniformTotalBounded}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$U = (M, D, F, W, T, C, P, N)$$

with the following displayed rows:

1. *M is the metric source row, exposing the point carrier, point classifier, distance witness, zero-distance, symmetry, triangle, and distance-transport ledgers read by the packet.*
2. *D is the dyadic precision-radius row. It records the positive requested tolerance, its dyadic refinement, and the radius ledger used to ask for a finite net at that scale.*
3. *F is the finite net family row. For each precision request supplied by D, it displays a closed* $\mathsf{ProbeBundle}$ *of centers, center-carrier rows over M, and membership rows for those centers.*
4. *W is the coverage witness row. It records, for every inspected source point, a bundled center from F and a displayed metric distance comparison whose bound is the dyadic radius carried by D.*
5. *T is the uniform transport row, recording componentwise* hsame *transport for the metric source, dyadic radius ledger, finite net family, coverage witnesses, replay, provenance, and local naming.*
6. *C records displayed* Cont *replay from a precision request through D, then through M, F, W, T, P, N.*
7. *P is the* Pkg *provenance over* $\mathsf{UniformTotalBounded}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{FiniteEpsilonNet}^{\uparrow}$, $\mathsf{FiniteNet}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$ *rows.*
8. *N is the local* $\mathsf{NameCert}_{\mathsf{UniformTotalBounded}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through M, D, F, W, T, C, P, N. It has no coordinate for open-cover compactness, selected finite subcovers, host lists of centers, quotient equality of metric points, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 8641.2 (Uniform total-bounded finite-net obligation)**.** *For every accepted* $\mathsf{UniformTotalBounded}^{\uparrow}$ *carrier*

$$U = (M, D, F, W, T, C, P, N),$$

the finite-net obligation surface consists exactly of metric source exposure through M, dyadic precision-radius exposure through D, finite net family exposure through F, coverage witness exposure through W, uniform hsame *transport through T, displayed* Cont *replay through C, package provenance through P, and local naming through N. Any compact-metric, completion-facing, or uniform-continuity consumer that reads total boundedness from the packet must expose these rows before it may use the finite-net claim.*

Proof. Project the carrier of Definition 8641.1. The only analytic rows are the metric source M, dyadic radius ledger D, finite net family F, and coverage witness row W; the remaining rows transport, replay, source, and name that same finite packet.

Read a tolerance request through the dyadic row D. The finite net family F is then indexed by the displayed radius rather than by an external cover. Its centers are closed ProbeBundle entries with center-carrier rows over M.

Coverage is the row W. For each inspected source point it supplies a bundled center and a metric comparison bounded by the dyadic radius already displayed by D. The transport row T and replay row C preserve this route uniformly across hsame-equivalent presentations.

Finally P and N record provenance and local naming for the same rows. Since the carrier contains no open-cover, selected-subcover, host-enumeration, quotient-equality, countable-choice, or ambient-completeness coordinate, every exported total-boundedness claim is exactly the listed finite-net obligation surface. □

Closure status for $\mathsf{NameCert}_{\mathsf{UniformTotalBounded}^{\uparrow}}$.

Constructive story: A $\mathsf{UniformTotalBounded}^{\uparrow}$ packet is generated from a metric source row, dyadic precision-radius row, finite net family row, coverage witness row, uniform hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{UniformTotalBounded}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8641.1 and Definition 8641.2 seed the finite-net uniformity certificate over displayed metric sources, dyadic precision radii, center bundles, coverage witnesses, transport, replay, provenance, and local naming.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{UniformTotalBounded}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim open-cover compactness, selected subcovers, host center enumeration, quotient metric equality, countable choice, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, dyadic radius exactness, finite net family exposure, coverage witness stability, uniform transport, replay, provenance, and local naming for BEDC.Derived.UniformTotalBoundedUp.

Chapter 8642

A Concrete Naming Certificate for $\mathsf{HeineBorelCoverSelector}^{\uparrow}$

Following Heine, Borel, Lebesgue, and Bishop and Bridges, the $\mathsf{HeineBorelCoverSelector}^{\uparrow}$ packet records the finite selector surface by which a displayed compact interval cover is consumed by Real and Completion routes. It sits after the finite-net interval packet of chapter 1379, the compact-metric source of chapter 129, the finite stream windows of chapter 126, the regular rational readback of chapter 301, the dyadic tolerance ledger of chapter 291, and the terminal real-name seal of chapter 38. It reads finite subcover budgets through chapter 8630 and interval net evidence through chapter 1808. The packet names a finite cover-selector carrier only; it does not assert arbitrary open-cover compactness, a choice function on covers, a quotient real equality principle, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 8642.1 (Heine–Borel cover-selector carrier)**.** *A* $\mathsf{HeineBorelCoverSelector}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (I, K, W, R, D, E, F, L, H, C, P, N)$$

with the following displayed rows:

1. *I is the* $\mathsf{HeineBorelInterval}^{\uparrow}$ *finite interval-net source.*
2. *K is the* $\mathsf{CompactMetric}^{\uparrow}$ *finite-net coverage row over the same interval carrier.*
3. *W is the* $\mathsf{StreamName}^{\uparrow}$ *row exposing the finite cover-window entries inspected by the selector.*
4. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for endpoint and radius observations.*
5. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger comparing cover radii, mesh widths, and overlap slack.*
6. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached only after I, K, W, R, D are visible.*
7. *F is the finite selected-subcover ledger, listing exactly the displayed cover entries retained by the selector.*
8. *L is the local lower-bound and overlap ledger proving that the retained entries cover the displayed interval windows.*
9. *H records componentwise* hsame *transport for all selector rows.*
10. *C records displayed* Cont *replay from interval source to finite selector ledger and Real seal.*
11. *P is the* Pkg *provenance over* $\mathsf{HeineBorelCoverSelector}^{\uparrow}$, $\mathsf{HeineBorelInterval}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*

12. N is the local $\mathsf{NameCert}_{\mathsf{HeineBorelCoverSelector}^{\uparrow}}$ *row.*

The carrier has no coordinate for an infinite cover family, a host-side choice function, selected representatives of real names, open-cover compactness beyond the displayed interval net, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 8642.2 (Heine–Borel cover-selector finite-net subcover)**.** *Let $S = (I, K, W, R, D, E, F, L, H, C, P, N)$ be an accepted* $\mathsf{HeineBorelCoverSelector}^{\uparrow}$ *carrier. Every selected subcover exported by the packet must first expose the* $\mathsf{HeineBorelInterval}^{\uparrow}$ *row I, the* $\mathsf{CompactMetric}^{\uparrow}$ *finite-net row K, the finite* $\mathsf{StreamName}^{\uparrow}$ *cover windows W, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback R, and the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger D. Only then may the finite selector ledger F, coverage ledger L, Real seal E, transport, replay, provenance, and local naming rows be consumed.*

The route exports no arbitrary open-cover compactness theorem, countable choice schedule, host cover selector, quotient real equality, selected completed real, or ambient $\mathsf{Real}^{\uparrow}$ *completeness coordinate.*

Proof. Project the carrier of Definition 8642.1. The accepted packet displays the interval source, compact-metric finite-net source, finite cover windows, rational readback, dyadic tolerance ledger, selector ledger, coverage ledger, Real seal, and structural rows.

Read the finite-net side first. The $\mathsf{HeineBorelInterval}^{\uparrow}$ and $\mathsf{CompactMetric}^{\uparrow}$ rows identify the same displayed interval-net surface, while W, R, D restrict inspection to finitely many named cover entries and tolerances.

The selector ledger F and coverage ledger L are downstream of those rows. Transport, replay, provenance, and local naming preserve the same finite packet, so the excluded choice, quotient, open-cover compactness, selected-real, and ambient-completeness principles cannot be read from the carrier. □

Theorem 8642.3 (Heine–Borel cover-selector NameCert obligations)**.** *For an accepted* $\mathsf{HeineBorelCoverSelector}^{\uparrow}$ *carrier $S = (I, K, W, R, D, E, F, L, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{HeineBorelCoverSelector}^{\uparrow}}$ *surface consists exactly of carrier admission, interval finite-net exposure through I, compact-metric coverage exposure through K, finite cover-window exposure through W, regular rational readback through R, dyadic tolerance accounting through D, Real sealing through E, selected-subcover ledger exposure through F, coverage ledger exposure through L, componentwise transport through H, displayed replay through C, package provenance through P, and local naming through N.*

Proof. Carrier admission is projection from Definition 8642.1. The rows I, K, W, R, D expose the displayed interval-net and finite cover-window source before any selected subcover can be inspected.

Apply Definition 8642.2. It forces the selector ledger F and coverage ledger L to remain downstream of the displayed finite-net, stream-window, rational, and dyadic rows.

Finally read E, H, C, P, N. These rows seal, transport, replay, package, and name the same finite selector carrier. Since no extra coordinate is present, the listed obligations exhaust the local NameCert surface. □

Falsifiable prediction: Any accepted $\mathsf{HeineBorelCoverSelector}^{\uparrow}$ consumer that reads a selected subcover without displaying the $\mathsf{HeineBorelInterval}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, selector, coverage, transport, replay, provenance, and local $\mathsf{NameCert}$ rows refutes the carrier.

Independence witness: heineborelinterval, compactmetric, real, streamname, regseqrat, dyadicratcore: no listed sibling is bijective with $\mathsf{HeineBorelCoverSelector}^{\uparrow}$ because this packet jointly

carries an interval finite-net source, compact-metric coverage, finite cover windows, rational readback, dyadic tolerance accounting, selected-subcover ledger, coverage ledger, Real seal, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{HeineBorelCoverSelector}\uparrow}$.

Constructive story: A $\mathsf{HeineBorelCoverSelector}^{\uparrow}$ packet is generated from a HeineBorelIntervalUp finite-net source, CompactMetricUp coverage rows, StreamNameUp finite cover windows, RegSeqRatUp readback, DyadicRatCoreUp tolerance accounting, a finite selected-subcover ledger, a coverage ledger, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{HeineBorelCoverSelector}\uparrow}, \mathsf{seed})$

Scope closed: Definition 8642.1, Definition 8642.2, and Definition 8642.3 seed the finite cover-selector route over HeineBorelInterval, CompactMetric, StreamName, RegSeqRat, DyadicRatCore, and Real rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{HeineBorelCoverSelector}\uparrow}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close arbitrary open-cover compactness, host cover choice, quotient real equality, selected completed reals, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, finite-net subcover routing, selected-subcover ledger exactness, coverage ledger exactness, Real-seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.HeineBorelCoverSelectorUp.

Chapter 8643

A Concrete Naming Certificate for $\mathsf{AntiSpecker}^{\uparrow}$

Following Specker and Bishop–Bridges constructive analysis, the $\mathsf{AntiSpecker}^{\uparrow}$ packet records the compactness boundary where a displayed stream of located real probes is refuted by finite-net data rather than by a selected convergent subsequence or a host compactness theorem. It sits over the finite observation surface of chapter 126, the regular rational readback of chapter 301, the terminal real-name seal of chapter 38, the compact-metric source of chapter 129, and the finite-net coverage row named by $\mathsf{TotallyBounded}^{\uparrow}$.

Definition 8643.1 (Anti-Specker carrier)**.** *An* $\mathsf{AntiSpecker}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$A = (K, T, S, R, E, F, G, H, C, P, N)$$

with the following displayed rows:

1. *K is the* $\mathsf{CompactMetric}^{\uparrow}$ *source row whose compact information is exposed only as finite metric and cover data;*
2. *T is the* $\mathsf{TotallyBounded}^{\uparrow}$ *finite-net row, carrying the finite centers, radii, and membership alternatives used by the boundary argument;*
3. *S is the* $\mathsf{StreamName}^{\uparrow}$ *row for the inspected probe stream;*
4. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row attached to the requested rational windows of the stream;*
5. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row for each displayed probe window after the regular-rational readback has been exposed;*
6. *F is the finite escape ledger, recording the inspected net cell, the displayed probe window, and the positive separation row for that cell;*
7. *G is the compact finite-net refusal row, stating that the escape ledger is read as a finite obstruction to a universal compact accumulation claim;*
8. *H records componentwise* hsame *transport for the compact source, net row, stream row, regular readback, real seal, escape ledger, refusal row, provenance, and local name;*
9. *C records displayed* Cont *replay from compact finite-net inspection through stream windows, regular readback, real sealing, finite escape, and refusal;*

10. *P records* Pkg *provenance over* $\mathsf{AntiSpecker}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{TotallyBounded}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert*;*
11. *N is the local* $\mathsf{NameCert}_{\mathsf{AntiSpecker}^{\uparrow}}$ *registration row.*

The carrier has no coordinate for open-cover compactness, sequential compactness, selected subsequences, countable choice, quotient stream equality, or $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 8643.2 (Anti-Specker NameCert obligations)**.** *For every accepted* $\mathsf{AntiSpecker}^{\uparrow}$ *carrier $A = (K, T, S, R, E, F, G, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{AntiSpecker}^{\uparrow}}$ *surface consists exactly of compact-source admission through K, finite-net admission through T, stream-window exposure through S, regular-rational readback through R, terminal real-name sealing through E, finite escape recording through F, compact finite-net refusal through G, componentwise transport through H, displayed replay through C, provenance through P, and local naming through N.*

Proof. Project the displayed carrier. The compact source is read through K and the finite-net row T, while the probe stream is read through S, R, and E before any escape datum is available.

The finite escape ledger F is then a row over the already displayed net cell and probe window. It records a positive separation row for that finite inspection, not a global compactness theorem.

The refusal row G packages this finite escape as the local boundary consumed by compactness-facing readers. The structural rows H, C, P, N transport, replay, source, and name the same finite packet. No remaining coordinate can supply open-cover compactness, sequential compactness, selected subsequences, countable choice, quotient stream equality, or real completeness. □

Theorem 8643.3 (Anti-Specker finite escape route)**.** *Every compactness-facing consumer of an accepted* $\mathsf{AntiSpecker}^{\uparrow}$ *packet must read the route*

$$K, T, S, R, E, F, G, H, C, P, N$$

in that order: compact finite-net data first, then stream and regular-rational windows, then the terminal real-name seal, then the finite escape and refusal rows. The route provides a constructive compactness boundary over displayed finite-net rows and exports no selected subsequence, no countable-choice schedule, no open-cover compactness theorem, no quotient stream equality, and no $\mathsf{Real}^{\uparrow}$ *completeness principle.*

Proof. Start with the local NameCert obligations of Definition 8643.2. They force any consumer to inspect the compact source and finite-net row before reading a stream window or regular-rational readback.

The real-facing seal E is downstream of S and R, so a consumer cannot treat the probe as a detached completed real. The escape row F is attached to that displayed window and to the finite-net cell named by T.

Finally the refusal row G is read only after the finite escape has been displayed, and H, C, P, N only transport, replay, source, and name this route. The packet therefore remains a finite constructive boundary rather than a sequential compactness, choice, open-cover, quotient, or completeness principle. □

Closure status for $\mathsf{NameCert}_{\mathsf{AntiSpecker}^{\uparrow}}$.

Constructive story: An $\mathsf{AntiSpecker}^{\uparrow}$ packet is generated from a CompactMetricUp source row, a TotallyBoundedUp finite-net row, StreamName windows, RegSeqRat readback, RealUp seal rows, a finite escape ledger, a compact finite-net refusal row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{AntiSpecker}^{\uparrow}}$, seed)

Scope closed: Definition 8643.1, Definition 8643.2, and Definition 8643.3 seed the finite compactness-boundary route over displayed stream, regular-rational, real-seal, compact-metric, and finite-net rows.

Formal verification: FormalStatus(NameCert$_{\mathsf{AntiSpecker}\uparrow}$, unformalized)

Bridge status: none

Origin: human

Not claimed: This chapter does not close open-cover compactness, sequential compactness, selected subsequences, countable choice, quotient stream equality, or Real$^{\uparrow}$ completeness.

Upgrade path: Obligation closure requires carrier admission, finite-net exactness, stream and regular-rational read-back, real-seal nonescape, finite escape ledger coverage, transport stability, and provenance scope for BEDC.Derived.AntiSpeckerUp.

Chapter 8644

A Concrete Naming Certificate for $\mathsf{RealCompletionReflector}^{\uparrow}$

Following Bishop and Bridges and Kelley on metric completion, the $\mathsf{RealCompletionReflector}^{\uparrow}$ packet names the finite boundary by which a displayed metric source reaches a Real-sealed completion reflector without quotienting streams, selecting limits, invoking trichotomy, or using countable choice. It sits after the minimality route of chapter 1606, the reflector-unit packet of chapter 8626, the metric-completion service of chapter 1506, the regular rational name surface of chapter 301, and the terminal real-name seal of chapter 38. The packet is a reflector boundary for Real and Completion consumers; it is not Real completeness, a selected limit theorem, quotient stream equality, trichotomy, or a countable-choice principle.

Definition 8644.1 (Real completion reflector carrier)**.** *A* $\mathsf{RealCompletionReflector}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$R = (M, Q, E, U, F, T, H, C, P, N)$$

with the following displayed rows:

1. *M is the source metric row, exposing the source carrier, source classifier, distance row, zero-distance, symmetry, triangle, and distance-transport ledgers read by the reflector.*
2. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *and* $\mathsf{Real}^{\uparrow}$ *seal row. It records the regular rational readback route, the finite dyadic tolerance requests inherited from* $\mathsf{DyadicRatCore}^{\uparrow}$*, the inspected* $\mathsf{StreamName}^{\uparrow}$ *windows, and the terminal Real seal exposed to consumers.*
3. *E is the completion object row, displaying the* $\mathsf{MetricCompletion}^{\uparrow}$ *object together with the minimality and reflector-unit references supplied by the sibling completion packets.*
4. *U is the unit row from the source metric into the displayed completion object. It records only the finite graph of inspected source points and their completion names.*
5. *F is the universal arrow row. For each inspected uniformly continuous source-to-complete-target route, it records the finite factorization through U and the target's displayed Real-sealed completion readback.*
6. *T is the transport row, carrying componentwise* hsame *comparison for the source metric, regular rational and Real seal, completion object, unit, factorization route, replay, provenance, and local naming.*

7. *H records the reflector handoff to the existing* $\mathsf{CauchyCompletionMinimality}^{\uparrow}$, $\mathsf{CauchyCompletionReflectorUnit}^{\uparrow}$, *and* $\mathsf{MetricCompletion}^{\uparrow}$ *packets.*
8. *C records displayed* Cont *replay from source metric inspection through Q, E, U, F, T, H, P, N.*
9. *P is the* Pkg *provenance over* $\mathsf{RealCompletionReflector}^{\uparrow}$, $\mathsf{MetricCompletion}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{CauchyCompletionMinimality}^{\uparrow}$, $\mathsf{CauchyCompletionReflectorUnit}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$ *rows.*
10. *N is the local* $\mathsf{NameCert}_{\mathsf{RealCompletionReflector}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $M, Q, E, U, F, T, H, C, P, N$. It has no coordinate for Real completeness, selected limits, quotient streams, trichotomy, countable choice, or host equality of completion representatives.

Theorem 8644.2 (Real completion reflector NameCert obligations)**.** *For every accepted* $\mathsf{RealCompletionReflector}^{\uparrow}$ *carrier*

$$R = (M, Q, E, U, F, T, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{RealCompletionReflector}^{\uparrow}}$ *obligation surface consists exactly of source metric admission through M, regular rational and Real-seal readback through Q, completion-object exposure through E, unit exposure through U, universal-arrow factorization through F, componentwise transport through T, completion-packet handoff through H, displayed replay through C, provenance through P, and local naming through N.*

Proof. Project the carrier of Definition 8644.1. The source metric data is confined to M, while the Real-facing readback is confined to Q through displayed regular rational names, finite stream windows, dyadic tolerance requests, and the terminal seal.

The completion object and unit are the rows E and U. Their meaning is read through the sibling minimality, reflector-unit, and metric-completion packets recorded in H, not through an ambient completion theorem.

The universal-arrow surface is exactly F. It records a finite factorization route for each inspected source-to-complete-target map after M, Q, E, U have been displayed. The structural rows T, C, P, N transport, replay, source, and name this same route.

Since the carrier contains no coordinate for Real completeness, selected limits, quotient streams, trichotomy, countable choice, or host equality of representatives, those principles cannot be exported by the local NameCert surface. □

Theorem 8644.3 (Universal arrow factorization)**.** *Let $R = (M, Q, E, U, F, T, H, C, P, N)$ be an accepted* $\mathsf{RealCompletionReflector}^{\uparrow}$ *packet. Every completion-facing consumer that reads a uniformly continuous source route from M to a displayed complete target must factor its read through the unit row U and the universal-arrow row F before it may inspect the Real-sealed completion row Q or the completion handoff row H.*

Proof. The NameCert obligations of Definition 8644.2 force any consumer to expose the source metric row M before a completion-facing route is available. The unit row U is the only row that connects the source metric to the displayed completion object.

The factorization row F is downstream of U. It stores the inspected arrow through the displayed completion object and no other coordinate stores such a route. The replay row C and transport row T preserve this same factorization under displayed continuity and componentwise hsame comparison.

The handoff row H then records the relationship with the existing minimality, reflector-unit, and metric-completion packets. Thus every completion-facing read passes through U and F before reaching Q or H. □

Theorem 8644.4 (Minimality handoff)**.** *Let $R = (M, Q, E, U, F, T, H, C, P, N)$ be an accepted* $\mathsf{RealCompletionReflector}^{\uparrow}$ *packet. Every completion-facing read that reaches the completion object row E and the handoff row H must pass through the displayed* $\mathsf{CauchyCompletionMinimality}^{\uparrow}$, $\mathsf{CauchyCompletionReflectorUnit}^{\uparrow}$, *and* $\mathsf{MetricCompletion}^{\uparrow}$ *rows before exporting the Real-sealed reflector interface through Q, F, T, C, P, N.*

The handoff exports no Real completeness theorem, selected limit operation, quotient stream equality, trichotomy principle, countable-choice schedule, or host equality of completion representatives.

Proof. Start with the local obligations of Definition 8644.2. They make E the only completion-object row and H the only row that records the sibling completion packets, so a completion-facing read cannot obtain a completion service by bypassing those two rows.

Apply the universal-arrow factorization of Definition 8644.3. Before the read may inspect the Real-sealed row Q or the handoff row H, it has already passed through the source metric row M, the unit row U, and the factorization row F.

The handoff row is then interpreted through the Cauchy-completion boundary. The NameCert obligations of Definition 1606.2 and the universal factorization route of Definition 1606.4 force the minimality-facing part of the read through the displayed source, dense embedding, universal-property, uniformly continuous extension, separatedness, transport, replay, provenance, and local naming rows. The reflector-unit route of Definition 1606.5 supplies the unit-facing entrance to the same route, while the $\mathsf{MetricCompletion}^{\uparrow}$ row supplies the displayed completion object named by E.

Thus the reflector packet exports only the composed finite route through E, H and the named sibling completion packets before returning to Q, F, T, C, P, N. Since each cited route omits Real completeness, selected limits, quotient streams, trichotomy, countable choice, and host equality, the Real-sealed reflector interface cannot export any of those principles. □

Theorem 8644.5 (Real-seal nonescape)**.** *Every Real-facing consumer read exported by an accepted* $\mathsf{RealCompletionReflector}^{\uparrow}$ *packet factors through the displayed route*

$$M, Q, E, U, F, T, H, C, P, N.$$

The packet supplies a Real-sealed completion reflector boundary and exports no Real completeness theorem, no selected limit operation, no quotient stream equality, no trichotomy principle, and no countable-choice schedule.

Proof. The route begins at M and Q. These rows expose the source metric and the regular rational, stream-window, dyadic-tolerance, and terminal Real-seal data that the consumer may inspect.

The completion object, unit, and universal-arrow rows E, U, F then determine how the completion-facing read is routed. The handoff row H connects this route to the existing completion packets without adding any additional analytic coordinate.

Finally T, C, P, N transport, replay, source, and name the same finite packet. Because Real completeness, selected limits, quotient streams, trichotomy, and countable choice are absent from the carrier, the Real-seal read cannot escape the displayed route. □

Closure status for $\mathsf{NameCert}_{\mathsf{RealCompletionReflector}^{\uparrow}}$.

Constructive story: A $\mathsf{RealCompletionReflector}^{\uparrow}$ packet is generated from a source metric row, RegSeqRat and Real seal row, completion object row, unit row, universal-arrow factorization row, componentwise hsame transport, completion-packet handoff, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RealCompletionReflector}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8644.1, Definition 8644.2, Definition 8644.3, Definition 8644.4, and Definition 8644.5 seed the finite reflector boundary over displayed metric, regular-rational, stream-window, dyadic-tolerance, Real-seal, completion-object, unit, universal-arrow, transport, handoff, replay, provenance, and local naming rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RealCompletionReflector}^{\uparrow}}, \mathsf{unformalized})$

Lean target: `BEDC.Derived.RealCompletionReflectionUp.RealCompletionReflectionTasteGate\_single\_carrier\_alignmen`

Bridge status: none

Not claimed: This chapter does not claim Real completeness, selected limits, quotient streams, trichotomy, countable choice, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, Real-seal readback, completion object exposure, unit stability, universal-arrow factorization, transport, handoff, replay, provenance, and local naming for BEDC.Derived.RealCompletionReflecto

Chapter 8645

A Concrete Naming Certificate for $\mathsf{SequentialContinuityCriterion}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{SequentialContinuityCriterion}^{\uparrow}$ packet records the constructive criterion that a displayed continuous real map carries convergent source sequences to convergent image sequences through finite observation and modulus data. It sits over the $\mathsf{StreamName}^{\uparrow}$ window discipline of chapter 126, the $\mathsf{RegSeqRat}^{\uparrow}$ readback surface of chapter 301, the terminal $\mathsf{Real}^{\uparrow}$ seal of chapter 38, the displayed continuity rows of $\mathsf{Continuous}^{\uparrow}$, and the real-completeness route of chapter 9238. The packet gives Real and Completion consumers a sequence-continuity criterion without quotient streams, host function equality, selected limits, countable choice, or ambient completeness.

Definition 8645.1 (Sequential continuity criterion carrier)**.** *A* $\mathsf{SequentialContinuityCriterion}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (X, Y, F, S_X, S_Y, W_X, W_Y, M, R_X, R_Y, E_X, E_Y, H, C, P, N)$$

with the following displayed rows:

1. *X and Y are the source and target* $\mathsf{Real}^{\uparrow}$ *rows whose sequence windows are inspected.*
2. *F is the* $\mathsf{Continuous}^{\uparrow}$ *continuity row for the displayed map, carrying only graph and tolerance data visible to the certificate.*
3. *S_X and S_Y are the source and image sequence rows, exposed as finite* $\mathsf{StreamName}^{\uparrow}$ *observations.*
4. *W_X and W_Y are the source sequence windows and image sequence windows read from S_X and S_Y.*
5. *M is the continuity-modulus row. It records the finite tolerance-to-precision requests used to turn a source-window convergence request into an image-window convergence request.*
6. *R_X and R_Y are the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback rows for the source and image windows.*
7. *E_X and E_Y are the* $\mathsf{Real}^{\uparrow}$ *seal rows reached only after the corresponding regular-rational readbacks have been displayed.*
8. *H records componentwise* hsame *transport for the source, target, map, sequence windows, modulus, readbacks, seals, replay, provenance, and local name.*
9. *C records displayed* Cont *replay from source sequence windows through the continuity modulus into image sequence windows, then through regular readback and Real seals.*

10. *P is the* Pkg *provenance over* $\mathsf{SequentialContinuityCriterion}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{Continuous}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

11. *N is the local* $\mathsf{NameCert}_{\mathsf{SequentialContinuityCriterion}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these rows. It has no coordinate for quotient stream equality, host function equality, selected representatives, countable choice, an external limit selector, or an ambient $\mathsf{Real}^{\uparrow}$ *completeness theorem.*

Theorem 8645.2 (Sequential continuity criterion NameCert obligations)**.** *For every accepted* $\mathsf{SequentialContinuityCriterion}^{\uparrow}$ *carrier* $K = (X, Y, F, S_X, S_Y, W_X, W_Y, M, R_X, R_Y, E_X, E_Y, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{SequentialContinuityCriterion}^{\uparrow}}$ *surface consists exactly of source and target Real rows, a displayed* $\mathsf{Continuous}^{\uparrow}$ *row, source and image sequence windows, a finite continuity-modulus row,* $\mathsf{StreamName}^{\uparrow}$ *observations,* $\mathsf{RegSeqRat}^{\uparrow}$ *readbacks, terminal* $\mathsf{Real}^{\uparrow}$ *seals, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming.*

Proof. Project the carrier. The source sequence is visible only through S_X, W_X, R_X, E_X, and the image sequence is visible only through S_Y, W_Y, R_Y, E_Y.

The continuity information is the displayed row F together with the finite modulus row M. A convergence request for the image sequence must first read the requested target tolerance in M, then inspect the source windows W_X at the corresponding precision, and only then open the image windows W_Y.

The structural rows H, C, P, N preserve and name that finite route. Since quotient streams, host function equality, selected representatives, choice, external limit selection, and ambient completeness are absent from the carrier, the listed rows exhaust the local NameCert obligations. □

Theorem 8645.3 (Sequential continuity criterion StreamName handoff)**.** *Every Real or Completion consumer that applies the* $\mathsf{SequentialContinuityCriterion}^{\uparrow}$ *packet to a displayed source sequence must read the finite handoff*

$$S_X, W_X, M, F, W_Y, S_Y$$

before any regular-rational readback or Real seal is opened. Thus the criterion is consumed through $\mathsf{StreamName}^{\uparrow}$ *observations of source and image windows, not through quotient streams, host function equality, selected limits, or countable choice.*

Proof. Start from the carrier definition. The only sequence-facing rows are S_X, S_Y, W_X, W_Y, and the only bridge from source windows to image windows is the pair M, F.

Given a target tolerance, the consumer first reads the modulus row M. The requested source precision is then inspected in W_X as a finite StreamName window, and the displayed continuity row F routes that window to the image window W_Y.

Only after this finite handoff may the consumer continue to readback and seal rows. The handoff therefore remains a window route and cannot be replaced by an equality of streams, a host-level function equation, a selected limit, or a choice schedule. □

Theorem 8645.4 (Sequential continuity criterion RegSeqRat and Real seal)**.** *For every accepted* $\mathsf{SequentialContinuityCriterion}^{\uparrow}$ *carrier K, any image-convergence read that reaches a* $\mathsf{Real}^{\uparrow}$ *seal must pass through the source* $\mathsf{RegSeqRat}^{\uparrow}$ *readback R_X, the image* $\mathsf{RegSeqRat}^{\uparrow}$ *readback R_Y, and the terminal seals E_X, E_Y in the displayed carrier. The route is compatible with the real-completeness vision of chapter 9238 because it exposes regular rational windows before the seal, but it does not itself assert ambient completeness or select a limit outside the packet.*

Proof. Use the StreamName handoff of Definition 8645.3. It places the source and image windows before any Real-facing conclusion.

The regular-rational rows then supply the only readback surface. The source readback R_X records the regular information consumed by the modulus, and the image readback R_Y records the regular information exported to a Real or Completion consumer.

Finally the seals E_X, E_Y are terminal rows downstream of R_X, R_Y. The structural rows H, C, P, N keep the same finite packet visible, so the route aligns with the regular-Cauchy discipline of the real-completeness vision while refusing ambient completeness, selected limits, quotient streams, host equality, and countable choice. □

Closure status for $\mathsf{NameCert}_{\mathsf{SequentialContinuityCriterion}^{\uparrow}}$.

Constructive story: A $\mathsf{SequentialContinuityCriterion}^{\uparrow}$ packet is generated from source and target RealUp rows, a ContinuousUp row, finite source and image StreamName windows, a continuity-modulus row, RegSeqRat readbacks, RealUp seals, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{SequentialContinuityCriterion}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8645.1, Definition 8645.2, Definition 8645.3, and Definition 8645.4 seed the finite criterion route from displayed source sequence windows through continuity-modulus data to image readback and Real seals.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{SequentialContinuityCriterion}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient stream equality, host function equality, selected limits, countable choice, ambient Real completeness, Lean verification, or bridge checking for $\mathsf{SequentialContinuityCriterion}^{\uparrow}$.

Upgrade path: Obligation closure requires checked carrier admission, StreamName source and image window handoff, continuity-modulus exactness, RegSeqRat readback, RealUp seal ordering, transport stability, provenance, and local naming for BEDC.Derived.SequentialContinuityCriterionUp.

Chapter 8646

A Concrete Naming Certificate for HausdorffCompletionFunctor$^{\uparrow}$

Following Bourbaki and Bishop–Bridges on separated uniform completions, the HausdorffCompletionFunctor$^{\uparrow}$ packet records the finite map-level surface that turns separated completion into a displayed functorial route. It sits over the envelope packet of chapter 5789 and the pullback comparison of chapter 8585; it also reads the unit-facing separated-completion rows already exposed by the Hausdorff completion route. The packet is not an ambient categorical completion theorem: it is a finite NameCert carrier for source and target completion rows, uniformly continuous map data, unit compatibility, pullback compatibility, transport, replay, provenance, and local naming.

Definition 8646.1 (HausdorffCompletionFunctor carrier)**.** *A* HausdorffCompletionFunctor$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$F = (X, Y, M, C, U, P, H, R, Q, N)$$

with the following visible rows:

1. *X is the source separated-completion row, including the displayed Hausdorff separation, stream-window, regular-rational readback, dyadic tolerance, and terminal real-seal coordinates already named by the envelope route.*
2. *Y is the target separated-completion row, with the same visible row shape for the codomain.*
3. *M is the uniformly continuous map row from the source presentation to the target presentation, carried only as displayed finite map and modulus data.*
4. *C is the completion action row, recording the induced map on completion names as a finite readback route rather than as a host function on quotient completions.*
5. *U is the unit-compatibility row, requiring source values to enter the source completion and then map forward along the same route as direct application followed by the target unit row.*
6. *P is the pullback-compatibility row, forcing comparisons of two completed map reads to pass through the public pullback packet of chapter 8585.*
7. *H stores the componentwise* hsame *transports for source completion, target completion, map row, completion action, unit row, pullback row, replay, provenance, and local certificate.*
8. *R stores displayed* Cont *replay for source observation, target observation, uniform-continuity readback, completion action, unit compatibility, and pullback compatibility.*

9. *Q is the* Pkg *provenance over* HausdorffCompletionFunctor$^{\uparrow}$, HausdorffCompletionEnvelope$^{\uparrow}$, HausdorffCompletionI HausdorffCompletion$^{\uparrow}$, StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, Real$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

10. *N is the local* NameCert$_{\text{HausdorffCompletionFunctor}^{\uparrow}}$ *row.*

The carrier predicate says that these rows form one finite functorial separated-completion packet. It has no coordinate for quotient-completion equality, selected representatives, countable choice, a host function extensionality theorem, or ambient completeness.

Lean4 (statement) BEDC.Derived.HausdorffCompletionFunctorUp

Theorem 8646.2 (HausdorffCompletionFunctor obligation surface)**.** *For every accepted* HausdorffCompletionFunct *carrier $F = (X, Y, M, C, U, P, H, R, Q, N)$, the local* NameCert$_{\text{HausdorffCompletionFunctor}^{\uparrow}}$ *surface consists exactly of source completion admission through X, target completion admission through Y, uniformly continuous map admission through M, completion-action readback through C, unit compatibility through U, pullback compatibility through P, componentwise transport through H, replay through R, provenance through Q, and local naming through N. A consumer therefore reads functoriality only through the displayed finite route*

$$X, Y, M \longmapsto C, U, P, H, R, Q, N.$$

Proof. Project the carrier of Definition 8646.1. The source and target rows are the two separated-completion surfaces, and the map row is the displayed uniformly continuous input.

The completion action C is admitted only after those rows are visible. Unit compatibility is then checked by U, and pullback compatibility is checked by P through the sibling pullback packet rather than through host equality of completed maps.

Finally H, R, Q, and N replay, transport, package, and name the same finite rows. Since the carrier has no coordinate for quotient equality, selected representatives, countable choice, function extensionality, or ambient completeness, the listed rows exhaust the obligation surface. □

Theorem 8646.3 (HausdorffCompletionFunctor unit-pullback route)**.** *Every unit-facing or comparison-facing read from an accepted* HausdorffCompletionFunctor$^{\uparrow}$ *carrier factors through the source row X, target row Y, uniformly continuous map row M, completion action row C, unit row U, and pullback row P before any real-facing seal or completion comparison is public. The unit read is therefore tied to the displayed separated-completion envelope of chapter 5789, and the comparison read is tied to the public pullback packet of chapter 8585.*

Proof. Read the completion action coordinate C. It is downstream of the displayed source and target completion rows and the uniformly continuous map row, so no unit-facing consumer can inspect a completed value before X, Y, M are fixed.

The unit coordinate U compares direct source admission with mapped target admission only through those same rows. It does not introduce a separate representative selector or a host equality proof.

For comparison-facing reads, use the pullback coordinate P. It routes the comparison through the Hausdorff completion pullback packet, where the two separated-completion projections remain visible before the comparison becomes public. □

Theorem 8646.4 (HausdorffCompletionFunctor nonescape)**.** *No accepted* HausdorffCompletionFunctor$^{\uparrow}$ *carrier exports a map on completed Hausdorff objects except through the displayed rows*

$$X, Y, M, C, U, P, H, R, Q, N.$$

In particular, every real-facing or completion-facing consumer must keep the source and target completion rows, uniformly continuous map row, unit compatibility row, pullback compatibility row, transport, replay, provenance, and local naming visible; the route exports no quotient-completion equality, selected representative, countable-choice selector, host function extensionality, or ambient completeness witness.

Proof. Start from the obligation surface of Definition 8646.2. It lists the only rows through which functoriality is admitted.

Apply the unit-pullback route of Definition 8646.3. Unit reads are tied to X, Y, M, C, U, and comparison reads are tied to X, Y, M, C, P before downstream consumers can inspect a completed value or comparison.

The structural rows H, R, Q, N preserve the same finite route under transport, replay, provenance, and naming. Thus the carrier contains no escape coordinate for quotient-completion equality, representative choice, countable choice, host extensionality, or ambient completeness. □

Closure status for $\mathsf{NameCert}_{\mathsf{HausdorffCompletionFunctor}\uparrow}$.

Constructive story: A $\mathsf{HausdorffCompletionFunctor}^{\uparrow}$ packet is generated from source and target separated-completion rows, a uniformly continuous map row, completion-action readback, unit compatibility, pullback compatibility, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{HausdorffCompletionFunctor}\uparrow}, \mathsf{seed})$

Scope closed: Definition 8646.1 seeds the finite functorial separated-completion carrier over envelope, pullback, unit, stream, regular-rational, dyadic, and Real-facing rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{HausdorffCompletionFunctor}\uparrow}, \mathsf{formalTarget})$

Lean target: `BEDC.Derived.HausdorffCompletionFunctorUp`

Bridge status: none

Not claimed: This chapter does not claim quotient-completion equality, selected representatives, countable choice, host function extensionality, ambient completeness, theorem checking, or bridge checking.

Upgrade path: Obligation closure requires checked source and target completion admission, uniformly continuous map routing, unit compatibility, pullback compatibility, transport, replay, provenance, and nonescape for BEDC.Derived.HausdorffCompletionFuncto

Chapter 8647

A Concrete Naming Certificate for $\mathsf{FaaDiBruno}^{\uparrow}$

Following Faà di Bruno and the classical finite chain-rule formulae, the $\mathsf{FaaDiBruno}^{\uparrow}$ packet records the finite partition expansion for iterated derivatives of a composite as displayed NameCert data. It sits after the derivative observation surface of chapter 122, the finite Taylor theorem route of chapter 5898, the Taylor-polynomial truncation packet of chapter 6674, the polynomial carrier of chapter 50, the regular-rational readback rows of chapter 301, and the terminal real-name seals of chapter 38. The packet names only a finite partition-and-coefficient handoff; it does not import host equality of functions, analytic completeness, quotient real equality, selected infinite power series, or an ambient smooth calculus.

Definition 8647.1 (Faà di Bruno finite-partition carrier)**.** *A* $\mathsf{FaaDiBruno}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$F = (n, D, T, U, P, A, R, E, H, C, Q, N)$$

with the following displayed rows:

1. *n is the unary derivative order requested from the composite.*
2. *D is the finite* $\mathsf{Derivative}^{\uparrow}$ *observation row listing the derivative endpoints of the outer and inner maps that may be inspected up to order n.*
3. *T is the* $\mathsf{TaylorTheorem}^{\uparrow}$ *jet row that bounds the finite derivative reads used by the chain-rule expansion.*
4. *U is the* $\mathsf{TaylorPolynomial}^{\uparrow}$ *truncation row exposing exactly the polynomial degree needed for the requested order.*
5. *P is the* $\mathsf{Poly}^{\uparrow}$ *monomial and coefficient ledger for the Bell-polynomial partition monomials.*
6. *A is the finite partition ledger. Each row records one integer partition of n, its multiplicities, and the combinatorial coefficient consumed by the expansion.*
7. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the displayed coefficients and derivative values.*
8. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row for the finite coefficient and derivative reads.*
9. *H stores componentwise* hsame *transport for the order, derivative observations, Taylor rows, polynomial rows, partition ledger, readback rows, real seals, provenance, and local naming rows.*

10. *C stores displayed* Cont *replay from the partition ledger through the derivative, Taylor, polynomial, readback, and real-seal rows.*
11. *Q is the* Pkg *provenance over* $\mathsf{FaaDiBruno}^{\uparrow}$, $\mathsf{Derivative}^{\uparrow}$, $\mathsf{TaylorTheorem}^{\uparrow}$, $\mathsf{TaylorPolynomial}^{\uparrow}$, $\mathsf{Poly}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*
12. *N is the local* $\mathsf{NameCert}_{\mathsf{FaaDiBruno}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these displayed rows. It has no coordinate for host function equality, an infinite derivative tower, an analytic convergence theorem, quotient equality of real names, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 8647.2 (Faà di Bruno NameCert obligations)**.** *For every accepted* $\mathsf{FaaDiBruno}^{\uparrow}$ *carrier*

$$F = (n, D, T, U, P, A, R, E, H, C, Q, N),$$

the local $\mathsf{NameCert}_{\mathsf{FaaDiBruno}^{\uparrow}}$ *surface consists exactly of carrier admission for the displayed order, derivative observations, Taylor-theorem jet, Taylor-polynomial truncation, polynomial coefficient ledger, finite partition ledger, regular-rational readbacks, real seals, componentwise transport, displayed replay, package provenance, and local naming rows.*

The partition exactness obligation requires every summand of the chain-rule expansion to cite one row of A, one coefficient row of P, the derivative observations in D, the Taylor support rows T, U, and the readback route R, E before a consumer may inspect the composite-derivative coefficient. No other analytic obligation is part of the packet.

Proof. Project the carrier of Definition 8647.1. The theorem-facing rows are exactly n, D, T, U, P, A, R, E, and the structural rows are exactly H, C, Q, N.

The expansion is finite because the request order n is unary and the partition ledger A lists only the partitions of that order. Each listed row names its multiplicities and coefficient, while P supplies the polynomial monomial and coefficient source used by that row.

The derivative and Taylor dependencies are also displayed. The row D supplies only the derivative observations used by the summand, and T, U restrict those observations to a finite Taylor jet and a finite Taylor polynomial truncation.

Finally route the displayed coefficients and derivative reads through R, E, H, C, Q, N. Since the carrier stores no host function equality, infinite derivative tower, convergence theorem, quotient real equality, countable choice, or ambient completeness principle, the listed rows exhaust the local NameCert obligations. □

Theorem 8647.3 (Faà di Bruno finite-partition handoff)**.** *Every accepted* $\mathsf{FaaDiBruno}^{\uparrow}$ *carrier exports a composite-derivative coefficient only through the finite route*

$$\mathsf{Derivative}^{\uparrow}, \mathsf{TaylorTheorem}^{\uparrow}, \mathsf{TaylorPolynomial}^{\uparrow}, \mathsf{Poly}^{\uparrow} \longmapsto A, P \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}.$$

More precisely, a consumer must first read the order row n, derivative observation row D, Taylor-theorem row T, Taylor-polynomial truncation U, polynomial ledger P, finite partition ledger A, regular-rational readback R, real seal E, transport H, replay C, provenance Q, and local NameCert *row N before using the coefficient. The handoff exports only the finite partition expansion for the displayed order, not a host chain-rule theorem over arbitrary functions, an infinite Bell-polynomial family, quotient real equality, selected representatives, or analytic completeness.*

Proof. Start with an accepted carrier $F = (n, D, T, U, P, A, R, E, H, C, Q, N)$. The requested order n fixes a finite partition set, and A displays exactly the partition rows consumed by the packet.

Read the derivative and Taylor support next. The row D supplies the derivative observations, while T and U restrict those reads to the finite jet and finite polynomial truncation needed by the requested order.

The polynomial coefficient ledger P and the partition ledger A assemble the displayed summands. Each summand is therefore read from named finite rows before any coefficient reaches a regular-rational consumer.

Finally pass through R, E, H, C, Q, N. Regular rational readback precedes the terminal real seals, and the structural rows preserve the same finite partition route. Because the carrier has no coordinate for host function equality, infinite families, quotient real equality, selected representatives, or analytic completeness, every exported coefficient is exhausted by the finite handoff above. □

Falsifiable prediction: Every accepted $\mathsf{FaaDiBruno}^{\uparrow}$ composite-derivative coefficient read factors through displayed Derivative, TaylorTheorem, TaylorPolynomial, Polynomial, finite partition, RegSeqRat, Real, componentwise hsame, Cont replay, Pkg provenance, and local NameCert rows.

Independence witness: derivative, taylor-theorem, taylor-polynomial, polynomial, regseqrat, real: $\mathsf{FaaDiBruno}^{\uparrow}$ is not bijective to any listed sibling because it jointly binds one derivative order, finite derivative observations, Taylor support, polynomial coefficient rows, partition multiplicities, coefficient readback, endpoint seals, transport, replay, provenance, and local naming in one finite chain-rule certificate.

Closure status for $\mathsf{NameCert}_{\mathsf{FaaDiBruno}^{\uparrow}}$.

Constructive story: A $\mathsf{FaaDiBruno}^{\uparrow}$ packet is generated from a unary derivative order, finite DerivativeUp observation rows, TaylorTheoremUp jet support, TaylorPolynomialUp truncation, PolynomialUp coefficient rows, a finite partition ledger, RegSeqRatUp readbacks, RealUp seals, componentwise hsame transport, displayed Cont replay, package provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{FaaDiBruno}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8647.1, Definition 8647.2, and Definition 8647.3 seed the finite partition chain-rule route over $\mathsf{Derivative}^{\uparrow}$, $\mathsf{TaylorTheorem}^{\uparrow}$, $\mathsf{TaylorPolynomial}^{\uparrow}$, $\mathsf{Poly}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{FaaDiBruno}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host equality of functions, an infinite derivative tower, analytic convergence, quotient real equality, selected representatives, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, finite partition exactness, derivative and Taylor support routing, polynomial coefficient handoff, readback sealing, transport and replay stability, and nonescape for BEDC.Derived.FaaDiBrunoUp.

Chapter 8648

A Concrete Naming Certificate for $\mathsf{KnoppTailCondensation}^{\uparrow}$

Following Knopp and Bishop–Bridges constructive analysis, the $\mathsf{KnoppTailCondensation}^{\uparrow}$ packet records the finite tail-condensation route needed by the Real and Completion series corridor. It starts from displayed $\mathsf{RealSeries}^{\uparrow}$ source rows, opens Cauchy-condensation block rows, reads dyadic tolerances through $\mathsf{DyadicRatCore}^{\uparrow}$, hands the finite regular sequence data through $\mathsf{RegSeqRat}^{\uparrow}$, and reaches a $\mathsf{Real}^{\uparrow}$ seal only after those rows have been exposed. The packet is a finite NameCert surface; it is not a host summability theorem, selected sum, quotient equality, countable-choice rule, or ambient completeness principle.

The source series surface is supplied by chapter 1581. The condensation block discipline is the one isolated in chapter 1478. Dyadic tolerances, regular-sequence readback, and Real sealing are inherited only as named rows from chapter 291, chapter 301, and chapter 38.

Definition 8648.1 (Knopp tail-condensation carrier)**.** *A* $\mathsf{KnoppTailCondensation}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (S, T, B, D, R, A, H, C, P, N)$$

with the following displayed rows:

1. *S is the* $\mathsf{RealSeries}^{\uparrow}$ *source row whose nonnegative tail is being read;*
2. *T is the displayed tail-window row selected from the source series;*
3. *B is the finite Cauchy-condensation block row over dyadic tail intervals;*
4. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row controlling the block bounds;*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row that records the regular tail handoff;*
6. *A is the* $\mathsf{Real}^{\uparrow}$ *seal row reached only after T, B, D, R are displayed;*
7. *H records componentwise* hsame *transport for the source, tail window, block, tolerance, readback, seal, provenance, and local naming rows;*
8. *C records the displayed* Cont *routes from S through T, B, D, R into A;*
9. *P records* Pkg *provenance over* $\mathsf{RealSeries}^{\uparrow}$, $\mathsf{CauchyCondensationTest}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and certificate rows;*
10. *N is the local* $\mathsf{NameCert}_{\mathsf{KnoppTailCondensation}^{\uparrow}}$ *row.*

The local classifier compares accepted carriers only through the visible rows $S, T, B, D, R, A, H, C, P, N$.

Theorem 8648.2 (Knopp tail-condensation NameCert obligations)**.** *The local* $\mathsf{NameCert}_{\mathsf{KnoppTailCondensation}^{\uparrow}}$ *surface for Definition 8648.1 consists of carrier admission for $K = (S, T, B, D, R, A, H, C, P, N)$, source-series exposure through S, tail-window exposure through T, condensation-block exposure through B, dyadic tolerance exposure through D, regular readback through R,* $\mathsf{Real}^{\uparrow}$ *seal delivery through A, componentwise* hsame *stability through H, displayed* Cont *route replay through C,* Pkg *provenance through P, and local naming through N.*

Proof. Carrier admission is projection from the displayed tuple in Definition 8648.1. The source series, tail window, condensation block, dyadic tolerance, regular readback, seal, transport, route, provenance, and naming rows are all visible coordinates of one finite packet.

Read the obligations in order. The source row S opens only the displayed tail window T; the block row B records the finite condensation slices; the dyadic row D supplies the tolerance data consumed by the block; and the regular readback row R is downstream of those displayed finite rows.

The $\mathsf{Real}^{\uparrow}$ seal row A is available only after T, B, D, R have been exposed. Since the carrier has no coordinate for selected sums, quotient stream equality, countable choice, host summability, or ambient completeness, the listed rows exhaust the local NameCert surface. □

Theorem 8648.3 (Knopp tail-condensation L10 handoff)**.** *Every accepted* $\mathsf{KnoppTailCondensation}^{\uparrow}$ *carrier hands its Real-and-Completion consumer the finite route*

$$S, T, B, D, R, A, H, C, P, N$$

from $\mathsf{RealSeries}^{\uparrow}$ *source data through Cauchy-condensation blocks,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerances,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback, and the* $\mathsf{Real}^{\uparrow}$ *seal. The handoff cannot bypass the displayed tail window by invoking host summability, selected sums, quotient equality, countable choice, or ambient Real completeness.*

Proof. Project the accepted carrier to its displayed rows. The route row C is the only continuation surface by which a consumer reaches A, and it passes through the same tail, block, tolerance, and regular readback rows.

Apply the NameCert obligations of Definition 8648.2. They force the source, tail window, block row, dyadic tolerance, regular readback, seal, transport, provenance, and naming rows to remain the same finite packet under componentwise hsame transport.

Finally inspect the carrier inventory. No coordinate stores a host-selected sum, quotient stream equality, countable-choice selector, hidden limit, or ambient completeness proof, so the L10 handoff is exactly the displayed finite route. □

Falsifiable prediction: A tail-condensation packet that reaches a $\mathsf{Real}^{\uparrow}$ seal without a displayed Cauchy-condensation block row is not an accepted $\mathsf{KnoppTailCondensation}^{\uparrow}$ carrier.

Independence witness: realseries, cauchycondensationtest, dyadicratcore, regseqrat, real: these siblings expose source, block, tolerance, readback, or seal rows separately, while $\mathsf{KnoppTailCondensation}^{\uparrow}$ binds them into one finite tail-condensation handoff surface, so no row-preserving bijection exists.

Closure status for $\mathsf{NameCert}_{\mathsf{KnoppTailCondensation}^{\uparrow}}$.

Constructive story: A $\mathsf{KnoppTailCondensation}^{\uparrow}$ packet is generated from a displayed $\mathsf{RealSeries}^{\uparrow}$ source row, finite tail window, Cauchy-condensation block row, $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance row, $\mathsf{RegSeqRat}^{\uparrow}$ readback row, $\mathsf{Real}^{\uparrow}$ seal row, componentwise hsame transport, displayed Cont routes, package provenance, and a local naming row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{KnoppTailCondensation}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8648.1, Definition 8648.2, and Definition 8648.3 bind the finite tail-condensation carrier and its Real-and-Completion handoff surface.

Formal verification: FormalStatus(NameCert$_{\mathsf{KnoppTailCondensation}\uparrow}$, unformalized)

Lean target: `BEDC.Derived.KnoppTailCondensationUp`

Bridge status: none

Origin: human

Not claimed: This chapter does not close Lean theorem verification, host summability, selected sums, quotient equality, countable choice, ambient RealUp completeness, or a public standard bridge.

Upgrade path: Obligation closure requires checked carrier admission, source-series exposure, condensation-block exposure, dyadic tolerance readback, RegSeqRat handoff, RealUp seal delivery, route stability, provenance, and non-escape for the same finite packet.

Chapter 8649

A Concrete Naming Certificate for $\mathsf{RealIntervalCauchyFilter}^{\uparrow}$

Following Bishop and Bridges constructive analysis and Bourbaki's finite-neighbourhood reading of filters, the $\mathsf{RealIntervalCauchyFilter}^{\uparrow}$ packet records an interval-indexed Cauchy filter around displayed real names as finite BEDC NameCert data. It sits between the terminal real-name seal of chapter 38, the filter surface of chapter 333, the dyadic tolerance core of chapter 291, the finite stream schedule of chapter 126, the regular rational readback of chapter 301, and the metric comparison row of chapter 57. The packet names only the finite interval-filter route by which Real and Completion consumers inspect a Cauchy neighbourhood; it does not select a limit, quotient filter, host real equality, open-cover compactness principle, countable-choice selector, or ambient $\mathsf{Real}^{\uparrow}$ completeness witness.

Definition 8649.1 (RealIntervalCauchyFilter carrier)**.** *A* $\mathsf{RealIntervalCauchyFilter}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$I = (R, F, D, W, Q, M, H, C, P, N)$$

with the following displayed rows:

1. *R is the* $\mathsf{Real}^{\uparrow}$ *source row naming the real endpoint or center data whose interval neighbourhoods are inspected.*
2. *F is the* $\mathsf{CauchyFilter}^{\uparrow}$ *finite filter-basis row, listing the accepted interval-neighbourhood requests and their tail order.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row recording radii, refinements, and dyadic containment comparisons for the inspected intervals.*
4. *W is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row that opens only the stream prefixes needed by the filter request.*
5. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the displayed windows and dyadic tolerances.*
6. *M is the* $\mathsf{Met}^{\uparrow}$ *comparison row that records interval containment and diameter checks before any Real-facing handoff is exposed.*
7. *H records componentwise* hsame *transport for the Real source, filter basis, dyadic tolerance row, stream window, regular readback, metric comparison, replay, provenance, and local naming.*
8. *C records displayed* Cont *replay from an interval-filter request through R, F, D, W, Q, M, H.*

9. *P is the* Pkg *provenance over* $\mathsf{RealIntervalCauchyFilter}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{CauchyFilter}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*
10. *N is the local* $\mathsf{NameCert}_{\mathsf{RealIntervalCauchyFilter}^{\uparrow}}$ *row.*

The carrier has no coordinate for quotient filters, selected limits, countable choice, host real equality, open-cover compactness, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 8649.2 (RealIntervalCauchyFilter NameCert obligations)**.** *For every accepted* $\mathsf{RealIntervalCauchyFilter}^{\uparrow}$ *carrier $I = (R, F, D, W, Q, M, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{RealIntervalCauchyFilter}^{\uparrow}}$ *surface consists exactly of Real source admission through R, finite Cauchy filter-basis exposure through F, dyadic interval tolerance exposure through D, stream-window exposure through W, regular rational readback through Q, metric interval comparison through M, componentwise* hsame *transport through H, displayed* Cont *replay through C,* Pkg *provenance through P, and local naming through N. A consumer therefore reads interval Cauchy-filter data only through the finite route*

$$R, F, D, W, Q, M \longmapsto H, C, P, N.$$

Proof. Project the accepted carrier of Definition 8649.1. The rows R and F expose the Real source and finite filter-basis request before any interval read is available.

The dyadic tolerance row D, stream window W, regular readback Q, and metric comparison row M then display the interval containment route. These rows make the inspected neighbourhood finite and visible rather than a hidden quotient filter or selected completion object.

Finally the structural rows H, C, P, N transport, replay, source, and name the same carrier. Since the carrier has no coordinate for quotient filters, selected limits, countable choice, host real equality, open-cover compactness, or ambient Real completeness, the listed rows exhaust the NameCert obligations. □

Theorem 8649.3 (RealIntervalCauchyFilter tail basis)**.** *Every accepted* $\mathsf{RealIntervalCauchyFilter}^{\uparrow}$ *tail read factors through the same finite filter-basis row F, dyadic tolerance row D,* $\mathsf{StreamName}^{\uparrow}$ *window W,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback Q, and* $\mathsf{Met}^{\uparrow}$ *comparison row M before H, C, P, N may replay or name the read. In particular, interval refinement is a displayed basis operation inside $I = (R, F, D, W, Q, M, H, C, P, N)$ and not an appeal to an ambient neighbourhood filter or countable family of representatives.*

Proof. Start with the NameCert obligations of Definition 8649.2. They force every accepted tail read to expose the filter-basis row F and the dyadic interval row D before the route can reach stream or rational readback data.

The finite window W and regular readback Q then inspect only the prefixes and rational values listed by the carrier. The metric comparison row M records containment and diameter checks on that same displayed basis.

The rows H, C, P, N preserve the basis route under transport, continuation replay, provenance, and local naming. Thus no ambient neighbourhood filter, quotient representative, selected limit, or countable-choice schedule is exported by the tail read. □

Theorem 8649.4 (RealIntervalCauchyFilter Real handoff)**.** *Every Real-facing consumer of an accepted* $\mathsf{RealIntervalCauchyFilter}^{\uparrow}$ *packet must consume the displayed route*

$$\mathsf{Real}^{\uparrow},\ \mathsf{CauchyFilter}^{\uparrow},\ \mathsf{DyadicRatCore}^{\uparrow},\ \mathsf{StreamName}^{\uparrow},\ \mathsf{RegSeqRat}^{\uparrow},\ \mathsf{Met}^{\uparrow}$$

through the carrier rows $R, F, D, W, Q, M, H, C, P, N$. The handoff supplies a finite interval-filter witness for Real and Completion neighbours, but it exports no quotient filter, selected limit, host real

equality, open-cover compactness theorem, countable-choice selector, or ambient $\mathsf{Real}^{\uparrow}$ *completeness principle.*

Proof. Apply the tail-basis theorem, Definition 8649.3. It keeps every interval-filter read on the displayed basis row F, dyadic tolerance row D, stream window W, regular readback Q, and metric comparison row M.

The Real source row R is therefore consumed together with the same finite basis route. No consumer can detach the terminal Real read from the filter, dyadic, stream, rational, and metric rows that make the interval request visible.

Finally use the structural rows H, C, P, N from the NameCert obligations. They replay and name the same finite packet, so the handoff cannot introduce quotient filters, selected limits, host real equality, open-cover compactness, countable choice, or ambient Real completeness. □

Falsifiable prediction: Every accepted $\mathsf{RealIntervalCauchyFilter}^{\uparrow}$ read exposes a RealUp source row, a finite CauchyFilterUp basis row, a DyadicRatCoreUp interval tolerance row, a StreamNameUp finite window, a RegSeqRatUp readback row, a MetricUp comparison row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming before any Real-facing handoff is visible.

Independence witness: real, cauchyfilter, dyadicratcore, streamname, regseqrat, metric: RealIntervalCauchyFilter is not bijective to any listed sibling because it jointly binds Real interval source data, finite filter-basis rows, dyadic tolerance rows, finite stream windows, regular rational readback, metric interval comparisons, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{RealIntervalCauchyFilter}^{\uparrow}}$.

Constructive story: A $\mathsf{RealIntervalCauchyFilter}^{\uparrow}$ packet is generated from a RealUp source row, a finite CauchyFilterUp basis row, a DyadicRatCoreUp interval tolerance row, a StreamNameUp finite window, a RegSeqRatUp readback row, a MetricUp comparison row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RealIntervalCauchyFilter}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8649.1 and Definition 8649.2 seed the finite interval Cauchy-filter carrier over RealUp, CauchyFilterUp, DyadicRatCoreUp, StreamNameUp, RegSeqRatUp, MetricUp, BHist, hsame, Cont, Pkg, and NameCert rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RealIntervalCauchyFilter}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim quotient filters, selected limits, countable choice, host real equality, open-cover compactness, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, finite filter-basis exactness, dyadic interval tolerance stability, StreamName window admission, RegSeqRat readback, Metric comparison nonescape, replay stability, and local naming for BEDC.Derived.RealIntervalCauchyFilterUp.

Chapter 8650

A Concrete Naming Certificate for $\mathsf{CartanDieudonne}^{\uparrow}$

Following Cartan and Dieudonne's finite-dimensional reflection theorem for nondegenerate quadratic spaces, the $\mathsf{CartanDieudonne}^{\uparrow}$ packet records the finite reflection factorization boundary as BEDC NameCert data. It sits beside the bilinear-form source of chapter 146, the Clifford word package of chapter 147, the even reflection route of chapter 148, the full parity route of chapter 149, and the finite reflection tuple of chapter 993. These siblings expose quadratic-pairing rows, Clifford products, Spin and Pin parity rows, and tuple-image readback; this chapter binds them into a seed certificate for a finite reflection ledger and its orthogonal-action boundary.

Definition 8650.1 (Cartan–Dieudonne carrier)**.** *A* $\mathsf{CartanDieudonne}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$C = (V, Q, B, R, W, O, S, P, H, T, N)$$

with the following displayed rows:

1. *V is the displayed vector-space or module source row whose finite-dimensional boundary is being inspected.*
2. *Q is the quadratic-form row read through the diagonal and symmetry data of* $\mathsf{BilinForm}^{\uparrow}$*.*
3. *B is the nondegenerate bilinear-pairing row that keeps radical and orthogonality tests visible.*
4. *R is the finite reflection tuple, listing the reflection rows that generate the inspected isometry.*
5. *W is the Clifford word row that types the same reflection product inside* $\mathsf{Clifford}^{\uparrow}$*.*
6. *O is the orthogonal-action boundary row, recording that the reflected endpoints preserve the displayed quadratic row Q.*
7. *S records the Spin and Pin sibling reads needed to distinguish even reflection products from the full reflection-parity surface.*
8. *P is the* Pkg *provenance over* $\mathsf{BilinForm}^{\uparrow}$*,* $\mathsf{Clifford}^{\uparrow}$*,* $\mathsf{SpinGroup}^{\uparrow}$*,* $\mathsf{PinGroup}^{\uparrow}$*,* $\mathsf{FiniteReflectionTuple}^{\uparrow}$*,* BHist*,* hsame*,* Cont*, and* $\mathsf{NameCert}$ *rows.*
9. *H records componentwise* hsame *transport for the vector source, quadratic row, bilinear row, reflection tuple, Clifford word, orthogonal boundary, parity row, provenance, replay, and local naming.*
10. *T records displayed* Cont *replay from an orthogonal-action request through $V, Q, B, R, W, O, S, P, H$.*

11. *N is the local* $\mathsf{NameCert}_{\mathsf{CartanDieudonne}^{\uparrow}}$ *row.*

The carrier has no coordinate for an ambient orthogonal group, a host matrix representation, a selected basis, a quotient Clifford algebra, infinite reflection products, or analytic spectral diagonalization.

Theorem 8650.2 (Cartan–Dieudonne NameCert obligations)**.** *For every accepted* $\mathsf{CartanDieudonne}^{\uparrow}$ *packet $C = (V, Q, B, R, W, O, S, P, H, T, N)$, the local* $\mathsf{NameCert}_{\mathsf{CartanDieudonne}^{\uparrow}}$ *surface consists exactly of carrier admission for the vector source V, quadratic row Q, nondegenerate bilinear row B, finite reflection tuple R, Clifford word row W, orthogonal-action boundary O, Spin–Pin parity row S, package provenance P, componentwise transport H, displayed replay T, and local naming row N. Any consumer that reads a finite reflection factorization must keep all of these rows visible before treating the action as an orthogonal boundary.*

Proof. Project the carrier of Definition 8650.1. The source geometry is displayed by V, Q, B: the vector or module row is named, the quadratic row is read through the bilinear-form sibling, and the nondegenerate pairing row records the orthogonality tests used by each reflection.

Next read the factorization rows R, W, O, S. The tuple row R lists the finite reflection factors, the Clifford word row W places their product in the Clifford sibling, the orthogonal-action row O records preservation of Q, and the parity row S keeps the Spin and Pin readings separate.

Finally inspect P, H, T, N. Provenance, transport, replay, and local naming preserve the same finite reflection ledger. Since the carrier has no coordinate for an ambient orthogonal group, selected basis, host matrix action, quotient Clifford algebra, infinite product, or analytic diagonalization, the listed rows exhaust the local NameCert obligations. □

Falsifiable prediction: Every accepted $\mathsf{CartanDieudonne}^{\uparrow}$ reflection read exposes a vector source row, quadratic row, nondegenerate bilinear row, finite reflection tuple, Clifford word row, orthogonal-action boundary, Spin–Pin parity row, package provenance, componentwise hsame transport, displayed Cont replay, and local naming before any orthogonal-facing consumer can inspect the factorization.

Independence witness: bilinform, clifford, spingroup, pingroup, finitereflectiontuple: $\mathsf{BilinForm}^{\uparrow}$ supplies pairing rows without a reflection ledger; $\mathsf{Clifford}^{\uparrow}$ supplies word and quadratic-boundary rows without an orthogonal factorization boundary; $\mathsf{SpinGroup}^{\uparrow}$ and $\mathsf{PinGroup}^{\uparrow}$ supply parity-specific reflection surfaces without the Cartan–Dieudonne finite factorization ledger; $\mathsf{FiniteReflectionTuple}^{\uparrow}$ supplies tuple image and readback without the bilinear, Clifford, and parity obligations bound into one carrier. None is bijective to $\mathsf{CartanDieudonne}^{\uparrow}$.

Closure status for $\mathsf{NameCert}_{\mathsf{CartanDieudonne}^{\uparrow}}$**.**

Constructive story: A $\mathsf{CartanDieudonne}^{\uparrow}$ packet is generated from a finite vector or module source row, quadratic row, nondegenerate bilinear row, finite reflection tuple, Clifford word row, orthogonal-action boundary, Spin–Pin parity row, package provenance, componentwise hsame transport, displayed Cont replay, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{CartanDieudonne}^{\uparrow}}$, seed)

Scope closed: Definition 8650.1 and Definition 8650.2 seed the finite reflection-factorization packet over BilinFormUp, CliffordUp, SpinGroupUp, PinGroupUp, FiniteReflectionTupleUp, BHist, hsame, Cont, Pkg, and NameCert rows.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{CartanDieudonne}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim Lean verification, bridge checking, an ambient orthogonal group, a selected basis, host matrix representation, quotient Clifford algebra, infinite reflection products, or analytic spectral diagonalization.

Upgrade path: Obligation closure requires checked carrier admission, finite reflection tuple exactness, bilinear nondegeneracy visibility, Clifford word compatibility, Spin–Pin parity separation, orthogonal-action preservation, transport, replay, provenance, and local naming for BEDC.Derived.CartanDieudonneUp.

Chapter 8651

A Concrete Naming Certificate for $\mathsf{ClarkeSubdifferential}^{\uparrow}$

Following Clarke's nonsmooth analysis and Rockafellar's convex-analysis presentation of generalized gradients, the $\mathsf{ClarkeSubdifferential}^{\uparrow}$ packet records the finite locally Lipschitz slope surface needed to expose a convexified generalized-gradient read inside BEDC. It sits beside the subgradient support surface of chapter 3712, the feasible-direction surface of chapter 3596, the convex carrier of chapter 208, the terminal real and norm rows of chapter 38 and chapter 89, and the stationarity and duality consumers of chapter 300 and chapter 321. The packet names a finite Clarke-style generalized-gradient certificate; it does not assert a host differentiability theorem, selected limiting gradient, measurable selection, ambient compactness, or quotient dual-space equality.

8651.1 ClarkeSubdifferential Carrier

Definition 8651.1 (ClarkeSubdifferential carrier)**.** *A* $\mathsf{ClarkeSubdifferential}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$G = (X, F, x, W, D, T, S, V, R, H, C, P, N)$$

with the following visible rows:

1. *X is the displayed* $\mathsf{VecSpace}^{\uparrow}$*,* $\mathsf{Met}^{\uparrow}$*,* $\mathsf{Norm}^{\uparrow}$*, and* $\mathsf{Real}^{\uparrow}$ *ambient row in which base points, direction rows, and slope comparisons are read.*
2. *F is the locally Lipschitz functional row, including the finite* $\mathsf{LipschitzModulus}^{\uparrow}$ *windows and value-comparison rows actually inspected by the packet.*
3. *x is the base-point row admitted by the displayed* $\mathsf{ConvexSet}^{\uparrow}$ *domain of F.*
4. *W is the finite locally Lipschitz window ledger around x, listing the inspected radii, norm bounds, and Real-valued comparison budgets.*
5. *D is the directional-slope ledger. It records the displayed direction rows and the upper finite slope comparisons read from the rows $F(x + hv) - F(x)$ over the windows in W.*
6. *T is the* $\mathsf{TangentCone}^{\uparrow}$ *row exposing the feasible-direction surface used by constrained consumers.*
7. *S is the* $\mathsf{Subdifferential}^{\uparrow}$ *support row, read only as a sibling support ledger and not as an ambient choice of subgradient.*

8. *V is the convex-hull and provenance row for the finite slope witnesses, recording which displayed direction and support rows contribute to each generalized-gradient candidate.*
9. *R is the stationarity and duality readback row consumed by* $\mathsf{KKT}^{\uparrow}$ *and* $\mathsf{FenchelDuality}^{\uparrow}$ *only after D, T, S, V are visible.*
10. *H records componentwise* hsame *transport for the ambient, functional, base point, Lipschitz windows, directional slopes, tangent-cone row, support row, convex-hull provenance, readback, replay, provenance, and local naming rows.*
11. *C records displayed* Cont *replay from a generalized-gradient request through $X, F, x, W, D, T, S, V, R, H$.*
12. *P is the* Pkg *provenance over* $\mathsf{ClarkeSubdifferential}^{\uparrow}$, $\mathsf{Subdifferential}^{\uparrow}$, $\mathsf{TangentCone}^{\uparrow}$, $\mathsf{ConvexSet}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{Norm}^{\uparrow}$, $\mathsf{LipschitzModulus}^{\uparrow}$, $\mathsf{KKT}^{\uparrow}$, $\mathsf{FenchelDuality}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
13. *N is the local* $\mathsf{NameCert}_{\mathsf{ClarkeSubdifferential}^{\uparrow}}$ *row.*

The carrier compares accepted packets only through $X, F, x, W, D, T, S, V, R, H, C, P, N$. It has no coordinate for a selected differentiability point, a host limiting-gradient closure, measurable selection, quotient dual-space equality, ambient compactness, or a global nonsmooth chain rule.

Lean4 (definition) `BEDC.Derived.ClarkeSubdifferentialUp.ClarkeSubdifferentialUp`

8651.2 ClarkeSubdifferential Certificate

Theorem 8651.2 (ClarkeSubdifferential NameCert obligations)**.** *For every accepted* $\mathsf{ClarkeSubdifferential}^{\uparrow}$ *carrier $G = (X, F, x, W, D, T, S, V, R, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{ClarkeSubdifferential}^{\uparrow}}$ *surface consists exactly of the following finite obligations:*

1. *carrier admission for the ambient vector, metric, norm, and real rows; the locally Lipschitz functional row; the base point; the finite window ledger; the directional-slope ledger; the tangent-cone row; the sibling support row; the convex-hull provenance row; the stationarity and duality readback row; transport; replay; provenance; and local naming;*
2. *Lipschitz-window exactness, requiring every exported slope comparison to pass through the displayed windows W and the value-comparison rows of F;*
3. *directional-slope exposure, requiring every generalized-gradient read to display the direction row and the finite upper-slope comparison stored in D;*
4. *tangent and support compatibility, requiring constrained reads to pass through T and support-facing reads to pass through S before the convex-hull row V may be inspected;*
5. *convex-hull provenance, requiring each generalized-gradient candidate to list the displayed slope and support rows used by its finite convex combination;*
6. *non-escape from selected limiting gradients, quotient dual spaces, measurable selections, host differentiability theorems, ambient compactness, and global nonsmooth calculus rules.*

Proof. Project the accepted carrier of Definition 8651.1. The analytic rows are $X, F, x, W, D, T, S, V, R$, and the structural rows are H, C, P, N.

Lipschitz-window exactness is read first. A slope comparison can be exported only when the relevant norm, real, and value-comparison rows are visible through X, F, W.

The directional row then passes through D. Constrained consumers also expose the tangent-cone row T, and support-facing consumers expose the subdifferential row S, before the convex-hull provenance row V may name a generalized-gradient candidate.

Finally R hands the same finite route to KKT and Fenchel-duality consumers, while H, C, P, N transport, replay, source, and name the packet. Since no coordinate of G stores a selected limiting gradient, quotient dual space, measurable selection, host differentiability theorem, compactness theorem, or global nonsmooth calculus rule, the listed rows exhaust the local certificate. □

Theorem 8651.3 (ClarkeSubdifferential Lipschitz-gradient route)**.** *Every* $\mathsf{KKT}^{\uparrow}$, $\mathsf{FenchelDuality}^{\uparrow}$, *or* $\mathsf{Subdifferential}^{\uparrow}$ *consumer of an accepted* $\mathsf{ClarkeSubdifferential}^{\uparrow}$ *packet must factor through the displayed route*

$$X, F, x, W, D, T, S, V, R \longmapsto H, C, P, N.$$

In particular, a generalized-gradient read is public only after the locally Lipschitz window ledger, the finite directional-slope rows, the tangent-cone row, the sibling support row, and the convex-hull provenance row have all been displayed. The route supplies no selected limiting gradient, no host differentiability theorem, no quotient dual-space equality, no measurable selection, and no ambient completeness principle.

Proof. Begin with the NameCert obligations of Definition 8651.2. They force every generalized-gradient read to expose the locally Lipschitz window row W and the directional-slope ledger D before any candidate gradient row is available.

The constrained and support-facing boundaries are then read through T and S. These rows keep the Clarke packet attached to the tangent-cone and subdifferential siblings rather than to a host limiting-gradient construction.

The convex-hull row V records only the displayed finite provenance, and R hands that same provenance to KKT or Fenchel-duality consumers. Transport, replay, package provenance, and local naming preserve the route through H, C, P, N, so the consumer cannot bypass the finite Lipschitz, slope, tangent, support, and convex-hull rows. □

Falsifiable prediction: Every accepted $\mathsf{ClarkeSubdifferential}^{\uparrow}$ read exposes VecSpaceUp, MetricUp, NormUp, RealUp, locally Lipschitz window rows, finite directional-slope rows, TangentCone rows, SubdifferentialUp support rows, convex-hull provenance rows, KKTUp or FenchelDualityUp readback rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert before any generalized-gradient output is visible.

Independence witness: subdifferential, tangent-cone, convexset, real, norm, kkt, fenchelduality: $\mathsf{ClarkeSubdifferential}^{\uparrow}$ is not bijective to any listed sibling because it jointly binds locally Lipschitz windows, directional-slope ledgers, feasible-direction rows, support rows, convex-hull provenance, stationarity and duality readback, transport, replay, provenance, and local naming in one finite packet.

Closure status for $\mathsf{NameCert}_{\mathsf{ClarkeSubdifferential}^{\uparrow}}$.

Constructive story: A $\mathsf{ClarkeSubdifferential}^{\uparrow}$ packet is generated from vector, metric, norm, Real, locally Lipschitz, base-point, directional-slope, TangentCone, SubdifferentialUp support, convex-hull provenance, KKTUp or FenchelDualityUp readback, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert rows.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{ClarkeSubdifferential}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8651.1, Definition 8651.2, and Definition 8651.3 seed the finite nonsmooth generalized-gradient certificate surface over locally Lipschitz windows, directional slopes, tangent cones, support rows, convex hulls, and optimization consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{ClarkeSubdifferential}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim a host limiting-gradient theorem, selected differentiability points, measurable selection, quotient dual-space equality, ambient compactness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, Lipschitz-window exactness, directional-slope exposure, tangent and support compatibility, convex-hull provenance, KKT and Fenchel readback, replay stability, and local naming for BEDC.Derived.ClarkeSubdifferentialUp.

Chapter 8652

A Concrete Naming Certificate for $\mathsf{FiniteLatticePath}^{\uparrow}$

Following Stanley's enumerative combinatorics, the $\mathsf{FiniteLatticePath}^{\uparrow}$ packet records a finite grid walk by endpoint, step-list, and prefix-ledger rows. It sits beside the unary size carrier of chapter 28, the finite spine carrier of chapter 36, the ordered-pair carrier of chapter 34, and the comparison rows of chapter 1378; its Dyck-prefix special case is consumed by the Catalan surface of chapter 8503. The packet names only displayed finite walks, not an ambient grid, infinite path space, quotient endpoint equality, or external enumeration theorem.

Definition 8652.1 (Finite lattice path carrier)**.** *A* $\mathsf{FiniteLatticePath}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (s, t, W, E, P, B, H, C, G, N)$$

with the following displayed rows:

1. *s is the start endpoint row, a* $\mathsf{Prod}^{\uparrow}$ *pair of* $\mathsf{Nat}^{\uparrow}$ *coordinates.*
2. *t is the terminal endpoint row, another* $\mathsf{Prod}^{\uparrow}$ *pair of* $\mathsf{Nat}^{\uparrow}$ *coordinates.*
3. *W is the finite* $\mathsf{List}^{\uparrow}$ *step row whose entries are the displayed horizontal and vertical unit steps.*
4. *E is the endpoint ledger: iterating the steps of W from s reaches t through finite* $\mathsf{Prod}^{\uparrow}$ *coordinate updates.*
5. *P is the prefix ledger: every prefix of W has a displayed* $\mathsf{Prod}^{\uparrow}$ *endpoint and an* $\mathsf{Order}^{\uparrow}$ *comparison row whenever a boundary condition is part of the path request.*
6. *B is the bounded-size row, read through* $\mathsf{Nat}^{\uparrow}$*, that records the length of W and the coordinate budgets consumed by E and P.*
7. *H records componentwise* hsame *transport for the endpoints, step list, endpoint ledger, prefix ledger, bounded-size row, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from endpoint and prefix requests to the finite step-list ledger.*
9. *G is the* Pkg *provenance over* $\mathsf{FiniteLatticePath}^{\uparrow}$*,* $\mathsf{Nat}^{\uparrow}$*,* $\mathsf{List}^{\uparrow}$*,* $\mathsf{Prod}^{\uparrow}$*,* $\mathsf{Order}^{\uparrow}$*,* $\mathsf{CatalanNumber}^{\uparrow}$*,* BHist*,* hsame*,* Cont*, and* $\mathsf{NameCert}$*.*
10. *N is the local* $\mathsf{NameCert}_{\mathsf{FiniteLatticePath}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these ten rows. It has no coordinate for a completed lattice, infinite walk, quotient endpoint equality, unbounded search, or host enumeration principle.

Theorem 8652.2 (Finite lattice path NameCert obligations)**.** *For every accepted* $\mathsf{FiniteLatticePath}^{\uparrow}$ *carrier* $L = (s, t, W, E, P, B, H, C, G, N)$*, the local* $\mathsf{NameCert}_{\mathsf{FiniteLatticePath}^{\uparrow}}$ *surface consists exactly of start and terminal endpoint admission through* $\mathsf{Prod}^{\uparrow}$ *pairs of* $\mathsf{Nat}^{\uparrow}$ *coordinates, finite step-list admission through* $\mathsf{List}^{\uparrow}$*, endpoint-ledger exactness, prefix-ledger visibility, bounded-size accounting, componentwise* hsame *stability, displayed* Cont *replay,* Pkg *provenance, local naming, and non-escape from ambient grids, infinite path spaces, quotient endpoint equality, unbounded search, or external enumeration theorems.*

Proof. Project the accepted packet. The start and terminal rows are displayed $\mathsf{Prod}^{\uparrow}$ pairs of $\mathsf{Nat}^{\uparrow}$ coordinates, and the step row W is a finite $\mathsf{List}^{\uparrow}$ spine.

Read the endpoint ledger E. It iterates the displayed steps from s and records the terminal endpoint t as a finite coordinate calculation, so no ambient lattice carrier or quotient endpoint equality is available.

Read the prefix ledger P and bounded-size row B. Each prefix endpoint is displayed as a $\mathsf{Prod}^{\uparrow}$ pair, and each boundary comparison is an $\mathsf{Order}^{\uparrow}$ row attached to that prefix. The length and coordinate budgets are $\mathsf{Nat}^{\uparrow}$ rows, hence the accepted path is finite at every inspected prefix.

Finally H, C, G, N transport, replay, source, and name this same route. Since the carrier has no coordinate for an infinite walk, unbounded search, or external enumeration theorem, the local NameCert obligations are exhausted by the displayed rows. □

Theorem 8652.3 (Finite lattice path endpoint and prefix ledger route)**.** *Every downstream consumer of an accepted* $\mathsf{FiniteLatticePath}^{\uparrow}$ *packet must read the route*

$$\mathsf{Nat}^{\uparrow},\ \mathsf{Prod}^{\uparrow},\ \mathsf{List}^{\uparrow},\ \mathsf{Order}^{\uparrow} \longmapsto (s, t, W, E, P, B) \longmapsto \mathsf{NameCert}_{\mathsf{FiniteLatticePath}^{\uparrow}}$$

before it may consume the path as a Catalan, Dyck-prefix, ballot, grid-walk, or finite-enumeration object. The $\mathsf{CatalanNumber}^{\uparrow}$ *consumer receives only the special case where* P *records the nonnegative prefix balance and zero terminal balance; it does not receive an unrestricted path space or an analytic counting theorem.*

Proof. Start with a consumer of the accepted packet L. Carrier admission exposes the endpoint rows s, t, the finite step list W, the endpoint ledger E, the prefix ledger P, and the bounded-size row B before the local name row can be read.

The endpoint rows are $\mathsf{Prod}^{\uparrow}$ pairs whose coordinates are $\mathsf{Nat}^{\uparrow}$ rows. The step list is a $\mathsf{List}^{\uparrow}$ spine, so any scan of the path factors through the finite list carrier rather than through an ambient function space.

The prefix ledger is the only place where order information appears. When a consumer asks for a boundary condition, it receives an $\mathsf{Order}^{\uparrow}$ comparison attached to a displayed prefix endpoint, not a detached order relation on a host grid.

For the Catalan-facing special case, the same prefix ledger records balance nonnegativity and terminal balance zero. Thus the Catalan packet can consume the lattice-path row as a Dyck-prefix surface, while the finite lattice path packet itself remains the endpoint-and-prefix ledger route described above. □

Falsifiable prediction: Every accepted $\mathsf{FiniteLatticePath}^{\uparrow}$ read must expose the start endpoint, terminal endpoint, finite step list, endpoint ledger, prefix ledger, bounded-size row, componentwise

hsame transport, displayed Cont replay, Pkg provenance, and local NameCert evidence before it may be consumed by Catalan, Dyck-prefix, ballot, grid-walk, or finite-enumeration chapters.

Independence witness: nat, list, prod, order, catalan-number: $\mathsf{FiniteLatticePath}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries endpoint pairs, a finite step spine, endpoint iteration, prefix comparisons, bounded-size accounting, transport, replay, provenance, and local naming. NatUp has sizes without path spines; ListUp has spines without coordinate endpoints; ProdUp has endpoint pairs without iteration; OrderUp has comparisons without prefix history; CatalanNumberUp consumes a Dyck-prefix special case without carrying arbitrary finite grid endpoints.

Closure status for $\mathsf{NameCert}_{\mathsf{FiniteLatticePath}^{\uparrow}}$.

Constructive story: A $\mathsf{FiniteLatticePath}^{\uparrow}$ packet is generated from NatUp coordinate rows, ProdUp endpoint pairs, a finite ListUp step spine, endpoint iteration, prefix OrderUp comparisons, bounded-size accounting, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{FiniteLatticePath}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8652.1, Definition 8652.2, and Definition 8652.3 seed the finite endpoint and prefix-ledger route for lattice-path packets.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{FiniteLatticePath}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close Catalan recurrence uniqueness, ballot enumeration, reflection principles, quotient endpoint equality, infinite path spaces, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, endpoint-ledger exactness, prefix-ledger visibility, bounded-size accounting, transport, replay, provenance, and local naming for BEDC.Derived.FiniteLatticePathUp.

Chapter 8653

A Concrete Naming Certificate for $\mathsf{LevyContinuity}^{\uparrow}$

Following Feller's characteristic-function proof of weak convergence and Billingsley's finite-dimensional distribution conventions, the $\mathsf{LevyContinuity}^{\uparrow}$ packet records the finite BEDC surface used by a Levy-continuity readback without importing completed measure spaces or host almost-sure quotient equality. It sits over the probability source of chapter 184, the random-variable observation surface of chapter 185, the distribution readback of chapter 186, the rational regular-window discipline of chapter 301, and the terminal real seal of chapter 38. The characteristic-function rows are finite windows: each accepted read exposes only the inspected frequency grid, tolerance ledger, distribution readback, transport, replay, provenance, and local naming rows.

Definition 8653.1 (Levy continuity carrier)**.** *A* $\mathsf{LevyContinuity}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (P, X, D, W, Q, R, H, C, G, N)$$

with the following rows:

1. *P is the* $\mathsf{ProbSpace}^{\uparrow}$ *probability-source row for the inspected finite event algebra and probability requests.*
2. *X is the* $\mathsf{RandomVar}^{\uparrow}$ *observation row, exposing the displayed random-variable reads used by the packet.*
3. *D is the* $\mathsf{Distribution}^{\uparrow}$ *readback row, recording the finite distribution observations attached to X.*
4. *W is the* $\mathsf{CharacteristicFunction}^{\uparrow}$ *finite-window row, naming the inspected frequency grid and the complex-valued read requests admitted on that grid.*
5. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *tolerance row for the finite characteristic-function and distribution comparisons.*
6. *R is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached only after P, X, D, W, Q remain visible.*
7. *H stores componentwise* hsame *transport for the probability source, random-variable observation, distribution readback, characteristic-function window, tolerance ledger, real seal, replay, provenance, and local naming rows.*
8. *C stores displayed* Cont *replay from probability reads to random-variable observations, from observations to distribution rows, and from distribution rows to characteristic-function finite windows.*

9. *G is the* Pkg *provenance over* $\mathsf{LevyContinuity}^{\uparrow}$, $\mathsf{ProbSpace}^{\uparrow}$, $\mathsf{RandomVar}^{\uparrow}$, $\mathsf{Distribution}^{\uparrow}$, $\mathsf{CharacteristicFunction}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*
10. *N is the local* $\mathsf{NameCert}_{\mathsf{LevyContinuity}^{\uparrow}}$ *row.*

The accepted carrier stores no measure-completion coordinate, no host almost-sure quotient equality, no selected limit distribution, no countable-choice selector, and no ambient Real completeness witness.

Lean4 (statement) `BEDC.Derived.LevyContinuityUp`

Theorem 8653.2 (Levy continuity NameCert obligations)**.** *For an accepted packet $L = (P, X, D, W, Q, R, H, C, G,$ the local* $\mathsf{NameCert}_{\mathsf{LevyContinuity}^{\uparrow}}$ *obligations are exhausted by probability-source admission through P, random-variable observation through X, distribution readback through D, characteristic-function finite windows through W, rational tolerance exposure through Q, terminal real sealing through R, componentwise* hsame *stability through H, displayed* Cont *replay through C,* Pkg *provenance through G, and local naming through N.*

Proof. Project the carrier of Definition 8653.1. The probability row P and random-variable row X expose only the finite probability and observation requests stored in the packet.

Read the analytic rows next. The distribution row D is available before the characteristic-function window W, and W records only the inspected frequency grid together with the tolerance ledger Q.

Finally inspect R, H, C, G, N. These rows seal, transport, replay, package, and name the same displayed data. Since the carrier has no coordinate for measure completion, host almost-sure quotient equality, a selected limit law, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness, no local NameCert obligation can read one. □

Theorem 8653.3 (Levy continuity characteristic-function route)**.** *Every distribution-facing consumer of an accepted* $\mathsf{LevyContinuity}^{\uparrow}$ *packet must expose the finite route*

$$\mathsf{ProbSpace}^{\uparrow}, \mathsf{RandomVar}^{\uparrow} \longmapsto \mathsf{Distribution}^{\uparrow} \longmapsto \mathsf{CharacteristicFunction}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}$$

before the transport, replay, provenance, and local naming rows can be consumed. Thus characteristic-function convergence is read only through displayed finite windows and their rational tolerance ledger, not through completed measure objects, host equality of random variables, selected weak limits, or ambient real completeness.

Proof. Start with the NameCert obligations of Definition 8653.2. They force every accepted read to expose P, X, D, W, Q before the terminal real seal and structural rows are available.

The characteristic-function row W is therefore a finite-window handoff between the distribution readback D and the rational tolerance row Q. Its continuation replay C keeps the probability, observation, distribution, and window reads in the same displayed packet.

The structural rows H, G, N preserve that route by transport, provenance, and local naming. Since no completed measure carrier, almost-sure quotient equality, selected weak limit, countable-choice selector, or ambient completeness row appears in Definition 8653.1, no distribution-facing consumer can bypass the finite characteristic-function route. □

Falsifiable prediction: Every accepted $\mathsf{LevyContinuity}^{\uparrow}$ read exposes a $\mathsf{ProbSpace}^{\uparrow}$ source, $\mathsf{RandomVar}^{\uparrow}$ observation row, $\mathsf{Distribution}^{\uparrow}$ readback, $\mathsf{CharacteristicFunction}^{\uparrow}$ finite window, $\mathsf{RegSeqRat}^{\uparrow}$ tolerance ledger, terminal $\mathsf{Real}^{\uparrow}$ seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming before any downstream weak-convergence or central-limit packet may consume it.

Independence witness: probspace, randomvar, distribution, regseqrat, real: none is bijective to LevyContinuityUp because the packet jointly carries probability-source, random-variable, distribution-readback, characteristic-window, tolerance, seal, transport, replay, provenance, and local NameCert rows.

Closure status for $\mathsf{NameCert}_{\mathsf{LevyContinuity}\uparrow}$.

Constructive story: A $\mathsf{LevyContinuity}^{\uparrow}$ packet is generated from a probability source row, random-variable observation row, distribution readback, characteristic-function finite windows, a rational tolerance ledger, a terminal Real seal, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{LevyContinuity}\uparrow}, \mathsf{seed})$

Scope closed: Definition 8653.1, Definition 8653.2, and Definition 8653.3 seed the finite Levy-continuity carrier between probability sources, random-variable observations, distribution readbacks, characteristic-function windows, RegSeqRat tolerances, and Real-facing consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{LevyContinuity}\uparrow}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim measure completion, almost-sure quotient equality, selected weak limits, countable choice, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, characteristic-window exactness, distribution readback stability, tolerance-ledger stability, and downstream nonescape for BEDC.Derived.LevyContinuityUp.

Chapter 8654

A Concrete Naming Certificate for $\mathsf{DieudonneCompletion}^{\uparrow}$

Following Dieudonne, Bourbaki, and Kelley on completion of uniform spaces, the $\mathsf{DieudonneCompletion}^{\uparrow}$ packet records the finite BEDC boundary by which a displayed uniform source hands Cauchy-filter and Cauchy-net evidence to the separated-completion corridor. It sits beside the uniform-space completion route of chapter 3560, the separated-completion boundary of chapter 1612, the finite stream-name windows of chapter 126, the regular rational readback of chapter 301, the dyadic tolerance ledger of chapter 291, and the terminal real-name seal of chapter 38. The packet gives Real and Completion consumers a traditional uniform-completion interface without quotient completion objects, selected representatives, countable choice, host equality of completed points, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 8654.1 (Dieudonne completion carrier)**.** *A* $\mathsf{DieudonneCompletion}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$D = (U, F, T, S, W, R, Q, E, H, C, P, N)$$

with the following displayed rows:

1. *U is the* $\mathsf{UniformSpace}^{\uparrow}$ *source row, recording the displayed entourage base, finite refinement reads, and uniform source data admitted by chapter 3560.*
2. *F is the* $\mathsf{CauchyFilter}^{\uparrow}$ *row, exposing finite filter-base demands and Cauchy eventuality checks over the same uniform source.*
3. *T is the* $\mathsf{CauchyNet}^{\uparrow}$ *row, exposing directed Cauchy windows when the same completion request is presented in Moore–Smith form.*
4. *S is the* $\mathsf{SeparatedCompletion}^{\uparrow}$ *handoff row, recording the separated boundary consumed before a completion-facing point can be public.*
5. *W is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row through which the filter or net observations are inspected.*
6. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row, translating the inspected windows into regular rational observations.*
7. *Q is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, recording dyadic radii, refinement slack, and comparison budgets used by the Cauchy-filter or Cauchy-net rows.*
8. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row, available only after U, F, T, S, W, R, Q have all been displayed.*

9. *H records componentwise* hsame *transport for the uniform source, Cauchy-filter row, Cauchy-net row, separated handoff, finite windows, regular readback, dyadic ledger, Real seal, replay, provenance, and local naming rows.*

10. *C records displayed* Cont *replay from a uniform-completion request through*

$$U, F, T, S, W, R, Q, E \longmapsto \mathsf{NameCert}_{\mathsf{DieudonneCompletion}^{\uparrow}}.$$

11. *P is the* Pkg *provenance over* $\mathsf{DieudonneCompletion}^{\uparrow}$, $\mathsf{UniformSpace}^{\uparrow}$, $\mathsf{CauchyFilter}^{\uparrow}$, $\mathsf{CauchyNet}^{\uparrow}$, $\mathsf{SeparatedCompletion}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *dependency rows.*

12. *N is the local* $\mathsf{NameCert}_{\mathsf{DieudonneCompletion}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $U, F, T, S, W, R, Q, E, H, C, P, N$. It has no coordinate for quotient completion classes, selected Cauchy representatives, countable choice, host equality of completed points, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 8654.2 (Dieudonne completion NameCert obligations)**.** *For every accepted* $\mathsf{DieudonneCompletion}^{\uparrow}$ *carrier*

$$D = (U, F, T, S, W, R, Q, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{DieudonneCompletion}^{\uparrow}}$ *surface consists exactly of carrier admission for the uniform source row, Cauchy-filter row, Cauchy-net row, separated-completion handoff, finite StreamName windows, RegSeqRat readback, DyadicRatCore tolerance ledger, terminal Real seal, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. Any completion-facing read must keep these rows visible before it consumes the separated boundary or the Real seal.*

Proof. Project the carrier of Definition 8654.1. The rows U, F, T, S, W, R, Q, E are the only analytic coordinates through which a consumer can read uniform source data, Cauchy evidence, separated completion data, finite windows, rational readback, dyadic tolerance, and the terminal Real seal.

The uniform side begins at U. Filter-style evidence is read through F, while directed-net evidence is read through T; both remain attached to the same displayed entourage and refinement rows rather than to a quotient of Cauchy presentations.

The separated and numerical side then passes through S, W, R, Q, E. The separated-completion handoff is displayed before the public completion boundary is consumed, and the finite windows, regular rational readback, dyadic ledger, and Real seal keep the route inspectable by Real and Completion consumers.

Finally H, C, P, N transport, replay, source, and locally name the same packet. Since the carrier contains no coordinate for quotient completion classes, selected representatives, countable choice, host equality, or ambient Real completeness, the listed rows exhaust the local NameCert obligation surface. □

Theorem 8654.3 (Dieudonne completion uniform handoff)**.** *Every Real or Completion-facing consumer of an accepted* $\mathsf{DieudonneCompletion}^{\uparrow}$ *carrier factors through the displayed route*

$$\mathsf{UniformSpace}^{\uparrow} \longmapsto (\mathsf{CauchyFilter}^{\uparrow}, \mathsf{CauchyNet}^{\uparrow}) \longmapsto \mathsf{SeparatedCompletion}^{\uparrow} \longmapsto \mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto$$

The consumer first reads the uniform source, then the displayed filter or net Cauchy evidence, then the separated-completion handoff, and only then the finite-window, rational-readback, dyadic-ledger, and Real-seal rows.

Proof. Begin with the NameCert obligations of Definition 8654.2. They place every public read inside the carrier rows $U, F, T, S, W, R, Q, E, H, C, P, N$.

The first step is uniform. A filter presentation uses F, and a net presentation uses T, but both are read over the same displayed source row U and share the same downstream packet boundary.

The separated handoff is the next public boundary. The row S must be displayed before a completion-facing consumer can treat the Cauchy evidence as separated data, so the route cannot skip to a completed point by quotienting filters or nets.

The final read is numerical and structural. The windows W, regular readback R, dyadic ledger Q, and Real seal E are replayed through H, C, P, N, leaving no route for selected representatives, countable choice, host equality of completed points, or ambient $\mathsf{Real}^{\uparrow}$ completeness to enter the packet. □

Falsifiable prediction: Every accepted $\mathsf{DieudonneCompletion}^{\uparrow}$ completion read exposes a UniformSpace source row, a CauchyFilter or CauchyNet row, a SeparatedCompletion handoff, finite StreamName windows, RegSeqRat readback, DyadicRatCore tolerance accounting, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming.

Independence witness: uniform-space-completion, separatedcompletion, streamname, regseqrat, dyadicratcore, real: $\mathsf{DieudonneCompletion}^{\uparrow}$ is not bijective to any listed sibling because it jointly binds a uniform source, filter-style and net-style Cauchy evidence, separated-completion handoff, finite windows, rational readback, dyadic tolerance accounting, Real sealing, transport, replay, provenance, and local naming in one uniform-completion boundary packet.

Closure status for $\mathsf{NameCert}_{\mathsf{DieudonneCompletion}^{\uparrow}}$.

Constructive story: A $\mathsf{DieudonneCompletion}^{\uparrow}$ packet is generated from a UniformSpace source row, CauchyFilter and CauchyNet evidence rows, a SeparatedCompletion handoff, StreamName finite windows, RegSeqRat readback, DyadicRatCore tolerance ledger, RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{DieudonneCompletion}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8654.1, Definition 8654.2, and Definition 8654.3 seed the finite traditional uniform-completion route from displayed uniform data through Cauchy-filter or Cauchy-net evidence, separated handoff, finite windows, rational readback, dyadic ledger, Real seal, transport, replay, provenance, and local naming.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{DieudonneCompletion}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient completions, selected Cauchy representatives, countable choice, host equality of completed points, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, uniform-source exposure, Cauchy-filter and Cauchy-net evidence, separated-completion handoff, finite-window inspection, regular rational readback, dyadic tolerance accounting, Real sealing, transport, replay, provenance, and local naming for BEDC.Derived.DieudonneCompletionUp.

Chapter 8655

A Concrete Naming Certificate for $\mathsf{UniformFilterBase}^{\uparrow}$

Following Kelley and Bourbaki on uniform spaces and filter bases, the $\mathsf{UniformFilterBase}^{\uparrow}$ packet records the finite L10 route by which a displayed uniform-entourage request is refined through a directed filter-base row before it is handed to Cauchy-filter and real-completion consumers. It sits over the filter-base discipline of chapter 1601, the uniform-space entourage discipline of chapter 339, the Cauchy-filter boundary of chapter 333, the finite stream-name observations of chapter 126, the regular rational readback of chapter 301, the dyadic tolerance core of chapter 291, and the terminal real seal of chapter 38.

Definition 8655.1 (Uniform filter-base carrier)**.** *A* $\mathsf{UniformFilterBase}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$F = (U, B, C, S, R, D, A, H, K, P, N)$$

with the following displayed rows:

1. *U is the* $\mathsf{UniformSpace}^{\uparrow}$ *entourage request row naming the requested uniform neighbourhood.*
2. *B is the* $\mathsf{FilterBase}^{\uparrow}$ *directed refinement row, carrying the displayed base element and its refinement relation.*
3. *C is the* $\mathsf{CauchyFilter}^{\uparrow}$ *readiness row, asserting that the directed refinement can be read by a Cauchy-filter consumer.*
4. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite observation-window row for reading the selected base element.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row attached to the finite observations in S.*
6. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row recording the requested dyadic radius and slack.*
7. *A is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row, available only after U, B, C, S, R, D have been displayed.*
8. *H records componentwise* hsame *transport for the entourage request, directed base refinement, Cauchy readiness, readback, tolerance, terminal seal, provenance, and local name.*
9. *K records the displayed* Cont *replay by which a consumer reads $U, B, C, S, R, D, A, H, P, N$ in order.*
10. *P is the* Pkg *provenance over* $\mathsf{UniformFilterBase}^{\uparrow}$, $\mathsf{FilterBase}^{\uparrow}$, $\mathsf{UniformSpace}^{\uparrow}$, $\mathsf{CauchyFilter}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.

11. N is the local $\mathsf{NameCert}_{\mathsf{UniformFilterBase}^{\uparrow}}$ *row.*
The carrier has no coordinate for quotient filters, selected limits, countable choice, host equality of filters, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 8655.2 (Uniform filter-base NameCert obligations)**.** *For the carrier of Definition 8655.1, the local* $\mathsf{NameCert}_{\mathsf{UniformFilterBase}^{\uparrow}}$ *surface consists exactly of carrier admission for*

$$F = (U, B, C, S, R, D, A, H, K, P, N),$$

entourage-request exposure through U, directed filter-base refinement through B, Cauchy readiness through C, finite observation and readback through S, R, dyadic tolerance through D, terminal real sealing through A, componentwise hsame *stability through H, displayed* Cont *replay through K,* Pkg *provenance through P, and local naming through N.*

Proof. Carrier admission is projection from Definition 8655.1. The rows U and B expose the uniform-entourage request and the directed filter-base refinement before any Cauchy or completion-facing consumer may inspect the packet.

The Cauchy and readback side is read through C, S, R, D. The Cauchy readiness row keeps the filter-base route finite, while the stream, regular rational, and dyadic rows provide the displayed observation and tolerance data needed for a real-completion handoff.

Finally A, H, K, P, N seal, transport, replay, package, and name the same displayed rows. Since the carrier contains no further coordinate, the listed rows exhaust the local NameCert surface. □

Theorem 8655.3 (Uniform filter-base Cauchy handoff)**.** *Every accepted* $\mathsf{UniformFilterBase}^{\uparrow}$ *packet factors any* $\mathsf{CauchyFilter}^{\uparrow}$ *read through the displayed route*

$$\mathsf{UniformSpace}^{\uparrow},\ \mathsf{FilterBase}^{\uparrow},\ U,\ B,\ C,\ S,\ R,\ D \longrightarrow \mathsf{CauchyFilter}^{\uparrow}.$$

The handoff supplies a uniform entourage request, a directed base refinement, Cauchy readiness, finite observation windows, regular rational readback, and dyadic tolerance data; it does not supply quotient-filter equality, selected limit filters, countable choice, or host equality of filters.

Proof. Project the carrier in Definition 8655.1. The only rows available before the Cauchy read are U, B, C, S, R, D together with transport, replay, provenance, and local naming.

Read U through the uniform-space entourage surface and B through the directed filter-base surface. The row C is then a readiness row for the Cauchy-filter consumer, not a completed filter quotient or a selected limit.

The rows S, R, D provide the finite observation, rational readback, and dyadic tolerance budget attached to that same handoff. Since the carrier has no further coordinate, every accepted Cauchy read factors through the displayed route. □

Theorem 8655.4 (Uniform filter-base real-completion boundary)**.** *Every* $\mathsf{Real}^{\uparrow}$*-facing completion read of an accepted* $\mathsf{UniformFilterBase}^{\uparrow}$ *packet may inspect only the terminal seal A after the rows U, B, C, S, R, D have been displayed and transported through H, K, P, N. The boundary exposes no selected real limit, no ambient completeness theorem for* $\mathsf{Real}^{\uparrow}$*, no quotient equality of filters, and no countable-choice extraction.*

Proof. Start with Definition 8655.3. It confines the Cauchy-facing side of the packet to the uniform entourage request, directed base refinement, Cauchy readiness, finite observations, regular rational readback, and dyadic tolerance rows.

The terminal row A can be read only after those rows are present. It is a seal for completion-facing consumers, not a construction of a selected real limit or a proof of ambient real completeness.

The transport and replay rows H, K preserve the same displayed route, and P, N record provenance and local naming. Thus the real-completion boundary is exactly the finite seal over the displayed uniform-filter-base data. □

Closure status for $\mathsf{NameCert}_{\mathsf{UniformFilterBase}^{\uparrow}}$.

Constructive story: A $\mathsf{UniformFilterBase}^{\uparrow}$ packet is generated from a uniform-entourage request, a directed filter-base refinement, Cauchy readiness, finite StreamName observations, RegSeqRat readback, a DyadicRatCore tolerance row, a terminal Real seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{UniformFilterBase}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8655.1, Definition 8655.2, Definition 8655.3, and Definition 8655.4 display the finite uniform-filter-base carrier, Cauchy handoff, and real-completion boundary.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{UniformFilterBase}^{\uparrow}}, \mathsf{unformalized})$

Lean4 (statement) `BEDC.Derived.UniformFilterBaseUp`

Bridge status: none

Not claimed: This chapter does not close quotient filters, selected limits, countable choice, host equality of filters, ambient $\mathsf{Real}^{\uparrow}$ completeness, theorem-level Lean verification, or bridge checking.

Upgrade path: The next step is a checked NameCert obligation theorem for the displayed carrier rows and their Cauchy-filter handoff.

Chapter 8656

A Concrete Naming Certificate for $\mathsf{EquicontinuousCauchyFamily}^{\uparrow}$

Following Bishop and Bridges and Kelley, the $\mathsf{EquicontinuousCauchyFamily}^{\uparrow}$ packet records a finite completion-facing family of Cauchy real-name reads whose members share one displayed equicontinuity modulus on compact or bounded source windows. It sits after the Real-uniform entourage surface of chapter 1624, the finite window and readback rows of chapter 126 and chapter 301, the dyadic tolerance ledger of chapter 291, and the terminal Real spine of chapter 38. The packet supplies a traditional finite-means consumer for L10 Real and Completion work without asserting ambient completeness, quotient filters, selected limits, countable choice, host equality, or bridge credentials.

Definition 8656.1 (Equicontinuous Cauchy family carrier)**.** *An* $\mathsf{EquicontinuousCauchyFamily}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$E = (K, U, M, T, W, R, D, A, H, C, P, N)$$

with the following displayed rows:

1. *K is the compact or bounded source-window row, naming the finite portion of the domain on which the family is inspected.*
2. *U is the* $\mathsf{RealUniformStructure}^{\uparrow}$ *entourage row consumed by the shared continuity request.*
3. *M is the shared equicontinuity modulus row, assigning one finite tolerance-to-window rule for all accepted members of the family.*
4. *T is the Cauchy-family threshold row, recording the displayed tail budget used when two family indices are compared at a requested precision.*
5. *W is the* $\mathsf{StreamName}^{\uparrow}$ *window family opened for the source row, the modulus row, and every Cauchy threshold request.*
6. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *regular rational readback row attached to the stream windows.*
7. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row, carrying the dyadic scales, slack bounds, and comparison budgets used by U, M, T, W, R.*
8. *A is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached only after the source window, shared modulus, Cauchy threshold, StreamName, RegSeqRat, and DyadicRatCore rows have been displayed.*

9. *H records componentwise* hsame *transport for the source windows, Real-uniform entourage, shared modulus, Cauchy thresholds, stream windows, regular readback, dyadic tolerances, Real seals, replay, provenance, and local naming rows.*

10. *C records displayed* Cont *replay from any completion-facing family read through*

$$K \longrightarrow U \longrightarrow M \longrightarrow T \longrightarrow W \longrightarrow R \longrightarrow D \longrightarrow A.$$

11. *P is the* Pkg *provenance over* $\mathsf{EquicontinuousCauchyFamily}^{\uparrow}$, $\mathsf{RealUniformStructure}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

12. *N is the local* $\mathsf{NameCert}_{\mathsf{EquicontinuousCauchyFamily}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $K, U, M, T, W, R, D, A, H, C, P, N$. It has no coordinate for an ambient complete function space, a selected limiting function, quotient filter equality, countable choice, host equality, or bridge checking.

Theorem 8656.2 (Equicontinuous Cauchy family NameCert obligations)**.** *For every accepted* $\mathsf{EquicontinuousCauchyFamily}^{\uparrow}$ *carrier*

$$E = (K, U, M, T, W, R, D, A, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{EquicontinuousCauchyFamily}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the compact or bounded source windows, Real-uniform entourage, shared equicontinuity modulus, Cauchy-family thresholds, StreamName windows, RegSeqRat readback, DyadicRatCore tolerances, terminal Real seals, transport, replay, provenance, and local naming rows;*

2. *uniform-source exactness, requiring every family read to expose K and U before a modulus or Cauchy threshold is inspected;*

3. *shared-modulus exactness, requiring the same row M to answer every memberwise equicontinuity request over the displayed source windows;*

4. *Cauchy-threshold exactness, requiring T to supply only finite tail thresholds at the requested DyadicRatCore precision;*

5. *L10 readback discipline, requiring W, R, D to mediate all rational observations before any terminal* $\mathsf{Real}^{\uparrow}$ *seal A is public;*

6. *structural stability, requiring H, C, P, N to transport, replay, source, and name exactly the displayed route.*

No local obligation is stored outside these rows.

Lean4 ✓ `BEDC.Derived.EquicontinuousCauchyFamilyUp.EquicontinuousCauchyFamilyTasteGate single carrier alignment`

Proof. Carrier admission is projection from Definition 8656.1. The accepted packet displays the source-window, Real-uniform, shared-modulus, Cauchy-threshold, stream, regular-readback, dyadic, Real-seal, transport, replay, provenance, and local naming rows.

Uniform-source exactness is the first part of the route. A completion-facing family consumer must read K and then U, so the shared modulus is interpreted over the Real-uniform entourage row of chapter 1624.

Shared-modulus and Cauchy-threshold exactness are the next projections. The row M is the only equicontinuity modulus coordinate, and T is the only Cauchy threshold coordinate, so neither can be replaced by a hidden cover, quotient filter, or chosen limit.

The L10 readback discipline is the terminal part of the route. Stream windows, regular rational readback, and dyadic tolerances appear as W, R, D before the $\mathsf{Real}^{\uparrow}$ seal row A is available.

Finally, H, C, P, N transport, replay, source, and name this same route. Since the carrier contains no ambient complete function space, selected limiting function, quotient filter equality, countable choice, host equality, or bridge credential, the listed rows exhaust the local NameCert surface. □

Theorem 8656.3 (Equicontinuous Cauchy family completion handoff)**.** *Every L10 completion-facing consumer of an accepted* $\mathsf{EquicontinuousCauchyFamily}^{\uparrow}$ *packet reaches the terminal* $\mathsf{Real}^{\uparrow}$ *seal only through the finite route*

$$K \longrightarrow U \longrightarrow M \longrightarrow T \longrightarrow W \longrightarrow R \longrightarrow D \longrightarrow A$$

with componentwise transport, replay, provenance, and local naming supplied by H, C, P, N*. The handoff may be consumed by Real and Completion chapters that read uniform Cauchy-family data, but it does not export ambient completeness, a selected limit family, quotient-filter equality, countable choice, host real equality, open-cover compactness, or bridge checking.*

Proof. Project the carrier of Definition 8656.1. The source-window row K fixes the compact or bounded part of the domain, and the Real-uniform row U fixes the entourage request before any family threshold is read.

Apply Definition 8656.2. The shared modulus row M and Cauchy threshold row T are required before the finite observation rows W, R, D and before the terminal Real seal.

The L10 Real spine is then the same finite window-readback-seal route used by chapter 38. The completion consumer receives A only after StreamName windows, RegSeqRat readback, and DyadicRatCore tolerances have been displayed.

The structural rows H, C, P, N do not add analytic data. They transport, replay, source, and name the route already displayed, so no ambient completeness theorem, selected limit family, quotient-filter equality, countable-choice schedule, host equality, open-cover compactness, or bridge credential can be exported. □

Theorem 8656.4 (Equicontinuous Cauchy family tail stability)**.** *Let* $E = (K, U, M, T, W, R, D, A, H, C, P, N)$ *and* $E' = (K, U, M, T, W', R', D', A', H', C', P', N')$ *be accepted* $\mathsf{EquicontinuousCauchyFamily}^{\uparrow}$ *packets. Suppose the two packets agree on the source-window row* K*, the RealUniformStructure row* U*, the shared modulus row* M*, and every StreamName, RegSeqRat, and DyadicRatCore row beyond a displayed Cauchy threshold* T*. Then every completion-facing consumer reads the same terminal* $\mathsf{Real}^{\uparrow}$ *seal route through*

$$K \longmapsto U \longmapsto M \longmapsto T \longmapsto W \longmapsto R \longmapsto D \longmapsto A \longmapsto H, C, P, N$$

and

$$K \longmapsto U \longmapsto M \longmapsto T \longmapsto W' \longmapsto R' \longmapsto D' \longmapsto A' \longmapsto H', C', P', N'.$$

No selected limit family or quotient-filter equality is exported.

Proof. Project both accepted carriers using Definition 8656.1. The shared rows K, U, M, T force the two packets to present the same source window, entourage row, modulus row, and threshold before any tail-sensitive data is read.

Now compare the tail rows beyond T. The displayed hypothesis says the StreamName, RegSeqRat, and DyadicRatCore rows agree on the part of the packet available to the consumer, so the completion route has the same finite readback pattern in both packets.

Finally replay the structural rows. Componentwise hsame transport and displayed Cont replay preserve the same terminal Real seal route, so the completion-facing consumer sees identical tail-stable output without exporting a selected limit family or quotient-filter equality. □

Theorem 8656.5 (Equicontinuous Cauchy family obligation package)**.** *For every accepted* EquicontinuousCauchyFa *carrier*

$$E = (K, U, M, T, W, R, D, A, H, C, P, N),$$

the rows $K, U, M, T, W, R, D, A, H, C, P, N$ assemble an obligation-closure package consisting exactly of carrier admission, uniform-source exactness, shared-modulus exactness, Cauchy-threshold exactness, L10 readback discipline, and structural stability. The package admits no additional coordinate for selected limits, quotient-filter equality, countable choice, host equality, open-cover compactness, ambient $\mathsf{Real}^{\uparrow}$ *completeness, or bridge checking.*

Proof. Project the displayed carrier of Definition 8656.1. Its rows expose the source-window coordinate K, the Real-uniform coordinate U, the shared modulus M, the Cauchy threshold row T, the StreamName window row W, the RegSeqRat readback row R, the DyadicRatCore tolerance row D, and the terminal Real seal A.

Apply Definition 8656.2. The carrier admission, uniform-source exactness, shared-modulus exactness, Cauchy-threshold exactness, L10 readback discipline, and structural stability clauses are precisely the listed finite obligation rows.

Apply Definition 8656.3 and Definition 8656.4. These results force every completion-facing read and every tail-stable comparison to pass through the same finite route, with H, C, P, N supplying only transport, replay, provenance, and naming.

Because the carrier has no row for a selected limit, quotient filter, countable-choice schedule, host equality, open-cover compactness, ambient Real completeness theorem, or bridge credential, the obligation package is exhausted by the displayed rows. □

Theorem 8656.6 (Equicontinuous Cauchy family Real-seal tail nonescape)**.** *Let*

$$E = (K, U, M, T, W, R, D, A, H, C, P, N)$$

be an accepted $\mathsf{EquicontinuousCauchyFamily}^{\uparrow}$ *packet. No tail-stable completion-facing read can expose the terminal* $\mathsf{Real}^{\uparrow}$ *seal A before the rows K, U, M, T, W, R, D have been displayed, and no such read can export selected limits, quotient-filter equality, countable choice, host equality, open-cover compactness, ambient* $\mathsf{Real}^{\uparrow}$ *completeness, or bridge checking.*

Proof. Start with the carrier projection in Definition 8656.1. The seal row A occurs after the source-window, Real-uniform, shared-modulus, Cauchy-threshold, StreamName, RegSeqRat, and DyadicRatCore rows in the displayed route.

Apply Definition 8656.2. Its L10 readback clause requires W, R, D to mediate the rational observations before any terminal Real seal is public.

Apply Definition 8656.3. A completion-facing consumer receives A only through the finite route $K \to U \to M \to T \to W \to R \to D \to A$.

Finally apply Definition 8656.4. Tail agreement can preserve the displayed route, but it adds no coordinate for selected limits, quotient-filter equality, countable choice, host equality, open-cover compactness, ambient Real completeness, or bridge checking. □

Closure status for $\mathsf{NameCert}_{\mathsf{EquicontinuousCauchyFamily}^{\uparrow}}$.

Constructive story: An $\mathsf{EquicontinuousCauchyFamily}^{\uparrow}$ packet is generated from compact or bounded source windows, a RealUniformStructure entourage row, a shared equicontinuity modulus, Cauchy-family thresholds, StreamName windows, RegSeqRat readback, DyadicRatCore tolerances, terminal Real seals, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{EquicontinuousCauchyFamily}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8656.1, Definition 8656.2, and Definition 8656.3 seed the finite completion-facing equicontinuous Cauchy-family route over the L10 Real spine.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{EquicontinuousCauchyFamily}^{\uparrow}}, \mathsf{theoremChecked})$

Lean target: `BEDC.Derived.EquicontinuousCauchyFamilyUp.EquicontinuousCauchyFamilyTasteGate\_single\_carrier\_alig`

Bridge status: none

Not claimed: This chapter does not close ambient completeness, selected limits, quotient-filter equality, countable choice, host equality, open-cover compactness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, shared-modulus exactness, Cauchy-threshold exactness, L10 readback discipline, transport, replay, provenance, and local naming for BEDC.Derived.EquicontinuousCauchyFamilyUp.

Chapter 8657

A Concrete Naming Certificate for $\mathsf{DyadicIntervalNetCompactness}^{\uparrow}$

Following Bishop and Bridges on compact intervals and finite dyadic covers, the $\mathsf{DyadicIntervalNetCompactness}^{\uparrow}$ packet records the finite interval-net compactness route as displayed BEDC data. It sits over the dyadic interval-net carrier of chapter 5966, the dyadic arithmetic core of chapter 291, the StreamName windows of chapter 126, the regular rational readback of chapter 301, and the terminal Real seal of chapter 38. The packet names finite subdivision-depth coverage and downstream finite-cover handoff only; it does not assert open-cover compactness, selected subcovers, host real equality, countable choice, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 8657.1 (Dyadic interval-net compactness carrier)**.** *A* $\mathsf{DyadicIntervalNetCompactness}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (I, D, J, E, S, R, Q, H, C, P, N)$$

whose rows are read in the following order. The row I is an accepted $\mathsf{DyadicIntervalNet}^{\uparrow}$ *carrier. The rows D, J, E are the* $\mathsf{DyadicRatCore}^{\uparrow}$ *endpoint arithmetic, finite cell list, and endpoint-incidence data displayed by that net. The row S is the* $\mathsf{StreamName}^{\uparrow}$ *endpoint-window row, R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *tolerance readback row, and Q is the terminal* $\mathsf{Real}^{\uparrow}$ *seal. The structural rows H, C, P, N record componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance over the named packets, and the local* $\mathsf{NameCert}_{\mathsf{DyadicIntervalNetCompactness}^{\uparrow}}$ *row.*

The classifier compares accepted compactness packets only through $I, D, J, E, S, R, Q, H, C, P, N$. It has no coordinate for arbitrary open covers, selected finite subcovers, host interval compactness, quotient stream equality, countable choice, trichotomy, or ambient real completeness.

Theorem 8657.2 (Dyadic interval-net compactness obligations)**.** *For every accepted* DyadicIntervalNetCompactness *carrier*

$$K = (I, D, J, E, S, R, Q, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{DyadicIntervalNetCompactness}^{\uparrow}}$ *obligation surface is exhausted by the accepted* $\mathsf{DyadicIntervalNet}^{\uparrow}$ *source row, dyadic endpoint arithmetic, finite cell coverage, endpoint incidence, StreamName endpoint windows, RegSeqRat tolerance readback, terminal Real seal, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. A consumer may read a finite interval-net compactness conclusion only after those rows are displayed in that order.*

Proof. Project the carrier of Definition 8657.1. The compactness-facing data are the interval-net source I together with its dyadic endpoint, finite cell, and endpoint-incidence rows D, J, E.

Use the obligation surface of Definition 5966.10 and the finite-chain coverage route of Definition 5966.16. They require every finite cover read to inspect the listed cells and endpoint arithmetic before StreamName, RegSeqRat, or Real-facing rows are available.

Finally read S, R, Q, H, C, P, N as the downstream seal and structural rows. Since the carrier has no row for open covers, selected subcovers, quotient equality, choice, trichotomy, or ambient completeness, the listed rows exhaust the local NameCert obligations. □

Theorem 8657.3 (Dyadic interval-net finite-cover route)**.** *Every compact-interval or uniform-modulus consumer that reads finite-cover compactness from an accepted* $\mathsf{DyadicIntervalNetCompactness}^{\uparrow}$ *packet factors through*

$$I, D, J, E \longmapsto S, R \longmapsto Q, H, C, P, N.$$

The read first exposes the $\mathsf{DyadicIntervalNet}^{\uparrow}$ *finite cell route, then the* $\mathsf{DyadicRatCore}^{\uparrow}$ *endpoint arithmetic and endpoint incidence, then the* $\mathsf{StreamName}^{\uparrow}$ *and* $\mathsf{RegSeqRat}^{\uparrow}$ *readback rows, and only then the* $\mathsf{Real}^{\uparrow}$ *seal and structural packet rows. The route exports a finite interval-net cover handoff, not open-cover compactness or an ambient completeness principle.*

Proof. Start with the source net row I. By Definition 5966.2, any finite cover request is refined into displayed dyadic cells whose endpoint and incidence data are read through D, J, E.

Apply subdivision-depth coverage from Definition 5966.6. The finite refinement depth keeps each refined cell inside the same endpoint arithmetic, cell list, endpoint incidence, StreamName, RegSeqRat, and Real-seal route.

The compact-interval or uniform-modulus consumer therefore receives only the displayed finite route. Replaying H, C, P, N preserves the same rows, so the finite-cover conclusion cannot be replaced by selected subcovers, quotient stream equality, countable choice, trichotomy, host real equality, or ambient $\mathsf{Real}^{\uparrow}$ completeness. □

Theorem 8657.4 (Dyadic interval-net compactness Real seal boundary)**.** *For every accepted* $\mathsf{DyadicIntervalNetCompactness}^{\uparrow}$ *carrier* $K = (I, D, J, E, S, R, Q, H, C, P, N)$*, the terminal* $\mathsf{Real}^{\uparrow}$ *seal row* Q *may be read only after the finite interval-net route* I, D, J, E, S, R *is displayed. Once* Q *is reached, the rows* H, C, P, N *preserve the same finite packet and do not create host real equality, open-cover compactness, selected subcovers, countable choice, trichotomy, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the carrier. The row Q is downstream of the accepted interval-net source, dyadic endpoint arithmetic, finite cell list, endpoint incidence, StreamName windows, and RegSeqRat tolerance readback.

Apply the Real seal nonescape theorem Definition 5966.13. It prevents a Real-facing consumer from opening Q before the finite dyadic route has been displayed.

Finally replay the compactness packet's structural rows. The componentwise transport, continuation replay, provenance, and local naming rows keep the same finite route visible, so the Real seal remains a boundary for finite-cover handoff rather than a completeness or host-equality endpoint. □

Closure status for $\mathsf{NameCert}_{\mathsf{DyadicIntervalNetCompactness}^{\uparrow}}$**.**

Constructive story: A $\mathsf{DyadicIntervalNetCompactness}^{\uparrow}$ packet is generated from an accepted dyadic interval-net source, finite subdivision-depth coverage, StreamName windows, RegSeqRat tolerance readback, Real seal rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{DyadicIntervalNetCompactness}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8657.1, Definition 8657.2, Definition 8657.3, and Definition 8657.4 seed the finite interval-net compactness carrier and its finite-cover route over DyadicIntervalNet, DyadicRatCore, StreamName, RegSeqRat, Real, transport, replay, provenance, and local naming rows.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{DyadicIntervalNetCompactness}\uparrow}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close open-cover compactness, selected subcovers, host real equality, quotient stream equality, countable choice, trichotomy, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, finite subdivision-depth coverage, finite-cover consumer routing, Real seal nonescape, transport stability, replay stability, provenance, and local naming for BEDC.Derived.DyadicIntervalNetCompactnessUp.

Chapter 8658

A Concrete Naming Certificate for $\mathsf{LawvereTheory}^{\uparrow}$

From Lawvere's finite-product algebraic theories, the $\mathsf{LawvereTheory}^{\uparrow}$ packet records a categorical presentation of finitary algebraic syntax as finite NameCert data. It reads the small category surface of chapter 61, the product-preserving comparison route of chapter 62, the finite-product rows of chapter 34, and the syntactic arity ledger of chapter 197. The packet therefore exposes algebraic operations by their finite-product arities and equations, not by importing a host algebraic theory, quotient syntax, or an external clone object.

Definition 8658.1 (Lawvere theory carrier)**.** *A* $\mathsf{LawvereTheory}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (C, A, O, I, E, H, R, P, N)$$

with the following displayed rows:

1. *C is the category source row, recording the small categorical carrier, identities, composition, and finite-product comparison surface.*
2. *A is the finite-product arity row, recording the distinguished finite powers of the generic object and their projections.*
3. *O is the operation-symbol row, recording each inspected operation as a morphism out of one displayed finite product.*
4. *I is the product-preserving interpretation row, recording the functorial read that carries arities and operations through finite-product preserving maps.*
5. *E is the equation ledger, recording only finite diagrams between displayed operation composites and projection composites.*
6. *H stores componentwise* hsame *transport for the category source, arity row, operation-symbol row, interpretation row, equation ledger, replay, provenance, and local naming row.*
7. *R stores displayed* Cont *replay from categorical composition and product projections to operation interpretation and equation checking.*
8. *P is the* Pkg *provenance over* $\mathsf{LawvereTheory}^{\uparrow}$, $\mathsf{Cat}^{\uparrow}$, $\mathsf{Functor}^{\uparrow}$, $\mathsf{Prod}^{\uparrow}$, $\mathsf{FirstOrder}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$ *rows.*
9. *N is the local* $\mathsf{NameCert}_{\mathsf{LawvereTheory}^{\uparrow}}$ *row.*

The accepted carrier has no coordinate for host quotient syntax, a selected term algebra, an external variety of algebras, or a global equality principle beyond the displayed finite equation ledger.

Theorem 8658.2 (Lawvere theory NameCert obligations)**.** *For an accepted packet $L = (C, A, O, I, E, H, R, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{LawvereTheory}^{\uparrow}}$ *obligations are exhausted by carrier admission for the category source C, finite-product arities A, operation symbols O, product-preserving interpretation row I, equation ledger E, componentwise transport H, displayed replay R, package provenance P, and local naming row N.*

Proof. Project the carrier of Definition 8658.1. The categorical source and finite-product arities are exactly the rows C and A, so every operation read must pass through a displayed morphism in O whose domain is one of the finite products recorded by A.

The interpretation row I is read only after the functorial and product-preserving data have been displayed. Equation checks are then finite ledger reads from E: each equation compares two displayed composites built from projections, operations, identities, and composition in C.

Transport, replay, provenance, and naming are componentwise through H, R, P, N. Since the carrier has no host term quotient, selected term algebra, external variety coordinate, or global equality principle, the local NameCert surface cannot export any of those objects. □

Theorem 8658.3 (Lawvere theory finite-product clone route)**.** *Every clone-facing or algebraic-syntax consumer of an accepted* $\mathsf{LawvereTheory}^{\uparrow}$ *packet must first read the category source C, finite-product arities A, operation symbols O, product-preserving interpretation row I, and finite equation ledger E. Only after those rows are displayed may the consumer reuse the packet as a finite-product clone route through H, R, P, N; no read bypasses the displayed products by invoking host syntax, quotient terms, ambient algebras, or a choice of representatives.*

Proof. Start with the finite-product arity row. It identifies each operation by a morphism from a displayed finite power of the generic object, so the consumer has only the arities and projections recorded in A and O.

Next read the interpretation and equation rows. Product-preserving interpretation through I keeps arities tied to the same finite-product structure, while the ledger E verifies only the finite composites that have been displayed.

Finally repack the route through H, R, P, N. Componentwise transport and replay preserve the same categorical rows, so the resulting clone-facing surface is a finite-product route and not an imported syntax quotient, a selected term model, or an ambient algebraic-theory object. □

Falsifiable prediction: Every accepted $\mathsf{LawvereTheory}^{\uparrow}$ algebraic-syntax read passes through a category source, finite-product arity row, operation-symbol row, product-preserving interpretation row, finite equation ledger, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming before any clone-facing surface is visible.

Independence witness: category, functor, prod, firstorder: none is bijective to LawvereTheoryUp because the packet jointly carries finite-product arities, operation morphisms, product-preserving interpretation, equation ledger, transport, replay, provenance, and local NameCert rows.

Closure status for $\mathsf{NameCert}_{\mathsf{LawvereTheory}^{\uparrow}}$**.**

Constructive story: A $\mathsf{LawvereTheory}^{\uparrow}$ packet is generated from a category source, finite-product arities, operation-symbol morphisms, product-preserving interpretation, a finite equation ledger, componentwise hsame transport, displayed Cont replay, package provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{LawvereTheory}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8658.1, Definition 8658.2, and Definition 8658.3 seed the finite-product algebraic-theory packet over CategoryUp, FunctorUp, ProdUp, FirstOrderUp, BHist, hsame, Cont, Pkg, and NameCert rows.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{LawvereTheory}\uparrow}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim host quotient syntax, a selected term algebra, an external variety of algebras, Lean verification, or a standard bridge.

Upgrade path: Obligation closure requires checked carrier admission, product-preserving interpretation, finite equation-ledger replay, transport, provenance, and clone-facing nonescape for BEDC.Derived.LawvereTheoryUp.

Chapter 8659

A Concrete Naming Certificate for $\mathsf{LocatedCantorSet}^{\uparrow}$

Following Bishop and Bridges on located subsets of constructive metric spaces, the $\mathsf{LocatedCantorSet}^{\uparrow}$ packet records the middle-third Cantor set as a finite located-subset certificate over real-name windows rather than as a host closed subset of the line. It sits after the located-apartness boundary of chapter 6450, the dyadic tolerance core of chapter 291, the finite stream-window surface of chapter 126, the regular rational readback of chapter 301, the terminal real-name seal of chapter 38, and the compact-metric carrier of chapter 129. The chapter supplies a concrete L10 neighbour for located-real and compact-metric routes; it does not claim open-cover compactness, a selected ternary expansion, quotient real equality, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 8659.1 (Located Cantor set carrier)**.** *A* $\mathsf{LocatedCantorSet}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (X, S, R, D, A, I, B, M, H, C, P, N)$$

with the following displayed rows:

1. *X is the* $\mathsf{Real}^{\uparrow}$ *name whose Cantor-membership distance is being inspected.*
2. *S is the finite* $\mathsf{StreamName}^{\uparrow}$ *window row through which X is read.*
3. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the displayed rational approximants.*
4. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger containing the inspected dyadic scale and the interval-stage endpoints.*
5. *A is the* $\mathsf{LocatedRealApartness}^{\uparrow}$ *apartness row separating X from a displayed removed middle-third interval whenever such a separation is visible.*
6. *I is the finite interval-stage ledger: it lists the retained closed dyadic-rational cells and the removed gap cells at the inspected stage.*
7. *B is the bisection row saying that the next stage is obtained by splitting each retained cell and deleting its middle gap through displayed dyadic comparisons.*
8. *M is the* $\mathsf{CompactMetric}^{\uparrow}$ *consumer row, recording that finite retained cells are passed to compact-metric consumers only as a total-boundedness and Cauchy-window surface.*
9. *H records componentwise* hsame *transport for the real name, stream window, regular readback, dyadic ledger, apartness row, interval ledger, bisection row, compact-metric row, replay, provenance, and local naming.*

10. *C records displayed* Cont *replay from a located-subset request through* $X, S, R, D, A, I, B, M, H, P, N$.
11. *P is the* Pkg *provenance over* $\mathsf{LocatedCantorSet}^{\uparrow}$, $\mathsf{LocatedRealApartness}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
12. *N is the local* $\mathsf{NameCert}_{\mathsf{LocatedCantorSet}^{\uparrow}}$ *row.*

The carrier predicate compares accepted packets only through these rows. It has no coordinate for a selected ternary expansion, quotient stream equality, open-cover compactness, countable choice, host subset equality, or ambient real completeness.

Theorem 8659.2 (Located Cantor set NameCert obligations)**.** *For every accepted* $\mathsf{LocatedCantorSet}^{\uparrow}$ *carrier*

$$K = (X, S, R, D, A, I, B, M, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{LocatedCantorSet}^{\uparrow}}$ *surface consists exactly of real-name admission for X, finite stream-window admission for S, regular-rational readback for R, dyadic interval-stage exactness for D and I, located-apartness exposure for A, bisection-stage replay for B, compact-metric handoff for M, componentwise* hsame *transport through H, displayed* Cont *replay through C, sibling provenance through P, and local naming through N.*

No located Cantor-set obligation is stored outside these rows.

Proof. Project the carrier of Definition 8659.1. The inspected point is the real-name row X, and it is visible only through the finite stream window S and regular-rational readback R.

The dyadic ledger D and interval ledger I supply the finite stage being inspected. The located-apartness row A records separation from a removed gap when the window falls outside a retained cell, while the bisection row B records the next retained-cell refinement.

The compact-metric row M is downstream of these interval data. It receives only retained finite cells and Cauchy-window information, so it cannot turn the packet into open-cover compactness or a selected point theorem.

Finally H, C, P, N transport, replay, source, and name the same finite route. Since the carrier lists no other coordinate, the stated rows exhaust the local NameCert obligations. □

Theorem 8659.3 (Located Cantor set bisection route)**.** *Every accepted* $\mathsf{LocatedCantorSet}^{\uparrow}$ *bisection read factors through the finite route*

$$\mathsf{Real}^{\uparrow}, \mathsf{StreamName}^{\uparrow}, \mathsf{RegSeqRat}^{\uparrow}, \mathsf{DyadicRatCore}^{\uparrow}, \mathsf{LocatedRealApartness}^{\uparrow}, \mathsf{CompactMetric}^{\uparrow}, \mathsf{NameCert}_{\mathsf{LocatedCantorSet}^{\uparrow}}$$

At each displayed stage, the consumer first reads the real-name window, then the regular rational approximants, then the dyadic interval ledger, then the located-apartness row for the removed middle gap, and only then the retained-cell row offered to compact-metric consumers. The route exports no selected ternary expansion, quotient real equality, open-cover compactness, countable choice, selected limit, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Begin with the window-readback part of the carrier. The rows X, S, R expose a finite real-name observation, not a completed point of a host subset.

Read the dyadic ledger D and the interval ledger I. These rows display the current retained cells and removed gap cells at the inspected stage.

The located-apartness row A can only certify separation from one displayed removed gap, and the bisection row B can only refine the displayed retained cells. Thus the stage handoff remains a finite interval calculation.

The compact-metric row M consumes the retained-cell data after those rows have been displayed. The structural rows H, C, P, N preserve the same route, so the bisection read cannot export any of the refused ambient or choice-dependent objects. □

Closure status for $\mathsf{NameCert}_{\mathsf{LocatedCantorSet}^{\uparrow}}$.

Constructive story: A $\mathsf{LocatedCantorSet}^{\uparrow}$ packet is generated from a RealUp name row, a finite StreamName window, RegSeqRat readback, a DyadicRatCore interval-stage ledger, a LocatedRealApartness gap row, a retained-cell bisection row, a CompactMetric handoff row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{LocatedCantorSet}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8659.1, Definition 8659.2, and Definition 8659.3 seed the finite located Cantor-set packet over real-name windows, dyadic interval stages, located gap apartness, retained-cell bisection, and compact-metric handoff rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{LocatedCantorSet}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim open-cover compactness, selected ternary expansions, quotient real equality, countable choice, selected limits, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked real-name admission, finite-window admission, regular-rational readback, dyadic interval-stage exactness, located gap-apartness exposure, bisection replay, compact-metric handoff, transport, replay, provenance, and non-escape for BEDC.Derived.LocatedCantorSetUp.

Chapter 8660

A Concrete Naming Certificate for $\mathsf{LocatedIntervalLebesgueNumber}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{LocatedIntervalLebesgueNumber}^{\uparrow}$ packet records the located-interval Lebesgue-number handoff at the point where the $\mathsf{LocatedClosedIntervalFiniteNet}^{\uparrow}$ surface, finite interval nets, $\mathsf{DyadicRatCore}^{\uparrow}$ comparison budgets, $\mathsf{Real}^{\uparrow}$ endpoint seals, and $\mathsf{HeineBorelFiniteNet}^{\uparrow}$ finite-subcover radius ledgers are still visible. It sits after chapter 1808, chapter 5966, chapter 291, and chapter 3471, where the finite subcover radius ledger already appears in Definition 3471.8 and Definition 3471.9. The packet gives L10 compact-uniform and finite-subcover consumers a located Lebesgue-number handoff without claiming arbitrary open-cover compactness, selected subcovers, countable choice, quotient interval equality, host real equality, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Definition 8660.1 (Located interval Lebesgue-number carrier)**.** *A* $\mathsf{LocatedIntervalLebesgueNumber}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (I, F, L, D, E, H, C, P, N)$$

with the following displayed rows:

1. *I is the located interval row. It exposes the located endpoints and interval-order data used by the cover request.*
2. *F is the finite cover row. It records the displayed finite interval net and cover witnesses attached to the located interval.*
3. *L is the positive Lebesgue radius row. It gives the radius ledger that makes the displayed finite cover effective.*
4. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *comparison ledger. It records dyadic slack, mesh refinement, and endpoint comparison budgets for the cover route.*
5. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row. It is read only after the located interval, finite cover, positive radius, and dyadic comparison rows have been displayed.*
6. *H records componentwise* hsame *transport for the located interval, finite cover, positive radius, dyadic ledger, Real seal, replay, provenance, and local naming rows.*
7. *C records displayed* Cont *replay from the finite cover request through I, F, L, D, E, H, P, N.*

8. *P is the* Pkg *provenance over* $\mathsf{LocatedIntervalLebesgueNumber}^{\uparrow}$, $\mathsf{LocatedClosedIntervalFiniteNet}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
9. *N is the local* $\mathsf{NameCert}_{\mathsf{LocatedIntervalLebesgueNumber}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $I, F, L, D, E, H, C, P, N$. It has no coordinate for arbitrary open-cover compactness, a selected subcover, countable choice, quotient interval equality, host real equality, ambient $\mathsf{Real}^{\uparrow}$ *completeness, Lean verification, or bridge checking.*

Theorem 8660.2 (Located interval Lebesgue-number NameCert obligations)**.** *For every accepted* $\mathsf{LocatedIntervalLebesgueNumber}^{\uparrow}$ *carrier $L = (I, F, L, D, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{LocatedIntervalLebesgueNumbe}}$ *surface consists exactly of carrier admission, interval exposure, radius compatibility, finite-net transfer, and nonescape:*

1. *carrier admission for the located interval row, finite cover row, positive Lebesgue radius row, dyadic comparison ledger, Real seal, transport, replay, provenance, and local naming rows;*
2. *interval exposure, requiring the cover request to display I and F before any cover witness is read;*
3. *radius compatibility, requiring the positive radius row L and the dyadic comparison row D to control mesh width, endpoint containment, and finite cover slack;*
4. *finite-net transfer, requiring every finite-cover read to pass through the route $I \longmapsto F \longmapsto L \longmapsto D \longmapsto E$ before any uniform-modulus or subcover route is visible;*
5. *nonescape, requiring H, C, P, N to transport, replay, source, and name only the displayed packet.*

The obligation surface may cite chapter 1808, chapter 5966, chapter 291, and chapter 3471; it does not add arbitrary open-cover compactness, selected subcovers, countable choice, quotient interval equality, host real equality, or bridge checking.

Proof. Project the carrier of Definition 8660.1. The visible rows are exactly the located interval, finite cover, positive radius, dyadic comparison, Real seal, transport, replay, provenance, and local naming rows.

The interval exposure is immediate. A finite cover consumer must read I and F before any witness is inspected, so the located interval and the displayed finite interval net are already public before a radius is used.

The radius compatibility is then forced through L and D. The positive Lebesgue radius row and the dyadic comparison ledger control the mesh width, endpoint containment, and finite-cover slack before the terminal seal is opened.

Finally the finite-net transfer and nonescape are carried by the same packet. The route goes through $I \longmapsto F \longmapsto L \longmapsto D \longmapsto E$ and then through H, C, P, N, so the chapter cannot export arbitrary compactness, selected subcovers, countable choice, quotient interval equality, host real equality, ambient completeness, or bridge checking. □

Theorem 8660.3 (Located interval Lebesgue-number finite-cover handoff)**.** *Every finite-cover consumer of an accepted* $\mathsf{LocatedIntervalLebesgueNumber}^{\uparrow}$ *packet reads through the route*

$$I \longmapsto F \longmapsto L \longmapsto D \longmapsto E \longmapsto H, C, P, N.$$

The handoff is the located-interval, finite-cover, positive-radius, DyadicRatCore, and RealUp route that later feeds compact-uniform-modulus and finite-subcover consumers, but it does not export a selected subcover, arbitrary open-cover compactness, quotient interval equality, countable choice, host real equality, ambient $\mathsf{Real}^{\uparrow}$ *completeness, Lean verification, or bridge checking.*

Proof. Project the accepted carrier of Definition 8660.1. The consumer first sees the located interval row I and the finite cover row F, so the read is already confined to the displayed interval data.

Apply Definition 8660.2. It forces the positive radius row L and dyadic comparison row D to mediate every cover witness before the Real seal E can be consumed.

Finally replay the structural rows. The transport, replay, provenance, and local naming rows preserve the same finite route, so every finite-cover consumer factors through the displayed handoff before any uniform-modulus or subcover route can be used. □

Closure status for $\mathsf{NameCert}_{\mathsf{LocatedIntervalLebesgueNumber}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{LocatedIntervalLebesgueNumber}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8660.1, Definition 8660.2, and Definition 8660.3 seed the located-interval Lebesgue-number route for finite-cover consumers over located intervals, positive radii, dyadic comparison budgets, and Real seals.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{LocatedIntervalLebesgueNumber}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close arbitrary open-cover compactness, selected subcovers, countable choice, quotient interval equality, host real equality, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, interval exposure, radius compatibility, finite-net transfer, nonescape, transport, replay, provenance, and local naming for BEDC.Derived.LocatedIntervalLebesgueNumberUp.

Constructive story: A $\mathsf{LocatedIntervalLebesgueNumber}^{\uparrow}$ packet is generated from a located interval row, a finite cover row, a positive Lebesgue radius row, a DyadicRatCore comparison ledger, a RealUp seal, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Chapter 8661

A Concrete Naming Certificate for $\mathsf{Sobrification}^{\uparrow}$

Following Johnstone and Gierz–Hofmann–Keimel–Lawson–Mislove–Scott, the $\mathsf{Sobrification}^{\uparrow}$ packet records the sober-point completion of a topological carrier as finite NameCert data. It consumes the topology carrier of chapter 88, the Sierpinski classifier surface of chapter 1860, the order-facing route of chapter 5950, the localic point boundary of chapter 5153, and the compact-open comparison surface of chapter 7424. The chapter names sober completion without importing host point-set topology, choice of generic points, or a spectral-space representation theorem.

Definition 8661.1 (Sobrification carrier)**.** *A* $\mathsf{Sobrification}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Q = (T, I, \Sigma, \preceq, G, H, C, P, N)$$

with the following displayed rows:

1. *T is the source* $\mathsf{Topology}^{\uparrow}$ *carrier row whose closed and open predicates are read only through the accepted topology packet.*
2. *I is the irreducible-closed predicate row, recording nonempty closedness and the finite meet-test boundary for irreducibility.*
3. *Σ is the* $\mathsf{SierpinskiSpace}^{\uparrow}$ *classifier row that reads opens as characteristic maps into the Sierpinski carrier.*
4. *$\preceq$ is the specialization preorder row induced by the topology surface.*
5. *G is the generic-point witness row for irreducible closed data, stored as local witness data rather than as a global point-selection principle.*
6. *H records componentwise* hsame *transport for the topology, irreducibility, classifier, specialization, witness, provenance, and local naming rows.*
7. *C records displayed* Cont *routes from topology opens through Sierpinski classifiers and specialization reads to the generic-point row.*
8. *P is the* Pkg *provenance over* $\mathsf{Sobrification}^{\uparrow}$, $\mathsf{Topology}^{\uparrow}$, $\mathsf{SierpinskiSpace}^{\uparrow}$, $\mathsf{ScottTopology}^{\uparrow}$, $\mathsf{LocaleSpace}^{\uparrow}$, $\mathsf{StoneSpace}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
9. *N is the local* $\mathsf{NameCert}_{\mathsf{Sobrification}^{\uparrow}}$ *row.*

The packet has no coordinate for choice of all generic points, ambient spectral-space duality, quotient point creation, classical prime-filter selection, or host topological reflection.

Theorem 8661.2 (Sobrification NameCert obligations)**.** *For the carrier of Definition 8661.1, the local* $\mathsf{NameCert}_{\mathsf{Sobrification}^{\uparrow}}$ *surface consists exactly of carrier admission for*

$$Q = (T, I, \Sigma, \preceq, G, H, C, P, N),$$

irreducible-closed exposure through I*, Sierpinski classifier exposure through* Σ*, specialization-order exposure through* $\preceq$*, generic-point witness locality through* G*, componentwise* hsame *stability through* H*, displayed* Cont *routing through* C*,* Pkg *provenance through* P*, and local naming through* N*.*

Proof. Carrier admission is projection from Definition 8661.1. The topology row T is the only source of open and closed data, so every irreducibility read must pass through the displayed topology carrier.

The classifier row Σ supplies the Sierpinski-facing open classifier, and the specialization row $\preceq$ records the induced preorder. The witness row G is local to the displayed irreducible closed row I and does not select generic points globally.

Finally H, C, P, N transport, route, source, and name the same finite packet. Since the carrier contains no further coordinate, the listed rows exhaust the NameCert obligations. □

Theorem 8661.3 (Sobrification specialization sober-point surface)**.** *Every accepted* $\mathsf{Sobrification}^{\uparrow}$ *read that exposes a sober point factors through the specialization preorder row* $\preceq$*, the Sierpinski classifier row* Σ*, and the generic-point witness row* G *of*

$$Q = (T, I, \Sigma, \preceq, G, H, C, P, N).$$

It cannot replace those rows by a host sober-reflection theorem, a chosen generic-point function on all irreducible closed sets, or a spectral-space representation claim.

Proof. Start with the carrier of Definition 8661.1. A sober-point read has access to topology data only through T, to irreducible closed data only through I, and to open classifiers only through Σ.

The specialization preorder $\preceq$ is then the displayed order surface connecting topology opens to point comparison. The witness row G is read through that same finite route, so it supplies only the local generic point named by the packet.

Apply Definition 8661.2. Transport, continuation replay, provenance, and local naming remain inside H, C, P, N, and the excluded global principles have no carrier coordinate. □

Closure status for $\mathsf{NameCert}_{\mathsf{Sobrification}^{\uparrow}}$**.**

Constructive story: A $\mathsf{Sobrification}^{\uparrow}$ packet is generated from topology, irreducible-closed, Sierpinski classifier, specialization preorder, generic-point witness, transport, route, provenance, and local naming rows.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{Sobrification}^{\uparrow}}$, obligation)

Scope closed: Definition 8661.1, Definition 8661.2, and Definition 8661.3 bind the sober-point surface to topology, irreducible-closed, Sierpinski classifier, specialization, witness, transport, route, provenance, and local NameCert rows.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{Sobrification}^{\uparrow}}$, formalTarget)

Bridge status: none

Not claimed: This chapter does not close a checked Lean carrier, global choice of generic points, ambient spectral duality, or bridge checking.

Upgrade path: Formal closure requires a Lean carrier and NameCert obligation theorem for the displayed sobrification packet.

Chapter 8662

A Concrete Naming Certificate for $\mathsf{HardCertificateLayer}^{\uparrow}$

The $\mathsf{HardCertificateLayer}^{\uparrow}$ packet realizes the verification layer of section 9462.5 as finite NameCert data. It records backend-relative proof-object acceptance, trust-boundary exposure, classifier preservation, verification-ledger routing, and local naming without turning a checked theorem into a new classifier. The packet sits beside chapter 526, chapter 546, chapter 630, and chapter 1157 as a certificate-hardening surface rather than as an audit gate, kernel witness, negative boundary, or host-primitive leak detector.

Definition 8662.1 (HardCertificateLayer carrier)**.** *A* $\mathsf{HardCertificateLayer}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Q = (B, \Phi, \Pi, T, C, L, H, R, P, N)$$

with the following displayed rows:

1. *B is the verification backend row, naming the formal language, checker, proof-object format, accepted dependencies, and trust boundary.*
2. *Φ is the formal statement row translated from an already displayed certificate row.*
3. *Π is the proof-object row accepted by B for Φ.*
4. *T is the trust-boundary row, recording checked components, trusted components, unchecked components, and portability limits.*
5. *C is the classifier-preservation row, requiring the source classifier to remain unchanged by the hardening read.*
6. *L is the verification-ledger row that records assumptions, dependencies, proof artifact, backend, uncovered certificate fields, and not-claimed endpoints.*
7. *H records componentwise* hsame *transport for backend, statement, proof object, trust boundary, classifier, ledger, provenance, and local naming rows.*
8. *R records displayed* Cont *replay from the certificate row being hardened through backend acceptance and back to the unchanged classifier.*
9. *P is the* Pkg *provenance over* $\mathsf{HardCertificateLayer}^{\uparrow}$*, the source NameCert row, the verification backend, proof object, trust boundary, classifier-preservation row, ledger row,* BHist*,* hsame*,* Cont*, and* $\mathsf{NameCert}$*.*

10. N is the local $\mathsf{NameCert}_{\mathsf{HardCertificateLayer}^{\uparrow}}$ *row.*
The packet has no coordinate for classifier creation, backend-independent truth, transfer across proof assistants, replacement of a source NameCert, or discovery credit from verification alone.

Theorem 8662.2 (HardCertificateLayer NameCert obligations)**.** *For the carrier of Definition 8662.1, the local* $\mathsf{NameCert}_{\mathsf{HardCertificateLayer}^{\uparrow}}$ *surface consists exactly of carrier admission for*

$$Q = (B, \Phi, \Pi, T, C, L, H, R, P, N),$$

backend-relative proof acceptance through B, Φ, Π*, trust-boundary exposure through* T*, classifier preservation through* C*, verification-ledger routing through* L*, componentwise* hsame *stability through* H*, displayed* Cont *replay through* R*,* Pkg *provenance through* P*, and local naming through* N*.*

Proof. Carrier admission is projection from Definition 8662.1. The backend, statement, and proof-object rows are the only hard-certificate evidence rows, so every verification read passes through B, Φ, Π.

The trust-boundary row T and ledger row L record what the proof object does and does not cover. The classifier-preservation row C binds the hardening read to the same classifier surface that existed before the backend accepted the proof object.

Finally H, R, P, N transport, replay, source, and name the same finite packet. Since the carrier omits classifier creation, backend-independent truth, proof-assistant transfer, source-NameCert replacement, and discovery credit, none of those endpoints is a local NameCert obligation. □

Theorem 8662.3 (HardCertificateLayer classifier preservation)**.** *Every accepted* $\mathsf{HardCertificateLayer}^{\uparrow}$ *transition preserves the classifier row it hardens. If a verification-only transition changes the classifier row, then it is not a* $\mathsf{HardCertificateLayer}^{\uparrow}$ *transition.*

Proof. Read the carrier of Definition 8662.1. The classifier row C is preservation data, not an output slot for a new classifier.

Apply Definition 8662.2. Backend acceptance through B, Φ, Π and trust-boundary exposure through T, L harden a displayed certificate row while C keeps the classifier surface fixed.

Thus any transition that changes the classifier leaves the displayed carrier and cannot be cited as a $\mathsf{HardCertificateLayer}^{\uparrow}$ read. □

Falsifiable prediction: If a verification-only transition changes the classifier row, then it is not a $\mathsf{HardCertificateLayer}^{\uparrow}$ transition.

Independence witness: auditgateboundary, kernelauditwitness, negativecertificateboundary, hostprimitiveleakage: none is bijective because $\mathsf{HardCertificateLayer}^{\uparrow}$ stores backend-relative proof-object acceptance, trust-boundary exposure, classifier preservation, verification-ledger routing, transport, replay, provenance, and local NameCert rows in one carrier. AuditGateBoundaryUp records gate admission rather than proof-object acceptance; KernelAuditWitnessUp records kernel witness data rather than classifier-preserving hardening; NegativeCertificateBoundaryUp records negative evidence boundaries rather than backend-relative proof artifacts; HostPrimitiveLeakageUp records primitive leakage rather than the ledgered preservation of a source classifier.

The Lean follow-up should provide Nontrivial $\mathsf{HardCertificateLayer}^{\uparrow}$ and FieldFaithful $\mathsf{HardCertificateLayer}^{\uparrow}$ instances in `lean4/BEDC/Derived/HardCertificateLayerUp/TasteGate.lean`.

Closure status for $\mathsf{NameCert}_{\mathsf{HardCertificateLayer}^{\uparrow}}$**.**

Constructive story: A $\mathsf{HardCertificateLayer}^{\uparrow}$ packet is generated from backend, statement, proof-object, trust-boundary, classifier-preservation, verification-ledger, transport, replay, provenance, and local naming rows.

Theory closure: TheoryGate(NameCert$_{\mathsf{HardCertificateLayer}\uparrow}$, obligation)

Scope closed: Definition 8662.1, Definition 8662.2, and Definition 8662.3 bind hard-certificate reads to backend-relative proof objects, trust boundaries, classifier preservation, verification ledger rows, transport, replay, provenance, and local NameCert rows.

Formal verification: FormalStatus(NameCert$_{\mathsf{HardCertificateLayer}\uparrow}$, formalTarget)

Bridge status: none

Not claimed: This chapter does not close Lean instances, backend-independent truth, classifier creation, source-NameCert replacement, proof-assistant transfer, or bridge checking.

Upgrade path: Formal closure requires the Lean carrier, Nontrivial and FieldFaithful instances, and a checked NameCert obligation theorem for the displayed hard-certificate-layer packet.

Chapter 8663

A Concrete Naming Certificate for $\mathsf{RealCompletionDiagonalRouter}^{\uparrow}$

Following Bishop and Bridges, *Constructive Analysis*, the $\mathsf{RealCompletionDiagonalRouter}^{\uparrow}$ packet records the finite diagonal handoff used by the Real and Completion route of chapter 9238. It sits after the dyadic tolerance ledger of chapter 291, the stream-window carrier of chapter 126, the regular-rational readback surface of chapter 301, the terminal real-name seal of chapter 38, and the minimal completion service boundary of chapter 1606. Its role is to route one finite precision window through those rows before a completion-facing consumer reads the $\mathsf{Real}^{\uparrow}$ seal; it is not a quotient-stream construction, selected limit, countable-choice schedule, host real equality, or ambient completeness theorem.

Definition 8663.1 (RealCompletionDiagonalRouter carrier)**.** *A* $\mathsf{RealCompletionDiagonalRouter}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Q = (W, D, R, E, M, H, C, P, N)$$

with the following visible rows:

1. W *is the* $\mathsf{StreamName}^{\uparrow}$ *finite precision-window row requested by the diagonal consumer.*
2. D *is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *dyadic tolerance and readback row for the same window.*
3. R *is the* $\mathsf{RegSeqRat}^{\uparrow}$ *regular-rational handoff row built from the stream window and dyadic readback.*
4. E *is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached by that regular-rational handoff.*
5. M *is the* $\mathsf{CauchyCompletionMinimality}^{\uparrow}$ *service row that records dense-image coverage, universal factorization, separated comparison, and replay non-escape for the completion-facing read.*
6. H *records componentwise* hsame *transport for the window, dyadic, regular-rational, Real seal, minimality, replay, provenance, and local naming rows.*
7. C *records the displayed* Cont *replay through* W, D, R, E, M, H, P, N *in the order in which a diagonal consumer may read the packet.*
8. P *is the* Pkg *provenance over* $\mathsf{RealCompletionDiagonalRouter}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{CauchyCompletionMinimality}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$ *rows.*
9. N *is the local* $\mathsf{NameCert}_{\mathsf{RealCompletionDiagonalRouter}^{\uparrow}}$ *row.*

The carrier has no coordinate for quotient streams, selected diagonal limits, host real equality, countable choice, open-cover compactness, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 8663.2 (RealCompletionDiagonalRouter NameCert obligations)**.** *For every accepted* $\mathsf{RealCompletionDiagonalRouter}^{\uparrow}$ *carrier* $Q = (W, D, R, E, M, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{RealCompletionDiagonalRoute}}$ *surface consists exactly of carrier admission for the finite StreamName window, dyadic readback, RegSeqRat handoff, Real seal, CauchyCompletionMinimality route, componentwise transport, displayed replay, provenance, and local naming rows.*

Every completion-facing diagonal read must expose the route

$$W \longmapsto D \longmapsto R \longmapsto E \longmapsto M \longmapsto H \longmapsto C \longmapsto P \longmapsto N$$

before it can present the Real seal as a finite completion handoff. The obligation surface exports no quotient stream, selected limit, host equality, countable-choice schedule, open-cover compactness, or ambient $\mathsf{Real}^{\uparrow}$ *completeness coordinate.*

Proof. Carrier admission is projection from Definition 8663.1. The tuple displays exactly the finite window, dyadic readback, regular-rational handoff, terminal Real seal, minimal completion service, transport, replay, provenance, and local naming rows.

The diagonal route is forced by the order of the displayed carrier. A consumer first reads the StreamName window W, then the DyadicRatCore tolerance row D, then the RegSeqRat handoff R, and only then reaches the Real seal E.

The completion-facing part is controlled by M. By Definition 1606.13, the minimality row exports dense-image coverage, universal factorization, separated reflection, replay non-escape, and finite-row induction without quotient completion, selected limits, host equality, choice, compactness, or ambient real-completeness data.

Finally H, C, P, N transport, replay, source, and name the same finite packet. Since none of the carrier rows contains an off-route completion principle, the local NameCert obligations are exhausted by the stated finite diagonal handoff. □

Theorem 8663.3 (RealCompletionDiagonalRouter precision-window route)**.** *Every accepted* $\mathsf{RealCompletionDiago}$ *packet routes a finite precision-window request from* $\mathsf{StreamName}^{\uparrow}$ *through* $\mathsf{DyadicRatCore}^{\uparrow}$ *readback and* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff to the* $\mathsf{Real}^{\uparrow}$ *seal before the* $\mathsf{CauchyCompletionMinimality}^{\uparrow}$ *service row can be consumed. The route is finite, componentwise transported by* H*, replayed by* C*, sourced by* P*, and named by* N*.*

The packet does not identify Real names by quotient streams, choose a diagonal limit representative, assert host real equality, call on countable choice, or close ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start with the NameCert obligations of Definition 8663.2. They require any diagonal read to pass through $W, D, R, E, M, H, C, P, N$ in the displayed order.

The StreamName, DyadicRatCore, and RegSeqRat rows provide only a finite precision-window route. The Real seal row is therefore reached as a named finite handoff rather than as a selected representative of a quotient stream.

Apply Definition 1606.13 to the minimality row. It keeps the completion-facing consumer inside dense-image, universal-factorization, separated-reflection, replay, and finite-row obligations, so the packet cannot import host equality, choice, compactness, or ambient completeness after the Real seal is read. □

Closure status for $\mathsf{NameCert}_{\mathsf{RealCompletionDiagonalRouter}^{\uparrow}}$ **.**

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RealCompletionDiagonalRouter}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8663.1, Definition 8663.2, and Definition 8663.3 seed the finite precision-window route from StreamName and RegSeqRat data through DyadicRatCore readback to the RealUp seal.

Formal verification: FormalStatus(NameCert$_{\mathsf{RealCompletionDiagonalRouter}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close quotient stream equality, selected diagonal limits, host real equality, countable choice, open-cover compactness, or ambient Real$^{\uparrow}$ completeness.

Upgrade path: Obligation closure requires checked carrier admission, precision-window readback, RegSeqRat handoff, Real seal non-escape, CauchyCompletionMinimality consumption, transport, replay, provenance, and local naming for BEDC.Derived.RealCompletionDiagonalRouterUp.

Constructive story: A RealCompletionDiagonalRouter$^{\uparrow}$ packet is generated from a StreamName finite window, DyadicRatCore tolerance readback, RegSeqRat handoff, RealUp seal, CauchyCompletionMinimality route, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 8664

A Concrete Naming Certificate for $\mathsf{CompactUniformDiagonalModulus}^{\uparrow}$

Following the Heine–Cantor compactness-to-uniform-continuity route in chapter 9237, the CompactUniformDiagonal packet records the finite diagonal-modulus surface obtained from compact nets, pointwise moduli, rational lower-bound folds, and metric replay. It sits over the compact source of chapter 60, the continuous pointwise-modulus rows of chapter 59, the metric distance carrier of chapter 57, the rational lower-bound fold of chapter 37, and the downstream $\mathsf{UniformModulus}^{\uparrow}$ handoff of chapter 369. The packet exposes a tolerance-only modulus as displayed BEDC data, not as an external function selector.

Definition 8664.1 (CompactUniformDiagonalModulus carrier)**.** *A* $\mathsf{CompactUniformDiagonalModulus}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$D = (K, F, \mathcal{P}, M, R, B, U, H, C, N)$$

with the following displayed rows:

1. *K is the* $\mathsf{Compact}^{\uparrow}$ *source row carrying the finite net or finite-cover witness.*
2. *F is the* $\mathsf{Continuous}^{\uparrow}$ *pointwise-modulus row for the displayed source and target metric carriers.*
3. *$\mathcal{P}$ is the finite* ProbeBundle *spine over which the compact net is read.*
4. *M records the local modulus rows attached to the probes in $\mathcal{P}$.*
5. *R records the positive* $\mathsf{Rat}^{\uparrow}$ *lower-bound candidates read from the local radius rows.*
6. *B is the diagonal lower-bound ledger certifying one rational precision below all displayed candidates.*
7. *U is the* $\mathsf{UniformModulus}^{\uparrow}$ *handoff row exposed from the tolerance history and the diagonal ledger.*
8. *H records componentwise* hsame *transport for the compact source, pointwise rows, bundle, candidates, diagonal ledger, handoff, replay, provenance, and local naming rows.*
9. *C records displayed* Cont *replay of the finite diagonal route.*
10. *N is the local* $\mathsf{NameCert}_{\mathsf{CompactUniformDiagonalModulus}^{\uparrow}}$ *row, with* Pkg *provenance over* CompactUniformDiagonalModu $\mathsf{Compact}^{\uparrow}$, $\mathsf{Continuous}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{Rat}^{\uparrow}$, $\mathsf{UniformModulus}^{\uparrow}$, ProbeBundle, BHist, hsame, Cont, *and* NameCert.

The carrier has no coordinate for an open-cover choice function, a host minimum over a finite set, a selected point outside the bundle, quotient point equality, an external modulus function, or ambient completeness of $\mathsf{Real}^{\uparrow}$.

Theorem 8664.2 (CompactUniformDiagonalModulus NameCert obligations)**.** *For every accepted* $\mathsf{CompactUniformDiagonalModulus}^{\uparrow}$ *carrier*

$$D = (K, F, \mathcal{P}, M, R, B, U, H, C, N),$$

the local $\mathsf{NameCert}_{\mathsf{CompactUniformDiagonalModulus}^{\uparrow}}$ *surface consists exactly of compact source exposure, pointwise-modulus admission, finite* $\mathsf{ProbeBundle}$ *spine admission, local-radius row exposure, positive* $\mathsf{Rat}^{\uparrow}$ *candidate admission, diagonal lower-bound certification,* $\mathsf{UniformModulus}^{\uparrow}$ *handoff, componentwise transport, displayed replay, and local naming with provenance. Every uniform-modulus read factors through the finite route*

$$\mathsf{Compact}^{\uparrow}, \quad \mathsf{Continuous}^{\uparrow}, \quad \mathsf{Met}^{\uparrow}, \quad \mathsf{Rat}^{\uparrow}, \quad \mathsf{UniformModulus}^{\uparrow}.$$

Proof. Project the carrier in Definition 8664.1. The compact source, continuous pointwise rows, finite bundle, local modulus rows, rational candidates, lower-bound ledger, and uniform-modulus handoff are displayed coordinates.

The finite diagonal route first reads the compact net $\mathcal{P}$, then reads the local modulus rows M at each bundled probe. The positive rational candidates R provide the finite input to the lower-bound ledger B.

The handoff U is exposed only after the lower-bound ledger has been transported and replayed by H and C. Since the carrier contains no open-cover choice, host minimum, off-bundle point selector, quotient point equality, external modulus function, or completeness row, the listed obligations exhaust the certificate surface. □

Theorem 8664.3 (CompactUniformDiagonalModulus uniform handoff)**.** *An accepted* CompactUniformDiagonalMo *packet exposes a* $\mathsf{UniformModulus}^{\uparrow}$ *precision row only after the compact source* K*, pointwise-modulus row* F*, finite bundle* $\mathcal{P}$*, local modulus rows* M*, rational candidates* R*, and diagonal lower-bound ledger* B *have been displayed. Thus the compact-uniform route is a finite diagonal-modulus packet and not a host Heine–Cantor theorem, open-cover selector, quotient equality principle, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness claim.*

Proof. Begin with an accepted carrier $D = (K, F, \mathcal{P}, M, R, B, U, H, C, N)$. Projection gives the compact and pointwise-continuity source rows before any uniform handoff is visible.

The finite bundle $\mathcal{P}$ is the only index surface for the diagonal route. Reading M and R over that bundle supplies the local radii and positive rational candidates inspected by the lower-bound ledger.

The row B certifies one displayed precision below the candidates, and U exposes that precision as a tolerance-only $\mathsf{UniformModulus}^{\uparrow}$ row. Transport, replay, provenance, and local naming keep the read inside the displayed packet, so none of the excluded host or completeness objects can be exported. □

Closure status for $\mathsf{NameCert}_{\mathsf{CompactUniformDiagonalModulus}^{\uparrow}}$.

Constructive story: A $\mathsf{CompactUniformDiagonalModulus}^{\uparrow}$ packet is generated from a CompactUp finite-net source, a ContinuousUp pointwise-modulus row, a finite ProbeBundle spine, local modulus rows, positive RatUp candidates, a diagonal lower-bound ledger, a UniformModulusUp handoff, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{CompactUniformDiagonalModulus}^{\uparrow}}$, seed)

Scope closed: Definition 8664.1, Definition 8664.2, and Definition 8664.3 seed the finite compact-net diagonal modulus packet used by compact-uniform-continuity consumers.

Formal verification: FormalStatus(NameCert$_{\mathsf{CompactUniformDiagonalModulus}\uparrow}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim open-cover choice, host finite minima, off-bundle point selection, quotient point equality, external modulus functions, ambient completeness of Real$^{\uparrow}$, Lean verification, or a public standard bridge.

Upgrade path: Obligation closure requires checked compact-source admission, pointwise-modulus admission, finite bundle coverage, rational lower-bound stability, uniform-modulus handoff, and non-escape for BEDC.Derived.CompactUniformDiagonalModulu

Chapter 8665

A Concrete Naming Certificate for $\mathsf{RegularCauchySubsequenceEquivalence}^{\uparrow}$

Following Bishop and Bridges, *Constructive Analysis*, the $\mathsf{RegularCauchySubsequenceEquivalence}^{\uparrow}$ packet records cofinal-subsequence invariance for regular Cauchy rational names as finite BEDC data. It sits over the regular rational readback of chapter 301, the finite schedule surface of chapter 126, the cofinal subsequence handoff of chapter 381, and the terminal real-name seal of chapter 38. The packet compares the source name and the cofinal subsequence only through displayed windows, tolerance rows, and replay data before any Real-facing consumer reads the invariant boundary.

Definition 8665.1 (RegularCauchySubsequenceEquivalence carrier)**.** *A* $\mathsf{RegularCauchySubsequenceEquivalence}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$E = (R, S, T, W, D, L, H, C, P, N)$$

with the following displayed rows:

1. *R is the source* $\mathsf{RegSeqRat}^{\uparrow}$ *row, carrying the original regular Cauchy rational name.*
2. *S is the cofinal subsequence schedule row, carrying the monotone index route read by* $\mathsf{StreamName}^{\uparrow}$*.*
3. *T is the transported subsequence* $\mathsf{RegSeqRat}^{\uparrow}$ *row obtained by replay along S.*
4. *W records the finite source and subsequence windows compared by the packet.*
5. *D is the dyadic tolerance ledger used to compare windows at a requested precision.*
6. *L is the Real-facing invariant handoff row exposed after R, S, T, W, D have been displayed.*
7. *H records componentwise* hsame *transport for all displayed rows.*
8. *C records displayed* Cont *replay of the same finite route.*
9. *P records the* Pkg *provenance over* $\mathsf{RegularCauchySubsequenceEquivalence}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{RegularCauchySubsequenceEquivalence}^{\uparrow}}$ *row.*

The classifier compares accepted packets only by $R, S, T, W, D, L, H, C, P, N$. It has no coordinate for quotient representatives, host stream equality, host real equality, countable choice, or ambient completeness of $\mathsf{Real}^{\uparrow}$*.*

Theorem 8665.2 (RegularCauchySubsequenceEquivalence NameCert obligations)**.** *For every accepted* $\mathsf{RegularCauchySubsequenceEquivalence}^{\uparrow}$ *carrier*

$$E = (R, S, T, W, D, L, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{RegularCauchySubsequenceEquivalence}^{\uparrow}}$ *surface consists of five finite obligations:*

1. *source and subsequence admission, requiring the displayed* $\mathsf{RegSeqRat}^{\uparrow}$ *rows* R *and* T *and the cofinal schedule* S*;*
2. *window comparability, requiring* W *to display the finite source and subsequence windows consumed by the comparison;*
3. *tolerance stability, requiring the dyadic ledger* D *to witness the same requested precision for both windows;*
4. *invariant handoff, requiring* L *to be exposed only after the source, schedule, subsequence, window, and tolerance rows are visible;*
5. *non-escape, requiring* H, C, P, N *to transport, replay, source, and name only the displayed packet without quotient representatives, host equality, countable choice, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the carrier in Definition 8665.1. The source name, cofinal schedule, transported subsequence name, windows, and dyadic tolerance ledger are all displayed coordinates.

The usual constructive subsequence argument is read through those coordinates. Cofinality lets each requested source precision be met by a later subsequence window, and regularity of R supplies the dyadic comparison recorded in D.

The handoff row L is therefore a finite invariant boundary, not a quotient representative. Transport, replay, provenance, and local naming preserve only this route, so the five obligations exhaust the certificate surface. □

Theorem 8665.3 (RegularCauchySubsequenceEquivalence cofinal tail stability)**.** *Let* $E = (R, S, T, W, D, L, H, C,$ *be an accepted* $\mathsf{RegularCauchySubsequenceEquivalence}^{\uparrow}$ *carrier. Every Real-facing consumer read of the cofinal subsequence invariant factors through the finite route*

$$R, S, T, W, D, L, H, C, P, N.$$

Thus discarding a finite prefix and replaying along a monotone cofinal schedule preserves the displayed regular Cauchy name boundary, while exporting no quotient representatives, host equality, countable-choice schedule, or ambient $\mathsf{Real}^{\uparrow}$ *completeness principle.*

Proof. Start with the accepted carrier. Projection gives the source regular name R, the cofinal schedule S, the subsequence readback T, the comparison windows W, and the tolerance ledger D.

For any requested tail precision, cofinality of S places a selected subsequence window beyond the source tail bound. Regularity of R then compares the source window and the replayed subsequence window through the same dyadic tolerance row.

The rows L, H, C, P, N only expose, transport, replay, source, and name that finite comparison. Since the classifier has no coordinate for quotient representatives, host equality, countable choice, or ambient completeness, every consumer read remains on the displayed route. □

Closure status for $\mathsf{NameCert}_{\mathsf{RegularCauchySubsequenceEquivalence}^{\uparrow}}$**.**

Constructive story: A $\mathsf{RegularCauchySubsequenceEquivalence}^{\uparrow}$ packet is generated from a RegSeqRat source row, a cofinal subsequence schedule, a transported RegSeqRat row, finite StreamName windows, a DyadicRatCore tolerance

ledger, a Real-facing invariant handoff, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\mathsf{RegularCauchySubsequenceEquivalence}^{\uparrow}}$, seed)

Scope closed: Definition 8665.1, Definition 8665.2, and Definition 8665.3 seed the finite cofinal-subsequence invariance packet for regular Cauchy rational names.

Formal verification: FormalStatus(NameCert$_{\mathsf{RegularCauchySubsequenceEquivalence}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close quotient representatives, host stream equality, host real equality, countable choice, ambient completeness of Real$^{\uparrow}$, Lean verification, or a public standard bridge.

Upgrade path: Obligation closure requires checked carrier admission, cofinal schedule admission, window comparability, dyadic tolerance stability, invariant handoff, and non-escape for BEDC.Derived.RegularCauchySubsequenceEquivalenceUp.

Chapter 8666

A Concrete Naming Certificate for BishopFilteredRegularCompletion$^{\uparrow}$

Following Bishop and Bridges on regular Cauchy real names and filter-base completion, the BishopFilteredRegularCompletion$^{\uparrow}$ packet binds the regular Cauchy completion route to a displayed filter-base completion route through one finite window-induction carrier. It sits after the regular Cauchy completion surface of chapter 1639, the located filter-base packet of chapter 6434, the Cauchy filter-base surface of chapter 1915, the finite stream-name route of chapter 126, the regular rational readback of chapter 301, the dyadic tolerance core of chapter 291, and the terminal real-name seal of chapter 38. The packet records a finite handoff between regular Cauchy and filter-base completion readings; it does not assert quotient equality of filters or streams, select a limit, invoke countable choice, or claim ambient completeness of Real$^{\uparrow}$.

Definition 8666.1 (Bishop filtered regular completion carrier)**.** *A* BishopFilteredRegularCompletion$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$F = (B, R, W, D, A, H, C, P, N)$$

with the following displayed rows:

1. *B is the filter-base row, exposing the directed base element and the located refinement relation consumed from* BishopLocatedFilterBase$^{\uparrow}$ *and* CauchyFilterBase$^{\uparrow}$*.*
2. *R is the regular Cauchy readback row, reading the same request through* BishopRegularCauchyCompletion$^{\uparrow}$*,* StreamName$^{\uparrow}$*, and* RegSeqRat$^{\uparrow}$*.*
3. *W is the finite tail-window row, recording the window in which the filter-base and regular Cauchy readings are compared.*
4. *D is the* DyadicRatCore$^{\uparrow}$ *tolerance row, recording the displayed dyadic radius, slack, and containment comparisons attached to W.*
5. *A is the terminal* Real$^{\uparrow}$ *seal row, visible only after B, R, W, D have been displayed.*
6. *H records componentwise* hsame *transport for the filter-base, regular readback, window, tolerance, real seal, replay, provenance, and local naming rows.*
7. *C records displayed* Cont *replay from a completion request through B, R, W, D, A, H.*
8. *P is the* Pkg *provenance over* BishopFilteredRegularCompletion$^{\uparrow}$*,* BishopRegularCauchyCompletion$^{\uparrow}$*,* BishopLocatedFilterBase$^{\uparrow}$*,* CauchyFilterBase$^{\uparrow}$*,* StreamName$^{\uparrow}$*,* RegSeqRat$^{\uparrow}$*,* DyadicRatCore$^{\uparrow}$*,* Real$^{\uparrow}$*,* BHist*,* hsame*,* Cont*, and* NameCert*.*

9. N is the local $\mathsf{NameCert}_{\mathsf{BishopFilteredRegularCompletion}^{\uparrow}}$ *row.*
The carrier has no coordinate for quotient filters, quotient streams, selected limits, countable choice, host real equality, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 8666.2 (Bishop filtered regular completion obligations)**.** *For every accepted* BishopFilteredRegularComple *carrier $F = (B, R, W, D, A, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{BishopFilteredRegularCompletion}^{\uparrow}}$ *surface consists exactly of carrier admission for the displayed tuple, filter-base exposure through B, regular Cauchy readback through R, finite tail-window synchronization through W, dyadic tolerance exposure through D, terminal* $\mathsf{Real}^{\uparrow}$ *sealing through A, componentwise* hsame *transport through H, displayed* Cont *replay through C,* Pkg *provenance through P, local naming through N, and nonescape excluding every unlisted completion object.*

Proof. Project the carrier of Definition 8666.1. The filter-base side is the row B, while the regular Cauchy side is the row R.

The finite comparison surface is W, D. The window row W fixes the tail segment shared by the two readings, and the dyadic tolerance row D records the finite radius and containment budget used inside that segment.

The terminal Real read is downstream of B, R, W, D. The rows H, C, P, N preserve, replay, source, and name the same packet, so no quotient filter, quotient stream, selected limit, choice schedule, host real equality, or ambient completeness datum can enter the local NameCert surface. □

Theorem 8666.3 (Bishop filtered regular completion filter-window induction)**.** *Every accepted* $\mathsf{BishopFilteredRegularCompletion}^{\uparrow}$ *completion read is obtained by finite induction on the displayed tail-window row W. The base window reads the filter-base row B and the regular Cauchy row R at the first displayed dyadic tolerance in D. The induction step refines the directed base element and the regular Cauchy tail inside the next displayed window while preserving the same* hsame*,* Cont*,* Pkg*, and local* NameCert *rows. The terminal* $\mathsf{Real}^{\uparrow}$ *seal A is exposed only after this finite window induction has synchronized B, R, W, D.*

Proof. Use the obligation theorem to identify the rows available to the induction. The base step reads the first displayed window in W, then inspects the filter-base row B, the regular Cauchy readback row R, and the dyadic tolerance row D for that window.

For the step, refine along the directed filter-base relation recorded in B and along the regular Cauchy tail readback recorded in R. The next window is still a row of W, so the dyadic comparisons remain in D and the route does not leave the finite carrier.

The structural rows H, C, P, N transport, replay, source, and name each induction step componentwise. After the final displayed window has been synchronized, the Real seal row A may be read; before that point no Real-facing completion consumer is exposed. □

Falsifiable prediction: Every accepted $\mathsf{BishopFilteredRegularCompletion}^{\uparrow}$ read displays a filter-base row, regular Cauchy readback row, finite tail-window row, DyadicRatCoreUp tolerance row, RealUp seal row, hsame transport, Cont replay, Pkg provenance, and local NameCert row before any completion-facing consumer can inspect the terminal Real seal.

Independence witness: bishop-regular-cauchy-completion, bishop-located-filter-base, cauchy-filter-base, streamname, regseqrat, dyadicratcore, real: $\mathsf{BishopFilteredRegularCompletion}^{\uparrow}$ is not bijective to any listed sibling because it jointly binds filter-base refinement, regular Cauchy readback, finite tail-window synchronization, dyadic tolerance, Real sealing, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{BishopFilteredRegularCompletion}^{\uparrow}}$.

Constructive story: A $\mathsf{BishopFilteredRegularCompletion}^{\uparrow}$ packet is generated from a filter-base row, regular Cauchy readback row, finite tail-window row, DyadicRatCoreUp tolerance row, RealUp seal row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BishopFilteredRegularCompletion}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8666.1, Definition 8666.2, and Definition 8666.3 seed the finite filter-compatible regular completion packet over filter bases, regular Cauchy readbacks, tail windows, dyadic tolerances, Real sealing, transport, replay, provenance, and local naming.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BishopFilteredRegularCompletion}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient filters, quotient streams, selected limits, countable choice, host real equality, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, filter-base exposure, regular Cauchy readback, finite window synchronization, dyadic tolerance stability, Real seal nonescape, replay stability, provenance, and local naming for BEDC.Derived.BishopFilteredRegularCompletionUp.

Chapter 8667

A Concrete Naming Certificate for FiniteVariationMeshCompactness$^{\uparrow}$

Following Jordan's finite-variation ledger and Bishop–Bridges finite-mesh practice, the FiniteVariationMeshCompactn packet records the finite route by which a displayed variation mesh is read as compact-data support for later Real and interval consumers. It sits beside the bounded-variation real-function surface of chapter 3654, the finite variation partition surface of chapter 6386, the dyadic arithmetic core of chapter 291, the finite cover refinement route of chapter 3430, the located interval compactness packet of chapter 3431, the compact interval finite-net route of chapter 6607, and the terminal Real seal of chapter 38. The packet names a finite variation-mesh compactness surface; it does not claim open-cover compactness, ambient Real completeness, or a selected limit.

Definition 8667.1 (Finite variation mesh compactness carrier)**.** *A* FiniteVariationMeshCompactness$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$V = (I, \Pi, D, V, M, R, S, K, H, C, P, N)$$

with the following displayed rows:

1. *I is the* Real$^{\uparrow}$ *interval source row naming the displayed endpoints.*
2. *Π is the displayed finite partition row from the bounded-variation surface.*
3. *D is the* DyadicRatCore$^{\uparrow}$ *budget row recording the finite dyadic comparison and endpoint-arithmetic data.*
4. *V is the* FiniteVariationPartition$^{\uparrow}$ *ledger row read from the same partition data.*
5. *M is the finite mesh row recording the displayed subdivision points and adjacent cell comparisons.*
6. *R is the* RegSeqRat$^{\uparrow}$ *readback row attached to the mesh and partition data.*
7. *S is the* StreamName$^{\uparrow}$ *window row that supplies the finite observation route before any Real-facing consumer reads the packet.*
8. *K is the* CompactInterval$^{\uparrow}$ *handoff row reached only after I, Π, D, V, M, R, S are displayed.*
9. *H records componentwise* hsame *transport for the interval, partition, dyadic budget, variation, mesh, readback, window, compact-handoff, provenance, and local naming rows.*

10. *C records displayed* Cont *replay through the finite variation mesh route into the compact interval handoff.*
11. *P is the* Pkg *provenance over* $\mathsf{FiniteVariationMeshCompactness}^{\uparrow}$, $\mathsf{BoundedVariationRealFunction}^{\uparrow}$, $\mathsf{FiniteVariationPartition}^{\uparrow}$, $\mathsf{FiniteCoverRefinement}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{LocatedIntervalCompactness}^{\uparrow}$, $\mathsf{CompactInterval}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
12. *N is the local* $\mathsf{NameCert}_{\mathsf{FiniteVariationMeshCompactness}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through $I, \Pi, D, V, M, R, S, K, H, C, P, N$. It has no coordinate for a host variation supremum, a selected open-cover subfamily, quotient equality of functions, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 8667.2 (Finite variation mesh compactness NameCert obligations)**.** *For every accepted* $\mathsf{FiniteVariationMeshCompactness}^{\uparrow}$ *carrier $V = (I, \Pi, D, V, M, R, S, K, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{FiniteVariationMeshCompactness}^{\uparrow}}$ *surface consists exactly of carrier admission for the displayed interval, finite partition, dyadic budget, finite variation ledger, finite mesh, regular-rational readback, StreamName window, compact-interval handoff, componentwise transport, displayed replay, provenance, and local naming.*

Proof. Project the carrier of Definition 8667.1. The analytic rows are I, Π, D, V, M, R, S, K, and the structural rows are H, C, P, N.

The interval and partition rows are the starting point. The row I displays the interval source, while Π and V read the same finite partition as a bounded-variation ledger rather than as an arbitrary partition family.

The dyadic row D and mesh row M then record the finite comparison data used by the packet. The regular-rational readback R and StreamName window S keep the mesh route finite before the compact-interval handoff K is visible.

Finally H, C, P, N transport, replay, source, and name the same displayed route. Since the carrier has no row for open-cover compactness, a selected subcover, quotient equality of functions, countable choice, or ambient completeness, those principles cannot be exported by the NameCert surface. □

Theorem 8667.3 (Finite variation mesh compactness L10 route)**.** *Every completion-facing read of an accepted* $\mathsf{FiniteVariationMeshCompactness}^{\uparrow}$ *packet factors through*

$$I, \Pi, D, V, M \longmapsto R, S \longmapsto K, H, C, P, N$$

before any compact-interval consumer can read the packet as a compact-mesh route. The read first exposes the interval and displayed partition, then the dyadic budget, finite variation ledger, and mesh, then the regular-rational and StreamName readback rows, and only then the compact-interval handoff and structural packet rows. The route exports no open-cover compactness, selected subcover, host supremum, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start with the interval source row I and the displayed partition Π. They identify the finite variation surface before any compactness-facing consumer is allowed to inspect the ledger.

Next apply the dyadic row D, variation row V, and mesh row M. These rows keep the route inside the same finite partition data and supply the displayed cell comparisons used by later consumers.

The regular-rational readback R and StreamName window S then expose the finite observation route. The compact-interval handoff K is downstream of that route, so the packet can be read as a compact-facing mesh object only after the displayed variation data have been exposed.

Finally the structural rows H, C, P, N preserve the same displayed packet. Since the carrier contains no supremum, selected subcover, quotient equality, countable-choice, or ambient completeness coordinate, none of those principles can be exported by the route. □

Theorem 8667.4 (Finite variation mesh compactness non-escape)**.** *An accepted* $\mathsf{FiniteVariationMeshCompactness}^{\uparrow}$ *carrier cannot be used to recover data outside the displayed tuple* $I, \Pi, D, V, M, R, S, K, H, C, P, N$*. In particular, it exports no host variation supremum, no selected subcover, no quotient equality of functions, no countable-choice selection, and no ambient* $\mathsf{Real}^{\uparrow}$ *completeness principle.*

Proof. The NameCert obligations identify every row available to a downstream consumer. The interval, partition, dyadic, variation, mesh, readback, window, and compact-interval rows are the only analytic content rows, and H, C, P, N only transport, replay, package, and name those rows.

Apply Definition 8667.3 to any completion-facing read. It forces the read through the finite variation mesh route before the compact-interval handoff can be consumed.

Since no additional coordinate is present, the packet has no source for host variation suprema, selected subcovers, quotient equality, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness. □

Falsifiable prediction: A variation-mesh packet that lacks a displayed finite partition row is not an accepted $\mathsf{FiniteVariationMeshCompactness}^{\uparrow}$ carrier.

Independence witness: boundedvariationrealfunction, finitevariationpartition, finitecoverrefinement, dyadicratcore, locatedintervalcompactness, compactinterval: these siblings expose partition, ledger, refinement, dyadic, location, or compact-interval rows separately, while $\mathsf{FiniteVariationMeshCompactness}^{\uparrow}$ binds the finite variation mesh route with all of them as one packet.

Closure status for $\mathsf{NameCert}_{\mathsf{FiniteVariationMeshCompactness}^{\uparrow}}$**.**

Constructive story: A $\mathsf{FiniteVariationMeshCompactness}^{\uparrow}$ packet is generated from a RealUp interval row, a displayed finite partition row, a dyadic budget row, a finite variation ledger, a finite mesh row, RegSeqRat readback, StreamName windows, a CompactIntervalUp handoff, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{FiniteVariationMeshCompactness}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8667.1, Definition 8667.2, Definition 8667.3, and Definition 8667.4 bind the finite variation mesh compactness surface over interval, partition, dyadic, variation, mesh, readback, StreamName, compact-interval handoff, transport, replay, provenance, and local naming rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{FiniteVariationMeshCompactness}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Origin: human

Not claimed: This chapter does not close Lean verification, ambient RealUp completeness, quotient equality of functions, selected subcovers, countable choice, or a public standard bridge.

Upgrade path: Obligation closure requires checked carrier admission, partition exposure, dyadic budget exposure, finite mesh exposure, readback routing, compact-interval handoff, transport, replay, provenance, and local naming for BEDC.Derived.FiniteVariationMeshCompactnessUp.

Chapter 8668

A Concrete Naming Certificate for MetaCICNormalizationAuditRow$^{\uparrow}$

The MetaCICNormalizationAuditRow$^{\uparrow}$ packet realizes the finite audit-row reading of chapter 9383. It sits beside the normalization audit packet of chapter 3779, the normalization audit surface of chapter 750, the normalization frontier of chapter 892, the normal-endpoint cut of chapter 5143, and the residual-checker normalization budget of chapter 6666. The packet records a finite candidate set, fuel trace, closed typing fragment, residual checker row, and normal endpoint row before a normalization-audit consumer may read the result. It refuses global strong normalization, kernel consistency, quotient term equality, evaluator equality, and subject reduction.

Definition 8668.1 (MetaCIC normalization audit-row carrier)**.** *A* MetaCICNormalizationAuditRow$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M = (S, F, T, R, E, O, H, C, P, N)$$

with the following displayed rows:

1. *S is the candidate-set row, listing the finite candidate entries whose normalization evidence may be inspected.*
2. *F is the fuel-trace row, recording the bounded reduction budget and the inspected trace segment.*
3. *T is the closed typing fragment row, exposing the finite context boundary, term, type, and closedness data used by the audit.*
4. *R is the residual checker row, recording which residual fragments have been checked inside the same bounded window.*
5. *E is the normal endpoint row, available only when the candidate-set, fuel, closed typing, and residual checker rows all support the endpoint read.*
6. *O is the refusal row for requests that ask for global strong normalization, kernel consistency, quotient term equality, evaluator equality, subject reduction, hidden semantic candidates, or an unbounded evaluator.*
7. *H records componentwise* hsame *transport for $S, F, T, R, E, O, C, P, N$.*
8. *C records displayed* Cont *replay from a normalization-audit request through S, F, T, R, E, O, H.*

9. *P is the* Pkg *provenance over* MetaCICNormalizationAuditRow$^{\uparrow}$, MetaCICNormalizationAuditPacket$^{\uparrow}$, MetaCICNormalizationAudit$^{\uparrow}$, MetaCICNormalizationFrontier$^{\uparrow}$, MetaCICNormalEndpointCut$^{\uparrow}$, MetaCICResidualCh BHist, hsame, Cont, *and* NameCert.

10. *N is the local* NameCert$_{\mathsf{MetaCICNormalizationAuditRow}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $S, F, T, R, E, O, H, C, P, N$ and has no coordinate for an unbounded normalization theorem or kernel-level consistency theorem.

Theorem 8668.2 (MetaCIC normalization audit-row obligations)**.** *For every accepted* MetaCICNormalizationAuditI *carrier $M = (S, F, T, R, E, O, H, C, P, N)$, the local* NameCert$_{\mathsf{MetaCICNormalizationAuditRow}^{\uparrow}}$ *surface consists exactly of carrier admission, candidate-set exposure through S, fuel-trace exposure through F, closed typing fragment exposure through T, residual checker exposure through R, normal endpoint exposure through E, refusal retention through O, componentwise* hsame *transport through H, displayed* Cont *replay through C,* Pkg *provenance through P, and local naming through N.*

Proof. Project the carrier. The finite candidate set, bounded fuel trace, closed typing fragment, residual checker, normal endpoint, and refusal rows are displayed as S, F, T, R, E, O.

The endpoint row E is downstream of the finite rows. A consumer must inspect the candidate set, fuel trace, closed typing fragment, and residual checker before reading the endpoint as an audit result.

The refusal row O keeps broader requests outside the carrier. The structural rows H, C, P, N preserve, replay, source, and name the finite audit row without adding global strong normalization, kernel consistency, quotient term equality, evaluator equality, subject reduction, or hidden semantic candidate data. □

Theorem 8668.3 (MetaCIC normalization audit-row finite endpoint route)**.** *Every public endpoint read from an accepted* MetaCICNormalizationAuditRow$^{\uparrow}$ *packet factors through the finite route*

$$S, F, T, R \longmapsto E \longmapsto O, H, C, P, N.$$

The route records candidate-set membership, bounded fuel, closed typing, residual checking, and a normal endpoint inside one finite audit row. It does not export global strong normalization, kernel consistency, quotient term equality, evaluator equality, subject reduction, or an unbounded evaluator.

Proof. Apply the obligation theorem. It orders the endpoint row E after the candidate-set, fuel-trace, closed-typing, and residual-checker rows.

The route is finite because S lists the candidate entries, F bounds the trace, T fixes the inspected closed typing fragment, and R records only residual checks inside that window. The endpoint is therefore an audit-row endpoint, not a kernel-wide normalization theorem.

Finally read O, H, C, P, N. The refusal row blocks the listed global claims, while transport, replay, provenance, and local naming preserve the same displayed route without adding unbounded evaluator or subject-reduction data. □

Falsifiable prediction: Every accepted MetaCICNormalizationAuditRow$^{\uparrow}$ read exposes a candidate set, fuel trace, closed typing fragment, residual checker, normal endpoint row, refusal row, hsame transport, Cont replay, Pkg provenance, and local NameCert row before a normalization-audit endpoint is visible.

Independence witness: metacic-normalization-audit-packet, metacicnormalizationaudit, metacicnormalizationfrontier, metacic-normal-endpoint-cut, metacic-residual-checker-normalization-budget:

$\mathsf{MetaCICNormalizationAuditRow}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries candidate-set rows, fuel traces, closed typing fragments, residual checker rows, normal endpoints, refusal retention, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{MetaCICNormalizationAuditRow}^{\uparrow}}$.

Constructive story: A $\mathsf{MetaCICNormalizationAuditRow}^{\uparrow}$ packet is generated from a candidate-set row, fuel-trace row, closed typing fragment, residual checker row, normal endpoint row, refusal row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{MetaCICNormalizationAuditRow}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8668.1, Definition 8668.2, and Definition 8668.3 seed the finite normalization audit row over candidate sets, fuel traces, closed typing fragments, residual checking, normal endpoints, refusal retention, transport, replay, provenance, and local naming.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{MetaCICNormalizationAuditRow}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close global strong normalization, kernel consistency, quotient term equality, evaluator equality, subject reduction, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, candidate-set exposure, fuel-trace exactness, closed typing fragment preservation, residual checker nonescape, normal endpoint routing, refusal retention, transport, replay, provenance, and local naming for BEDC.Derived.MetaCICNormalizationAuditRowUp.

Chapter 8669

A Concrete Naming Certificate for $\mathsf{BishopFiniteTailComparison}^{\uparrow}$

Following Bishop and Bridges, *Constructive Analysis*, the $\mathsf{BishopFiniteTailComparison}^{\uparrow}$ packet records the finite shared-tail comparison used before equality-facing Real seals are read. It sits between the regular Cauchy source rows of chapter 301, the finite StreamName windows of chapter 126, the dyadic tolerance budgets of chapter 291, the L10 difference route of chapter 1874, and the terminal Real packet of chapter 38. The packet names only the finite comparison surface: two source names, one shared window, one displayed tolerance budget, one verdict row, one terminal seal boundary, transport, replay, provenance, and local naming.

Definition 8669.1 (BishopFiniteTailComparison carrier)**.** *A* $\mathsf{BishopFiniteTailComparison}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (X, Y, W, D, Q, E, H, C, P, N)$$

with the following visible rows:

1. *X and Y are* $\mathsf{RegSeqRat}^{\uparrow}$ *source rows for two regular Cauchy names sharing the same comparison context.*
2. *W is a shared* $\mathsf{StreamName}^{\uparrow}$ *finite tail-window row recording the indices that are simultaneously visible to X and Y.*
3. *D is a* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance-budget row used to compare the two visible tails inside the window W.*
4. *Q is the finite comparison-verdict row, read only after the source rows, window row, and dyadic budget have been displayed.*
5. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal-boundary row that may be inspected only after Q and the* $\mathsf{CauchyDifferenceCriterion}^{\uparrow}$ *route have been read.*
6. *H records componentwise* hsame *transport for the source, window, dyadic-budget, verdict, seal-boundary, replay, provenance, and local naming rows.*
7. *C records the displayed* Cont *replay through $X, Y, W, D, Q, E, H, P, N$ in the order in which a consumer may read the packet.*
8. *P is the* Pkg *provenance over* $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{CauchyDifferenceCriterion}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*

9. *N is the local* $\mathsf{NameCert}_{\mathsf{BishopFiniteTailComparison}^{\uparrow}}$ *row naming this finite shared-tail comparison packet.*

The carrier has no coordinate for Real completeness, quotient stream equality, selected limits, trichotomy, countable choice, host equality of completed reals, or bridge checking.

Theorem 8669.2 (BishopFiniteTailComparison NameCert obligations)**.** *For an accepted* BishopFiniteTailComparis *carrier $B = (X, Y, W, D, Q, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{BishopFiniteTailComparison}^{\uparrow}}$ *surface consists exactly of these obligations:*

1. *carrier admission for the two* $\mathsf{RegSeqRat}^{\uparrow}$ *source rows, shared* $\mathsf{StreamName}^{\uparrow}$ *window,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance budget, finite verdict, terminal* $\mathsf{Real}^{\uparrow}$ *seal boundary, componentwise transport, continuation replay, provenance, and local naming row;*
2. *shared-window discipline, requiring every comparison read to expose the same finite tail window W for both source rows before the verdict Q is inspected;*
3. *tolerance-budget discipline, requiring the dyadic row D to be displayed before the verdict is consumed;*
4. *difference-route compatibility, requiring any equality-facing read beyond Q to pass through the* $\mathsf{CauchyDifferenceCriterion}^{\uparrow}$ *route before the terminal seal row E is exposed;*
5. *ledger non-escape, stating that H, C, P, N expose no Real completeness theorem, quotient stream equality, selected limit, trichotomy, countable-choice schedule, host equality of completed reals, Lean verification, or bridge check.*

Proof. Carrier admission is projection from Definition 8669.1. The tuple displays exactly the two source rows, shared finite window, dyadic tolerance budget, verdict, seal boundary, transport, replay, provenance, and local naming data.

The shared-window and tolerance-budget obligations are read from W and D before Q. Since the verdict row is downstream of both rows, the comparison cannot be inspected from one source tail alone and cannot use an undisplayed tolerance.

For equality-facing reads, use the placement of E behind Q and the cited $\mathsf{CauchyDifferenceCriterion}^{\uparrow}$ route. The structural rows H, C, P, N only transport, replay, source, and name the same finite packet. Hence no excluded Real completeness, quotient equality, selected-limit, trichotomy, choice, host-equality, Lean-verification, or bridge-check principle is exported. □

Theorem 8669.3 (BishopFiniteTailComparison shared-window comparison)**.** *Let $B = (X, Y, W, D, Q, E, H, C, P,$ be an accepted* $\mathsf{BishopFiniteTailComparison}^{\uparrow}$ *carrier. Any finite comparison of the two source rows X, Y must first display the shared* $\mathsf{StreamName}^{\uparrow}$ *window W and the* $\mathsf{DyadicRatCore}^{\uparrow}$ *budget D, then read the verdict row Q, and only then continue toward the terminal seal boundary E through the* $\mathsf{CauchyDifferenceCriterion}^{\uparrow}$ *route.*

The shared-window route exports no comparison from a one-sided tail, no quotient stream equality, no selected limit, no trichotomy, no countable-choice schedule, and no ambient $\mathsf{Real}^{\uparrow}$ *completeness theorem.*

Proof. Project the carrier of Definition 8669.1. The comparison-facing rows are ordered as the two source names X, Y, the shared window W, the dyadic budget D, and the verdict Q.

Apply the NameCert obligations of Definition 8669.2. They force the same window to be displayed for both sources and force the dyadic budget to be available before Q is inspected.

The continuation row C replays the same order through the terminal seal boundary E. Since E is read only after the verdict and the $\mathsf{CauchyDifferenceCriterion}^{\uparrow}$ route, the shared-window comparison remains finite and does not export any excluded equality, limit-selection, trichotomy, choice, or Real-completeness principle. □

Theorem 8669.4 (BishopFiniteTailComparison Real-seal boundary)**.** *Let $B = (X, Y, W, D, Q, E, H, C, P, N)$ be an accepted* $\mathsf{BishopFiniteTailComparison}^{\uparrow}$ *carrier. The terminal* $\mathsf{Real}^{\uparrow}$ *seal boundary E is readable only after the source rows X, Y, the shared finite window W, the dyadic tolerance budget D, the comparison verdict Q, and the* $\mathsf{CauchyDifferenceCriterion}^{\uparrow}$ *handoff have all been displayed. The boundary is therefore a finite pre-seal route for equality-facing Real reads, not a proof of Real completeness or quotient stream equality.*

Proof. Start with the shared-window comparison theorem Definition 8669.3. It supplies the finite route through X, Y, W, D, Q before any terminal seal-boundary read can occur.

Use the difference-route compatibility clause of Definition 8669.2. It requires equality-facing reads past the verdict to pass through the displayed $\mathsf{CauchyDifferenceCriterion}^{\uparrow}$ route before the terminal $\mathsf{Real}^{\uparrow}$ seal boundary E is exposed.

Finally read the ledger non-escape clause. The carrier and structural rows contain no Real completeness theorem, quotient stream equality, selected limit, trichotomy, countable-choice schedule, host equality of completed reals, Lean verification, or bridge check, so the seal boundary remains exactly the stated finite pre-seal route. □

Closure status for $\mathsf{NameCert}_{\mathsf{BishopFiniteTailComparison}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BishopFiniteTailComparison}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8669.1, Definition 8669.2, Definition 8669.3, and Definition 8669.4 seed the finite shared-tail comparison route from two RegSeqRat source rows through a shared StreamName window, DyadicRatCore budget, finite verdict, CauchyDifferenceCriterion handoff, and terminal Real seal boundary.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BishopFiniteTailComparison}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close $\mathsf{Real}^{\uparrow}$ completeness, quotient stream equality, selected limits, trichotomy, countable choice, host equality of completed reals, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, shared-window discipline, tolerance-budget discipline, difference-route compatibility, Real seal nonescape, and TasteGate field faithfulness for BEDC.Derived.BishopFiniteTailComparisonUp.

Constructive story: A $\mathsf{BishopFiniteTailComparison}^{\uparrow}$ packet is generated from two RegSeqRat source rows, one shared StreamName finite window, one DyadicRatCore tolerance budget, one finite comparison verdict, one terminal Real seal-boundary row, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Chapter 8670

A Concrete Naming Certificate for $\mathsf{IntertwiningOperator}^{\uparrow}$

Following Fulton and Harris on intertwiners between finite-dimensional representation spaces, the $\mathsf{IntertwiningOperator}^{\uparrow}$ packet records an equivariant linear map between two displayed finite representation rows as NameCert data. It consumes the finite representation carrier of chapter 3662, the linear-map source of chapter 48, the Schur-facing Hom boundary of chapter 5882, and the direct-sum and tensor ledger of chapter 246. The packet names only the displayed morphism surface; it does not assert irreducibility, Schur scalarity, quotient representation equality, or a host category of representations.

Definition 8670.1 (IntertwiningOperator carrier)**.** *An* $\mathsf{IntertwiningOperator}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$I = (G, U, V, L, E, S, C, H, T, P, N)$$

with the following displayed rows:

1. *G is the common finite group source row read through the two representation packets.*
2. *U is the source* $\mathsf{FiniteGroupRepresentation}^{\uparrow}$ *row.*
3. *V is the target* $\mathsf{FiniteGroupRepresentation}^{\uparrow}$ *row over the same group source.*
4. *L is the consumed* $\mathsf{LinMap}^{\uparrow}$ *row naming the underlying linear map from the source vector-space row of U to the target vector-space row of V.*
5. *E is the equivariance ledger, recording for each displayed group row that applying the target action after L and applying L after the source action replay to the same named row.*
6. *S is the Schur-facing Hom boundary consumed by* $\mathsf{SchurLemma}^{\uparrow}$ *and* $\mathsf{SchurOrthogonality}^{\uparrow}$ *readers.*
7. *C is the* $\mathsf{RepresentationRing}^{\uparrow}$ *composition and operation ledger boundary, exposing only the rows needed by direct-sum, tensor, and composable-morphism consumers.*
8. *H records componentwise* hsame *transport for G, U, V, L, E, S, C.*
9. *T records displayed* Cont *replay for action compatibility, Schur-facing reads, and representation-ring operation reads.*
10. *P is the* Pkg *provenance over* $\mathsf{FiniteGroupRepresentation}^{\uparrow}$, $\mathsf{LinMap}^{\uparrow}$, $\mathsf{SchurLemma}^{\uparrow}$, $\mathsf{RepresentationRing}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$ *rows.*

11. N is the local $\mathsf{NameCert}_{\mathsf{IntertwiningOperator}^{\uparrow}}$ *row.*

No carrier coordinate stores all host linear maps, a quotient Hom space, a chosen basis, an irreducible decomposition, or a global representation category.

Theorem 8670.2 (IntertwiningOperator NameCert obligations)**.** *For every accepted* $\mathsf{IntertwiningOperator}^{\uparrow}$ *carrier* $I = (G, U, V, L, E, S, C, H, T, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{IntertwiningOperator}^{\uparrow}}$ *surface consists exactly of carrier admission for the displayed tuple, common-group exposure through* G*, source and target representation exposure through* U, V*, underlying linear-map exposure through* L*, equivariance exactness through* E*, Schur-facing Hom boundary through* S*, representation-ring consumer boundary through* C*, componentwise* hsame *transport through* H*, displayed* Cont *replay through* T*, package provenance through* P*, and local naming through* N*.*

The obligation surface is local to the finite representation rows. It does not claim Schur scalarity, nonzero Hom classification, representation-ring equality, quotient Hom computation, complete reducibility, or a host category of representations.

Proof. Project the carrier of Definition 8670.1. The tuple $G, U, V, L, E, S, C, H, T, P, N$ is the whole public surface, so carrier admission cannot introduce a second Hom object or a private linear-map equality.

Read U and V through the finite representation chapter and L through the linear-map chapter. The equivariance ledger E is then a finite row-by-row replay over the same group source G, comparing target action after L with L after source action only through displayed continuation rows.

Finally route downstream consumers through S and C. Schur-facing readers may inspect only the Hom boundary already named by the packet, and representation-ring readers may inspect only the displayed composition or operation rows. Repacking those rows with H, T, P, N gives the stated local NameCert surface and none of the refused global endpoints. □

Theorem 8670.3 (IntertwiningOperator composition stability)**.** *Let* $I = (G, U, V, L, E, S, C, H, T, P, N)$ *and* $J = (G, V, W, M, F, R, D, K, Q, B, O)$ *be accepted* $\mathsf{IntertwiningOperator}^{\uparrow}$ *packets sharing the middle representation row* V *and the same finite group source* G*. If the representation-ring composition boundary exposes the composable rows of* C *and* D*, then the displayed composite linear row* $M \circ L$ *carries a finite equivariance ledger obtained by replaying* E *and* F *in sequence. The resulting composite remains an* $\mathsf{IntertwiningOperator}^{\uparrow}$ *packet over* U *and* W *after componentwise transport, continuation replay, provenance, and local naming.*

This stability claim is only about the finite displayed composition surface. It does not identify a quotient Hom class, prove associativity for a host category, select bases, or derive Schur scalarity.

Proof. Begin with the source packet I. Its equivariance ledger E says that each displayed group action on U can be moved across the linear-map row L to the matching action on V by displayed continuation replay.

Next use the target packet J. Its ledger F moves the same displayed group action on V across M to the matching action on W.

Compose the two replays along the middle representation row. The representation-ring boundary rows C and D certify that the requested composition is a displayed finite operation row, while the structural rows H, T, P, N and K, Q, B, O transport, replay, source, and name the composite data.

The constructed carrier therefore has the same row shape as Definition 8670.1, with the composite linear row replacing L and the sequential replay replacing E. Since every step stays inside

the displayed rows, the theorem exports only composition stability for finite intertwiners and none of the refused host-level endpoints. □

Closure status for $\mathsf{NameCert}_{\mathsf{IntertwiningOperator}^{\uparrow}}$.

Constructive story: An $\mathsf{IntertwiningOperator}^{\uparrow}$ packet is generated from a common finite group source, source and target FiniteGroupRepresentationUp rows, a LinearMapUp row, a finite equivariance ledger, SchurLemmaUp and RepresentationRingUp consumer boundaries, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{IntertwiningOperator}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8670.1, Definition 8670.2, and Definition 8670.3 seed the finite equivariant-linear-map carrier, its NameCert obligation surface, and composition stability over displayed representation rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{IntertwiningOperator}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close Schur scalarity, irreducibility, quotient Hom computation, host representation categories, chosen bases, Lean verification, or bridge checking for $\mathsf{IntertwiningOperator}^{\uparrow}$.

Upgrade path: Obligation closure requires checked carrier admission, common-group exposure, source and target representation exposure, linear-map exactness, equivariance replay, Schur-facing boundary, representation-ring composition stability, transport, replay, provenance, and local naming for BEDC.Derived.IntertwiningOperatorUp.

Chapter 8671

A Concrete Naming Certificate for HyperbolicPhaseEnergyTransport$^{\uparrow}$

The HyperbolicPhaseEnergyTransport$^{\uparrow}$ packet realizes the hyperbolic phase transport rows of chapter 9463 as finite phase-energy transport data. It sits between the metric and disk carriers of chapter 3474 and chapter 6209, the reversible phase surface of chapter 6146, the energy ledger of chapter 6481, and the bounded phase-transport route of chapter 7134. The packet names a finite transport-with-energy readback surface; it does not assert physical energy conservation, continuous geodesic dynamics, global curvature integration, or selected observer motion.

Definition 8671.1 (HyperbolicPhaseEnergyTransport carrier)**.** *A* HyperbolicPhaseEnergyTransport$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$E = (D, M, Q, U, L, B, R, S, F, H, C, P, N)$$

with the following displayed rows:

1. *D is the consumed Poincare disk metric row.*
2. *M is the consumed hyperbolic metric row.*
3. *Q is the observer-phase groupoid transport row naming reversible phase motion between displayed endpoints.*
4. *U is the phase-energy transport row, recording the finite source endpoint, target endpoint, phase label, and energy-budget label.*
5. *L is the consumed* HyperbolicPhaseEnergyLedger$^{\uparrow}$ *row used to read the energy side of the transport.*
6. *B is the consumed* HyperbolicPhaseTransportBudget$^{\uparrow}$ *row bounding the transport before any public read.*
7. *R is the regular-rational readback row for the displayed transport budget.*
8. *S is the* Real$^{\uparrow}$ *seal preventing the budget readback from becoming an unlogged host scalar.*
9. *F is the TasteGate-facing row requiring Lean* `Nontrivial` *and* `FieldFaithful` *instances for the carrier fields.*
10. *H records componentwise* hsame *transport for disk, metric, phase groupoid, energy transport, ledger, budget, readback, seal, TasteGate-facing, replay, provenance, and local naming rows.*

11. *C records displayed* Cont *replay for phase transport, energy-ledger readback, budget exposure, and Real sealing.*
12. *P is the* Pkg *provenance over* PoincareDiskMetric$^{\uparrow}$, HyperbolicMetric$^{\uparrow}$, ObserverPhaseGroupoid$^{\uparrow}$, HyperbolicPhaseEnergyLedger$^{\uparrow}$, HyperbolicPhaseTransportBudget$^{\uparrow}$, RegSeqRat$^{\uparrow}$, Real$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*
13. *N is the local* NameCert$_{\text{HyperbolicPhaseEnergyTransport}^{\uparrow}}$ *row.*

No carrier coordinate stores a continuous geodesic flow, physical Hamiltonian system, global conservation law, host curvature integral, or selected observer trajectory.

Theorem 8671.2 (HyperbolicPhaseEnergyTransport NameCert obligations)**.** *For every accepted* HyperbolicPhaseEnergyTransport$^{\uparrow}$ *carrier $E = (D, M, Q, U, L, B, R, S, F, H, C, P, N)$, the local* NameCert$_{\text{HyperbolicPhas}}$ *surface consists exactly of disk-metric admission, hyperbolic-metric admission, reversible phase-groupoid transport, phase-energy transport exposure, energy-ledger readback, phase-transport budget exposure, regular-rational readback, Real-seal nonescape, TasteGate-facing nontriviality and field-faithfulness requirements, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming.*

The surface is a finite transport-with-energy packet. It does not claim global hyperbolic dynamics, physical conservation, curvature integration, selected observer motion, or a host analytic energy theorem.

Proof. Project the carrier of Definition 8671.1. The disk and metric rows D, M must be visible before the phase groupoid transport Q is read, and the transport row U is only a finite endpoint-and-budget row over that displayed metric surface.

Next expose the energy ledger L and phase-transport budget B. These rows keep the energy readback and transport bound inside the finite packet before the regular-rational row R and Real seal S can be inspected.

Finally use the TasteGate-facing row F and structural rows H, C, P, N. They require field separation, componentwise transport, displayed replay, provenance, and local naming for exactly the displayed rows, so no physical conservation law, global hyperbolic flow, host curvature integral, or selected trajectory is exported. □

Theorem 8671.3 (HyperbolicPhaseEnergyTransport budget nonescape)**.** *Any public read of an accepted* HyperbolicPhaseEnergyTransport$^{\uparrow}$ *packet must pass through the metric rows D, M, the phase-groupoid row Q, the transport row U, the energy ledger L, and the budget row B before it reaches the readback and Real-seal rows R, S. Therefore a read that omits any one of $D, M, Q, U, L, B, H, C, P, N$ is not a* HyperbolicPhaseEnergyTransport$^{\uparrow}$ *read, and the packet cannot be reread as a bare Real scalar or a physical energy law.*

Proof. The carrier definition orders the readback rows after the displayed metric, phase-transport, energy-ledger, and budget rows. Thus R and S are not independent numeric payloads; they are sealed readbacks of the finite route.

Componentwise transport and continuation replay preserve that route under H and C. Package provenance and local naming then repack the same displayed rows as the public certificate.

If a consumer reaches a Real-facing value without one of the named rows, it has left the carrier surface. The theorem therefore records nonescape for the finite budget route rather than any analytic or physical conservation claim. □

Falsifiable prediction: Every accepted $\mathsf{HyperbolicPhaseEnergyTransport}^{\uparrow}$ packet exposes $\mathsf{PoincareDiskMetric}^{\uparrow}$, $\mathsf{HyperbolicMetric}^{\uparrow}$, $\mathsf{ObserverPhaseGroupoid}^{\uparrow}$, $\mathsf{HyperbolicPhaseEnergyLedger}^{\uparrow}$, and $\mathsf{HyperbolicPhaseTransportBudget}^{\uparrow}$ rows before any $\mathsf{Real}^{\uparrow}$ energy-transport seal; a read that reaches the seal without those rows refutes the carrier surface.

Independence witness: hyperbolic-phase-energy-ledger, hyperbolic-phase-transport-budget, observer-phase-groupoid, hyperbolic-phase-curvature-budget, hyperbolic-phase-ledger: no listed sibling is bijective to $\mathsf{HyperbolicPhaseEnergyTransport}^{\uparrow}$ because this packet jointly carries disk metric data, hyperbolic metric comparison, reversible phase transport, energy-ledger readback, transport-budget exposure, regular readback, Real sealing, TasteGate-facing field separation, transport, replay, provenance, and local naming.

The Lean TasteGate file `lean4/BEDC/Derived/HyperbolicPhaseEnergyTransportUp/TasteGate.lean` must provide `Nontrivial` and `FieldFaithful` instances for $\mathsf{HyperbolicPhaseEnergyTransport}^{\uparrow}$. Those instances must preserve $D, M, Q, U, L, B, R, S, F, H, C, P, N$ as distinct fields before any carrier-alignment theorem can serve as a TasteGate witness.

Closure status for $\mathsf{NameCert}_{\mathsf{HyperbolicPhaseEnergyTransport}^{\uparrow}}$.

Constructive story: A $\mathsf{HyperbolicPhaseEnergyTransport}^{\uparrow}$ packet is generated from PoincareDiskMetricUp disk data, HyperbolicMetricUp metric rows, ObserverPhaseGroupoidUp reversible phase transport, a finite energy-transport row, HyperbolicPhaseEnergyLedgerUp readback, HyperbolicPhaseTransportBudgetUp bounds, RegSeqRatUp readback, a RealUp seal, TasteGate-facing field-separation requirements, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{HyperbolicPhaseEnergyTransport}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8671.1, Definition 8671.2, and Definition 8671.3 seed the finite phase-energy transport carrier, NameCert surface, and budget nonescape route.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{HyperbolicPhaseEnergyTransport}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close physical energy conservation, continuous geodesic dynamics, global curvature integration, selected observer motion, Lean verification, or bridge checking for $\mathsf{HyperbolicPhaseEnergyTransport}^{\uparrow}$.

Upgrade path: Obligation closure requires checked disk admission, metric admission, phase-groupoid transport, energy-transport exposure, energy-ledger readback, budget exposure, Real-seal nonescape, TasteGate nontriviality, field faithfulness, transport, replay, provenance, and local naming for BEDC.Derived.HyperbolicPhaseEnergyTransportUp.

Chapter 8672

A Concrete Naming Certificate for CauchyProductModulusMajorant$^{\uparrow}$

Following Hardy, Knopp, and Bishop–Bridges on constructive products of series, the CauchyProductModulusMajoran packet records the finite modulus-majorant route behind Cauchy products. It sits between the product-series surface of chapter 2214, the majorant tail ledger of chapter 1774, the shared uniform-tail route of chapter 1736, the regular rational readback of chapter 301, the dyadic arithmetic core of chapter 291, and the terminal real-name seal of chapter 38. It also supplies the product-tail control consumed by the Mertens packet of chapter 3584. The packet names a finite L10 route for product tails; it does not assert a host theorem on infinite Cauchy products, select a product sum, identify quotient series representatives, invoke countable choice, or import ambient Real$^{\uparrow}$ completeness.

Definition 8672.1 (Cauchy product modulus majorant carrier)**.** *A* CauchyProductModulusMajorant$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M = (A, B, W, Q, T, U, R, D, E, H, C, P, N)$$

with the following displayed rows:

1. *A and B are the two source-series rows. They expose finite term windows, partial-sum windows, and source tail requests already admitted by the neighboring Cauchy-series product route.*
2. *W is the convolution-window row. It lists the inspected product diagonals, the finite rectangular and triangular windows used to compare product partial sums, and the omitted tail cells.*
3. *Q is the product-modulus row. It records the requested output tolerance together with the finite source-tail indices that make every displayed product-window comparison small enough.*
4. *T is the majorant tail ledger. It records the nonnegative majorant schedules and tail bounds that dominate the omitted convolution cells.*
5. *U is the* UniformCauchySeries$^{\uparrow}$ *threshold row reached only after A, B, W, Q, T have all been displayed.*
6. *R is the* RegSeqRat$^{\uparrow}$ *readback row for the source windows, product partial sums, and modulus thresholds.*
7. *D is the* DyadicRatCore$^{\uparrow}$ *budget row, recording the dyadic tolerances, product-radius comparisons, and finite addition slack used by Q and T.*

8. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached only after the product modulus, majorant ledger, uniform tail threshold, regular readback, and dyadic budget rows have been inspected.*

9. *H records componentwise* hsame *transport for the source series, convolution windows, modulus row, majorant ledger, uniform threshold, readback, dyadic budget, Real seal, replay, provenance, and local naming rows.*

10. *C records displayed* Cont *replay from a product-tail request through*

$$A, B, W \longmapsto Q, T \longmapsto U, R, D \longmapsto E, H, P, N.$$

11. *P is the* Pkg *provenance over* $\mathsf{CauchyProductModulusMajorant}^{\uparrow}$, $\mathsf{CauchySeriesProduct}^{\uparrow}$, $\mathsf{CauchyMajorantSeries}^{\uparrow}$, $\mathsf{UniformCauchySeries}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

12. *N is the local* $\mathsf{NameCert}_{\mathsf{CauchyProductModulusMajorant}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $A, B, W, Q, T, U, R, D, E, H, C, P, N$. It has no coordinate for a host product theorem, selected infinite convolution sum, quotient equality of series, countable choice, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 8672.2 (Cauchy product modulus majorant NameCert obligations)**.** *For every accepted* $\mathsf{CauchyProductModulusMajorant}^{\uparrow}$ *carrier*

$$M = (A, B, W, Q, T, U, R, D, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{CauchyProductModulusMajorant}^{\uparrow}}$ *surface consists exactly of carrier admission for the two source-series rows, convolution-window exposure, product-modulus exactness, majorant tail control, uniform-tail thresholding, regular rational readback, dyadic budget accounting, Real seal nonescape, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming.*

No Cauchy product modulus-majorant obligation is stored outside these rows.

Proof. Project the carrier of Definition 8672.1. The source rows A and B and the convolution row W are the only product-facing data visible before a tail request is answered.

The modulus and majorant obligations are the rows Q and T. The modulus row stores the finite source-tail indices for the requested tolerance, while the majorant row supplies the displayed domination data for omitted convolution cells.

The endpoint-facing rows are downstream. The uniform threshold U, regular readback R, and dyadic budget D must be displayed before the terminal Real seal E is available.

Finally H, C, P, N transport, replay, source, and name the same finite route. Since the carrier has no coordinate for a host product theorem, selected convolution sum, quotient equality, countable choice, trichotomy, or ambient completeness, the listed rows exhaust the local NameCert surface. □

Theorem 8672.3 (Cauchy product modulus majorant uniform tail route)**.** *Every Real or Completion consumer of an accepted* $\mathsf{CauchyProductModulusMajorant}^{\uparrow}$ *packet factors its constructive Cauchy-product tail read through the displayed route*

$$\mathsf{CauchySeriesProduct}^{\uparrow} \longmapsto \mathsf{CauchyMajorantSeries}^{\uparrow} \longmapsto \mathsf{UniformCauchySeries}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{DyadicRatCore}^{\uparrow} \mapsto$$

In carrier notation, the consumer first reads the source rows and convolution window A, B, W, then the product modulus and majorant ledger Q, T, then the uniform threshold, readback, and

dyadic budget rows U, R, D, and only then the Real seal E and structural rows H, C, P, N. The route exports finite tail control for constructive Cauchy products without exporting a host infinite product theorem, selected product endpoint, quotient stream equality, countable-choice schedule, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start from the accepted carrier. The Cauchy-series product surface supplies the two source rows and the convolution window, so the product tail is first a displayed finite-window request through A, B, W.

Next read the modulus-majorant pair. The row Q gives the finite source-tail thresholds for the requested product tolerance, and the row T gives the majorant tail ledger that dominates the omitted convolution cells.

The handoff then enters the uniform-tail route. The $\mathsf{UniformCauchySeries}^{\uparrow}$ row U consumes the same finite threshold data, while R and D record the regular rational readback and dyadic tolerance budget needed before any endpoint-facing read is public.

Finally the Real seal E and structural rows H, C, P, N preserve that route. The consumer therefore receives exactly the finite modulus-majorant handoff and cannot replace it by a host product theorem, a selected infinite convolution sum, quotient equality, countable choice, or ambient completeness. □

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyProductModulusMajorant}^{\uparrow}}$.

Constructive story: A $\mathsf{CauchyProductModulusMajorant}^{\uparrow}$ packet is generated from two source-series rows, a convolution-window row, a product-modulus row, a majorant tail ledger, a UniformCauchySeries threshold row, RegSeqRat readback, a DyadicRatCore budget, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CauchyProductModulusMajorant}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8672.1, Definition 8672.2, and Definition 8672.3 seed the finite product-tail modulus route over CauchySeriesProduct, CauchyMajorantSeries, UniformCauchySeries, RegSeqRat, DyadicRatCore, Real sealing, transport, replay, provenance, and local naming.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CauchyProductModulusMajorant}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host Cauchy product theorems, selected infinite convolution sums, quotient equality of series, countable choice, trichotomy, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, convolution-window exactness, product-modulus exactness, majorant tail control, uniform-tail thresholding, regular readback, dyadic budget accounting, Real seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.CauchyProductModulusMajorantUp.

Chapter 8673

A Concrete Naming Certificate for UniformlyLocatedSequence$^{\uparrow}$

Following Bishop and Bridges, uniformly located sequences are represented by displayed finite located-window and modulus data rather than by selected limits or quotient stream representatives. The UniformlyLocatedSequence$^{\uparrow}$ packet sits after the located sequence modulus route of chapter 1801, the stream-window surface of chapter 126, the regular rational readback of chapter 301, the dyadic tolerance core of chapter 291, and the terminal real-name seal of chapter 38. It names the finite uniform locatedness surface used by the L10 Real and Completion route without asserting quotient streams, countable choice, trichotomy, selected limits, or ambient Real$^{\uparrow}$ completeness.

Definition 8673.1 (Uniformly located sequence carrier)**.** *A* UniformlyLocatedSequence$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$U = (L, M, D, S, R, E, H, C, P, N)$$

with the following displayed rows:

1. *L is the located-sequence window row, recording the finite index windows and located value reads exposed to the packet.*
2. *M is the shared monotone modulus schedule, sending each displayed tolerance request to a finite window bound reused by all completion-facing consumers.*
3. *D is the* DyadicRatCore$^{\uparrow}$ *tolerance scale that records the positive dyadic requests and comparison rows used by M.*
4. *S is the* StreamName$^{\uparrow}$ *finite-window row naming the inspected stream prefixes.*
5. *R is the* RegSeqRat$^{\uparrow}$ *readback row obtained from the displayed stream windows and dyadic tolerance scale.*
6. *E is the terminal* Real$^{\uparrow}$ *seal row, available only after L, M, D, S, R have been displayed.*
7. *H records componentwise* hsame *transport for located windows, the shared modulus schedule, dyadic tolerances, stream windows, regular rational readbacks, Real seals, replay, provenance, and local naming.*
8. *C records displayed* Cont *replay from a uniform locatedness request through L, M, D, S, R, E, H.*
9. *P is the* Pkg *provenance over* UniformlyLocatedSequence$^{\uparrow}$, LocatedSequenceModulus$^{\uparrow}$, StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, Real$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*

10. N is the local $\mathsf{NameCert}_{\mathsf{UniformlyLocatedSequence}^{\uparrow}}$ *row.*
The carrier has no coordinate for quotient stream equality, selected limits, countable choice over windows, trichotomy, host real equality, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 8673.2 (Uniformly located sequence NameCert obligations)**.** *For every accepted* UniformlyLocatedSequer *carrier $U = (L, M, D, S, R, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{UniformlyLocatedSequence}^{\uparrow}}$ *surface consists exactly of located-window admission through L, shared monotone modulus exposure through M, dyadic tolerance accounting through D,* $\mathsf{StreamName}^{\uparrow}$ *finite-window admission through S,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback through R, terminal* $\mathsf{Real}^{\uparrow}$ *sealing through E, componentwise* hsame *transport through H, displayed* Cont *replay through C, provenance through P, and local naming through N.*

Proof. Project the carrier of Definition 8673.1. The only rows that expose analytic data are the located windows L, the shared schedule M, the dyadic tolerance scale D, the stream window S, the regular rational readback R, and the terminal seal E.

The monotonicity requirement is read from the displayed schedule M. Reusing a smaller tolerance or a later completion request therefore reuses the same finite schedule row and the same dyadic tolerance scale rather than selecting a new stream representative.

The readback route then passes through S and R before the $\mathsf{Real}^{\uparrow}$ seal E is available. Rows H, C, P, N transport, replay, source, and name that same route, so a consumer cannot bypass the displayed finite packet.

Since no carrier coordinate records quotient stream equality, selected limits, countable choice, trichotomy, host real equality, or ambient Real completeness, row projection and monotone reuse of the displayed modulus schedule exhaust the NameCert obligations. □

Falsifiable prediction: Every accepted $\mathsf{UniformlyLocatedSequence}^{\uparrow}$ read exposes located sequence windows, a shared monotone modulus schedule, a DyadicRatCore tolerance scale, StreamName finite windows, RegSeqRat readback, a terminal RealUp seal, componentwise transport, continuation replay, provenance, and local naming.

Independence witness: located-sequence-modulus, streamname, regseqrat, dyadicratcore, real: $\mathsf{UniformlyLocatedSequence}^{\uparrow}$ is not identical to any listed sibling because it binds one shared monotone locatedness schedule across all finite sequence windows before regular rational readback and Real sealing.

Closure status for $\mathsf{NameCert}_{\mathsf{UniformlyLocatedSequence}^{\uparrow}}$**.**

Constructive story: A $\mathsf{UniformlyLocatedSequence}^{\uparrow}$ packet is generated from located sequence windows, a shared monotone modulus schedule, DyadicRatCore tolerance data, StreamName finite windows, RegSeqRat readback, a RealUp seal, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{UniformlyLocatedSequence}^{\uparrow}}$, seed)

Scope closed: Definition 8673.1 and Definition 8673.2 seed the finite uniformly located sequence route from displayed windows and a shared modulus schedule to RegSeqRat readback and the terminal RealUp seal.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{UniformlyLocatedSequence}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim quotient stream equality, selected limits, countable choice, trichotomy, host real equality, RealUp completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, located-window coverage, monotone modulus reuse, dyadic tolerance compatibility, StreamName window admission, RegSeqRat readback, Real seal nonescape, replay, provenance, and local naming for BEDC.Derived.UniformlyLocatedSequenceUp.

Chapter 8674

A Concrete Naming Certificate for $\mathsf{CompactCompletionFunctor}^{\uparrow}$

Following Bishop and Bridges and Kelley, the $\mathsf{CompactCompletionFunctor}^{\uparrow}$ packet records the finite route by which compact metric source data, total-bounded completion data, and L10 regular-name readback are offered as a functorial completion surface. It consumes the finite-net completion route of chapter 1573, the metric-completion interface of chapter 1506, and the compact metric source surface of chapter 129. Its L10 observation rows are read through chapter 126, chapter 301, chapter 291, and chapter 38. The packet names a displayed completion functor route; it does not assert open-cover compactness, quotient-completion equality, selected limits, countable choice, host equality of completed points, or ambient completeness of $\mathsf{Real}^{\uparrow}$.

Definition 8674.1 (Compact completion functor carrier)**.** *A* $\mathsf{CompactCompletionFunctor}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$F = (K, T, C, M, L, S, R, D, E, H, A, P, N)$$

with the following visible rows:

1. *K is the* $\mathsf{CompactMetric}^{\uparrow}$ *source row, displaying the compact metric carrier, metric classifier, and compact-facing finite observation surface before any completion read is exposed.*
2. *T is the* $\mathsf{TotallyBoundedCompletion}^{\uparrow}$ *row, recording the finite-net completion route, completion embedding, separated handoff, and total-bounded completion ledger consumed by the functor surface.*
3. *C is the* $\mathsf{CompleteMetric}^{\uparrow}$ *row attached to the completed target, displaying the complete metric seal used by completion-facing consumers.*
4. *M is the* $\mathsf{MetricCompletion}^{\uparrow}$ *row, exposing the metric-completion admissibility route and the displayed completion map from the source side to the completed side.*
5. *L is the* $\mathsf{Completion}^{\uparrow}$ *interface row, retaining only the functorial source-target ledger, identity route, composition route, and completion-seal handoff visible to downstream packets.*
6. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row opened from compact source names and completed target names before any regular readback is public.*
7. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row obtained from those finite windows and the dyadic tolerance ledger.*

8. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row, carrying the dyadic scales, finite-net radii, comparison ledgers, and precision requests used by T, S, R.*
9. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached only after K, T, C, M, L, S, R, D have been displayed.*
10. *H records componentwise* hsame *transport for the compact metric source, total-bounded completion route, complete metric seal, metric-completion map, completion interface, stream windows, regular readback, dyadic tolerance ledger, Real seal, replay, provenance, and local naming rows.*
11. *A records displayed* Cont *replay from a compact-source tolerance request through the finite-net completion route, completion map, stream windows, regular readback, and Real seal.*
12. *P is the* Pkg *provenance over* $\mathsf{CompactCompletionFunctor}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{TotallyBoundedCompletion}^{\uparrow}$, $\mathsf{CompleteMetric}^{\uparrow}$, $\mathsf{MetricCompletion}^{\uparrow}$, $\mathsf{Completion}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
13. *N is the local* $\mathsf{NameCert}_{\mathsf{CompactCompletionFunctor}^{\uparrow}}$ *row.*

The carrier predicate asserts exactly that these rows form one finite compact-completion functor packet. It has no coordinate for an open-cover compactness theorem, quotient representatives, a selected limit, countable choice, host equality of completed points, or ambient completeness of $\mathsf{Real}^{\uparrow}$.

Theorem 8674.2 (Compact completion functor NameCert obligations)**.** *For every accepted* CompactCompletionFu *carrier $F = (K, T, C, M, L, S, R, D, E, H, A, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{CompactCompletionFunctor}^{\uparrow}}$ *surface consists exactly of the following obligation rows:*

1. *carrier admission for the displayed compact metric source, total-bounded completion route, complete metric seal, metric-completion map, completion interface, stream windows, regular readback, dyadic tolerance ledger, Real seal, transport, replay, provenance, and local naming rows;*
2. *finite-net completion handoff, requiring every completion-facing tolerance request to read K, T, D before M, L are exposed;*
3. *complete-target seal, requiring every completed metric read to pass through C and then through the terminal* $\mathsf{Real}^{\uparrow}$ *row E;*
4. *functorial replay, requiring identity and composition reads in L to be replayed through the same S, R, D, E, H, A, P, N rows as the underlying completion request;*
5. *ledger non-escape, excluding open-cover compactness, quotient-completion equality, selected representatives, countable choice, host equality of completed points, and ambient* $\mathsf{Real}^{\uparrow}$ *completeness from the packet.*

No NameCert obligation is stored outside these rows.

Proof. Project the carrier of Definition 8674.1. The projected rows are exactly the compact metric source K, total-bounded completion route T, complete metric seal C, metric-completion map M, completion interface L, finite windows S, regular readback R, dyadic tolerances D, Real seal E, and structural rows H, A, P, N.

The finite-net completion handoff is inherited from chapter 1573 and chapter 1506. A tolerance request first reads compact metric source data and finite-net radii, then reaches the completion-facing map and interface rows.

The complete-target seal is downstream of chapter 128. The L10 observation spine through $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ keeps every completed metric read behind finite windows, regular readbacks, dyadic tolerances, and the terminal seal.

Functorial replay is the role of L together with H and A. Identity and composition reads preserve the displayed completion route and cannot replace it by quotient representatives, selected limits, or host equality. The provenance and naming rows P, N name only this finite route, so the excluded principles have no carrier coordinate from which to escape. □

Theorem 8674.3 (Compact completion functor finite-net handoff)**.** *Every completion-facing consumer of an accepted* $\mathsf{CompactCompletionFunctor}^{\uparrow}$ *carrier* $F = (K, T, C, M, L, S, R, D, E, H, A, P, N)$ *must first read the compact metric source row, the total-bounded finite-net completion route, the dyadic tolerance ledger, the metric-completion map, the completion interface, the finite* $\mathsf{StreamName}^{\uparrow}$ *windows, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback, and the terminal* $\mathsf{Real}^{\uparrow}$ *seal. In route notation, every public completion read factors through*

$$K, D, T \longmapsto M, L \longmapsto S, R \longmapsto C, E \longmapsto H, A, P, N.$$

Thus the handoff exports the L10 finite-net completion route and not an open-cover compactness principle, a quotient-completion equality, a selected limit, countable choice, host equality, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Begin with an accepted carrier $F = (K, T, C, M, L, S, R, D, E, H, A, P, N)$. The source compact metric packet is visible only through K, and the finite-net completion route is visible only through T together with dyadic tolerance data D.

Apply Definition 8674.2. It requires the finite-net route to be read before the metric-completion map M and completion interface L become public.

The L10 readback then passes through S, R, D, E. The finite $\mathsf{StreamName}^{\uparrow}$ windows and $\mathsf{RegSeqRat}^{\uparrow}$ readback carry the displayed precision request, while the $\mathsf{Real}^{\uparrow}$ seal is reached only after the complete metric row C has been displayed.

Finally, H, A, P, N transport, replay, source, and name the same route. Since the carrier contains no open-cover compactness row, quotient representative, selected limit, countable-choice schedule, host equality row, or ambient Real-completeness theorem, the route shown in the statement is the whole public handoff. □

Closure status for $\mathsf{NameCert}_{\mathsf{CompactCompletionFunctor}^{\uparrow}}$**.**

Constructive story: A $\mathsf{CompactCompletionFunctor}^{\uparrow}$ packet is generated from a compact metric source row, a total-bounded finite-net completion route, a complete metric seal, a metric-completion map, a completion interface, finite StreamName windows, RegSeqRat readback, DyadicRatCore tolerance data, a RealUp seal, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{CompactCompletionFunctor}^{\uparrow}}$, seed)

Scope closed: Definition 8674.1, Definition 8674.2, and Definition 8674.3 seed the finite NameCert surface for compact metric completion functoriality along the L10 completion route.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{CompactCompletionFunctor}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close open-cover compactness, quotient-completion equality, selected limits, countable choice, host equality of completed points, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, finite-net completion handoff, complete-target sealing, functorial replay, transport and replay stability, ledger non-escape, and TasteGate field faithfulness for BEDC.Derived.CompactCompletionFunctorUp.

Chapter 8675

A Concrete Naming Certificate for $\mathsf{BanachIndicatrix}^{\uparrow}$

Following Banach's indicatrix theorem for functions of bounded variation, the $\mathsf{BanachIndicatrix}^{\uparrow}$ packet records the finite BEDC surface by which level preimage counts are read from a bounded-variation real function before any area, variation, or Real-facing consumer sees the result. It sits after the bounded-variation real-function carrier of chapter 3654, the regular rational readback of chapter 301, the dyadic tolerance accounting of chapter 291, and the terminal Real seal of chapter 38. The packet is a finite level-count ledger over displayed interval and preimage rows; it does not introduce a host function quotient, a selected measurable representative, countable choice over levels, a measure-theoretic coarea formula, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 8675.1 (Banach indicatrix carrier)**.** *A* $\mathsf{BanachIndicatrix}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$I = (B, L, G, P, R, D, E, H, C, Q, N)$$

with the following displayed rows:

1. *B is the accepted* $\mathsf{BoundedVariationRealFunction}^{\uparrow}$ *source row on a displayed real interval.*
2. *L is a finite list of displayed level rows read through* $\mathsf{RegSeqRat}^{\uparrow}$ *names.*
3. *G is the finite interval ledger that records which displayed subintervals are inspected for each level row.*
4. *P is the finite preimage-count ledger; each entry records the counted crossings or endpoint hits for one displayed level row and one displayed interval window.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for function values, level names, and endpoint comparisons.*
6. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row for sign separation, endpoint equality tests, and count stability under displayed refinements.*
7. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached only after B, L, G, P, R, D have been displayed.*
8. *H records componentwise* hsame *transport for the bounded-variation source, level rows, interval ledger, preimage-count ledger, readback, tolerance, Real-seal, replay, provenance, and local naming rows.*
9. *C records displayed* Cont *replay from a level-count request through bounded variation, finite level rows, finite interval inspection, preimage counting, rational readback, dyadic tolerance, and terminal Real sealing.*

10. *Q is the* Pkg *provenance over* $\mathsf{BanachIndicatrix}^{\uparrow}$, $\mathsf{BoundedVariationRealFunction}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{BanachIndicatrix}^{\uparrow}}$ *row.*

Accepted packets are compared only through these displayed rows.

Theorem 8675.2 (Banach indicatrix NameCert obligations)**.** *For every accepted* $\mathsf{BanachIndicatrix}^{\uparrow}$ *carrier $I = (B, L, G, P, R, D, E, H, C, Q, N)$, the local* $\mathsf{NameCert}_{\mathsf{BanachIndicatrix}^{\uparrow}}$ *surface consists exactly of bounded-variation real-function source admission, finite level-row exposure, finite interval-ledger exposure, finite preimage-count exposure, RegSeqRat readback, DyadicRatCore tolerance accounting, Real seal nonescape, componentwise transport, displayed replay, provenance, and local naming.*

Proof. Project the carrier of Definition 8675.1. The source is the single row B, and every level inspected by the packet is already listed in the finite row L.

The counting surface is finite. The interval ledger G selects the displayed interval windows, and the preimage-count ledger P records only the crossings or endpoint hits supported by those windows.

Readback and tolerance remain downstream. The row R supplies regular rational names for values and levels, D supplies dyadic sign and endpoint tests, and E seals only the Real-facing boundary reached from those rows.

Finally H, C, Q, N transport, replay, source, and locally name the same packet. Since no row stores a host quotient of functions, a measurable representative, a choice family over all levels, a coarea measure, or ambient Real completeness, none of those objects is exported by the local NameCert surface. □

Theorem 8675.3 (Banach indicatrix finite level-count route)**.** *Every variation, area, or Real-facing consumer of an accepted* $\mathsf{BanachIndicatrix}^{\uparrow}$ *packet must first read the finite route*

$$\mathsf{BoundedVariationRealFunction}^{\uparrow},\ L,\ G,\ P,\ \mathsf{RegSeqRat}^{\uparrow},\ \mathsf{DyadicRatCore}^{\uparrow},\ \mathsf{Real}^{\uparrow} \longmapsto H, C, Q, N.$$

Thus the Banach indicatrix is exposed as finite level rows with finite interval and preimage-count ledgers, not as a host-level counting function over all real levels or a selected measure datum.

Proof. Apply Definition 8675.2. A consumer cannot read an indicatrix count until the bounded-variation real-function source, the displayed level rows, the interval ledger, and the preimage-count ledger have been exposed.

The handoff to Real-facing consumers then passes through rational readback and tolerance accounting. The $\mathsf{RegSeqRat}^{\uparrow}$ row R names function values and levels, the $\mathsf{DyadicRatCore}^{\uparrow}$ row D records the finite sign and endpoint tests, and the $\mathsf{Real}^{\uparrow}$ row E seals only the displayed result.

The structural rows H, C, Q, N preserve that finite route for downstream variation and area readers. They add no host function quotient, all-level counting function, selected measure representative, countable choice, or ambient Real-completeness coordinate. □

Falsifiable prediction: A purported $\mathsf{BanachIndicatrix}^{\uparrow}$ consumer that reads a level count while omitting the bounded-variation real-function source row, finite level rows, finite interval ledger, preimage-count ledger, RegSeqRat readback, DyadicRatCore tolerance accounting, Real seal, transport, replay, provenance, or local naming row refutes the packet.

Independence witness: bounded-variation-real-function, regseqrat, dyadicratcore, real: $\mathsf{BanachIndicatrix}^{\uparrow}$ is not bijective with any listed sibling because it joins the bounded-variation real-function source,

finite level rows, finite interval inspection, preimage-count ledger, rational readback, dyadic tolerance, Real sealing, transport, replay, provenance, and local naming as one level-count packet.

Closure status for $\mathsf{NameCert}_{\mathsf{BanachIndicatrix}^{\uparrow}}$.

Constructive story: A $\mathsf{BanachIndicatrix}^{\uparrow}$ packet is generated from a BoundedVariationRealFunctionUp source row, finite level rows, finite interval inspection rows, finite preimage-count rows, RegSeqRat readback, DyadicRatCore tolerance accounting, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BanachIndicatrix}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8675.1, Definition 8675.2, and Definition 8675.3 seed the finite Banach indicatrix route for bounded-variation real functions and Real-facing consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BanachIndicatrix}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim Lean verification, a host counting function over all real levels, a selected measurable representative, measure-theoretic coarea data, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, finite level-row exposure, interval-ledger exposure, preimage-count exposure, RegSeqRat readback, DyadicRatCore tolerance accounting, Real seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.BanachIndicatrixUp.

Chapter 8676

A Concrete Naming Certificate for $\mathsf{BishopLocatedComparison}^{\uparrow}$

Following Bishop and Bridges, located comparison of real names is read through explicit rational windows and dyadic tolerance data rather than through trichotomy or quotient-real equality. The $\mathsf{BishopLocatedComparison}^{\uparrow}$ packet sits after the dyadic tolerance core of chapter 291, the stream-window surface of chapter 126, the regular rational readback of chapter 301, the terminal real-name seal of chapter 38, and the located interval route of chapter 394. It names a finite comparison interface for L10 real and completion consumers without importing selected representatives, ambient real order, or completeness of $\mathsf{Real}^{\uparrow}$.

Definition 8676.1 (Bishop located-comparison carrier)**.** *A* $\mathsf{BishopLocatedComparison}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (L, R, D, W, S, E, H, C, P, N)$$

with the following displayed rows:

1. *L is the left regular real-name row, including the inspected* $\mathsf{StreamName}^{\uparrow}$ *windows and* $\mathsf{RegSeqRat}^{\uparrow}$ *readbacks used by the comparison.*
2. *R is the right regular real-name row, with the same kind of displayed stream windows and regular rational readbacks.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance and enclosure ledger, recording the positive dyadic requests, enclosure widths, and finite comparison rows used to separate or overlap the two displayed names.*
4. *W is the located-window comparison ledger, listing the finite pairs of left and right windows inspected at each dyadic tolerance.*
5. *S is the terminal* $\mathsf{Real}^{\uparrow}$ *seal surface for the left and right names after the displayed windows and readbacks have been fixed.*
6. *E records the comparison outcome rows available to downstream consumers: separated-left, separated-right, or retained-overlap data, each tied to a displayed tolerance and window pair.*
7. *H records componentwise* hsame *transport for the left and right real-name rows, dyadic tolerance ledger, window ledger, seal rows, comparison outcome rows, replay, provenance, and local naming.*
8. *C records displayed* Cont *replay from each comparison request through L, R, D, W, S, E, H.*

9. *P is the* Pkg *provenance over* $\mathsf{BishopLocatedComparison}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{LocatedInterval}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{BishopLocatedComparison}^{\uparrow}}$ *row.*

The carrier predicate says that these rows form one finite located-comparison packet. It has no coordinate for real trichotomy, quotient real equality, a selected representative stream, a host order oracle, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 8676.2 (Bishop located-comparison NameCert obligations)**.** *For every accepted* BishopLocatedComparisc *carrier $K = (L, R, D, W, S, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{BishopLocatedComparison}^{\uparrow}}$ *surface consists exactly of the following finite rows:*

1. *carrier admission for the finite packet of Definition 8676.1;*
2. *left and right source visibility through the displayed* $\mathsf{StreamName}^{\uparrow}$ *windows and* $\mathsf{RegSeqRat}^{\uparrow}$ *readbacks in L and R;*
3. *dyadic located-window comparison coverage through the tolerance and enclosure ledger D together with the paired window ledger W;*
4. *comparison stability under componentwise* hsame *transport and displayed* Cont *replay through H and C;*
5. $\mathsf{Real}^{\uparrow}$ *seal nonescape through S, requiring every real-facing consumer to pass through the displayed left and right window rows before reading a seal;*
6. *provenance and local naming through P and N.*

No further order, equality, choice, or completeness obligation is part of the packet.

Lean4 ✓ `BEDC.Derived.BishopLocatedComparisonUp.BishopLocatedComparisonTasteGate single carrier alignment`

Proof. Project the carrier of Definition 8676.1. The left and right sources expose only their displayed stream windows and regular rational readbacks, while the dyadic ledger D supplies the tolerance and enclosure rows used by the comparison.

The paired window ledger W records exactly which left and right windows were inspected at each tolerance. A separated or retained-overlap row in E is therefore read only after the corresponding entries of L, R, D, W have been displayed.

Transport and replay are componentwise. Rows H and C move the same left source, right source, dyadic tolerance, window, seal, and outcome rows together, so a consumer cannot replace the finite comparison route with an external order oracle.

Finally, P and N record provenance and local naming for that same route. Since the carrier has no coordinate for trichotomy, quotient equality, selected representatives, or completeness of $\mathsf{Real}^{\uparrow}$, the listed rows exhaust the NameCert surface. □

Theorem 8676.3 (Bishop located-comparison Real seal nonescape)**.** *Every comparison consumer of an accepted* $\mathsf{BishopLocatedComparison}^{\uparrow}$ *carrier routes through the displayed* $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, *and* $\mathsf{LocatedInterval}^{\uparrow}$ *rows before it can read a comparison outcome or a real-facing seal. Such a consumer cannot read real trichotomy, quotient real equality, selected stream representatives, a host order oracle, or* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Read the consumer route from the carrier. The source rows L and R expose the stream windows and regular rational readbacks, and the dyadic ledger D supplies the tolerance scale on which the comparison is staged.

The window ledger W ties those rows to the located interval boundary inherited from chapter 394. A comparison outcome in E is therefore attached to a finite pair of displayed windows and a displayed dyadic tolerance before the terminal seal S is available.

Rows H, C, P, N transport, replay, source, and name the same finite route. None of these rows contains trichotomy, quotient equality, a selected representative, an external order oracle, or completeness data for $\mathsf{Real}^{\uparrow}$. Hence every real-seal or comparison read remains inside the displayed finite packet. □

Falsifiable prediction: Every accepted $\mathsf{BishopLocatedComparison}^{\uparrow}$ read exposes left and right StreamName windows, RegSeqRat readbacks, DyadicRatCore tolerance data, located interval window coverage, RealUp seal rows, componentwise transport, continuation replay, provenance, and local naming.

Independence witness: dyadicratcore, streamname, regseqrat, real, locatedinterval: $\mathsf{BishopLocatedComparison}^{\uparrow}$ is not identical to any listed sibling because it binds two real-name routes to one located comparison ledger before any outcome or RealUp seal is consumed.

Closure status for $\mathsf{NameCert}_{\mathsf{BishopLocatedComparison}^{\uparrow}}$.

Constructive story: A $\mathsf{BishopLocatedComparison}^{\uparrow}$ packet is generated from left and right regular real-name rows, DyadicRatCore tolerance and enclosure rows, StreamName windows, RegSeqRat readbacks, terminal RealUp seals, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BishopLocatedComparison}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8676.1, Definition 8676.2, and Definition 8676.3 seed the finite Bishop located-comparison route from displayed dyadic windows to terminal real-name seals.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BishopLocatedComparison}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim real trichotomy, quotient real equality, selected stream representatives, a host order oracle, RealUp completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, left and right source visibility, dyadic located-window comparison coverage, transport stability, Real seal nonescape, provenance, and local naming for BEDC.Derived.BishopLocatedComparis

Chapter 8677

A Concrete Naming Certificate for ArchimedeanDyadicIntervalMesh$^{\uparrow}$

Following Bishop and Bridges, an Archimedean interval mesh is read as finite dyadic data: a requested scale is met by an explicit depth, listed endpoints, and displayed cell incidence before any Real-facing completion argument can inspect it. The ArchimedeanDyadicIntervalMesh$^{\uparrow}$ packet places this textbook construction between the dyadic arithmetic of chapter 291, the finite-cell surface of chapter 5966, the stream windows of chapter 126, the regular rational readback of chapter 301, and the terminal real-name seal of chapter 38.

Definition 8677.1 (Archimedean dyadic interval mesh carrier)**.** *An* ArchimedeanDyadicIntervalMesh$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M = (D, A, J, I, W, R, Q, H, C, P, N)$$

with the following displayed rows:

1. *D is the* DyadicRatCore$^{\uparrow}$ *endpoint ledger, listing the left and right dyadic endpoints, radius comparisons, and tolerance arithmetic used by the mesh.*
2. *A is the Archimedean depth witness: for the requested positive dyadic tolerance it displays a natural depth whose dyadic mesh size is below that tolerance.*
3. *J is the finite cell list, including the ordered dyadic subintervals at depth A and their endpoint-incidence rows.*
4. *I is the* DyadicIntervalNet$^{\uparrow}$ *handoff row that exposes J as a finite interval-net surface rather than as an open cover.*
5. *W is the* StreamName$^{\uparrow}$ *window row through which endpoint and cell observations are inspected.*
6. *R is the* RegSeqRat$^{\uparrow}$ *readback row obtained from the displayed windows and dyadic tolerance ledger.*
7. *Q is the terminal* Real$^{\uparrow}$ *seal row reached only after D, A, J, I, W, R have been replayed.*
8. *H stores componentwise* hsame *transport for endpoint, depth, cell, window, readback, seal, and local classifier rows.*
9. *C stores displayed* Cont *replay routes from a mesh request through D, A, J, I, W, R, Q.*

10. *P records* Pkg *provenance over* ArchimedeanDyadicIntervalMesh$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, DyadicIntervalNet$^{\uparrow}$, StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, Real$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* NameCert$_{\text{ArchimedeanDyadicIntervalMesh}^{\uparrow}}$ *row.*

The carrier has no coordinate for open-cover compactness, selected subcovers, quotient interval equality, selected real representatives, countable choice, trichotomy, or ambient Real$^{\uparrow}$ *completeness.*

Theorem 8677.2 (Archimedean dyadic interval mesh NameCert obligations)**.** *For every accepted* ArchimedeanDyadicIntervalMesh$^{\uparrow}$ *carrier $M = (D, A, J, I, W, R, Q, H, C, P, N)$, the local* NameCert$_{\text{ArchimedeanDyadicInte}}$ *surface is exhausted by the finite dyadic endpoint ledger, Archimedean depth witness, finite cell list,* DyadicIntervalNet$^{\uparrow}$ *cell handoff,* StreamName$^{\uparrow}$ *observation window,* RegSeqRat$^{\uparrow}$ *readback, terminal* Real$^{\uparrow}$ *seal, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming row. Any consumer of the mesh must read those rows in that order before it may use the packet as interval or completion data.*

Proof. Project the carrier of Definition 8677.1. The endpoint arithmetic, depth, listed cells, interval-net handoff, finite windows, readback, and terminal seal are the only analytic rows.

The Archimedean row A is not a completeness claim. It is a displayed finite depth witness whose dyadic mesh size is compared against the requested tolerance inside the ledger D.

The cell row J becomes interval-net data only through I. Thus a consumer receives listed dyadic cells and endpoint incidence from the DyadicIntervalNet$^{\uparrow}$ surface before any regular-name or Real-facing read is exposed.

Finally read the structural rows H, C, P, N. They transport, replay, source, and locally name the same finite packet. Since the carrier contains no row for open-cover compactness, selected subcovers, quotient interval equality, selected representatives, countable choice, trichotomy, or ambient Real completeness, the listed rows exhaust the NameCert obligations. □

Theorem 8677.3 (Archimedean dyadic interval mesh L10 handoff)**.** *Every L10 completion or finite-Real consumer of an accepted* ArchimedeanDyadicIntervalMesh$^{\uparrow}$ *packet must first expose the* DyadicRatCore$^{\uparrow}$ *endpoint ledger D, the Archimedean depth witness A, the finite cell list J, the* DyadicIntervalNet$^{\uparrow}$ *handoff I, the* StreamName$^{\uparrow}$ *window W, the* RegSeqRat$^{\uparrow}$ *readback R, and the terminal* Real$^{\uparrow}$ *seal Q. The handoff supplies a finite dyadic mesh object for interval and completion arguments; it does not supply open-cover compactness, selected finite subcovers, quotient stream equality, selected limits, countable choice, or ambient* Real$^{\uparrow}$ *completeness.*

Proof. Start with the NameCert obligations of Definition 8677.2. They force every mesh read through the endpoint ledger, depth row, finite cell list, interval-net handoff, finite window, regular readback, Real seal, and structural rows.

Use the sibling DyadicIntervalNet$^{\uparrow}$ route of chapter 5966. The row I exposes the displayed dyadic cells and endpoint incidence supplied by J, so the mesh reaches compact-interval or completion consumers only as finite interval-net data.

Next pass through the StreamName$^{\uparrow}$ and RegSeqRat$^{\uparrow}$ rows. The window row W records the inspected endpoint and cell observations, and R gives the regular rational readback obtained from those observations and the dyadic tolerance ledger.

The terminal seal Q is reached only after that finite route has been replayed. Rows H, C, P, N preserve the same route under transport, continuation replay, provenance, and local naming, so an L10 consumer receives a finite mesh handoff rather than an ambient compactness or completeness principle. □

Falsifiable prediction: Every accepted $\mathsf{ArchimedeanDyadicIntervalMesh}^{\uparrow}$ read exposes a DyadicRatCore endpoint ledger, an Archimedean depth witness, a finite dyadic cell list, a DyadicIntervalNet cell handoff, a StreamName window, a RegSeqRat readback, a terminal RealUp seal, componentwise transport, continuation replay, provenance, and local naming.

Independence witness: dyadicratcore, dyadic-interval-net, streamname, regseqrat, real: ArchimedeanDyadicInter is not identical to any listed sibling because it binds the Archimedean depth witness and the finite dyadic cell list before the interval-net and Real-facing handoff.

Closure status for $\mathsf{NameCert}_{\mathsf{ArchimedeanDyadicIntervalMesh}^{\uparrow}}$.

Constructive story: An $\mathsf{ArchimedeanDyadicIntervalMesh}^{\uparrow}$ packet is generated from a DyadicRatCore endpoint ledger, an Archimedean depth witness, a finite dyadic cell list, a DyadicIntervalNet handoff, a StreamName window, a RegSeqRat readback, a RealUp seal, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{ArchimedeanDyadicIntervalMesh}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8677.1, Definition 8677.2, and Definition 8677.3 seed the finite Archimedean dyadic mesh route from endpoint arithmetic to Real-facing completion reads.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{ArchimedeanDyadicIntervalMesh}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim open-cover compactness, selected subcovers, quotient interval equality, selected real representatives, countable choice, trichotomy, Lean verification, bridge checking, or ambient RealUp completeness.

Upgrade path: Obligation closure requires checked carrier admission, Archimedean depth exactness, dyadic cell coverage, endpoint incidence, StreamName and RegSeqRat readback routing, Real seal ordering, replay, provenance, and local naming for BEDC.Derived.ArchimedeanDyadicIntervalMeshUp.

Chapter 8678

A Concrete Naming Certificate for $\mathsf{BishopLocatedCompletionEnvelope}^{\uparrow}$

Following Bishop–Bridges constructive analysis, the $\mathsf{BishopLocatedCompletionEnvelope}^{\uparrow}$ packet records the finite envelope by which located Cauchy-name data is admitted to the Real and Completion route without quotienting names or selecting limits. It sits over the dyadic tolerance core of chapter 291, the stream-window surface of chapter 126, the regular rational readback of chapter 301, the terminal real seal of chapter 38, the directed-index substrate of chapter 1607, and the metric completion service of chapter 1506. The packet is a located completion envelope for finite NameCert consumers; it is not a quotient completion, a selected limit operation, ambient $\mathsf{Real}^{\uparrow}$ completeness, countable choice, or host equality of completed representatives.

Definition 8678.1 (Bishop located completion envelope carrier)**.** *A* $\mathsf{BishopLocatedCompletionEnvelope}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$E = (D, S, R, L, M, I, A, T, C, P, N)$$

with the following displayed rows:

1. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger for rational radii, slack witnesses, and refusal rows.*
2. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window schedule read by every Cauchy-name request.*
3. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *regular rational readback obtained from the displayed stream windows.*
4. *L is the located classifier row, recording the finite apartness and enclosure answers used to admit a Cauchy name to the envelope.*
5. *M is the* $\mathsf{MetricCompletion}^{\uparrow}$ *completion-service row exposed only after D, S, R, L have been displayed.*
6. *I is the* $\mathsf{DirectedSet}^{\uparrow}$ *request-index row for net-style or filter-style completion consumers that need a finite common-window witness.*
7. *A is the terminal* $\mathsf{Real}^{\uparrow}$ *seal reached by the envelope route.*
8. *T records componentwise* hsame *transport for the dyadic, stream, regular-rational, located, completion, directed-index, Real-seal, replay, provenance, and local naming rows.*
9. *C records displayed* Cont *replay from a completion request through $D, S, R, L, M, I, A, T, P, N$.*

10. *P is the* Pkg *provenance over* $\mathsf{BishopLocatedCompletionEnvelope}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{DirectedSet}^{\uparrow}$, $\mathsf{MetricCompletion}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{BishopLocatedCompletionEnvelope}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $D, S, R, L, M, I, A, T, C, P, N$. It has no coordinate for quotient completion, selected limits, ambient $\mathsf{Real}^{\uparrow}$ *completeness, countable choice, trichotomy, or host equality of completion representatives.*

Theorem 8678.2 (Bishop located completion envelope NameCert obligations)**.** *For an accepted* $\mathsf{BishopLocatedCompletionEnvelope}^{\uparrow}$ *carrier $E = (D, S, R, L, M, I, A, T, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{BishopLocatedCompl}}$ *surface consists exactly of the following five obligation families:*

1. *carrier envelope admission through the displayed packet $D, S, R, L, M, I, A, T, C, P, N$;*
2. *located Cauchy-name classification through the finite dyadic, stream-window, regular-rational, and located rows D, S, R, L;*
3. *componentwise* hsame *transport through T for every displayed row;*
4. *finite completion ledger exposure through M, I, A, C, P, N;*
5. *a no-choice boundary excluding quotient completion, selected limits, ambient* $\mathsf{Real}^{\uparrow}$ *completeness, countable-choice schedules, trichotomy, and host equality.*

Proof. Carrier admission is the tuple of Definition 8678.1. Every row consumed by a completion-facing reader is one of $D, S, R, L, M, I, A, T, C, P, N$, so the carrier envelope is finite and visible.

The located Cauchy-name classifier is confined to D, S, R, L. The dyadic ledger supplies tolerance requests, the stream row supplies finite observations, the regular rational row supplies readback, and the located row records the finite apartness or enclosure answer.

The completion ledger is then read through M, I, A, C, P, N. The metric-completion row and directed-index row expose only the finite request surface that reaches the terminal Real seal, while replay, provenance, and local naming keep the route inspectable.

Finally the carrier contains no coordinate for quotient completion, selected limits, ambient Real completeness, countable choice, trichotomy, or host equality. Componentwise transport through T preserves the displayed rows only, so none of those excluded principles can be exported by the local NameCert surface. □

Theorem 8678.3 (Located Cauchy-name classifier)**.** *Every completion-facing read of an accepted* $\mathsf{BishopLocatedCompletionEnvelope}^{\uparrow}$ *packet must pass through the located Cauchy-name route*

$$D \longmapsto S \longmapsto R \longmapsto L$$

before it may inspect the completion row M, directed-index row I, or terminal $\mathsf{Real}^{\uparrow}$ *seal A.*

Proof. The carrier definition places the dyadic tolerance ledger, stream windows, regular rational readback, and located classifier before any completion row. No later coordinate stores a second classifier for the same request.

Apply the NameCert obligation surface of Definition 8678.2. It identifies D, S, R, L as the only rows that admit a located Cauchy-name read. Therefore a consumer that reaches M, I, A has already displayed those rows.

The structural rows T, C, P, N transport and replay the same route. They do not add a hidden selector, quotient representative, or ambient completion proof. □

Theorem 8678.4 (Finite completion ledger)**.** *Let $E = (D, S, R, L, M, I, A, T, C, P, N)$ be an accepted* $\mathsf{BishopLocatedCompletionEnvelope}^{\uparrow}$ *packet. Every Real or Completion consumer reads the completion service only through the finite ledger*

$$D, S, R, L, M, I, A, T, C, P, N.$$

The ledger may cite $\mathsf{MetricCompletion}^{\uparrow}$ *and* $\mathsf{DirectedSet}^{\uparrow}$ *rows, but it exports no quotient completion, selected Moore–Smith limit, ambient* $\mathsf{Real}^{\uparrow}$ *completeness theorem, or countable-choice schedule.*

Proof. First expose the located Cauchy-name route of Definition 8678.3. It supplies D, S, R, L before any completion-facing row is read.

Next read the completion and directed-index rows M and I. These rows name the finite completion service and common-window substrate available to the consumer, rather than a quotient of all Cauchy names or a selected limiting point.

Finally the terminal Real seal A is transported and replayed through T, C, P, N. Since the ledger contains only these finite rows, any quotient completion, selected limit, Real completeness theorem, or countable-choice schedule must be supplied by a separate certificate. □

Theorem 8678.5 (No-choice boundary)**.** *An accepted* $\mathsf{BishopLocatedCompletionEnvelope}^{\uparrow}$ *packet exports a located completion envelope only through the displayed carrier, classifier, transport, and finite ledger rows. It does not supply quotient completion,* $\mathsf{Real}^{\uparrow}$ *completeness, selected limits, trichotomy, countable choice, or host equality of completion representatives.*

Proof. Inspect the carrier rows. The packet records dyadic tolerances, finite stream windows, regular rational readback, a located classifier, a metric-completion row, a directed-index row, a terminal Real seal, componentwise transport, replay, provenance, and local naming.

None of those rows is a quotient of Cauchy names, a selector for representatives, a global completeness theorem for $\mathsf{Real}^{\uparrow}$, a trichotomy oracle, or a countable-choice functional. The Real seal is downstream of the finite located classifier and completion ledger.

Thus every legal consumer remains inside the displayed envelope route. Any stronger completion theorem may cite this packet as input, but it must display its own completion, equality, or limit certificate. □

Closure status for $\mathsf{NameCert}_{\mathsf{BishopLocatedCompletionEnvelope}^{\uparrow}}$.

Constructive story: A $\mathsf{BishopLocatedCompletionEnvelope}^{\uparrow}$ packet is generated from a DyadicRatCore tolerance ledger, StreamName finite windows, RegSeqRat readback, a located Cauchy-name classifier, MetricCompletion service row, DirectedSet request index, RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{BishopLocatedCompletionEnvelope}^{\uparrow}}$, seed)

Scope closed: Definition 8678.1, Definition 8678.2, Definition 8678.3, Definition 8678.4, and Definition 8678.5 seed the finite envelope over displayed tolerance, stream-window, regular-rational, located, completion-service, directed-index, Real-seal, transport, replay, provenance, and local naming rows.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{BishopLocatedCompletionEnvelope}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim quotient completion, RealUp completeness, selected limits, countable choice, trichotomy, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, located Cauchy-name classification, componentwise transport, finite completion ledger exposure, provenance, local naming, and no-choice boundary for BEDC.Derived.BishopLocatedComplet

Chapter 8679

A Concrete Naming Certificate for $\mathsf{EventuallyFilter}^{\uparrow}$

Following Bishop–Bridges tail arguments for sequences and the Bourbaki–Kelley filter vocabulary, the $\mathsf{EventuallyFilter}^{\uparrow}$ packet records the finite evidence that a sequence claim is read only beyond a displayed threshold. It sits between the cofinite-tail surface of chapter 1564, the regular Cauchy tail-filter route of chapter 1605, the finite stream windows of chapter 126, the regular rational readback of chapter 301, and the terminal real-name seal of chapter 38. The packet is a finite eventual-tail certificate, not a quotient filter, selected limit, countable-choice schedule, host equality of streams, or ambient completeness principle.

Definition 8679.1 (EventuallyFilter carrier)**.** *An* $\mathsf{EventuallyFilter}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$V = (F, T, B, S, R, E, H, C, P, N)$$

with the following displayed rows:

1. *F is the cofinite threshold row, naming the displayed index after which the event is inspected.*
2. *T is the finite complement check, listing the bounded prefix ignored by the eventual read.*
3. *B is the* $\mathsf{FilterBase}^{\uparrow}$ *row whose accepted base elements are exactly the threshold tails generated by F and checked by T.*
4. *S is the* $\mathsf{StreamName}^{\uparrow}$ *window row read only on the displayed tail.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row obtained from the tail windows and their tolerance ledger.*
6. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal reached only after F, T, B, S, R have been exposed.*
7. *H records componentwise* hsame *transport for the threshold, finite complement, filter-basis, stream-window, readback, Real seal, continuation, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from threshold admission through finite complement checking, filter-basis exposure, tail-window readback, regular rational readback, and the Real seal.*
9. *P is the* Pkg *provenance over* $\mathsf{EventuallyFilter}^{\uparrow}$, $\mathsf{FrechetFilter}^{\uparrow}$, $\mathsf{RegularCauchyTailFilter}^{\uparrow}$, $\mathsf{FilterBase}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{EventuallyFilter}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $F, T, B, S, R, E, H, C, P, N$. It has no coordinate for quotient filters, selected limits, countable choice, host equality of streams, hidden infinite complements, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 8679.2 (EventuallyFilter NameCert obligations)**.** *For every accepted* $\mathsf{EventuallyFilter}^{\uparrow}$ *carrier* $V = (F, T, B, S, R, E, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{EventuallyFilter}^{\uparrow}}$ *surface consists exactly of cofinite threshold admission, finite complement checking, filter-basis exposure, tail* $\mathsf{StreamName}^{\uparrow}$ *windows,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback, terminal* $\mathsf{Real}^{\uparrow}$ *sealing, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. No obligation is stored outside these rows.*

Proof. Project the accepted carrier. The rows F, T, B, S, R, E are the only mathematical data coordinates available to an eventual-tail consumer.

The threshold row F determines the tail, and T records the bounded prefix that is not read by the eventual claim. The filter-basis row B then exposes exactly the cofinite threshold tails generated by those two rows.

The stream and regular-rational rows are downstream of the same basis. The window row S is read only on the displayed tail, and R records the corresponding regular rational readback before the seal E is exposed.

Finally the structural rows H, C, P, N transport, replay, source, and name this route. Since the carrier contains no quotient filter, selected-limit row, countable-choice schedule, host stream equality, hidden infinite-complement row, or ambient completeness principle, none can become a local obligation. □

Theorem 8679.3 (EventuallyFilter tail refinement)**.** *Let* $V = (F, T, B, S, R, E, H, C, P, N)$ *be an accepted* $\mathsf{EventuallyFilter}^{\uparrow}$ *carrier. If a displayed threshold tail is refined by deleting a further finite prefix, every accepted read remains in the same carrier route through the refined* F, T, B *rows and the downstream* S, R, E, H, C, P, N *rows. Thus finite prefix deletion changes only the inspected tail window and not the eventual-filter basis seen by completion-facing consumers.*

Proof. Start with the refinement of the threshold row. Deleting a further finite prefix changes the displayed threshold and enlarges the finite complement recorded by T.

The filter-basis row B is built from threshold tails, so the refined tail is a displayed base element of the same eventual-filter route. No quotient-filter comparison is needed; the refinement is recorded by the finite prefix ledger.

Read the downstream rows through the refined tail. The $\mathsf{StreamName}^{\uparrow}$ window S and $\mathsf{RegSeqRat}^{\uparrow}$ readback R are replayed by C after the refined F, T, B rows are exposed, while H transports the same componentwise route.

The terminal seal E therefore remains attached to the same eventual-tail certificate. Only the finite window and prefix ledger have changed, and no selected limit, countable choice, host stream equality, or ambient completeness row is introduced. □

Theorem 8679.4 (EventuallyFilter Real-facing route)**.** *Every* $\mathsf{Real}^{\uparrow}$*-facing consumer of an accepted* $\mathsf{EventuallyFilter}^{\uparrow}$ *packet reaches the seal row only through*

$$F, T, B \longrightarrow S \longrightarrow R \longrightarrow E.$$

The route factors the cofinite threshold, finite complement check, filter-basis row, StreamName windows, and RegSeqRat readback before any Real-facing completion or Cauchy-tail consumer can inspect the terminal seal.

Proof. Begin with a Real-facing read of the accepted packet. The carrier places the seal row E downstream of the stream-window and regular-rational readback rows.

Apply the NameCert obligations. They require the threshold F, finite complement check T, and filter-basis row B to be displayed before S can be read as a tail window.

The readback R is then obtained from that same tail window, and the continuation row replays the order from the threshold data to the Real seal. The route is exactly the displayed finite chain through F, T, B, S, R, E.

The sibling $\mathsf{FrechetFilter}^{\uparrow}$ and $\mathsf{RegularCauchyTailFilter}^{\uparrow}$ chapters may consume this cofinite-tail route, but they receive no quotient filter, selected limit, countable-choice schedule, host stream equality, or ambient completeness coordinate from the packet. □

Falsifiable prediction: Every accepted $\mathsf{EventuallyFilter}^{\uparrow}$ Real-facing read factors through cofinite threshold data, finite complement checks, a FilterBase row, StreamName tail windows, RegSeqRat readback, a terminal RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert rows.

Independence witness: frechetfilter, regular-cauchy-tail-filter, streamname, regseqrat, real: $\mathsf{EventuallyFilter}^{\uparrow}$ is not bijective with any listed sibling because this packet alone binds a plain eventual-tail threshold, finite complement ledger, filter-basis row, stream windows, regular readback, Real seal, transport, replay, provenance, and local naming into one finite certificate.

Closure status for $\mathsf{NameCert}_{\mathsf{EventuallyFilter}^{\uparrow}}$.

Constructive story: An $\mathsf{EventuallyFilter}^{\uparrow}$ packet is generated from a cofinite threshold row, finite complement checks, a FilterBase basis row, StreamName tail windows, RegSeqRat readback, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{EventuallyFilter}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8679.1, Definition 8679.2, Definition 8679.3, and Definition 8679.4 seed the finite eventual-tail route from cofinite threshold evidence through StreamName and RegSeqRat rows to a Real-facing seal.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{EventuallyFilter}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient filters, selected limits, countable choice, host equality of streams, hidden infinite complements, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked cofinite threshold admission, finite complement checking, filter-basis exposure, tail-window readback, Real-seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.EventuallyFilterU

Chapter 8680

A Concrete Naming Certificate for $\mathsf{CompactModulusExtractionLattice}^{\uparrow}$

Following Heine–Cantor and Bishop's finite-net proof of compact uniform continuity, the CompactModulusExtraction packet records the lattice-shaped finite ProbeBundle data that turns centerwise pointwise moduli into one tolerance-only uniform modulus. It refines the compact-modulus extraction surface of chapter 6750 by making the ProbeBundle fold, rational lower-bound row, and uniform-modulus row visible as separate lattice coordinates. It sits over the compact source rows of chapter 60, the compact metric rows of chapter 129, the continuous-map rows of chapter 130, the finite lower-bound fold of chapter 4096, the metric rows of chapter 57, and the terminal Real and uniform-modulus surfaces of chapter 38 and chapter 369. The packet is finite NameCert data, not an open-cover theorem, selected subcover, external modulus oracle, quotient function equality, or ambient compactness principle.

Definition 8680.1 (CompactModulusExtractionLattice carrier)**.** *A* $\mathsf{CompactModulusExtractionLattice}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (K, M, A, \mathcal{P}, B, Q, U, E, H, C, G, N)$$

with the following displayed rows:

1. *K is the* $\mathsf{Compact}^{\uparrow}$ *or* $\mathsf{CompactMetric}^{\uparrow}$ *finite-net row naming the inspected compact source, centers, and coverage radius.*
2. *M is the* $\mathsf{Met}^{\uparrow}$ *comparison row used to route a source point through a displayed center.*
3. *A is the* $\mathsf{ContinuousMap}^{\uparrow}$ *pointwise-modulus ledger attached to the displayed centers.*
4. *$\mathcal{P}$ is the finite* ProbeBundle *row listing center probes, overlap checks, and admissible tolerance requests.*
5. *B is the ProbeBundle fold row that gathers the centerwise moduli into one finite lattice of positive rational candidates.*
6. *Q is the* $\mathsf{FiniteLowerBoundFold}^{\uparrow}$ *rational lower-bound row selected from the finite lattice.*
7. *U is the* $\mathsf{UniformModulus}^{\uparrow}$ *row produced from $K, M, A, \mathcal{P}, B, Q$.*
8. *E is the* $\mathsf{Real}^{\uparrow}$ *seal boundary for target-distance and tolerance reads consumed by the uniform-modulus route.*

9. *H records componentwise* hsame *transport for compact, metric, pointwise-modulus, ProbeBundle, fold, rational-bound, uniform-modulus, Real-seal, provenance, and local naming rows.*
10. *C records displayed* Cont *replay from compact finite-net admission through pointwise moduli, ProbeBundle folding, rational lower-bound extraction, metric comparison, and uniform-modulus handoff.*
11. *G is the* Pkg *provenance over* $\mathsf{CompactModulusExtractionLattice}^{\uparrow}$, $\mathsf{Compact}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{FiniteLowerBoundFold}^{\uparrow}$, $\mathsf{UniformModulus}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
12. *N is the local* $\mathsf{NameCert}_{\mathsf{CompactModulusExtractionLattice}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $K, M, A, \mathcal{P}, B, Q, U, E, H, C, G, N$. It has no coordinate for selected infinite covers, open-cover compactness, host continuity theorems, quotient function equality, arbitrary suprema, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 8680.2 (CompactModulusExtractionLattice NameCert obligations)**.** *For every accepted* $\mathsf{CompactModulusExtractionLattice}^{\uparrow}$ *carrier $L = (K, M, A, \mathcal{P}, B, Q, U, E, H, C, G, N)$, the local* $\mathsf{NameCert}_{\mathsf{CompactModul}}$ *surface consists exactly of compact finite-net admission, metric comparison admission, pointwise-modulus rows, finite ProbeBundle exposure, ProbeBundle fold exactness, rational lower-bound extraction, uniform-modulus handoff, Real-seal boundary, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming.*

Proof. Project the accepted carrier. The mathematical rows are the compact finite-net data K, metric comparison M, centerwise pointwise-modulus ledger A, ProbeBundle spine $\mathcal{P}$, fold row B, rational lower-bound row Q, uniform-modulus output U, and Real seal E.

The ProbeBundle obligations are finite. Each probe listed by $\mathcal{P}$ is attached to a displayed center and a displayed tolerance request, and the fold row B gathers only those listed candidates.

The rational lower-bound row Q is downstream of the fold. It computes a positive rational bound from the finite lattice before the output row U can be consumed by a uniform-modulus reader.

Finally H, C, G, N transport, replay, source, and name this route. Since no selected infinite cover, open-cover theorem, host continuity proof, quotient function equality, arbitrary supremum, or ambient completeness row is part of the carrier, no local obligation can read one. □

Theorem 8680.3 (CompactModulusExtractionLattice ProbeBundle fold)**.** *Every accepted* CompactModulusExtrac *packet folds pointwise moduli only through the finite route*

$$K, M, A, \mathcal{P} \longrightarrow B \longrightarrow Q.$$

The row B is a fold over the displayed ProbeBundle lattice, and Q is the resulting positive rational lower-bound row consumed before any $\mathsf{UniformModulus}^{\uparrow}$ *handoff is public.*

Proof. Start with the compact and metric rows. They supply a finite list of centers and the comparison route by which nearby source points are checked against those centers.

Read the pointwise-modulus row A only at the probes listed by $\mathcal{P}$. The ProbeBundle spine stores the admissible center, overlap, and tolerance requests, so the fold has a finite domain.

The fold row B gathers those displayed candidates into a finite lattice. The lower-bound row Q then reads the lattice output as a positive rational bound rather than as an external infimum or selected subcover.

Thus any downstream uniform-modulus consumer receives the folded lower bound through the displayed ProbeBundle route and not through open-cover compactness, countable choice, quotient function equality, or ambient completeness. □

Theorem 8680.4 (CompactModulusExtractionLattice uniform-modulus route)**.** *Every* $\mathsf{UniformModulus}^{\uparrow}$ *consumer of an accepted* $\mathsf{CompactModulusExtractionLattice}^{\uparrow}$ *packet reaches the output row through*

$$K, M, A, \mathcal{P}, B, Q \longrightarrow U \longrightarrow E.$$

The uniform-modulus route is therefore a finite compact-net, ProbeBundle fold, rational lower-bound, metric-comparison, and Real-seal route; it exports no selected open subcover, host continuity theorem, quotient function equality, arbitrary supremum, or ambient Real completeness.

Proof. Begin with a uniform-modulus consumer. The carrier places U downstream of compact finite-net admission, metric comparison, pointwise-modulus rows, ProbeBundle folding, and rational lower-bound extraction.

Apply the ProbeBundle fold theorem. It forces the lower-bound row Q to be read from the displayed finite lattice $K, M, A, \mathcal{P}, B$ before the output row is available.

The Real-seal row E supplies the target-distance and tolerance boundary used by the same route, while H and C preserve the route under componentwise transport and replay. Provenance and local naming record no further analytic coordinate.

Consequently the uniform-modulus output is the displayed finite NameCert route. The excluded open-cover, selected-subcover, host-continuity, quotient-equality, arbitrary-supremum, and ambient-completeness objects are absent from the carrier. □

Falsifiable prediction: Every accepted $\mathsf{CompactModulusExtractionLattice}^{\uparrow}$ uniform-modulus read factors through compact finite-net rows, Metric comparison rows, ContinuousMap pointwise-modulus rows, a finite ProbeBundle spine, a ProbeBundle fold, a FiniteLowerBoundFold rational row, UniformModulus output, RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert rows.

Independence witness: compact-modulus-extraction, compact, compactmetric, continuousmap, finite-lower-bound-fold, metric, uniformmodulus, real: $\mathsf{CompactModulusExtractionLattice}^{\uparrow}$ is not bijective with any listed sibling because this packet alone exposes the ProbeBundle spine, fold row, rational lower-bound row, and uniform-modulus handoff as one finite lattice certificate.

Closure status for $\mathsf{NameCert}_{\mathsf{CompactModulusExtractionLattice}^{\uparrow}}$**.**

Constructive story: A $\mathsf{CompactModulusExtractionLattice}^{\uparrow}$ packet is generated from compact finite-net rows, metric comparison rows, ContinuousMap pointwise-modulus rows, a finite ProbeBundle spine, a ProbeBundle fold row, a FiniteLowerBoundFold rational lower-bound row, UniformModulus output, RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{CompactModulusExtractionLattice}^{\uparrow}}$, seed)

Scope closed: Definition 8680.1, Definition 8680.2, Definition 8680.3, and Definition 8680.4 seed the finite ProbeBundle lattice route from compact finite-net and pointwise-modulus data to a tolerance-only uniform-modulus handoff.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{CompactModulusExtractionLattice}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close open-cover compactness, selected subcovers, external modulus oracles, host continuity theorems, quotient function equality, arbitrary suprema, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked compact finite-net admission, metric comparison, pointwise-modulus exposure, ProbeBundle fold exactness, rational lower-bound extraction, uniform-modulus handoff, Real-seal boundary, transport, replay, provenance, and local naming for BEDC.Derived.CompactModulusExtractionLatticeUp.

Chapter 8681

A Concrete Naming Certificate for $\mathsf{MonoidAction}^{\uparrow}$

Following Bourbaki and Mac Lane, the $\mathsf{MonoidAction}^{\uparrow}$ packet records a monoid acting on a displayed carrier as finite BEDC NameCert data. It consumes the monoid source of chapter 40, the acted carrier vocabulary of chapter 3668 or chapter 3600, and the orbit-facing readback routes used by representation-style chapters such as chapter 3662 and chapter 246. The packet names action endpoints, identity and composition law rows, orbit and stabilizer handoff rows, transport, replay, provenance, and local naming; it does not construct a quotient orbit object, a selected representative, a group inverse action, or an ambient category of actions.

Definition 8681.1 (Monoid action carrier)**.** *A* $\mathsf{MonoidAction}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$A = (M, X, \alpha, I, C, H, R, P, N)$$

with the following displayed rows:

1. *M is the consumed* $\mathsf{Monoid}^{\uparrow}$ *source row, exposing the displayed carrier, multiplication, unit, associativity, identity, transport, replay, provenance, and local name rows of the acting monoid.*
2. *X is the acted carrier row, read through* $\mathsf{SetLike}^{\uparrow}$ *or* $\mathsf{TypeLike}^{\uparrow}$ *vocabulary with its local classifier and point rows visible.*
3. *α is the action graph row. For every displayed monoid element row m and acted point row x, it records the endpoint row $\alpha(m, x)$ as a point of X.*
4. *I is the identity-action law row, comparing $\alpha(e, x)$ with x through the identity row of M and the classifier of X.*
5. *C is the action-composition law row, comparing $\alpha(m, \alpha(n, x))$ with $\alpha(mn, x)$ through the multiplication and associativity rows of M.*
6. *H records componentwise* hsame *transport for $M, X, \alpha, I, C, R, P, N$ and for the displayed endpoint comparisons.*
7. *R records displayed* Cont *replay from monoid multiplication and acted carrier reads through action endpoints, identity rows, composition rows, orbit reads, and stabilizer reads.*
8. *P is the* Pkg *provenance over* $\mathsf{MonoidAction}^{\uparrow}$, $\mathsf{Monoid}^{\uparrow}$, $\mathsf{SetLike}^{\uparrow}$, $\mathsf{TypeLike}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.

9. N is the local $\mathsf{NameCert}_{\mathsf{MonoidAction}^{\uparrow}}$ *row.*
The classifier compares accepted carriers only through $M, X, \alpha, I, C, H, R, P, N$. It has no coordinate for quotient orbit equality, selected representatives, inverse actions, external function spaces, or an ambient category of actions.

Lean4 (statement) `BEDC.Derived.MonoidActionUp`

Theorem 8681.2 (Monoid action NameCert obligations)**.** *For every accepted* $\mathsf{MonoidAction}^{\uparrow}$ *carrier $A = (M, X, \alpha, I, C, H, R, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{MonoidAction}^{\uparrow}}$ *surface consists exactly of monoid-source admission through M; acted-carrier admission through X; action graph admission through α; identity-action exactness through I; action-composition exactness through C; componentwise* hsame *transport through H; displayed* Cont *replay through R; provenance through P; and local naming through N.*

Proof. Project the carrier of Definition 8681.1. The monoid row M and acted carrier row X are the only source rows, so every action endpoint must first display the acting element and acted point over those rows.

The action graph row α supplies the endpoint data. The law rows I and C are then read as finite comparisons over that same graph: I uses the unit row of M, while C uses the multiplication and associativity rows of M.

Finally H, R, P, N transport, replay, source, and name the same finite route. Since the carrier has no row for quotient orbit equality, selected representatives, inverse actions, function spaces, or an ambient action category, the listed rows exhaust the local NameCert surface. □

Theorem 8681.3 (Monoid action orbit-stabilizer handoff)**.** *Every orbit-facing or stabilizer-facing consumer of an accepted* $\mathsf{MonoidAction}^{\uparrow}$ *packet first reads*

$$M, \quad X, \quad \alpha, \quad I, \quad C, \quad H, \quad R, \quad P, \quad N.$$

The orbit read is the finite endpoint family displayed by the action graph row, and the stabilizer read is the finite subroute where those endpoints compare with the inspected point through hsame*. The handoff supplies no quotient orbit object, chosen orbit representative, inverse-action law, host function space, or ambient group-action theorem.*

Proof. Begin with the action graph row α. It is typed only after the monoid source M and acted carrier X have been displayed, so an orbit-facing consumer receives endpoint rows over the same finite source data.

Use the identity row I and composition row C to keep the endpoint family compatible with the monoid unit and multiplication. These rows are law ledgers over the displayed graph; they do not add inverses or quotient orbit data.

For a stabilizer-facing read, restrict the same endpoint family to rows where $\alpha(m, x)$ compares with x through hsame. Transport and replay then pass through H and R, while P and N record provenance and local naming. Thus representation-style and orbit-style consumers receive only the finite action route, not a stronger orbit or stabilizer construction. □

Falsifiable prediction: A $\mathsf{MonoidAction}^{\uparrow}$ read is refuted whenever an orbit-facing, stabilizer-facing, or representation-style consumer uses action endpoints without first displaying the MonoidUp source, acted carrier row, action graph row, identity-action row, action-composition row, componentwise hsame transport, Cont replay, Pkg provenance, and local NameCert row.

Closure status for $\mathsf{NameCert}_{\mathsf{MonoidAction}^{\uparrow}}$.

Constructive story: A MonoidAction$^{\uparrow}$ packet is generated from a Monoid source row, an acted SetLike or TypeLike carrier row, an action graph row, identity-action and action-composition law rows, orbit and stabilizer handoff rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\mathsf{MonoidAction}^{\uparrow}}$, seed)

Scope closed: Definition 8681.1, Definition 8681.2, and Definition 8681.3 seed the finite monoid action carrier, its local NameCert obligation surface, and the orbit-stabilizer handoff route.

Formal verification: FormalStatus(NameCert$_{\mathsf{MonoidAction}^{\uparrow}}$, unformalized)

Lean target: `BEDC.Derived.MonoidActionUp`

Bridge status: none

Not claimed: This chapter does not close quotient orbit spaces, selected representatives, inverse actions, group actions, ambient action categories, theorem-level Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, action graph admission, identity-action exactness, composition exactness, orbit and stabilizer handoff, transport, replay, provenance, and local naming for BEDC.Derived.MonoidActionUp.

Chapter 8682

A Concrete Naming Certificate for FiniteDyadicSubsequenceSelector$^{\uparrow}$

Following Bishop and Bridges on bounded sequences and finite dyadic interval refinements, the FiniteDyadicSubsequenceSelector$^{\uparrow}$ packet records the finite selector route by which a bounded real sequence exposes inspected dyadic cells and selected finite windows before any Real-and-Completion consumer reads a subsequence handoff. It sits over the dyadic arithmetic core of chapter 291, the finite window discipline of chapter 126, the regular rational readback of chapter 301, the terminal real seal of chapter 38, the bounded sequence source of chapter 1415, and the finite net surface of chapter 1250. The packet is a choice-free finite selector for bounded-window routes; it is not general sequential compactness, countable choice, quotient stream equality, or ambient Real$^{\uparrow}$ completeness.

Definition 8682.1 (Finite dyadic subsequence selector carrier)**.** *A* FiniteDyadicSubsequenceSelector$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (B, D, W, R, E, H, C, P, N)$$

with the following displayed rows:

1. *B is the bounded sequence schedule row, read through the* BoundedRealSequence$^{\uparrow}$ *source and the finite window requests it accepts.*
2. *D is the* DyadicRatCore$^{\uparrow}$ *cell ledger recording the dyadic interval cells inspected inside the displayed bounded range.*
3. *W is the selected finite-window row naming the subsequence windows admitted by the dyadic cell ledger and the bounded sequence schedule.*
4. *R is the* RegSeqRat$^{\uparrow}$ *readback row obtained from the selected windows and their dyadic tolerance data.*
5. *E is the terminal* Real$^{\uparrow}$ *seal row reached only after B, D, W, R have been displayed.*
6. *H records componentwise* hsame *transport for the schedule, dyadic ledger, selected windows, readback, seal, replay, provenance, and local naming rows.*
7. *C records displayed* Cont *replay from bounded-sequence requests through dyadic cell inspection, selected windows, regular rational readback, and the Real seal.*
8. *P is the* Pkg *provenance over* FiniteDyadicSubsequenceSelector$^{\uparrow}$, BoundedRealSequence$^{\uparrow}$, ClosedBoundedIntervalN DyadicRatCore$^{\uparrow}$, StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, Real$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

9. N is the local $\mathsf{NameCert}_{\mathsf{FiniteDyadicSubsequenceSelector}^{\uparrow}}$ *row.*
The classifier compares accepted packets only through $B, D, W, R, E, H, C, P, N$. It stores no coordinate for a host subsequence function, countable-choice selector, quotient stream equality, selected limit, general sequential compactness theorem, or ambient $\mathsf{Real}^{\uparrow}$ *completeness principle.*

Theorem 8682.2 (Finite dyadic subsequence selector NameCert obligations)**.** *For every accepted* $\mathsf{FiniteDyadicSubsequenceSelector}^{\uparrow}$ *carrier $S = (B, D, W, R, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{FiniteDyadicSubsequenceSele}}$ *surface consists exactly of carrier admission, bounded-window exposure, dyadic-cell compatibility, selected-window cofinal readback, RegSeqRat and Real handoff, componentwise transport, displayed replay, provenance, and local naming. Each selected window must be read through the bounded sequence schedule B, the dyadic cell ledger D, and the finite window row W before the regular rational row R or the terminal real seal E is public. The obligations export no sequential compactness theorem, countable-choice selector, quotient stream equality, selected host limit, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the carrier of Definition 8682.1. The rows B, D, W, R, E are the only analytic rows available before the structural support rows are read.

The bounded-window exposure starts with B. A downstream consumer receives only the displayed bounded sequence schedule and the finite requests it accepts, so no host subsequence function or countable-choice object is present at the source.

Next read the dyadic cell ledger D and selected window row W. Compatibility means that each selected window lies inside the inspected dyadic cell data and remains tied to the same bounded schedule. Cofinality is therefore a finite displayed window condition, not an infinite selection principle.

Finally read R and E. The regular rational readback is obtained from the same selected windows, and the real seal is downstream of that readback. Transport, replay, provenance, and local naming preserve only the displayed route, leaving no coordinate for quotient stream equality, selected limits, sequential compactness, or ambient completeness. □

Theorem 8682.3 (Finite dyadic subsequence selector bounded-window handoff)**.** *Every bounded-subsequence consumer of an accepted* $\mathsf{FiniteDyadicSubsequenceSelector}^{\uparrow}$ *packet reads through the finite dyadic route*

$$\mathsf{BoundedRealSequence}^{\uparrow}, \quad \mathsf{ClosedBoundedIntervalNet}^{\uparrow}, \quad \mathsf{DyadicRatCore}^{\uparrow}, \quad \mathsf{StreamName}^{\uparrow}, \quad \mathsf{RegSeqRat}^{\uparrow}, \quad \mathsf{Real}^{\uparrow}.$$

In carrier notation, the consumer must expose B, D, W, R, E before it treats the selected windows as a Real-and-Completion handoff, while H, C, P, N only transport, replay, source, and name the same packet.

Proof. Begin with the NameCert obligations of Definition 8682.2. They place every selected window downstream of the bounded sequence schedule, dyadic cell ledger, and finite window row.

Read the bounded interval net and dyadic ledger together. The bounded sequence source is usable by a subsequence consumer only through the inspected finite cells and their StreamName windows, so the route cannot jump directly from a bounded sequence to a completed real.

The regular rational and real-facing rows close the handoff. The row R reads back exactly the selected windows, and E is visible only after that readback. Since the support rows H, C, P, N preserve the same finite packet, no consumer can replace the route by general sequential compactness, countable choice, quotient stream equality, selected limits, or ambient $\mathsf{Real}^{\uparrow}$ completeness. □

Closure status for $\mathsf{NameCert}_{\mathsf{FiniteDyadicSubsequenceSelector}^{\uparrow}}$.

Constructive story: A $\mathsf{FiniteDyadicSubsequenceSelector}^{\uparrow}$ packet is generated from a bounded sequence schedule, dyadic cell ledger, selected finite windows, RegSeqRat readback, RealUp seal, componentwise transport, displayed replay, provenance, and local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{FiniteDyadicSubsequenceSelector}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8682.1, Definition 8682.2, and Definition 8682.3 seed the finite dyadic selector route from bounded sequence windows to RegSeqRat and Real handoff rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{FiniteDyadicSubsequenceSelector}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close general sequential compactness, countable choice, quotient stream equality, selected host limits, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, bounded-window exposure, dyadic-cell compatibility, selected-window cofinal readback, RegSeqRat and Real handoff, and structural non-escape for the same finite packet.

Chapter 8683

A Concrete Naming Certificate for $\mathsf{KrullDimension}^{\uparrow}$

Following Krull and Bourbaki/Zariski–Samuel, the $\mathsf{KrullDimension}^{\uparrow}$ packet records dimension as finite prime-chain NameCert data rather than as a global set-theoretic supremum. It sits over the ideal carrier of chapter 81, the Noetherian finiteness surface of chapter 3637, the principal-chain boundary of chapter 7991, the valuation-domain comparability route of chapter 6626, and the finite-intersection discipline of chapter 7643. The packet names only displayed chains of prime-ideal rows and their bounded handoff; it does not assert a maximal prime chain, choose a generic point, import excluded ideal equality, or identify schemes by ambient topology.

Definition 8683.1 (Krull dimension carrier)**.** *A* $\mathsf{KrullDimension}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (R, I, P, L, N, V, J, H, C, G)$$

where R is the displayed commutative-ring source, I is the $\mathsf{Ideal}^{\uparrow}$ *carrier row for finitely named ideals, P is the finite list of prime-ideal names, L is the listed strict-inclusion chain relation on those prime rows, N is the* $\mathsf{NoetherianRing}^{\uparrow}$ *finiteness handoff when such a bound is present, V is the valuation-domain comparability route when the chain is read through a valuation sibling, J is the principal-ideal or Dedekind-style height handoff route, H is componentwise* hsame *transport, C is displayed* Cont *replay, and G is the local* $\mathsf{NameCert}_{\mathsf{KrullDimension}^{\uparrow}}$ *row.*

Theorem 8683.2 (Krull dimension NameCert obligations)**.** *For every accepted* $\mathsf{KrullDimension}^{\uparrow}$ *carrier $K = (R, I, P, L, N, V, J, H, C, G)$, the local* $\mathsf{NameCert}_{\mathsf{KrullDimension}^{\uparrow}}$ *surface consists exactly of carrier admission for the displayed ring source, ideal-row admission through chapter 81, primality and strict-inclusion admission for the finite list P, L, optional Noetherian bound routing through chapter 3637, valuation comparability routing through chapter 6626, principal or Dedekind-style height routing through chapter 7991 and chapter 172, componentwise transport, replay, and local naming. No obligation row exports a chosen longest chain, quotient ideal equality, spectrum topology, scheme dimension, or classical maximal-prime principle.*

Proof. Project the carrier of Definition 8683.1. The rows R, I, P, L display the ring source, ideal carrier, prime names, and strict-inclusion chain before any dimension read is public.

Read the sibling finiteness and comparability routes next. The Noetherian row supplies only a finite bound witness when it is present, the valuation-domain row supplies a comparability handoff, and the principal or Dedekind-style route supplies a height-facing handoff through existing concrete algebra chapters.

Finally replay H, C, G. These rows preserve the displayed finite packet and provide the local name, so a consumer receives only the finite prime-chain obligation surface and cannot infer a selected maximal chain, quotient ideal equality, spectrum topology, scheme dimension, or a classical maximal-prime endpoint. □

Theorem 8683.3 (Krull dimension prime-chain handoff)**.** *Every downstream consumer of a* $\mathsf{KrullDimension}^{\uparrow}$ *read that asks for a local, scheme-facing, or valuation-facing dimension boundary must first expose the finite prime-chain rows* P, L*, the* $\mathsf{Ideal}^{\uparrow}$ *source row* I*, and the active sibling route through* $\mathsf{NoetherianRing}^{\uparrow}$*,* $\mathsf{PrincipalIdealDomain}^{\uparrow}$*,* $\mathsf{ValuationDomain}^{\uparrow}$*, or the Dedekind chapter before the dimension boundary is public. The handoff is a finite NameCert route through prime ideals and strict inclusions, not an ambient topological dimension theorem, not a selected irreducible component, and not a quotient construction on ideals.*

Proof. Start with the obligation theorem Definition 8683.2. It makes the ideal row, prime-name list, and strict-inclusion relation visible before any consumer-facing dimension row can be read.

Use the selected sibling route according to the consumer. A Noetherian consumer reads the finite-bound row, a principal-domain consumer reads the principal height handoff, a valuation-domain consumer reads comparability, and a Dedekind-facing consumer reads the height route through the existing Dedekind chapter.

The structural rows H, C, G then transport and replay the same finite packet. Since the carrier has no coordinate for spectrum topology, selected generic points, quotient ideal equality, or a longest-chain choice, the exported handoff is exactly the displayed prime-chain route. □

Closure status for $\mathsf{NameCert}_{\mathsf{KrullDimension}^{\uparrow}}$**.**

Constructive story: A $\mathsf{KrullDimension}^{\uparrow}$ packet is generated from a displayed ring source, IdealUp rows, finite prime-chain rows, optional NoetherianRingUp bounds, PrincipalIdealDomainUp or valuation comparability routes, componentwise hsame transport, displayed Cont replay, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{KrullDimension}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8683.1 and Definition 8683.2 seed the finite prime-chain NameCert surface for commutative-algebra dimension reads.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{KrullDimension}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim a selected maximal chain, quotient equality of ideals, spectrum topology, scheme dimension, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, prime-chain strictness, sibling finiteness routing, valuation comparability, height handoff, transport stability, replay stability, and nonescape for BEDC.Derived.KrullDimensionUp.

Chapter 8684

A Concrete Naming Certificate for $\mathsf{FiveLemma}^{\uparrow}$

Following Mac Lane's homological algebra and the standard abelian-category diagram chase, the $\mathsf{FiveLemma}^{\uparrow}$ packet records the finite route that turns two exact rows, five compatible vertical maps, and four local isomorphism-style witnesses into the middle vertical classifier witness. It sits over the abelian-category carrier of chapter 176 and consumes the same exact-row and boundary discipline used by the snake-lemma packet of chapter 5890. The packet names a bounded chase surface; it does not import element representatives, quotient object equality, ambient diagram extensionality, or an unbounded search oracle.

Definition 8684.1 (Five Lemma carrier)**.** *A* $\mathsf{FiveLemma}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$F = (A, R_0, R_1, V, L, M, Q, C, T, H, P, N)$$

with the following displayed rows:

1. *A is the* $\mathsf{AbelianCat}^{\uparrow}$ *source row exposing the additive kernel-cokernel surface in which both exact rows are read.*
2. *R_0 and R_1 are the upper and lower exact-row ledgers, each carrying five displayed object rows, four displayed horizontal morphism rows, and the local image-kernel containment rows used by the chase.*
3. *V records the five displayed vertical morphisms and the four commutative squares aligning R_0 with R_1.*
4. *L records the two left-side comparison rows used to move witnesses across the first and second vertical maps.*
5. *M records the two middle-neighbour comparison rows used to pass from the second and fourth vertical maps to the third vertical map.*
6. *Q records the two right-side comparison rows used to close the chase through the fourth and fifth vertical maps.*
7. *C is the finite chase ledger. It lists the kernel entry, exact-row transport, square transport, image-kernel handoff, cokernel exit, and middle classifier witness in bounded order.*
8. *T records displayed* Cont *replay from A, R_0, R_1, V, L, M, Q to the chase ledger C.*

9. *H records componentwise* hsame *transport for the abelian-category source, exact rows, vertical squares, comparison rows, chase ledger, replay, provenance, and local naming.*
10. *P is the* Pkg *provenance over* $\mathsf{FiveLemma}^{\uparrow}$, $\mathsf{AbelianCat}^{\uparrow}$, $\mathsf{SnakeLemma}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{FiveLemma}^{\uparrow}}$ *row.*

The classifier compares accepted five-lemma packets only through these rows. It contains no coordinate for selected elements outside the displayed histories, hidden kernel representatives, quotient representatives, host-object equality, or a completed ambient diagram category.

Lean4 (definition) `BEDC.Derived.FiveLemmaUp.FiveLemmaUp`

Theorem 8684.2 (Five Lemma NameCert obligations)**.** *For every accepted* $\mathsf{FiveLemma}^{\uparrow}$ *carrier*

$$F = (A, R_0, R_1, V, L, M, Q, C, T, H, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{FiveLemma}^{\uparrow}}$ *surface consists exactly of the abelian-category source row A, the upper and lower exact-row ledgers R_0, R_1, vertical-square compatibility through V, left comparison through L, middle-neighbour comparison through M, right comparison through Q, the finite chase ledger C, displayed replay through T, componentwise transport through H, package provenance through P, and local naming through N.*

Proof. Project the carrier of Definition 8684.1. The rows A, R_0, R_1, V expose the abelian-category source, the two exact rows, and the four commutative squares before any middle-map conclusion is available.

The comparison rows L, M, Q then record precisely which neighbouring vertical maps may be used by the chase. These rows are displayed certificate data, not ambient claims about all diagrams in the host category.

Read the chase ledger C next. Its entries are bounded by the five displayed vertical maps and the four displayed squares, so every witness passed through the exact rows is accounted for by a named row of the packet.

Finally T, H, P, N keep the same surface stable under replay, componentwise history equality, provenance, and local naming. Since no hidden representative, host-object equality, or unbounded diagram search appears among the carrier coordinates, the listed rows exhaust the certificate obligations. □

Theorem 8684.3 (Five Lemma finite diagram chase)**.** *Every downstream consumer of an accepted* $\mathsf{FiveLemma}^{\uparrow}$ *packet reads the middle vertical classifier witness only through the displayed route*

$$\mathsf{AbelianCat}^{\uparrow} \longmapsto (R_0, R_1, V) \longmapsto (L, M, Q) \longmapsto C \longmapsto (T, H, P, N).$$

Thus the consumer receives one finite diagram-chase packet of abelian-category source rows, exact-row ledgers, vertical-square compatibility rows, comparison rows, bounded chase entries, replay, transport, provenance, and local naming.

Proof. Begin with the source row A and the two exact rows R_0, R_1. The vertical compatibility row V makes the four squares visible, so the chase can move between the two rows only at named square entries.

Use L, M, Q to expose the neighbouring comparison data. These rows delimit the classical five-lemma assumptions as finite certificate coordinates: left-side transport, middle-neighbour transport, and right-side exit data are all displayed before the middle conclusion is read.

The ledger C then lists the bounded sequence of chase moves. Exactness supplies the image-kernel handoffs, square compatibility transports each handoff across the vertical maps, and the comparison rows provide the permitted entries and exits.

Replaying through T and transporting through H preserves the same finite route. The provenance and naming rows P, N therefore export the middle witness as a NameCert packet rather than as an ambient element chase. □

Closure status for $\mathsf{NameCert}_{\mathsf{FiveLemma}^{\uparrow}}$.

Constructive story: A $\mathsf{FiveLemma}^{\uparrow}$ packet is generated from an AbelianCat source row, two exact-row ledgers, five vertical maps, four commutative-square rows, comparison rows, a finite chase ledger, Cont replay, hsame transport, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{FiveLemma}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8684.1, Definition 8684.2, and Definition 8684.3 seed the finite Five Lemma packet over abelian-category source rows, exact-row ledgers, vertical-square compatibility, comparison rows, bounded chase entries, replay, transport, provenance, and local naming.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{FiveLemma}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close Lean verification, bridge checking, quotient-object equality, ambient diagram extensionality, selected-element semantics, or unbounded diagram-chase completeness.

Upgrade path: Obligation closure requires checked carrier admission, exact-row exposure, vertical-square compatibility, comparison-row exposure, finite chase-ledger construction, replay stability, transport stability, provenance exhaustion, and local naming for BEDC.Derived.FiveLemmaUp.

Chapter 8685

A Concrete Naming Certificate for HyperbolicSectorExpansion$^{\uparrow}$

The HyperbolicSectorExpansion$^{\uparrow}$ packet realizes the sector-expansion branch of chapter 9463 as finite NameCert data. It sits after the sector-envelope packet of chapter 8546, the observer-expansion packet of chapter 4167, the visual-boundary packet of chapter 4181, and the boundary-shadow expansion cocycle of chapter 5814. The carrier names only finite sector aperture, boundary shadow, visual radius, observer window, expansion comparison, transport, refusal, provenance, and local naming rows.

Definition 8685.1 (Hyperbolic sector-expansion carrier)**.** *A* HyperbolicSectorExpansion$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$X = (E, A, B, R, O, G, W, T, F, K, H, C, P, N)$$

with the following displayed rows:

1. *E is the* HyperbolicSectorEnvelope$^{\uparrow}$ *source row carrying the finite sector endpoints, visual-radius row, observer-window row, and refusal row.*
2. *A is the sector-aperture row, naming the visible opening budget of the sector in the observer window.*
3. *B is the boundary-shadow row tying the aperture to a displayed* HyperbolicBoundaryShadow$^{\uparrow}$ *readback.*
4. *R is the visual-radius comparison row inherited from the envelope and read again at the expanded sector boundary.*
5. *O is the observer-window row selecting the finite focus in which the expansion is measured.*
6. *G is the expansion-comparison row, recording the before-window and after-window sector readings and their classifier comparison.*
7. *W is the visual-boundary handoff row through* HyperbolicVisualBoundary$^{\uparrow}$.
8. *T is the transport row preserving aperture, boundary shadow, visual radius, observer window, and expansion comparison under componentwise classifier transport.*
9. *F is the refusal row excluding a completed hyperbolic boundary, hidden geodesic sectors, host metric equality, and a global observer expansion map.*

10. *K is the TasteGate request row requiring* Nontrivial HyperbolicSectorExpansion$^{\uparrow}$ *and* FieldFaithful HyperbolicSector *instances before the row inventory may be accepted by the Lean-side gate.*
11. *H records componentwise* hsame *transport for $E, A, B, R, O, G, W, T, F, K, C, P, N$.*
12. *C records displayed* Cont *replay through sector envelope, aperture, boundary shadow, visual radius, observer window, expansion comparison, transport, refusal, TasteGate requests, and naming.*
13. *P is the* Pkg *provenance over* HyperbolicSectorExpansion$^{\uparrow}$, HyperbolicSectorEnvelope$^{\uparrow}$, HyperbolicObserverExpansi HyperbolicVisualBoundary$^{\uparrow}$, HyperbolicBoundaryShadow$^{\uparrow}$, BoundaryShadowExpansionCocycle$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
14. *N is the local* NameCert$_{\text{HyperbolicSectorExpansion}^{\uparrow}}$ *row.*

The carrier has no coordinate for ambient boundary compactification, selected geodesic representatives, host hyperbolic metric equality, a completed sector family, or a global observer dynamics.

Theorem 8685.2 (Hyperbolic sector-expansion NameCert obligations)**.** *For every accepted* HyperbolicSectorExpans *carrier $X = (E, A, B, R, O, G, W, T, F, K, H, C, P, N)$, the local* NameCert$_{\text{HyperbolicSectorExpansion}^{\uparrow}}$ *surface consists exactly of sector envelope exposure through E, sector aperture through A, boundary shadow through B, visual-radius comparison through R, observer window through O, expansion comparison through G, visual-boundary handoff through W, transport through T, refusal through F, TasteGate requests through K, componentwise* hsame *transport through H, displayed* Cont *replay through C, package provenance through P, and local naming through N.*

No accepted read may expose an expansion comparison without displaying the aperture row, boundary-shadow row, visual-radius row, observer-window row, refusal row, and provenance row.

Proof. Project the carrier of Definition 8685.1. The envelope row E exposes the endpoint, radius, observer-window, and refusal data on which any sector expansion must depend.

The aperture, boundary-shadow, visual-radius, and observer-window rows A, B, R, O then delimit the measured expansion. The comparison row G can be read only after these coordinates are visible, and the visual-boundary handoff W remains downstream of the finite boundary-shadow surface.

Transport, refusal, TasteGate requests, componentwise history equality, replay, provenance, and naming are then projected from T, F, K, H, C, P, N. Since no hidden geodesic sector, completed boundary, host metric equality, or global observer map appears among the coordinates, the listed rows exhaust the local certificate obligations. □

Theorem 8685.3 (Hyperbolic sector-expansion observer route)**.** *Every accepted* HyperbolicSectorExpansion$^{\uparrow}$ *observer read factors through*

$$\text{HyperbolicSectorEnvelope}^{\uparrow} \longmapsto (A, B, R, O) \longmapsto (G, W, T, F) \longmapsto (K, H, C, P, N).$$

The route exposes finite sector aperture, boundary-shadow readback, visual-radius comparison, observer-window focus, expansion comparison, visual-boundary handoff, transport, refusal, TasteGate requests, replay, provenance, and local NameCert rows.

Proof. Start with the sector-envelope row. It provides the finite endpoint and observer-window context, so the expansion packet does not begin from a completed boundary sector.

Read the aperture, boundary-shadow, visual-radius, and observer-window rows next. These rows fix the local geometry in which an expansion comparison can be displayed.

The expansion comparison, visual-boundary handoff, and transport rows then record the only admitted observer route. Refusal prevents the route from being promoted to host metric equality, hidden geodesic selection, or a global observer dynamics.

Finally the TasteGate request, componentwise transport, replay, provenance, and local naming rows keep the same finite packet available to downstream observer-expansion chapters. □

Falsifiable prediction: An accepted sector-expansion read cannot expose an expansion comparison without displaying the aperture row, boundary-shadow row, visual-radius row, observer-window row, refusal row, and provenance row.

Independence witness: hyperbolic-sector-envelope, hyperbolic-observer-expansion, hyperbolic-visual-boundary, boundary-shadow-expansion-cocycle

The Lean-side TasteGate follow-up for this carrier requires explicit Nontrivial $\mathsf{HyperbolicSectorExpansion}^{\uparrow}$ and FieldFaithful $\mathsf{HyperbolicSectorExpansion}^{\uparrow}$ instances. Field faithfulness keeps $E, A, B, R, O, G, W, T, F, K, H, C, P$ as distinct rows before a classifier target may accept the packet.

Closure status for $\mathsf{NameCert}_{\mathsf{HyperbolicSectorExpansion}^{\uparrow}}$.

Constructive story: A $\mathsf{HyperbolicSectorExpansion}^{\uparrow}$ packet is generated from a sector-envelope source row, sector aperture, boundary shadow, visual radius, observer window, expansion comparison, visual-boundary handoff, transport, refusal, TasteGate requests, hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{HyperbolicSectorExpansion}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8685.1, Definition 8685.2, and Definition 8685.3 seed the finite observer-expansion sector packet over aperture, boundary shadow, visual radius, observer window, expansion comparison, handoff, transport, refusal, TasteGate, replay, provenance, and local naming rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{HyperbolicSectorExpansion}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim completed boundary sectors, selected geodesic representatives, host hyperbolic metric equality, global observer dynamics, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked envelope exposure, aperture admission, boundary-shadow handoff, visual-radius comparison, observer-window exposure, expansion comparison, transport, refusal, TasteGate nontriviality, field faithfulness, replay, provenance, and local naming for BEDC.Derived.HyperbolicSectorExpansionUp.

Chapter 8686

A Concrete Naming Certificate for $\mathsf{LusinTheorem}^{\uparrow}$

Following Lusin and Bishop–Bridges constructive measure theory, the $\mathsf{LusinTheorem}^{\uparrow}$ packet records the finite certificate surface for reading a measurable real-valued row by a compact-domain continuous representative outside a displayed exceptional set. It sits after the measure ledger of chapter 92, compact metric support of chapter 129, continuous-map carrier of chapter 130, regular rational readback of chapter 301, terminal real seal of chapter 38, and approximation route of chapter 4147. The packet names only the displayed finite NameCert obligations for a Lusin-theorem read; it does not assert the full host measure-theoretic theorem, completed measure algebra, quotient almost-everywhere equality, or a choice-selected compact approximation.

Definition 8686.1 (Lusin theorem carrier)**.** *A* $\mathsf{LusinTheorem}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (M, K, C, E, R, D, H, Q, P, N)$$

with the following displayed rows:

1. *M is the* $\mathsf{Measure}^{\uparrow}$ *source row, carrying the finite measurable-set ledger, finite measure budget, and inspected measurable real-valued row.*
2. *K is the compact approximation row, displaying the compact support or compact-domain window over the same measure ledger and the finite complement budget exposed to consumers.*
3. *C is the* $\mathsf{ContinuousMap}^{\uparrow}$ *representative row, naming the continuous representative over the compact window rather than an ambient function-space element.*
4. *E is the exceptional-set and error ledger, recording the displayed exceptional row, its measure budget, and the tolerance read consumed by the theorem route.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *and* $\mathsf{Real}^{\uparrow}$ *readback row, sealing the measured row, continuous representative, tolerance, and exceptional ledger into the terminal real-valued comparison route.*
6. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row, carrying the dyadic error budget used to compare the public theorem read with the approximation route of* $\mathsf{LusinApproximation}^{\uparrow}$*.*
7. *H records componentwise* hsame *transport for $M, K, C, E, R, D, Q, P, N$ and for the displayed compact approximation and exceptional-set reads.*
8. *Q records displayed* Cont *replay from the measure source through compact approximation, continuous representative, exceptional ledger, real readback, dyadic tolerance, transport, provenance, and local naming.*

9. *P is the* Pkg *provenance over* $\mathsf{LusinTheorem}^{\uparrow}$, $\mathsf{Measure}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{LusinApproximation}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{LusinTheorem}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $M, K, C, E, R, D, H, Q, P, N$. It has no coordinate for a host measurable-function quotient, a completed measure algebra, a choice-selected approximation, an ambient function space, countable choice, or host $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 8686.2 (Lusin theorem NameCert obligations)**.** *For every accepted* $\mathsf{LusinTheorem}^{\uparrow}$ *carrier*

$$L = (M, K, C, E, R, D, H, Q, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{LusinTheorem}^{\uparrow}}$ *surface consists exactly of the following obligation rows:*

1. *carrier admission for the* $\mathsf{Measure}^{\uparrow}$ *source row M, the compact approximation row K, and the* $\mathsf{ContinuousMap}^{\uparrow}$ *representative row C;*
2. *compact approximation exposure through K, requiring the compact window and its complement budget to be read in the same measure ledger as M;*
3. *continuous representative exactness through C, requiring every public representative read to stay on the displayed compact window;*
4. *exceptional-set and error-ledger exposure through E and the dyadic tolerance row D, requiring each theorem read to display its finite exceptional budget;*
5. $\mathsf{RegSeqRat}^{\uparrow}$ *and* $\mathsf{Real}^{\uparrow}$ *seal non-escape through R, requiring real-valued readback to remain tied to the measured row, representative row, and tolerance ledger;*
6. *structural stability through H, Q, P, N, requiring componentwise transport, displayed replay, provenance, and local naming to preserve exactly the rows M, K, C, E, R, D.*

No obligation may be discharged by importing a host measurable-function quotient, selecting an approximation outside the displayed compact row, completing the measure algebra, quotienting by almost-everywhere equality, or appealing to countable choice.

Proof. Project the carrier of Definition 8686.1. The measure-facing data are M, K, E, D, the representative data are C, R, and the structural route is H, Q, P, N.

The compact approximation row is read before any continuous representative is exported. Thus the representative in C is attached to the compact window K and to the exceptional-set ledger E, rather than to an ambient measurable-function quotient or a selected approximation.

The real-valued readback is sealed only after the dyadic tolerance row is visible. The row D supplies the finite error budget, while R keeps the $\mathsf{RegSeqRat}^{\uparrow}$ and $\mathsf{Real}^{\uparrow}$ comparison route tied to the same measured row, continuous representative, and exceptional ledger.

Finally H, Q, P, N transport, replay, source, and name only those displayed rows. Since the excluded host quotient, selected approximation, completed measure algebra, countable choice, and ambient real-completeness coordinates are absent, the listed rows exhaust the local NameCert obligations. □

Closure status for $\mathsf{NameCert}_{\mathsf{LusinTheorem}^{\uparrow}}$**.**

Constructive story: A $\mathsf{LusinTheorem}^{\uparrow}$ packet is generated from finite Measure rows, compact approximation rows, ContinuousMap representative rows, exceptional-set and error ledgers, RegSeqRat and Real readback rows, DyadicRatCore tolerance rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{LusinTheorem}^{\uparrow}}$, seed)

Scope closed: Definition 8686.1 and Definition 8686.2 seed the finite compact-approximation and continuous-representative route from Measure and DyadicRatCore tolerance rows to RegSeqRat and Real readback consumers.

Formal verification: FormalStatus(NameCert$_{\mathsf{LusinTheorem}\uparrow}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim the full host Lusin theorem, completed measure algebra, host measurable-function quotient, selected approximation, quotient almost-everywhere equality, countable choice, ambient Real$^{\uparrow}$ completeness, Lean verification, axiom-clean audit, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, compact approximation exactness, continuous representative exactness, exceptional-set ledger exposure, tolerance sealing, real readback non-escape, transport stability, and replay stability for BEDC.Derived.LusinTheoremUp.

Chapter 8687

A Concrete Naming Certificate for $\mathsf{RegularCauchyEventualWindow}^{\uparrow}$

Following Bishop and Bridges on regular Cauchy sequences and explicit moduli, the $\mathsf{RegularCauchyEventualWindow}^{\uparrow}$ packet records the finite eventual-window route by which a regular Cauchy request exposes a StreamName window, a DyadicRatCore tolerance row, a RegSeqRat readback, a Real seal, and a DiagonalLimitRepresentative handoff. It sits beside the finite-window discipline of chapter 126, the dyadic arithmetic core of chapter 291, the regular rational carrier of chapter 301, the terminal Real carrier of chapter 38, and the diagonal-limit representative packet of chapter 1205. The packet is a choice-free finite tail-window interface; it is not quotient stream equality, a selected host limit, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 8687.1 (Regular Cauchy eventual-window carrier)**.** *A* $\mathsf{RegularCauchyEventualWindow}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$W = (S, D, R, E, L, H, C, P, N)$$

with the following displayed rows:

1. *S is the* $\mathsf{StreamName}^{\uparrow}$ *eventual-window request row naming the finite tail stage and the precision at which the window is read.*
2. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row recording the dyadic comparison bound used inside the tail window.*
3. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row obtained from the displayed stream window and tolerance data.*
4. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row reached only after S, D, R have been displayed.*
5. *L is the* $\mathsf{DiagonalLimitRepresentative}^{\uparrow}$ *handoff row that consumes the same finite window before any diagonal-limit consumer reads a representative.*
6. *H records componentwise* hsame *transport for the window, tolerance, readback, seal, handoff, replay, provenance, and local naming rows.*
7. *C records displayed* Cont *replay from a regular Cauchy precision request through the eventual window, dyadic tolerance, RegSeqRat readback, Real seal, and diagonal-limit handoff.*
8. *P is the* Pkg *provenance over* $\mathsf{RegularCauchyEventualWindow}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*,* $\mathsf{DiagonalLimitRepresentative}^{\uparrow}$*,* BHist*,* hsame*,* Cont*, and* NameCert*.*

9. N is the local $\mathsf{NameCert}_{\mathsf{RegularCauchyEventualWindow}^{\uparrow}}$ *row.*
The classifier compares accepted packets only through $S, D, R, E, L, H, C, P, N$. It stores no coordinate for a quotient of streams, a chosen limit object, a countable-choice selector, or an ambient completeness theorem for $\mathsf{Real}^{\uparrow}$.

Theorem 8687.2 (Regular Cauchy eventual-window NameCert obligations)**.** *For every accepted* $\mathsf{RegularCauchyEventualWindow}^{\uparrow}$ *carrier $W = (S, D, R, E, L, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyEventualWindow}}$ *surface consists exactly of carrier admission, eventual-window exposure, dyadic tolerance compatibility, RegSeqRat readback, Real seal handoff, diagonal-limit representative handoff, componentwise transport, displayed replay, provenance, and local naming. A consumer must read the tail stage through S, the tolerance through D, and the regular rational row through R before the* $\mathsf{Real}^{\uparrow}$ *seal E or the diagonal-limit row L is public.*

Proof. Project the carrier of Definition 8687.1. The rows S, D, R, E, L are the only analytic rows available before the structural support rows are read.

The eventual-window exposure starts with S. A downstream consumer receives a displayed finite tail stage and precision request, not a global quotient of streams or a selected limit.

Next read the dyadic tolerance row D and the regular rational readback row R. Compatibility means that the tolerance data belongs to the same tail window and that the RegSeqRat row is obtained from that displayed window.

Finally read E and L. The Real seal and diagonal-limit representative handoff are both downstream of the same finite window. The rows H, C, P, N transport, replay, source, and name only this displayed packet, so the NameCert surface cannot import countable choice or ambient completeness. □

Theorem 8687.3 (Regular Cauchy eventual-window tail handoff)**.** *Every diagonal-limit or Real-completion consumer of an accepted* $\mathsf{RegularCauchyEventualWindow}^{\uparrow}$ *packet reads through the finite tail-window route*

$$\mathsf{StreamName}^{\uparrow}, \quad \mathsf{DyadicRatCore}^{\uparrow}, \quad \mathsf{RegSeqRat}^{\uparrow}, \quad \mathsf{Real}^{\uparrow}, \quad \mathsf{DiagonalLimitRepresentative}^{\uparrow}.$$

In carrier notation, the consumer must expose S, D, R, E, L before it treats the packet as a limit-facing handoff, while H, C, P, N only transport, replay, source, and name the same finite route.

Proof. Begin with the NameCert obligations of Definition 8687.2. They place every Real-facing or diagonal-limit-facing read downstream of the same displayed tail window and dyadic tolerance row.

Read the StreamName and DyadicRatCore rows together. The tail stage is usable only with its tolerance witness, so the route cannot jump directly from a regular Cauchy request to a completed real or a diagonal representative.

The RegSeqRat readback, Real seal, and diagonal-limit handoff close the finite route. Since the support rows H, C, P, N preserve the same packet, no consumer can replace the handoff by quotient stream equality, a selected limit, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness. □

Closure status for $\mathsf{NameCert}_{\mathsf{RegularCauchyEventualWindow}^{\uparrow}}$.

Constructive story: A $\mathsf{RegularCauchyEventualWindow}^{\uparrow}$ packet is generated from an eventual StreamName window, dyadic tolerance row, RegSeqRat readback, RealUp seal, diagonal-limit handoff, componentwise transport, displayed replay, provenance, and local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RegularCauchyEventualWindow}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8687.1, Definition 8687.2, and Definition 8687.3 seed the finite tail-window interface from regular Cauchy requests to diagonal-limit and Real-completion consumers.

Formal verification: FormalStatus(NameCert$_{\mathsf{RegularCauchyEventualWindow}\uparrow}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close quotient stream equality, selected host limits, countable choice, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, eventual-window exposure, dyadic tolerance compatibility, RegSeqRat readback, Real seal handoff, diagonal-limit handoff, and structural non-escape for the same finite packet.

Chapter 8688

A Concrete Naming Certificate for $\mathsf{WindingNumber}^{\uparrow}$

Following Poincare and the standard algebraic-topology treatment of loops in the circle, the $\mathsf{WindingNumber}^{\uparrow}$ packet records the finite certificate surface by which a displayed loop into $\mathsf{Circle}^{\uparrow}$ receives an integer degree read through $\mathsf{S}^{1\uparrow}$ and real-coordinate windows. It sits beside the phase-circle certificate of chapter 58, the topological circle boundary of chapter 4010, the continuous-map source of chapter 59, the integer target of chapter 31, and the real-coordinate seal of chapter 38. The chapter names only the finite loop-degree boundary; it does not claim a full fundamental-group computation, classical covering-space lifting, unrestricted homotopy invariance, or quotient path equality.

Definition 8688.1 (Winding-number carrier)**.** *A* $\mathsf{WindingNumber}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$W = (L, S, C, I, R, D, H, T, P, N)$$

with the following displayed rows:

1. *L is the closed loop-source row, naming the displayed loop interval and endpoint match.*
2. *S is the* $\mathsf{S}^{1\uparrow}$ *phase-boundary row read from the loop.*
3. *C is the* $\mathsf{Circle}^{\uparrow}$ *topological-circle row through which the same loop is inspected as a boundary object.*
4. *I is the* $\mathsf{Int}^{\uparrow}$ *degree row exported by the packet.*
5. *R is the* $\mathsf{Real}^{\uparrow}$ *coordinate-read row used for finite endpoint and arc-window checks.*
6. *D is the displayed degree-boundary ledger relating loop subdivision windows to the integer row I.*
7. *H records componentwise* hsame *transport for the loop, circle, phase, integer, real, degree-boundary, replay, provenance, and naming rows.*
8. *T records displayed* Cont *replay for the same finite rows.*
9. *P is the* Pkg *provenance over* $\mathsf{WindingNumber}^{\uparrow}$, $\mathsf{S}^{1\uparrow}$, $\mathsf{Circle}^{\uparrow}$, $\mathsf{CFun}^{\uparrow}$, $\mathsf{Int}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{WindingNumber}^{\uparrow}}$ *row.*

The carrier has no coordinate for a universal covering space, a host fundamental group, quotient path classes, selected lifts, or unrestricted homotopy classes.

Theorem 8688.2 (Winding-number NameCert obligations)**.** *For every accepted* $\mathsf{WindingNumber}^{\uparrow}$ *carrier*

$$W = (L, S, C, I, R, D, H, T, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{WindingNumber}^{\uparrow}}$ *surface consists exactly of loop-source exposure,* $\mathsf{S}^{1\uparrow}$ *phase-boundary exposure,* $\mathsf{Circle}^{\uparrow}$ *boundary exposure,* $\mathsf{CFun}^{\uparrow}$ *loop-continuity provenance,* $\mathsf{Int}^{\uparrow}$ *degree exposure,* $\mathsf{Real}^{\uparrow}$ *coordinate-window exposure, degree-boundary ledger exposure, componentwise transport, displayed replay, package provenance, and local naming. A winding-number consumer must read those finite rows before using the integer degree row* I*.*

Proof. Project the carrier of Definition 8688.1. The loop row L, the $\mathsf{S}^{1\uparrow}$ row S, the $\mathsf{Circle}^{\uparrow}$ row C, the $\mathsf{Real}^{\uparrow}$ row R, and the degree-boundary ledger D are displayed before the integer row is treated as public data.

The continuous-map requirement is part of the provenance row P: it records that the loop is read through the continuous-map certificate rather than through a detached host function. The rows H, T, N only transport, replay, and name the same finite packet.

Since the carrier contains no covering-space lift, quotient path class, host fundamental group, or unrestricted homotopy-class coordinate, the listed rows exhaust the NameCert obligations for the finite winding-number surface. □

Theorem 8688.3 (Winding-number $\mathsf{S}^{1\uparrow}$ loop-degree boundary)**.** *Every* $\mathsf{S}^{1\uparrow}$*-facing loop-degree read from an accepted* $\mathsf{WindingNumber}^{\uparrow}$ *packet factors through*

$$\mathsf{CFun}^{\uparrow} \longmapsto \mathsf{Circle}^{\uparrow} \longmapsto \mathsf{S}^{1\uparrow} \longmapsto \mathsf{Real}^{\uparrow} \longmapsto \mathsf{Int}^{\uparrow}$$

using the finite rows $L, C, S, R, D, I, H, T, P, N$*. The route exports a displayed integer degree for the loop boundary, but it does not export a full fundamental group theorem, a classical covering-space lift, quotient path equality, or unrestricted homotopy invariance.*

Proof. Start with the displayed loop row L and its continuity provenance inside P. This places the source in the continuous-map certificate surface before any degree read is available.

Next read the topological boundary row C and the phase-circle row S. These rows connect the same loop to $\mathsf{Circle}^{\uparrow}$ and $\mathsf{S}^{1\uparrow}$ without replacing the carrier by a quotient path object or an ambient covering space.

Finally read the real-coordinate windows R, the degree-boundary ledger D, and the integer row I. The structural rows H, T, P, N preserve this order, so the exported degree is exactly the finite loop-degree boundary and none of the refused classical endpoints is supplied. □

Closure status for $\mathsf{NameCert}_{\mathsf{WindingNumber}^{\uparrow}}$**.**

Constructive story: A $\mathsf{WindingNumber}^{\uparrow}$ packet is generated from a displayed loop row, SOne phase row, Circle boundary row, Int degree row, Real coordinate-read row, degree-boundary ledger, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{WindingNumber}^{\uparrow}}$, seed)

Scope closed: Definition 8688.1, Definition 8688.2, and Definition 8688.3 seed the finite loop-degree carrier, obligation surface, and SOne-facing degree route.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{WindingNumber}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close Lean verification, bridge checking, the full fundamental group of the circle, classical covering-space theory, quotient path equality, or unrestricted homotopy invariance.

Upgrade path: Obligation closure requires checked carrier admission, loop-continuity provenance, SOne and Circle boundary compatibility, Real coordinate-window exactness, Int degree exposure, transport, replay, provenance, and local naming for the same finite packet.

Chapter 8689

A Concrete Naming Certificate for $\mathsf{AlgorithmWTypeInference}^{\uparrow}$

Following Hindley and Milner, the $\mathsf{AlgorithmWTypeInference}^{\uparrow}$ packet records principal type inference for simply presented lambda terms as finite BEDC readback data. It consumes the $\mathsf{LambdaCalc}^{\uparrow}$ syntax surface of chapter 200, the typed-example coverage rows of chapter 923, and the MetaCIC audit routing of chapter 765. The chapter names only the displayed inference, constraint, unification, principal-type, transport, replay, provenance, and local NameCert rows; it does not import a host typechecker, an ambient unification oracle, quotient equality of types, or a completeness theorem for a host evaluator.

Definition 8689.1 (Algorithm W type-inference carrier)**.** *An* $\mathsf{AlgorithmWTypeInference}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$A = (L, E, M, C, U, T, H, R, P, N)$$

with the following displayed rows:

1. *L is the consumed* $\mathsf{LambdaCalc}^{\uparrow}$ *term packet. It exposes variables, abstractions, applications, substitution rows, alpha-beta classifier rows, and constructor case data as finite syntax rows.*
2. *E is the typed-example coverage row consumed from* $\mathsf{TypedExampleCoverageMatrix}^{\uparrow}$*. It records which variable, abstraction, application, let-shaped, and failure-facing examples are covered by the inference packet before any checker-audit consumer reads it.*
3. *M is the* $\mathsf{MetaCICCriticalPath}^{\uparrow}$ *audit row. It records the critical-path cells that will later consume inferred typing rows, normalization-facing rows, and checker-audit rows.*
4. *C is the constraint-generation ledger. Each entry names the source syntax row, context row, fresh type-variable row, and generated equality constraint for the visible constructor case.*
5. *U is the unification ledger. It records only finite occurs-check, substitution-extension, constraint-discharge, and residual-constraint rows.*
6. *T is the principal-type output row. It names the inferred type scheme, the solved substitution, the residual context, and the proof that every exported typed-example row reads through the same solved ledger.*
7. *H records componentwise* hsame *transport for the lambda syntax, typed-example coverage, MetaCIC audit, constraint, unification, principal-type, replay, provenance, and naming rows.*

8. *R records displayed* Cont *replay from L, E, M into C, from C into U, and from U into T before any MetaCIC typing or normalization audit route consumes the result.*
9. *P is the* Pkg *provenance over* $\mathsf{AlgorithmWTypeInference}^{\uparrow}$, $\mathsf{LambdaCalc}^{\uparrow}$, $\mathsf{TypedExampleCoverageMatrix}^{\uparrow}$, $\mathsf{MetaCICCriticalPath}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{AlgorithmWTypeInference}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these rows. It has no coordinate for a host typechecker, ambient type-scheme equality, host unification state, hidden principal-type theorem, or imported MetaCIC typing judgment.

Theorem 8689.2 (Algorithm W type-inference NameCert obligations)**.** *For every accepted* AlgorithmWTypeInferen *carrier $A = (L, E, M, C, U, T, H, R, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{AlgorithmWTypeInference}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the displayed lambda syntax, typed-example coverage, MetaCIC critical-path, constraint-generation, unification, principal-type, transport, continuation, provenance, and naming rows;*
2. *syntax coverage, requiring every inference read to enter through the consumed* $\mathsf{LambdaCalc}^{\uparrow}$ *constructor row of L;*
3. *typed-example coverage, requiring each exported example-facing typing row to be listed in E before it is consumed by a checker-audit route;*
4. *constraint generation, requiring constructor cases to append only the displayed context, fresh type-variable, and equality-constraint rows in C;*
5. *unification ledger exactness, requiring every solved substitution and residual constraint to be read from U rather than from a host unifier;*
6. *principal-type output, requiring the public type scheme and solved substitution to be exposed through T after C and U have been displayed;*
7. *transport, replay, provenance, and naming through H, R, P, N.*

No Algorithm W obligation is stored outside these rows.

Proof. Project the carrier of Definition 8689.1. Its coordinates list the lambda source, coverage row, MetaCIC audit row, constraint ledger, unification ledger, principal-type output, and structural rows.

The syntax and coverage obligations are forced by L and E. A consumer cannot ask for an inference row until the corresponding $\mathsf{LambdaCalc}^{\uparrow}$ constructor row and typed-example coverage cell have been displayed.

Constraint generation and unification are the roles of C and U. The packet records fresh type-variable rows, equality constraints, occurs-check rows, substitution extensions, and residual constraints as finite ledger entries, so a host typechecker or ambient unification oracle has no coordinate from which to enter.

Finally, the principal output T is downstream from C and U, while H, R, P, N transport, replay, package, and name the same finite route. Hence the local NameCert surface is exhausted by the rows stated above. □

Theorem 8689.3 (Algorithm W type-inference principal-type route)**.** *Every principal-type read exported by an accepted* $\mathsf{AlgorithmWTypeInference}^{\uparrow}$ *packet factors through*

$$\mathsf{LambdaCalc}^{\uparrow}, \mathsf{TypedExampleCoverageMatrix}^{\uparrow}, \mathsf{MetaCICCriticalPath}^{\uparrow} \longmapsto C \longmapsto U \longmapsto T \longmapsto H, R, P, N.$$

Thus a MetaCIC typing or normalization audit route may consume the inferred type scheme only after the lambda syntax row, typed-example coverage row, critical-path row, constraint-generation ledger, unification ledger, principal-type output row, hsame *transport,* Cont *replay,* Pkg *provenance, and local* NameCert *row have been displayed.*

Proof. Begin with a principal-type request. The source term must first be read as a $\mathsf{LambdaCalc}^{\uparrow}$ packet, and the typed-example consumer must read the corresponding coverage row of TypedExampleCoverageMatrix

The MetaCIC audit route is then constrained by M. It can request typing and normalization-facing rows only through the critical-path cells already displayed in the carrier.

Constraint generation sends the request into C, and unification discharges those generated constraints through U. The principal type scheme is exposed only by T, together with the solved substitution and residual context recorded in the same finite ledger.

The structural rows H, R, P, N preserve this route under transport and replay. Since the carrier has no host typechecker, ambient unifier, quotient type equality, hidden principal-type theorem, or imported MetaCIC typing judgment, the exported principal-type read is exactly the displayed route named in the statement. □

Closure status for $\mathsf{NameCert}_{\mathsf{AlgorithmWTypeInference}^{\uparrow}}$.

Constructive story: An $\mathsf{AlgorithmWTypeInference}^{\uparrow}$ packet is generated from LambdaCalc syntax rows, typed-example coverage rows, MetaCIC critical-path rows, a finite constraint-generation ledger, a finite unification ledger, a principal-type output row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{AlgorithmWTypeInference}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8689.1, Definition 8689.2, and Definition 8689.3 seed the finite Algorithm W inference packet over displayed syntax, coverage, critical-path, constraint, unification, principal-type, transport, replay, provenance, and naming rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{AlgorithmWTypeInference}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close a host typechecker, ambient unification oracle, quotient equality of types, a full Hindley-Milner completeness theorem, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, constructorwise constraint generation, unification ledger exactness, principal-type output, MetaCIC audit handoff, transport, replay, provenance, and local NameCert rows for BEDC.Derived.AlgorithmWTypeInferenceUp.

Chapter 8690

A Concrete Naming Certificate for $\mathsf{RieszMarkovKakutani}^{\uparrow}$

Following Riesz, Markov, and Kakutani, the $\mathsf{RieszMarkovKakutani}^{\uparrow}$ packet records the finite BEDC surface that routes a positive linear functional on displayed continuous functions over a compact source to a Radon-measure handoff. It sits over the compact source rows of chapter 129, the function rows of chapter 130, the real-name seal of chapter 38, and the measure rows of chapter 2263. The packet names the carrier, positivity ledger, linearity ledger, compact-support restriction, finite approximation route, measure handoff, transport, replay, provenance, and local naming; it does not import host dual spaces, selected representing measures, open-cover compactness, quotient function equality, or countable choice.

Definition 8690.1 (Riesz–Markov–Kakutani carrier)**.** *A* $\mathsf{RieszMarkovKakutani}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$R = (K, F, V, P, L, A, M, H, C, Q, N)$$

with the following displayed rows:

1. *K is the* $\mathsf{CompactMetric}^{\uparrow}$ *source row carrying the compact domain surface that every continuous-function read must inspect.*
2. *F is the* $\mathsf{ContinuousMap}^{\uparrow}$ *function-family row over K, with target observations sealed through* $\mathsf{Real}^{\uparrow}$ *rows.*
3. *V is the real-valued functional row, recording the finite evaluation requests and real-name outputs read by the positive functional.*
4. *P is the positivity ledger: nonnegative function rows in F are sent to nonnegative* $\mathsf{Real}^{\uparrow}$ *output rows.*
5. *L is the linearity ledger, recording displayed addition and scalar-multiplication compatibility for the finite function rows read by the packet.*
6. *A is the approximation row, routing compact finite probes and continuous-function modulus data to the finite test family used by the measure handoff.*
7. *M is the* $\mathsf{RadonMeasure}^{\uparrow}$ *handoff row, exposing the measure candidate only after K, F, V, P, L, A are visible.*

8. *H records componentwise* hsame *transport for the compact source, function family, real-valued functional, positivity, linearity, approximation, measure handoff, replay, provenance, and local naming rows.*
9. *C records displayed* Cont *replay through the same rows.*
10. *Q is the* Pkg *provenance over* $\mathsf{RieszMarkovKakutani}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{RadonMeasure}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{RieszMarkovKakutani}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these rows. It has no coordinate for an ambient dual Banach space, a selected representing measure, quotient equality of continuous functions, arbitrary open-cover compactness, countable choice, or a completed integration theory.

Theorem 8690.2 (Riesz–Markov–Kakutani NameCert obligations)**.** *For every accepted* $\mathsf{RieszMarkovKakutani}^{\uparrow}$ *carrier*

$$R = (K, F, V, P, L, A, M, H, C, Q, N),$$

the local $\mathsf{NameCert}_{\mathsf{RieszMarkovKakutani}^{\uparrow}}$ *surface consists exactly of compact-source admission through K, continuous-function admission through F, real-valued functional exposure through V, positivity through P, linearity through L, finite approximation through A, Radon-measure handoff through M, componentwise transport through H, displayed replay through C, package provenance through Q, and local naming through N.*

Proof. Project the carrier of Definition 8690.1. The rows K, F, V display the compact domain, continuous real-valued function data, and finite functional evaluations before any measure handoff is public.

Read the positivity and linearity ledgers next. They record exactly the functional laws needed by the handoff and do not introduce a host dual space or quotient equality of functions.

The approximation row A then ties compact finite probes to the continuous-function rows, and the measure row M is exposed only after that route is visible. Finally H, C, Q, N preserve, replay, source, and name the same packet, so the listed rows exhaust the local certificate obligations. □

Theorem 8690.3 (Riesz–Markov–Kakutani positive functional measure route)**.** *Every downstream* $\mathsf{RadonMeasure}^{\uparrow}$ *consumer of an accepted* $\mathsf{RieszMarkovKakutani}^{\uparrow}$ *packet must first read the compact source row K, the continuous-function row F, the real-valued functional row V, the positivity ledger P, the linearity ledger L, and the finite approximation row A. The measure handoff is therefore a displayed route*

$$\mathsf{CompactMetric}^{\uparrow} \longmapsto \mathsf{ContinuousMap}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow} \longmapsto (P, L, A) \longmapsto \mathsf{RadonMeasure}^{\uparrow}$$

inside the packet, not a selected representing-measure theorem in the host metatheory.

Proof. Start from the obligation theorem Definition 8690.2. It places the compact source, function family, functional row, positivity row, linearity row, and approximation row before the measure handoff.

The $\mathsf{CompactMetric}^{\uparrow}$ and $\mathsf{ContinuousMap}^{\uparrow}$ rows provide the finite domain and function observations, while $\mathsf{Real}^{\uparrow}$ seals the functional outputs. Positivity and linearity remain displayed ledgers attached to those observations.

Only after these rows are visible may a $\mathsf{RadonMeasure}^{\uparrow}$ consumer inspect M. Since the carrier has no selected measure coordinate, no quotient function equality, and no countable-choice coordinate, the exported measure read is exactly the displayed handoff route. □

Closure status for $\mathsf{NameCert}_{\mathsf{RieszMarkovKakutani}^{\uparrow}}$.

Constructive story: A $\mathsf{RieszMarkovKakutani}^{\uparrow}$ packet is generated from a CompactMetric source row, ContinuousMap real-valued function rows, RealUp functional outputs, positivity and linearity ledgers, finite approximation rows, a RadonMeasure handoff, componentwise hsame transport, displayed Cont replay, package provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RieszMarkovKakutani}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8690.1, Definition 8690.2, and Definition 8690.3 seed the positive-functional-to-measure NameCert surface over compact metric, continuous map, real-name, and Radon measure rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RieszMarkovKakutani}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close Lean verification, bridge checking, a selected representing measure, host dual-space equality, quotient equality of continuous functions, open-cover compactness, countable choice, or a completed integration theory.

Upgrade path: Obligation closure requires checked carrier admission, positivity exposure, linearity exposure, compact approximation routing, RadonMeasure handoff stability, replay stability, transport stability, provenance exhaustion, and local naming for BEDC.Derived.RieszMarkovKakutaniUp.

Chapter 8691

A Concrete Naming Certificate for $\mathsf{LoewenheimSkolem}^{\uparrow}$

Following Skolem and Tarski, the $\mathsf{LoewenheimSkolem}^{\uparrow}$ packet records the finite certificate surface by which a first-order theory request exposes a generated Skolem submodel boundary. It sits beside the syntax-and-deduction carrier of chapter 197, the satisfaction ledger of chapter 198, the displayed membership discipline of chapter 3668, and the typed-family route of chapter 3600. The packet names only a finite language row, a finite formula-family row, a generated Skolem-closure row, a submodel-witness row, a satisfaction ledger, transport, replay, provenance, and local naming; it does not assert a host cardinal theorem, selected elementary chain, quotient model equality, or unrestricted choice of witnesses.

Definition 8691.1 (Loewenheim-Skolem carrier)**.** *A* $\mathsf{LoewenheimSkolem}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (G, F, S, M, V, H, C, P, N)$$

with the following displayed rows:

1. *G is the finite language row, read through* $\mathsf{FirstOrder}^{\uparrow}$*, listing the function, relation, and constant symbols inspected by the packet.*
2. *F is the formula-family row, also read through* $\mathsf{FirstOrder}^{\uparrow}$*, exposing the formulas whose witnesses and truth values are tracked.*
3. *S is the generated Skolem-closure row. It records the finite closure steps that add named witness terms for the displayed formulas rather than a host-level closure operator.*
4. *M is the submodel-witness row, read through* $\mathsf{ModelTheory}^{\uparrow}$ *and* $\mathsf{SetLike}^{\uparrow}$*, displaying membership and interpretation compatibility for the generated carrier fragment.*
5. *V is the satisfaction ledger, read through* $\mathsf{ModelTheory}^{\uparrow}$*, recording that every inspected formula family keeps the same displayed truth row when evaluated inside the generated fragment.*
6. *H records componentwise* hsame *transport for the language, formula-family, Skolem-closure, submodel, satisfaction, replay, provenance, and naming rows.*
7. *C records displayed* Cont *replay from a submodel request through language exposure, formula exposure, closure generation, membership inspection, satisfaction readback, provenance, and local naming.*

8. *P is the* Pkg *provenance over* LoewenheimSkolem$^{\uparrow}$, FirstOrder$^{\uparrow}$, ModelTheory$^{\uparrow}$, SetLike$^{\uparrow}$, TypeLike$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

9. *N is the local* NameCert$_{\text{LoewenheimSkolem}^{\uparrow}}$ *row.*

The carrier has no coordinate for an ambient set-theoretic universe, a selected infinite elementary chain, quotient equality of models, or a cardinal arithmetic theorem.

Theorem 8691.2 (Loewenheim-Skolem NameCert obligations)**.** *For every accepted* LoewenheimSkolem$^{\uparrow}$ *carrier*

$$L = (G, F, S, M, V, H, C, P, N),$$

the local NameCert$_{\text{LoewenheimSkolem}^{\uparrow}}$ *surface consists exactly of finite language exposure through G, formula-family exposure through F, generated Skolem-closure exposure through S, submodel-witness exposure through M, satisfaction-ledger exposure through V, componentwise* hsame *transport through H, displayed* Cont *replay through C,* Pkg *provenance through P, and local naming through N. Every consumer of the generated submodel boundary must read those rows before citing a Loewenheim-Skolem conclusion.*

Proof. Project the carrier of Definition 8691.1. The first two rows G, F fix the first-order language and the formula family whose witnesses are being generated; they are read only through the FirstOrder$^{\uparrow}$ certificate surface.

Next inspect the generated closure and submodel rows. The row S records the finite Skolem steps, while M records membership and interpretation compatibility through the ModelTheory$^{\uparrow}$ and SetLike$^{\uparrow}$ siblings. These rows supply the displayed submodel boundary without selecting an ambient chain or quotient model.

Now read the satisfaction ledger V. It ties each inspected formula in F to the same displayed truth row before and after the generated-fragment read, so the packet exports only the finite satisfaction boundary that has been named in the carrier.

Finally H, C, P, N transport, replay, source, and name the same rows. Since the carrier has no coordinate for an external cardinal theorem, host universe, chosen elementary chain, or quotient model equality, the listed rows exhaust the local NameCert obligations. □

Falsifiable prediction: A consumer that claims a LoewenheimSkolem$^{\uparrow}$ generated submodel while omitting the finite language row, formula-family row, Skolem-closure row, submodel-witness row, satisfaction ledger, hsame, Cont, Pkg, or local NameCert row refutes the carrier of Definition 8691.1.

Independence witness: firstorder, modeltheory, setlike, typelike: LoewenheimSkolem$^{\uparrow}$ is not bijective to any listed sibling because it jointly carries finite language, formula-family, Skolem-closure, submodel-witness, satisfaction-ledger, transport, replay, provenance, and local NameCert rows. FirstOrderUp supplies syntax and deduction without generated submodels; ModelTheoryUp supplies satisfaction rows without a Skolem-closure boundary; SetLikeUp supplies membership without first-order witness generation; TypeLikeUp supplies displayed families without the model-theoretic satisfaction ledger.

Closure status for NameCert$_{\text{LoewenheimSkolem}^{\uparrow}}$.

Constructive story: A LoewenheimSkolem$^{\uparrow}$ packet is generated from a finite language row, formula-family row, generated Skolem-closure row, submodel-witness row, satisfaction ledger, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\text{LoewenheimSkolem}^{\uparrow}}$, seed)

Scope closed: Definition 8691.1 and Definition 8691.2 seed the generated-submodel carrier and obligation surface over FirstOrder$^{\uparrow}$, ModelTheory$^{\uparrow}$, SetLike$^{\uparrow}$, TypeLike$^{\uparrow}$, BHist, hsame, Cont, Pkg, and NameCert.

Formal verification: FormalStatus(NameCert$_{\text{LoewenheimSkolem}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close Lean verification, bridge checking, an external cardinal theorem, selected elementary chains, quotient model equality, or unrestricted witness choice.

Upgrade path: Obligation closure requires checked carrier admission, finite language exposure, formula-family exposure, generated Skolem-closure exposure, submodel-witness exposure, satisfaction-ledger stability, transport, replay, provenance, and local naming for the same packet.

Chapter 8692

A Concrete Naming Certificate for $\mathsf{EnrichedMetricSpace}^{\uparrow}$

Following Lawvere enriched metric spaces and the Isbell–Yoneda completion tradition, the $\mathsf{EnrichedMetricSpace}^{\uparrow}$ packet records the distance-as-hom profile that L10 completion routes need before a $\mathsf{LawvereMetric}^{\uparrow}$ or $\mathsf{YonedaCompletion}^{\uparrow}$ consumer reads completion-facing data. It sits over the metric carrier of chapter 57, the formal-ball surface of chapter 1510, the dyadic and regular rational readbacks of chapter 291 and chapter 301, the terminal real seal of chapter 38, the directed-distance packet of chapter 7212, and the Yoneda-profile route of chapter 2148. The packet names only the finite enriched-distance profile shared by those readers; it does not construct a quotient completion, select colimits, import host enriched categories, or assume ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 8692.1 (EnrichedMetricSpace carrier)**.** *An* $\mathsf{EnrichedMetricSpace}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$E = (X, D, U, T, B, Y, R, H, C, P, N)$$

whose rows have the following public roles:

1. *X is the displayed source-object row, read through the ordinary* $\mathsf{Met}^{\uparrow}$ *sibling when a symmetric metric source is present.*
2. *D is the enriched distance or hom-profile row, exposing directed values before any* $\mathsf{LawvereMetric}^{\uparrow}$ *or* $\mathsf{LawvereMetricCompletion}^{\uparrow}$ *consumer reads them.*
3. *U is the unit row, certifying the displayed self-distance or identity-hom value.*
4. *T is the triangle or composition row, certifying the finite comparison that composes two displayed hom values into a third.*
5. *B is the* $\mathsf{FormalBall}^{\uparrow}$ *probe row, carrying radius-indexed observations of the same profile.*
6. *Y is the* $\mathsf{YonedaCompletion}^{\uparrow}$ *profile row, recording the finite presheaf-style read seen by completion consumers.*
7. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *and* $\mathsf{Real}^{\uparrow}$ *seal row, with* $\mathsf{DyadicRatCore}^{\uparrow}$ *budgets attached before any terminal distance read.*
8. *H is componentwise* hsame *transport for X, D, U, T, B, Y, R.*
9. *C is the displayed* Cont *replay row for the same finite route.*

10. *P is the* Pkg *provenance over* $\mathsf{EnrichedMetricSpace}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{LawvereMetric}^{\uparrow}$, $\mathsf{FormalBall}^{\uparrow}$, $\mathsf{YonedaCompletion}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{EnrichedMetricSpace}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these rows. It has no coordinate for a quotient completion, selected colimit, host enriched category, ambient real-completeness theorem, choice functional, Lean proof credential, or standard bridge.

Theorem 8692.2 (EnrichedMetricSpace NameCert obligations)**.** *For every accepted* $\mathsf{EnrichedMetricSpace}^{\uparrow}$ *carrier* $E = (X, D, U, T, B, Y, R, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{EnrichedMetricSpace}^{\uparrow}}$ *surface consists exactly of seven finite obligation rows: carrier admission for the displayed source and profile rows; unit exactness through U; triangle or composition exactness through T;* $\mathsf{FormalBall}^{\uparrow}$ *and* $\mathsf{YonedaCompletion}^{\uparrow}$ *handoff through B, Y;* $\mathsf{RegSeqRat}^{\uparrow}$ *and* $\mathsf{Real}^{\uparrow}$ *nonescape through R with* $\mathsf{DyadicRatCore}^{\uparrow}$ *budgets; classifier transport through H, C; and provenance exhaustion through P, N.*

Proof. Project the carrier of Definition 8692.1. The rows $X, D, U, T, B, Y, R, H, C, P, N$ are the entire public surface, so carrier admission is exactly admission of those displayed rows.

The unit and triangle obligations are read from U and T. They attach identity and composition evidence to the same enriched distance row D, so a reader cannot replace them by a host enriched category or by an untracked order law.

The completion-facing handoff is the pair B, Y. The formal-ball probe row displays finite center-radius observations, and the Yoneda row reads the same enriched profile before any $\mathsf{LawvereMetricCompletion}^{\uparrow}$ route can inspect a completion seal.

Finally R, H, C, P, N seal the route. The real-valued read passes through $\mathsf{DyadicRatCore}^{\uparrow}$ budgets, $\mathsf{RegSeqRat}^{\uparrow}$ readback, and $\mathsf{Real}^{\uparrow}$ sealing; transport, replay, provenance, and local naming preserve the same packet and add no quotient completion, selected colimit, choice principle, Lean credential, or bridge check. □

Theorem 8692.3 (EnrichedMetricSpace Lawvere-Yoneda route)**.** *Every* $\mathsf{LawvereMetric}^{\uparrow}$ *and* $\mathsf{YonedaCompletion}^{\uparrow}$ *consumer of an accepted* $\mathsf{EnrichedMetricSpace}^{\uparrow}$ *carrier reads the same enriched distance profile through*

$$\mathsf{EnrichedMetricSpace}^{\uparrow} \longrightarrow \mathsf{FormalBall}^{\uparrow} \longrightarrow \mathsf{DyadicRatCore}^{\uparrow} \longrightarrow \mathsf{RegSeqRat}^{\uparrow} \longrightarrow \mathsf{Real}^{\uparrow}$$

before any completion-facing seal is available. Thus $\mathsf{LawvereMetricCompletion}^{\uparrow}$ *receives finite FormalBall, dyadic-budget, regular-rational, and real-seal data for the displayed profile, not a quotient completion, selected colimit, host enriched category, ambient completeness theorem, or choice-selected representative.*

Proof. Start with the NameCert obligations of Definition 8692.2. They force the source row, enriched distance row, unit row, triangle row, formal-ball probe, Yoneda profile, real-seal row, transport, replay, provenance, and local naming to remain rows of one packet.

A $\mathsf{LawvereMetric}^{\uparrow}$ consumer reads D, U, T as the directed-distance profile and its unit-composition ledger. A $\mathsf{YonedaCompletion}^{\uparrow}$ consumer reads the same profile only after B has exposed finite formal-ball probes.

The terminal read then passes through $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ inside R. Since the carrier has no coordinate for quotient completion, selected colimits, host enriched categories, ambient completeness, or choice, both consumers receive exactly the displayed finite route. □

Falsifiable prediction: Every accepted $\mathsf{EnrichedMetricSpace}^{\uparrow}$ read that lets a $\mathsf{LawvereMetric}^{\uparrow}$, $\mathsf{YonedaCompletion}^{\uparrow}$, or $\mathsf{LawvereMetricCompletion}^{\uparrow}$ consumer inspect a completion-facing seal without first displaying $D, U, T, B, Y, R, H, C, P, N$ is outside the carrier surface.

Independence witness: metric, lawvere-metric, formalball, yoneda-completion, dyadicratcore, regseqrat, real: $\mathsf{EnrichedMetricSpace}^{\uparrow}$ is not bijective to any listed sibling because it binds one enriched hom-profile to unit, triangle, FormalBall, Yoneda, dyadic-budget, regular-rational, Real-seal, transport, replay, provenance, and local NameCert rows while refusing quotient completion and host enriched categories.

Closure status for $\mathsf{NameCert}_{\mathsf{EnrichedMetricSpace}^{\uparrow}}$.

Constructive story: An $\mathsf{EnrichedMetricSpace}^{\uparrow}$ packet is generated from a displayed source row, enriched distance or hom-profile row, unit row, triangle or composition row, FormalBall probe row, Yoneda profile row, RegSeqRat and Real seal row with DyadicRatCore budgets, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{EnrichedMetricSpace}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8692.1, Definition 8692.2, and Definition 8692.3 seed the finite enriched-distance profile shared by LawvereMetric, YonedaCompletion, FormalBall, DyadicRatCore, RegSeqRat, and Real consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{EnrichedMetricSpace}^{\uparrow}}, \mathsf{unformalized})$

Lean target: `BEDC.Derived.EnrichedMetricSpaceUp`

Bridge status: none

Not claimed: This chapter does not close quotient completion, selected colimits, host enriched categories, ambient Real completeness, choice, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, unit exactness, triangle or composition exactness, FormalBall and Yoneda handoff, Real-seal nonescape, classifier transport, provenance exhaustion, and local naming for BEDC.Derived.EnrichedMetricSpaceUp.

Chapter 8693

A Concrete Naming Certificate for $\mathsf{CompletionReflectorMonad}^{\uparrow}$

Following Mac Lane on reflective subcategories and Bishop–Bridges/Kelley on metric completion, the $\mathsf{CompletionReflectorMonad}^{\uparrow}$ packet records the finite service boundary where completion is read simultaneously as a reflector and as a monad. It sits between the source metric rows of chapter 57, the displayed completion routes of chapter 1506, the monad rows of chapter 378, the reflector-unit route of chapter 8626, and the minimality route of chapter 1606. The packet is a finite NameCert carrier for completion-facing unit, bind, join, separated uniqueness, transport, replay, provenance, and local naming rows.

Definition 8693.1 (Completion reflector monad carrier)**.** *A* $\mathsf{CompletionReflectorMonad}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (S, R, U, J, E, H, C, P, N)$$

with the following displayed rows:

1. *S is the source metric row, exposing the source carrier, source classifier, distance observations, zero-distance row, symmetry row, triangle row, and distance-transport ledger consumed before any completion read is public.*
2. *R is the completion reflector row, recording the displayed completion object and reflector handoff through the existing metric-completion, reflector-unit, and minimality packets.*
3. *U is the unit embedding row from the source metric into the displayed completion surface, carrying only the finite graph of inspected source points and their completion names.*
4. *J is the bind and join schedule, read through the completion monad rows and the finite Kleisli route before a completion-valued consumer may flatten a nested completion request.*
5. *E is the separated uniqueness row, recording that two displayed extensions agree only through the separated completion comparison already named by the reflector boundary.*
6. *H records componentwise* hsame *transport for the source metric, reflector, unit embedding, bind and join schedule, separated uniqueness, replay, provenance, and local naming rows.*
7. *C records displayed* Cont *replay from a source metric request through R, U, J, E, H, P, N.*
8. *P is the* Pkg *provenance over* $\mathsf{CompletionReflectorMonad}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{MetricCompletion}^{\uparrow}$, $\mathsf{CauchyCompletionMonad}^{\uparrow}$, $\mathsf{CauchyCompletionUnit}^{\uparrow}$, $\mathsf{CauchyCompletionKleisli}^{\uparrow}$, $\mathsf{CauchyCompletionMultiplication}^{\uparrow}$, $\mathsf{CauchyCompletionReflector}$ $\mathsf{CauchyCompletionMinimality}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*

9. N is the local $\mathsf{NameCert}_{\mathsf{CompletionReflectorMonad}^{\uparrow}}$ *row.*
The carrier has no coordinate for quotient completion, selected representatives, host equality of completed objects, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 8693.2 (Completion reflector monad NameCert obligations)**.** *For every accepted* CompletionReflectorMon *carrier*

$$K = (S, R, U, J, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{CompletionReflectorMonad}^{\uparrow}}$ *surface consists exactly of source metric admission through S, completion reflector exposure through R, unit embedding through U, bind and join scheduling through J, separated uniqueness through E, componentwise transport through H, displayed replay through C, provenance through P, and local naming through N.*

Proof. Project the carrier of Definition 8693.1. The source metric data is confined to S, while the completion object and reflector handoff are confined to R through the named metric-completion, reflector-unit, and minimality packets.

The unit embedding row U is the only source-to-completion entrance. The bind and join schedule J is the only row that may flatten a completion-valued route, and it is read through the existing completion monad, unit, Kleisli, and multiplication packets.

The separated uniqueness row E supplies the reflector-side uniqueness boundary, and H, C, P, N transport, replay, source, and name the same finite packet. No other coordinate is available in the carrier, so the listed rows exhaust the local NameCert surface. □

Theorem 8693.3 (Completion reflector monad unit and bind laws)**.** *Every unit-facing or bind-facing read of an accepted* $\mathsf{CompletionReflectorMonad}^{\uparrow}$ *carrier factors through*

$$S, R, U, J, E, H, C, P, N.$$

The unit law is public only after the source metric row S, reflector row R, and unit embedding row U have been displayed. The bind and join laws are public only after the monad schedule J is read together with the separated uniqueness row E and the structural rows H, C, P, N.

Proof. Begin with a unit-facing request. The source metric row S and reflector row R display the domain and completion boundary, and U is the only row that admits source points into the completion surface.

For a bind-facing request, the carrier supplies no direct host operation on completed objects. The read must instead pass through J, where the completion monad, unit, Kleisli, and multiplication packets provide the finite flattening schedule.

Separated uniqueness is then read through E. It prevents a consumer from treating the unit or bind laws as host equality of representatives, while H, C, P, N preserve the same finite route under transport, replay, provenance, and local naming. □

Theorem 8693.4 (Completion reflector monad extension uniqueness)**.** *Let*

$$K = (S, R, U, J, E, H, C, P, N)$$

be an accepted $\mathsf{CompletionReflectorMonad}^{\uparrow}$ *carrier. If two completion-facing extension reads use the same source metric row S, reflector row R, unit embedding U, bind and join schedule J, separated uniqueness row E, componentwise transport H, displayed replay C, provenance P, and local naming row N, then they expose the same completion-facing public route.*

Proof. Project the shared carrier coordinates $S, R, U, J, E, H, C, P, N$. The source metric, completion reflector, unit embedding, and bind and join schedule are therefore read from the same finite packet for both extension requests.

Apply Definition 8693.3 to each read. The unit-facing part must pass through S, R, U, and the bind-facing part must pass through J before any completion-valued route is public.

The separated uniqueness row E compares the two displayed extensions after those operational rows have been exposed. Transport, replay, provenance, and naming through H, C, P, N carry that comparison back to the public route. Since the carrier has no coordinate for quotient completion, selected representatives, host equality, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness, the uniqueness claim is only the equality of the displayed completion-facing route. □

Theorem 8693.5 (Completion reflector monad nonescape)**.** *Every completion-facing consumer of an accepted* $\mathsf{CompletionReflectorMonad}^{\uparrow}$ *carrier reads only the displayed finite route*

$$S, R, U, J, E, H, C, P, N.$$

In particular, the packet exports no quotient completion, no selected representatives, no host equality of completed objects, no countable choice, and no ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Apply Definition 8693.2. It identifies the only public carrier rows as the source metric, reflector, unit embedding, bind and join schedule, separated uniqueness, transport, replay, provenance, and local naming rows.

Use Definition 8693.3 for the operational reads. Unit-facing and bind-facing consumers must pass through the same displayed packet before any completion law is available.

The excluded principles have no row in K. A request for quotient completion, selected representatives, host equality, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness therefore stays outside the carrier rather than becoming a hidden continuation through H, C, P, N. □

Closure status for $\mathsf{NameCert}_{\mathsf{CompletionReflectorMonad}^{\uparrow}}$.

Constructive story: A $\mathsf{CompletionReflectorMonad}^{\uparrow}$ packet is generated from source metric rows, a completion reflector row, a unit embedding row, a bind and join schedule, separated uniqueness, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CompletionReflectorMonad}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8693.1, Definition 8693.2, Definition 8693.3, and Definition 8693.5 seed the finite reflector-monad service boundary over source metric, completion reflector, unit embedding, bind and join, separated uniqueness, transport, replay, provenance, and local naming rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CompletionReflectorMonad}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim quotient completion, selected representatives, host equality, countable choice, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, reflector exposure, unit embedding, bind and join scheduling, separated uniqueness, transport, replay, provenance, and local naming for BEDC.Derived.CompletionReflectorMonadUp.

Chapter 8694

A Concrete Naming Certificate for MetricSeparatedReflectorUnit$^{\uparrow}$

Following Bishop and Bridges on metric apartness and separated reflection, the MetricSeparatedReflectorUnit$^{\uparrow}$ packet records the finite unit object that sends a displayed pseudometric source into its separated metric reflection before completion-facing consumers read the result. It sits after the pseudometric source of chapter 1614, the separated-reflection route of chapter 4151, the separated metric carrier of chapter 1411, the Hausdorffization packet of chapter 7153, and the metric completion boundary of chapter 1506. The packet names the unit and its factorization ledger without selecting quotient representatives, importing host equality, claiming completed reals, or invoking countable choice.

Definition 8694.1 (MetricSeparatedReflectorUnit carrier)**.** *A* MetricSeparatedReflectorUnit$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$R = (M, Z, S, U, F, H, C, P, N)$$

with the following displayed rows:

1. *M is the metric or pseudometric source row, exposing point admission, distance readback, symmetry, triangle, and zero-distance inspection.*
2. *Z is the zero-distance witness row consumed from M, recording exactly which source pairs are identified by the separated reflection.*
3. *S is the separated target row, carrying the reflected separated metric classifier and its public point surface.*
4. *U is the unit arrow row from the source row M into the separated target S.*
5. *F is the factorization ledger. It records that any separated metric consumer receiving a compatible arrow from M must read the arrow through U and then through a displayed target arrow out of S.*
6. *H records componentwise* hsame *transport for the source metric row, zero-distance witness, separated target, unit arrow, factorization ledger, replay, provenance, and local naming rows.*
7. *C records displayed* Cont *replay from a source metric request through M, Z, S, U, F, H before any completion or Hausdorff consumer reads the result.*
8. *P is the* Pkg *provenance over* MetricSeparatedReflectorUnit$^{\uparrow}$, Pseudometric$^{\uparrow}$, SeparatedReflection$^{\uparrow}$, SeparatedMetric$^{\uparrow}$, Hausdorffization$^{\uparrow}$, MetricCompletion$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*

9. N is the local $\mathsf{NameCert}_{\mathsf{MetricSeparatedReflectorUnit}^{\uparrow}}$ *row.*
The classifier compares accepted packets only through $M, Z, S, U, F, H, C, P, N$. It has no coordinate for quotient representatives, host equality of reflected points, selected section maps, completed limits, or ambient real completeness.

Theorem 8694.2 (MetricSeparatedReflectorUnit NameCert obligations)**.** *For every accepted* MetricSeparatedRefle *carrier $R = (M, Z, S, U, F, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{MetricSeparatedReflectorUnit}^{\uparrow}}$ *surface consists exactly of source metric exposure, zero-distance witness exposure, separated target exposure, unit-arrow exposure, factorization ledger exposure, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. Every separated or completion-facing consumer must read*

$$M, Z, S, U, F, H, C, P, N$$

before treating the separated reflection as public.

Proof. Project the carrier of Definition 8694.1. The rows $M, Z, S, U, F, H, C, P, N$ are exactly the displayed coordinates available to the local certificate.

The source metric and zero-distance rows are read first. The row Z is the only place where source points become identified, so a consumer cannot obtain reflected equality from a hidden quotient representative or host equality predicate.

The unit and factorization rows then expose the reflector-unit surface. The arrow row U supplies the map into the separated target S, and the ledger F records how every compatible arrow into a separated metric consumer factors through that unit.

Transport and replay preserve the same route. Componentwise hsame in H aligns each displayed coordinate, C replays the request through those coordinates, and P, N source and name the packet. Since quotient representatives, selected sections, completed limits, and ambient real completeness are absent from the carrier, no NameCert obligation can export them. □

Theorem 8694.3 (MetricSeparatedReflectorUnit factorization route)**.** *Let $R = (M, Z, S, U, F, H, C, P, N)$ be an accepted* $\mathsf{MetricSeparatedReflectorUnit}^{\uparrow}$ *carrier. Any downstream separated metric, Hausdorffization, or metric-completion consumer that receives a source-compatible arrow from M must read the route*

$$M, Z \longmapsto S, U, F \longmapsto H, C, P, N$$

before using the target as a separated metric object.

Proof. Start with the accepted carrier and project M and Z. These rows determine the pseudometric source and the zero-distance identifications that the separated target is allowed to recognize.

Apply Definition 8694.2. The separated target S, unit arrow U, and factorization ledger F are exposed only after the zero-distance witness has been displayed, and every public read continues through H, C, P, N.

A Hausdorffization or metric-completion consumer may consume the separated target, but it receives it through the unit route rather than through a quotient representative or selected completed point. Thus the factorization surface is the finite bridge from the pseudometric source to separated completion-facing use, with no completed real or host equality claim added by the packet. □

Theorem 8694.4 (MetricSeparatedReflectorUnit universal factorization)**.** *Let*

$$R = (M, Z, S, U, F, H, C, P, N)$$

be an accepted $\mathsf{MetricSeparatedReflectorUnit}^{\uparrow}$ *carrier. Any two separated-metric consumers receiving source-compatible arrows from the same pseudometric source row* M *factor through the same displayed unit row* U *whenever they agree on the zero-distance witness row* Z *and the separated target classifier row* S*.*

Proof. Project $M, Z, S, U, F, H, C, P, N$ from the accepted carrier. The source-compatible arrows begin with the same pseudometric source row and the same zero-distance witness row.

Use the factorization ledger F for each consumer. The ledger sends every separated-metric consumer through the displayed unit row U before a target arrow out of S can be read.

Agreement on Z and on the separated target row S identifies the displayed factorization route for the two consumers. The rows H, C, P, N then replay, transport, source, and name the common route. The carrier never supplies quotient representatives, selected sections, completed limits, host equality, or ambient $\mathsf{Real}^{\uparrow}$ completeness, so the conclusion is exactly the shared displayed factorization through U. □

Closure status for $\mathsf{NameCert}_{\mathsf{MetricSeparatedReflectorUnit}^{\uparrow}}$.

Constructive story: A $\mathsf{MetricSeparatedReflectorUnit}^{\uparrow}$ packet is generated from a source metric or pseudometric row, a zero-distance witness row, a separated target row, a unit arrow, a factorization ledger, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert evidence.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{MetricSeparatedReflectorUnit}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8694.1, Definition 8694.2, and Definition 8694.3 seed the finite separated-reflector unit interface over source metric data, zero-distance witnesses, unit routing, factorization, transport, replay, provenance, and naming.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{MetricSeparatedReflectorUnit}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close Lean verification, quotient representatives, selected sections, completed reals, ambient completeness, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, zero-distance exposure, separated target exposure, unit-arrow routing, factorization ledger stability, transport, replay, provenance, and local naming for BEDC.Derived.MetricSeparatedReflec

Chapter 8695

A Concrete Naming Certificate for $\mathsf{FiniteTriggerFlipGraph}^{\uparrow}$

The $\mathsf{FiniteTriggerFlipGraph}^{\uparrow}$ packet realizes the lift-flip and quotient support-flip rows of Definition 9462.1690, Definition 9462.1691, and Definition 9462.1692 as finite NameCert data. It sits after the minimal trigger lift bundle of chapter 4129, the nine-orbit minimal trigger classification of chapter 4192, and the codon lift orbit classifier of chapter 4059. The packet records only quotient supports, lift fibers, finite flip edges, edge-budget rows, transport, replay, provenance, and local naming; it is not a biological mechanism, stochastic dynamics, hidden enumeration oracle, or unbounded graph search.

Definition 8695.1 (FiniteTriggerFlipGraph carrier)**.** *A* $\mathsf{FiniteTriggerFlipGraph}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$G = (Q, L, E, B, H, C, P, N)$$

with the following displayed rows:

1. *Q is the quotient-trigger base row, listing the finite quotient-level minimal triggers by size and orbit source.*
2. *L is the lift-choice fiber row, recording the binary f_3 choices over each displayed quotient support.*
3. *E is the support and lift flip-edge row. Inside a fixed lift fiber it records single-coordinate lift flips, and inside a fixed quotient-size layer it records support replacements with symmetric difference two.*
4. *B is the edge-budget row, including the internal lift-flip count* 397 *under the displayed finite inventory.*
5. *H records componentwise* hsame *transport for quotient triggers, lift-choice fibers, edge rows, edge budgets, replay, provenance, and local naming rows.*
6. *C records displayed* Cont *replay from a finite trigger query through Q, L, E, B, H before any TasteGate or classifier consumer reads the graph.*
7. *P is the* Pkg *provenance over* $\mathsf{FiniteTriggerFlipGraph}^{\uparrow}$, $\mathsf{MinimalTriggerLiftBundle}^{\uparrow}$, $\mathsf{MinimalTriggerOrbitClassificatio}$ $\mathsf{CodonLiftOrbitClassifier}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$ *rows.*
8. *N is the local* $\mathsf{NameCert}_{\mathsf{FiniteTriggerFlipGraph}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through Q, L, E, B, H, C, P, N. It has no coordinate for hidden support semantics, stochastic transitions, biological fitness, unbounded graph enumeration, or a graph object outside the displayed finite rows.

Theorem 8695.2 (FiniteTriggerFlipGraph NameCert obligations)**.** *For every accepted* $\mathsf{FiniteTriggerFlipGraph}^{\uparrow}$ *carrier* $G = (Q, L, E, B, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{FiniteTriggerFlipGraph}^{\uparrow}}$ *surface consists exactly of quotient-trigger base exposure, lift-choice fiber exposure, support and lift flip-edge exposure, edge-budget exposure, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. A future Lean TasteGate file for this packet must include the nontriviality and field-faithfulness instance surface for the displayed graph rows before any classifier consumer reads the graph as admitted.*

Proof. Project the carrier of Definition 8695.1. The only available rows are Q, L, E, B, H, C, P, N, so every graph read begins with the quotient-trigger base and the lift-choice fibers.

The edge row E then separates the two finite adjacency sources. Lift flips remain inside one lift fiber and change exactly one binary lift coordinate, while support flips remain inside one quotient-size layer and change exactly one support by symmetric difference two.

The edge-budget row B binds the finite counts to the displayed inventory. Transport in H and replay in C preserve the same quotient, lift, edge, and budget rows, and P, N record provenance and local naming. Therefore no hidden enumeration oracle, stochastic transition law, biological mechanism, or off-packet graph coordinate is exported by the NameCert surface. □

Theorem 8695.3 (FiniteTriggerFlipGraph edge budget)**.** *For every accepted* $\mathsf{FiniteTriggerFlipGraph}^{\uparrow}$ *carrier* $G = (Q, L, E, B, H, C, P, N)$ *whose rows read the displayed finite inventory*

$$Q_1 \sqcup 25Q_2 \sqcup 22Q_3 \sqcup Q_4,$$

the internal lift-flip part of B *records exactly* 397 *lift-flip edges, and every downstream support-graph or TasteGate consumer must read that budget through* Q, L, E, B, H, C, P, N*.*

Proof. Read the finite inventory through Q and L. The source theorem Definition 9462.1691 computes the lift-flip contribution by summing the hypercube edge counts over the displayed quotient triggers.

The budget row B records that sum as part of the carrier, while E records which edges are lift flips and which are quotient support flips. Transport and replay then keep the count attached to the same quotient and lift rows before provenance and local naming seal the packet.

Thus the public edge-budget surface is the finite route Q, L, E, B, H, C, P, N. It does not claim an unrecorded search, an external graph equality, or any stochastic interpretation of the adjacency relation. □

Falsifiable prediction: For the displayed finite inventory $Q_1 \sqcup 25Q_2 \sqcup 22Q_3 \sqcup Q_4$, the edge-budget row B of any accepted $\mathsf{FiniteTriggerFlipGraph}^{\uparrow}$ packet records 397 internal lift-flip edges. A future independent enumeration that changes this count must reject the packet or replace the displayed inventory.

Independence witness: minimal-trigger-lift-bundle, minimal-trigger-orbit-classification, codon-lift-orbit-classifier, boolean-trigger-lattice-beyond-mstar, coverage-rank-algebra-beyond-mstar: $\mathsf{FiniteTriggerFlipGra}$ is not bijective to any listed sibling because it jointly carries quotient-trigger rows, lift-choice fibers, support and lift flip edges, edge-budget rows, TasteGate-facing instance obligations, transport, replay, provenance, and local NameCert evidence.

Closure status for $\mathsf{NameCert}_{\mathsf{FiniteTriggerFlipGraph}^{\uparrow}}$.

Constructive story: A $\mathsf{FiniteTriggerFlipGraph}^{\uparrow}$ packet is generated from quotient-trigger base rows, lift-choice fiber rows, support and lift flip-edge rows, edge-budget rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert evidence.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{FiniteTriggerFlipGraph}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8695.1, Definition 8695.2, and Definition 8695.3 seed the finite trigger flip graph interface over quotient supports, lift fibers, edge rows, edge budgets, transport, replay, provenance, and naming.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{FiniteTriggerFlipGraph}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close Lean verification, biological mechanism, stochastic transition semantics, unbounded graph search, TasteGate verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, quotient-trigger exposure, lift-fiber exposure, edge-row exactness, the 397 lift-flip edge budget, Nontrivial and FieldFaithful TasteGate instances, transport, replay, provenance, and local naming for BEDC.Derived.FiniteTriggerFlipGraphUp.

Chapter 8696

A Concrete Naming Certificate for $\mathsf{CompleteMetricPicardIterator}^{\uparrow}$

Following Banach's fixed-point theorem and Bishop–Bridges constructive complete-metric analysis, the $\mathsf{CompleteMetricPicardIterator}^{\uparrow}$ packet records the finite Picard-iteration surface available before a complete-metric consumer reads a fixed-point approximation. It sits after the complete-metric carrier of chapter 128, the separated-reflector unit of chapter 8694, the separated-reflection route of chapter 4151, and the contraction interface of chapter 3529. The packet names a constructive orbit-and-tail ledger; it does not select a limit point, quotient representatives, host-level function equality, countable choice, or ambient classical completeness.

Definition 8696.1 (CompleteMetricPicardIterator carrier)**.** *A* $\mathsf{CompleteMetricPicardIterator}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$I = (M, S, T, Q, O, W, H, C, P, N)$$

with the following displayed rows:

1. *M is the* $\mathsf{CompleteMetric}^{\uparrow}$ *source row, exposing point admission, metric readback, completeness witness data, and the separated target surface through which distances are read.*
2. *S is the separated-reflection row consumed before the iterator is allowed to treat zero-distance agreement as a public metric equality.*
3. *T is the contraction row, displaying the self-map, contraction budget, and compatibility with the metric row.*
4. *Q is the dyadic tail-control row, recording finite bounds that make the Picard tails Cauchy in the displayed complete metric.*
5. *O is the orbit row, listing the finite initial point, iterate window, and successor routing for the Picard chain.*
6. *W is the endpoint-window row. It records which finite windows may be exported to downstream fixed-point or Real-facing consumers before any completed endpoint is claimed.*
7. *H records componentwise* hsame *transport for the complete metric, separated reflection, contraction, tail-control, orbit, endpoint-window, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from a metric request through M, S, T, Q, O, W, H before an endpoint-facing consumer reads the packet.*

9. *P is the* Pkg *provenance over* CompleteMetricPicardIterator$^{\uparrow}$, CompleteMetric$^{\uparrow}$, MetricSeparatedReflectorUnit$^{\uparrow}$, SeparatedReflection$^{\uparrow}$, BanachContraction$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*
10. *N is the local* NameCert$_{\text{CompleteMetricPicardIterator}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $M, S, T, Q, O, W, H, C, P, N$. It has no coordinate for a chosen completed point, quotient representative, host equality of functions, countable-choice schedule, or classical fixed-point theorem.

Theorem 8696.2 (CompleteMetricPicardIterator NameCert obligations)**.** *For every accepted* CompleteMetricPicar *carrier $I = (M, S, T, Q, O, W, H, C, P, N)$, the local* NameCert$_{\text{CompleteMetricPicardIterator}^{\uparrow}}$ *surface consists exactly of complete-metric admission, separated-reflection exposure, contraction exposure, finite tail-control exposure, Picard-orbit exposure, endpoint-window exposure, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. Every fixed-point or completion-facing consumer must read*

$$M, S, T, Q, O, W, H, C, P, N$$

before treating the Picard iterator as endpoint evidence.

Proof. Project the carrier of Definition 8696.1. The rows $M, S, T, Q, O, W, H, C, P, N$ are exactly the displayed coordinates available to the local certificate.

The complete-metric and separated-reflection rows are read first. They expose the metric request surface and the zero-distance discipline before the contraction row is allowed to generate an orbit.

Next read the contraction, tail-control, orbit, and endpoint-window rows. These rows supply the constructive Picard data: a self-map with a displayed contraction budget, finite tail estimates, finite iterate windows, and the bounded endpoint windows that downstream consumers may inspect.

Finally transport and replay preserve the same route. Componentwise hsame aligns each row, Cont replay sends the request through the displayed coordinates, and P, N source and name the packet. Since no carrier coordinate stores a selected limit, quotient representative, host function equality, countable-choice schedule, or ambient classical completeness principle, no NameCert obligation can export one. □

Closure status for NameCert$_{\text{CompleteMetricPicardIterator}^{\uparrow}}$.

Constructive story: A CompleteMetricPicardIterator$^{\uparrow}$ packet is generated from complete-metric data, separated-reflection exposure, a contraction row, finite tail-control data, Picard orbit windows, endpoint-window rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert evidence.

Theory closure: TheoryGate(NameCert$_{\text{CompleteMetricPicardIterator}^{\uparrow}}$, seed)

Scope closed: Definition 8696.1 and Definition 8696.2 seed the constructive Picard-iteration interface over complete metric data, separated reflection, contraction budgets, finite tails, orbit windows, endpoint windows, transport, replay, provenance, and naming.

Formal verification: FormalStatus(NameCert$_{\text{CompleteMetricPicardIterator}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close Lean verification, selected fixed points, quotient representatives, host function equality, countable choice, ambient classical completeness, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, complete-metric exposure, separated-reflection exposure, contraction exposure, tail-control stability, orbit-window replay, endpoint-window routing, transport, provenance, and local naming for BEDC.Derived.CompleteMetricPicardIteratorUp.

Chapter 8697

A Concrete Naming Certificate for $\mathsf{CantorDiagonalTail}^{\uparrow}$

Following Cantor diagonal arguments and the finite-window discipline of Bishop–Bridges constructive analysis, the $\mathsf{CantorDiagonalTail}^{\uparrow}$ packet records the diagonal tail readback needed before a Real-facing consumer treats a stream of rational windows as a completed object. It sits between the StreamName windows of chapter 126, the regular rational readback of chapter 301, the dyadic tolerance spine of chapter 291, and the terminal seal of chapter 38. The packet records only finite diagonal indices, displayed tail windows, rational readback, dyadic tolerances, Real-facing terminal seals, transport, replay, provenance, and local naming; it does not export quotient stream equality, countable choice, selected limits, open-cover compactness, or ambient completeness of the reals.

Definition 8697.1 (Cantor diagonal tail carrier)**.** *A* $\mathsf{CantorDiagonalTail}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (D, T, Q, E, R, H, C, P, N)$$

with the following displayed rows:

1. *D is the diagonal index schedule, listing the finite diagonal coordinates whose tail reads are in scope.*
2. *T is the StreamName finite-window row, recording for each index in D the finite tail windows made visible to the packet.*
3. *Q is the RegSeqRat readback row, translating the displayed StreamName windows into regular rational comparison data.*
4. *E is the DyadicRatCore tolerance row, binding each readback in Q to a displayed dyadic tolerance and comparison budget.*
5. *R is the RealUp terminal seal row, recording only the Real-facing endpoint promised by the finite tail windows and dyadic tolerances.*
6. *H records componentwise* hsame *transport for the diagonal schedule, StreamName windows, RegSeqRat readbacks, DyadicRatCore tolerance rows, RealUp seals, replay, provenance, and local naming rows.*
7. *C records displayed* Cont *replay from a Real-facing query through D, T, Q, E, R, H before any consumer reads the diagonal tail.*

8. *P is the* Pkg *provenance over* $\mathsf{CantorDiagonalTail}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*

9. *N is the local* $\mathsf{NameCert}_{\mathsf{CantorDiagonalTail}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $D, T, Q, E, R, H, C, P, N$. It has no coordinate for a chosen infinite subsequence, quotient equality of streams, an unrecorded limiting real, an open-cover compactness argument, or a completeness principle outside the displayed finite rows.

Theorem 8697.2 (Cantor diagonal tail NameCert obligations)**.** *For every accepted* $\mathsf{CantorDiagonalTail}^{\uparrow}$ *carrier $K = (D, T, Q, E, R, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{CantorDiagonalTail}^{\uparrow}}$ *surface consists exactly of diagonal index exposure, StreamName finite-window exposure, RegSeqRat readback exposure, DyadicRatCore tolerance exposure, RealUp terminal-seal exposure, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. Any Real-facing consumer of the packet must read the diagonal argument through those rows and cannot infer quotient stream equality, countable choice, selected limits, open-cover compactness, or ambient Real completeness from the certificate.*

Proof. Project the carrier of Definition 8697.1. The only rows exposed to a certificate consumer are $D, T, Q, E, R, H, C, P, N$, so every diagonal read begins with the finite schedule D and the displayed StreamName windows in T.

The readback row Q then turns only those windows into regular rational comparison data, and the tolerance row E binds each comparison to a displayed DyadicRatCore budget. The terminal row R is therefore reached through a finite route, not through a chosen infinite stream or an ambient completeness theorem.

Transport in H and replay in C preserve the same schedule, windows, rational readbacks, tolerance rows, and terminal seal before provenance and local naming are inspected. Thus the NameCert obligations are exactly the displayed finite fields, and the packet exports no quotient stream equality, countable-choice selection, selected limit, compactness, or Real-completeness principle. □

Theorem 8697.3 (Cantor diagonal tail L10 handoff)**.** *Let $K = (D, T, Q, E, R, H, C, P, N)$ be an accepted* $\mathsf{CantorDiagonalTail}^{\uparrow}$ *carrier. Every L10 read handed from K to a Real-facing proof factors through the finite path*

$$D \longrightarrow T \longrightarrow Q \longrightarrow E \longrightarrow R$$

and then through H, C, P, N. In particular, the handoff exposes only finite diagonal-tail windows and their regular rational and dyadic tolerance readbacks; it does not provide an equality of quotient streams, a countable family of choices, a selected limiting real, an open-cover compactness witness, or an ambient completeness theorem for $\mathsf{Real}^{\uparrow}$.

Proof. Fix an L10 read from the packet. By carrier projection, the read can mention no row outside $D, T, Q, E, R, H, C, P, N$. The schedule row D selects a finite list of diagonal coordinates, and the StreamName row T gives exactly the finite windows associated with that list.

The RegSeqRat row Q supplies the rational readback of those windows, while E supplies the DyadicRatCore tolerance data used by the Real-facing boundary. The RealUp row R records the terminal seal reached from those displayed inputs.

It remains to check that the handoff cannot smuggle a stronger principle through transport or provenance. Componentwise hsame in H transports only the displayed rows, Cont replay in C replays only the same finite path, and P, N add provenance and local naming without adding a new data coordinate. Hence every L10 handoff factors through the finite diagonal-tail route

and remains silent about quotient stream equality, countable choice, selected limits, open-cover compactness, and ambient Real completeness. □

Falsifiable prediction: Any accepted $\mathsf{CantorDiagonalTail}^{\uparrow}$ packet whose L10 read reaches a Real-facing proof without passing through the displayed finite route $D, T, Q, E, R, H, C, P, N$ is rejected by the local NameCert interface.

Independence witness: streamname, regseqrat, dyadicratcore, real: $\mathsf{CantorDiagonalTail}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries a diagonal index schedule, finite StreamName tail windows, RegSeqRat readbacks, DyadicRatCore tolerance rows, RealUp terminal seals, transport, replay, provenance, and local NameCert evidence.

Closure status for $\mathsf{NameCert}_{\mathsf{CantorDiagonalTail}^{\uparrow}}$.

Constructive story: A $\mathsf{CantorDiagonalTail}^{\uparrow}$ packet is generated from a finite diagonal schedule, StreamName tail windows, RegSeqRat readbacks, DyadicRatCore tolerance rows, RealUp terminal seals, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert evidence.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CantorDiagonalTail}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8697.1, Definition 8697.2, and Definition 8697.3 seed the finite diagonal-tail interface over schedules, windows, rational readback, dyadic tolerances, terminal seals, transport, replay, provenance, and naming.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CantorDiagonalTail}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close Real completeness, quotient stream equality, countable choice, selected limits, open-cover compactness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, diagonal schedule exposure, StreamName window exposure, RegSeqRat readback exposure, DyadicRatCore tolerance exposure, RealUp terminal-seal exposure, transport, replay, provenance, and local naming for BEDC.Derived.CantorDiagonalTailUp.

Chapter 8698

A Concrete Naming Certificate for $\mathsf{BanachPicardOrbit}^{\uparrow}$

Following Banach's contraction principle and Bishop–Bridges constructive fixed-point analysis, the $\mathsf{BanachPicardOrbit}^{\uparrow}$ packet records the finite orbit surface generated by a displayed contraction over complete metric data. It sits after the complete-metric carrier of chapter 128, the contraction packet of chapter 3529, the Lipschitz interface of chapter 410, the stream-name surface of chapter 126, the regular rational readback of chapter 301, and the terminal real-name seal of chapter 38. The packet realizes a compact-uniform-continuity route through finite contraction, Cauchy-tail, complete-metric, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ rows without selecting a completed fixed point.

Definition 8698.1 (BanachPicardOrbit carrier)**.** *A* $\mathsf{BanachPicardOrbit}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$O = (M, K, L, S, R, E, T, W, H, C, P, N)$$

with the following displayed rows:

1. *M is the* $\mathsf{CompleteMetric}^{\uparrow}$ *row carrying the metric source, separated readback, and completeness witness data.*
2. *K is the* $\mathsf{BanachContraction}^{\uparrow}$ *row naming the self-map and contraction budget.*
3. *L is the* $\mathsf{LipschitzMap}^{\uparrow}$ *row exposing the Lipschitz readback used by compact-uniform-modulus consumers.*
4. *S is the* $\mathsf{StreamName}^{\uparrow}$ *orbit-window row, recording finite observations of the Picard iterates.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *regular rational readback row attached to the same windows and tail budgets.*
6. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row available only after M, K, L, S, R and the tail data have been displayed.*
7. *T is the Cauchy-tail row recording finite contraction-tail estimates for the orbit.*
8. *W is the compact-uniform window row that records which finite orbit windows may be consumed by uniform-modulus and endpoint-facing readers.*
9. *H records componentwise* hsame *transport for the complete metric, contraction, Lipschitz, stream, regular-rational, Real-seal, tail, window, replay, provenance, and local naming rows.*

10. *C records displayed* Cont *replay from a compact-uniform request through $M, K, L, S, R, E, T, W, H$ before any endpoint or modulus consumer reads the packet.*
11. *P is the* Pkg *provenance over* $\mathsf{BanachPicardOrbit}^{\uparrow}$, $\mathsf{CompleteMetric}^{\uparrow}$, $\mathsf{BanachContraction}^{\uparrow}$, $\mathsf{LipschitzMap}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*
12. *N is the local* $\mathsf{NameCert}_{\mathsf{BanachPicardOrbit}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $M, K, L, S, R, E, T, W, H, C, P, N$. It has no coordinate for a selected fixed point, quotient orbit equality, host function equality, countable choice, or ambient classical completeness.

Theorem 8698.2 (BanachPicardOrbit NameCert obligations)**.** *For every accepted* $\mathsf{BanachPicardOrbit}^{\uparrow}$ *carrier $O = (M, K, L, S, R, E, T, W, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{BanachPicardOrbit}^{\uparrow}}$ *surface consists exactly of complete-metric exposure, contraction exposure, Lipschitz readback, finite stream-window exposure, regular rational readback, Real-seal routing, Cauchy-tail exposure, compact-uniform window exposure, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. Every compact-uniform-continuity or constructive fixed-point consumer must read*

$$M, K, L, S, R, E, T, W, H, C, P, N$$

before treating the orbit as endpoint or modulus evidence.

Proof. Project the carrier of Definition 8698.1. The rows $M, K, L, S, R, E, T, W, H, C, P, N$ are exactly the displayed coordinates available to the local certificate.

The complete-metric, contraction, and Lipschitz rows expose the source of the orbit and its finite contraction budget. The stream and regular-rational rows then record the finite windows through which the iterates are observed.

The Real seal and tail row are read only through those windows. Thus an endpoint-facing consumer receives finite Cauchy-tail and readback data rather than a selected completed point.

Finally the compact-uniform window, transport, replay, provenance, and naming rows keep the same route visible for uniform-modulus consumers. Since the carrier lacks coordinates for selected fixed points, quotient orbit equality, host function equality, countable choice, or ambient classical completeness, no NameCert obligation can export those objects. □

Closure status for $\mathsf{NameCert}_{\mathsf{BanachPicardOrbit}^{\uparrow}}$.

Constructive story: A $\mathsf{BanachPicardOrbit}^{\uparrow}$ packet is generated from complete-metric data, Banach contraction data, Lipschitz readback, StreamName orbit windows, RegSeqRat readback, a Real seal, finite Cauchy-tail estimates, compact-uniform windows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert evidence.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{BanachPicardOrbit}^{\uparrow}}$, seed)

Scope closed: Definition 8698.1 and Definition 8698.2 seed the finite Picard-orbit interface over complete metric, contraction, Lipschitz, stream, regular-rational, Real-seal, Cauchy-tail, compact-uniform, transport, replay, provenance, and naming rows.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{BanachPicardOrbit}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close Lean verification, selected fixed points, quotient orbit equality, host function equality, countable choice, ambient classical completeness, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, complete-metric exposure, contraction exposure, Lipschitz readback, finite stream-window routing, regular rational readback, Real-seal routing, Cauchy-tail stability, compact-uniform replay, transport, provenance, and local naming for BEDC.Derived.BanachPicardOrbitUp.

Chapter 8699

A Concrete Naming Certificate for $\mathsf{CoareaFormula}^{\uparrow}$

Following Federer and Evans–Gariepy, the $\mathsf{CoareaFormula}^{\uparrow}$ packet records the finite BEDC surface by which a displayed Lipschitz or chartwise regular map may hand slice-count data to an integral consumer. It sits after the measure carrier of chapter 92, the finite integral route of chapter 123, the chart naming of chapter 96, the Real-facing seal of chapter 38, and the compact metric window of chapter 129. The packet is a finite coarea ledger over displayed chart, slice, Jacobian, and integral rows; it does not claim unrestricted Lebesgue theory, choice of slices, quotient measure classes, or ambient real completeness.

Definition 8699.1 (Coarea formula carrier)**.** *A* $\mathsf{CoareaFormula}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$\mathsf{Coarea}(M, X, F, J, S, I, R, K, H, C, P, N)$$

with the following displayed rows:

1. *M is the* $\mathsf{Measure}^{\uparrow}$ *source row for the displayed domain window.*
2. *X is the* $\mathsf{Manifold}^{\uparrow}$ *chart row, naming only the finite chart windows used by the packet.*
3. *F is the displayed map row, storing the finite source, target, and Lipschitz or chartwise regularity certificates read by the packet.*
4. *J is the Jacobian-density ledger, recording the finite determinant or metric-volume rows exposed for the displayed chart windows.*
5. *S is the slice ledger; each entry names a displayed slice window, its admissibility row, and the finite preimage data attached to that slice.*
6. *I is the* $\mathsf{Integral}^{\uparrow}$ *readout row for the domain-side and slice-side finite integral requests.*
7. *R is the terminal* $\mathsf{Real}^{\uparrow}$ *comparison row for the displayed values produced by I.*
8. *K is the* $\mathsf{CompactMetric}^{\uparrow}$ *localization row that bounds the chart and slice windows used by X, F, J, S, I, R.*
9. *H records componentwise* hsame *transport for measure, chart, map, Jacobian, slice, integral, Real, localization, replay, provenance, and local naming rows.*
10. *C records displayed* Cont *replay from a coarea request through the finite measure, chart, map, Jacobian, slice, integral, Real, and compact-metric rows.*

11. *P is the* Pkg *provenance over* $\mathsf{CoareaFormula}^{\uparrow}$, $\mathsf{Measure}^{\uparrow}$, $\mathsf{Integral}^{\uparrow}$, $\mathsf{Manifold}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
12. *N is the local* $\mathsf{NameCert}_{\mathsf{CoareaFormula}^{\uparrow}}$ *row.*

Accepted packets are compared only through these rows. The classifier has no coordinate for unrestricted Lebesgue theory, a slice-choice function, quotient measure classes, a completed ambient real line, or an all-charts theorem outside the displayed finite windows.

Theorem 8699.2 (Coarea formula NameCert obligations)**.** *For every accepted* $\mathsf{CoareaFormula}^{\uparrow}$ *carrier* $\mathsf{Coarea}(M, X, F, J, S, I, R, K, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{CoareaFormula}^{\uparrow}}$ *surface consists exactly of measure-source exposure through M, finite chart exposure through X, displayed map exposure through F, Jacobian-density exposure through J, slice-ledger exposure through S, Integral readout through I, Real comparison through R, compact-metric localization through K, componentwise transport through H, displayed replay through C, provenance nonescape through P, and local naming through N.*

Proof. Project the carrier of Definition 8699.1. The only analytic rows available before the structural rows are the measure source M, the chart row X, the displayed map row F, the Jacobian ledger J, the slice ledger S, the integral row I, the Real comparison row R, and the compact-metric localization row K.

The slice side is finite. Each slice row in S is tied to a displayed chart window and a displayed preimage entry, and the Jacobian row J is read only through the same chart windows. Thus a consumer cannot replace the ledger by a choice of slices or by a quotient class of measures.

The integral readout is also finite. The row I sends only the displayed domain-side and slice-side requests to $\mathsf{Integral}^{\uparrow}$, while R records the terminal $\mathsf{Real}^{\uparrow}$ comparisons reached from those requests and K keeps the chart windows localized inside $\mathsf{CompactMetric}^{\uparrow}$.

Finally H, C, P, N transport, replay, source, and locally name the same packet. Since no row stores unrestricted Lebesgue theory, a selected slice family, quotient measure classes, or ambient Real completeness, the listed rows exhaust the local NameCert surface. □

Theorem 8699.3 (Coarea formula slice handoff)**.** *Every measure, integration, or geometry consumer of an accepted* $\mathsf{CoareaFormula}^{\uparrow}$ *packet that asks for a slice calculation must first read the finite route*

$$\mathsf{Measure}^{\uparrow},\ \mathsf{Manifold}^{\uparrow},\ F,\ J,\ S,\ \mathsf{Integral}^{\uparrow},\ \mathsf{Real}^{\uparrow},\ \mathsf{CompactMetric}^{\uparrow} \longmapsto H, C, P, N.$$

The consumer receives only displayed chart windows, map rows, Jacobian-density rows, slice-ledger rows, integral readouts, Real comparisons, compact-metric localization, transport, replay, provenance, and local naming. It receives no unrestricted Lebesgue theory, no choice of slices, no quotient measure class, and no ambient real-completeness theorem.

Proof. Apply Definition 8699.2. A consumer cannot ask for slice data until the measure source, chart window, displayed map, Jacobian ledger, slice ledger, integral readout, Real comparison, and compact-metric localization rows have all been exposed.

The route is local to the displayed windows. The chart row X and localization row K bound the windows, while F, J, S provide only the map, density, and slice records visible in those windows.

The handoff to integration then passes through I and R. These rows compare the displayed integral values through $\mathsf{Integral}^{\uparrow}$ and $\mathsf{Real}^{\uparrow}$, but they do not add an all-slices selector, a quotient measure class, an unrestricted Lebesgue theory, or ambient Real completeness.

The structural rows H, C, P, N preserve that finite route for downstream readers. Therefore a later analysis or geometry packet may cite $\mathsf{CoareaFormula}^{\uparrow}$ as a slice handoff only at the finite NameCert surface described above. □

Falsifiable prediction: A purported $\mathsf{CoareaFormula}^{\uparrow}$ certificate fails if its slice calculation omits the displayed measure source, chart window, map row, Jacobian ledger, slice ledger, Integral readout, Real comparison, compact-metric localization, transport, replay, provenance, or local naming row.

Independence witness: measure, integral, manifold, real, compactmetric: $\mathsf{CoareaFormula}^{\uparrow}$ is not bijective with any listed sibling because it joins the measure source, finite chart windows, displayed map rows, Jacobian-density rows, slice ledgers, integral readouts, Real comparisons, compact-metric localization, transport, replay, provenance, and local naming as one slice-calculation packet.

Closure status for $\mathsf{NameCert}_{\mathsf{CoareaFormula}^{\uparrow}}$**.**

Constructive story: A $\mathsf{CoareaFormula}^{\uparrow}$ packet is generated from MeasureUp source rows, finite ManifoldUp chart rows, displayed map rows, Jacobian-density rows, slice-ledger rows, IntegralUp readout, RealUp comparison, CompactMetricUp localization, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{CoareaFormula}^{\uparrow}}$, seed)

Scope closed: Definition 8699.1, Definition 8699.2, and Definition 8699.3 seed the finite coarea slice handoff for measure, integral, and geometry consumers.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{CoareaFormula}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim Lean verification, unrestricted Lebesgue theory, choice of slices, quotient measure classes, ambient $\mathsf{Real}^{\uparrow}$ completeness, or bridge checking.

Upgrade path: Obligation closure requires checked measure-source exposure, chart exposure, displayed-map exposure, Jacobian-density exposure, slice-ledger exposure, Integral readout, Real comparison, compact-metric localization, transport, replay, provenance, and local naming for BEDC.Derived.CoareaFormulaUp.

Chapter 8700

A Concrete Naming Certificate for $\mathsf{EffectiveOpenBallBasis}^{\uparrow}$

Following Bishop–Bridges constructive metric topology, the $\mathsf{EffectiveOpenBallBasis}^{\uparrow}$ packet records the finite center-radius basis rows by which metric open balls are exposed to topology consumers. It sits over the metric source of chapter 4230, the dyadic positive-radius ledger of chapter 291, the finite observation windows of chapter 126, the regular rational readback of chapter 301, the terminal real-name seal of chapter 38, and the indexed open-set surface of chapter 88. The packet is a finite basis object for Phase Real and Completion consumers; it does not import open-cover compactness, quotient equality, trichotomy, choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 8700.1 (Effective open-ball basis carrier)**.** *An* $\mathsf{EffectiveOpenBallBasis}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (M, C, D, W, R, E, T, H, K, P, N)$$

with the following displayed rows:

1. *M is the* $\mathsf{Met}^{\uparrow}$ *source row whose distance comparison supplies the ball predicate.*
2. *C is the finite center schedule row, naming the displayed centers that may be used by basis consumers.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *positive-radius ledger, carrying the requested radii, slack rows, and comparison budgets.*
4. *W is the* $\mathsf{StreamName}^{\uparrow}$ *window row through which finite observations of centers and requested points are read.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row attached to the same windows and dyadic tolerance ledger.*
6. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row for the finite real-name reads used in distance and radius comparison.*
7. *T is the* $\mathsf{Topology}^{\uparrow}$ *handoff row, exporting only the indexed open rows generated by displayed center-radius data.*
8. *H records componentwise* hsame *transport for the metric source, centers, dyadic radii, windows, readback, real seal, topology handoff, replay, provenance, and local naming rows.*
9. *K records displayed* Cont *replay of the metric-ball-to-topology route.*
10. *P is the* Pkg *provenance over* $\mathsf{EffectiveOpenBallBasis}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{Topology}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.

11. *N is the local* $\mathsf{NameCert}_{\mathsf{EffectiveOpenBallBasis}^{\uparrow}}$ *row.*
The classifier compares accepted carriers only through $M, C, D, W, R, E, T, H, K, P, N$. It has no coordinate for open-cover compactness, quotient equality of points, real trichotomy, countable choice, selected completions, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 (statement) `BEDC.Derived.EffectiveOpenBallBasisUp`

Theorem 8700.2 (Effective open-ball basis NameCert obligations)**.** *For every accepted* $\mathsf{EffectiveOpenBallBasis}^{\uparrow}$ *carrier*

$$B = (M, C, D, W, R, E, T, H, K, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{EffectiveOpenBallBasis}^{\uparrow}}$ *surface consists exactly of metric-source admission, finite center schedule exposure, dyadic positive-radius exactness, stream-window readback, regular rational replay, real-name sealing, topology handoff, componentwise transport, displayed continuation replay, provenance, and non-escape. In particular, a topology consumer may read an open-ball basis row only after the rows $M, C, D, W, R, E, T, H, K, P, N$ have been displayed in the same finite packet.*

Lean4 ✓ `BEDC.Derived.EffectiveOpenBallBasisUp.EffectiveOpenBallBasisTasteGate single carrier alignment`

Proof. Project the carrier of Definition 8700.1. The metric source M, center schedule C, and dyadic radius ledger D are the only rows that can generate a basis ball.

The readback rows W, R, E then fix how finite observations and real-name comparisons are exposed. They keep distance and radius comparison inside displayed stream windows, regular rational data, and the terminal real seal.

The topology handoff row T exports only the indexed open rows generated from those displayed center-radius data. Transport, replay, provenance, and local naming are carried by H, K, P, N for the same packet.

Since no row stores open-cover compactness, quotient equality, trichotomy, choice, selected completions, or ambient Real completeness, the listed coordinates exhaust the NameCert obligations. □

Theorem 8700.3 (Effective open-ball basis metric topology route)**.** *Every* $\mathsf{Topology}^{\uparrow}$ *consumer of an accepted* $\mathsf{EffectiveOpenBallBasis}^{\uparrow}$ *packet must factor its open-set read through the displayed* $\mathsf{Met}^{\uparrow}$ *source row M, the center schedule C, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *radius ledger D, the* $\mathsf{StreamName}^{\uparrow}$ *and* $\mathsf{RegSeqRat}^{\uparrow}$ *readback rows W, R, the* $\mathsf{Real}^{\uparrow}$ *seal E, and the topology handoff row T. The route exports a finite center-radius basis surface and no open-cover compactness theorem, quotient point equality, real trichotomy, choice principle, or ambient completion of* $\mathsf{Real}^{\uparrow}$.

Proof. Start with the carrier projection. The rows M, C, D display the metric source, the available centers, and the positive radii before any topological read occurs.

Next read W, R, E. These rows make the finite distance and radius comparisons visible through stream windows, regular rational readback, and the Real seal, so the basis route is not a host-side predicate over hidden points.

Finally consume T together with H, K, P, N. The topology handoff is therefore the image of the displayed metric-ball rows under recorded transport and replay, and the consumer receives no additional compactness, quotient, trichotomy, choice, or ambient-completeness coordinate. □

Falsifiable prediction: Every accepted $\mathsf{EffectiveOpenBallBasis}^{\uparrow}$ consumer must display a $\mathsf{Met}^{\uparrow}$ source row, a finite center schedule, a $\mathsf{DyadicRatCore}^{\uparrow}$ radius ledger, $\mathsf{StreamName}^{\uparrow}$ windows, $\mathsf{RegSeqRat}^{\uparrow}$ readback, a $\mathsf{Real}^{\uparrow}$ seal, a $\mathsf{Topology}^{\uparrow}$ handoff, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local $\mathsf{NameCert}$ row before an open-ball basis row can be consumed.

Independence witness: metricspace, dyadicratcore, streamname, regseqrat, real, topology: $\mathsf{EffectiveOpenBallBasis}^{\uparrow}$ is not bijective to any listed sibling because it binds metric centers and dyadic radii into a topology-facing basis handoff before any indexed open row becomes public.

Closure status for $\mathsf{NameCert}_{\mathsf{EffectiveOpenBallBasis}^{\uparrow}}$.

Constructive story: An $\mathsf{EffectiveOpenBallBasis}^{\uparrow}$ packet is generated from a MetricSpace source row, finite center schedule, DyadicRatCore positive-radius ledger, StreamName windows, RegSeqRat readback, Real seal, Topology handoff, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{EffectiveOpenBallBasis}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8700.1, Definition 8700.2, and Definition 8700.3 seed the finite metric open-ball basis route from displayed center-radius data into indexed topology rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{EffectiveOpenBallBasis}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close open-cover compactness, quotient equality, trichotomy, choice, selected completions, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean theorem checking, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, radius-ledger exactness, metric-ball readback, topology handoff, transport, replay, provenance, and non-escape for BEDC.Derived.EffectiveOpenBallBasisUp.

Chapter 8701

A Concrete Naming Certificate for $\mathsf{RadiusOfConvergence}^{\uparrow}$

Following Cauchy's power-series tests and Hadamard's formula for the radius of convergence, the $\mathsf{RadiusOfConvergence}^{\uparrow}$ packet records the finite BEDC data by which a power-series consumer may compare candidate radii before any Real-facing analytic claim is read. It sits after the finite power-series carrier of chapter 7045, the ratio-test route of chapter 2244, the dyadic arithmetic core of chapter 291, the regular rational readback of chapter 301, and the terminal Real seal of chapter 38. The packet names only finite coefficient windows, displayed candidate-radius ledgers, convergence and divergence budgets, regular rational readback, Real sealing, transport, replay, provenance, and local naming; it does not assert a host supremum, analytic continuation, quotient real equality, trichotomy, selected limit, or ambient completeness.

Definition 8701.1 (Radius of convergence carrier)**.** *A* $\mathsf{RadiusOfConvergence}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$R = (A, W, D, C, V, Q, E, H, T, P, N)$$

with the following displayed rows:

1. *A is the coefficient source row, exposing the finite coefficient data consumed from the surrounding power-series packet.*
2. *W is the finite power-series window row, recording the displayed coefficient and exponent range in which the radius comparison is in scope.*
3. *D is the dyadic candidate-radius ledger, carrying candidate radii and comparison budgets through* $\mathsf{DyadicRatCore}^{\uparrow}$ *arithmetic.*
4. *C is the convergence-side budget row, listing the finite tests that certify convergence reads for candidates inside the displayed ledger.*
5. *V is the divergence-side budget row, listing the finite obstruction reads for candidates outside the displayed ledger.*
6. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the same candidate-radius ledger and finite test windows.*
7. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row, available only after A, W, D, C, V, Q have been displayed.*
8. *H records componentwise* hsame *transport for coefficient, window, dyadic ledger, convergence budget, divergence budget, readback, seal, replay, provenance, and local naming rows.*

9. *T records displayed* Cont *replay from a radius query through A, W, D, C, V, Q, E, H before a consumer reads the packet.*

10. *P is the* Pkg *provenance over* $\mathsf{RadiusOfConvergence}^{\uparrow}$, $\mathsf{PowerSeries}^{\uparrow}$, $\mathsf{RealSeriesRatioTest}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*

11. *N is the local* $\mathsf{NameCert}_{\mathsf{RadiusOfConvergence}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $A, W, D, C, V, Q, E, H, T, P, N$. It has no coordinate for a host supremum over radii, analytic continuation, quotient equality of real names, trichotomy over the Real seal, selected limiting radius, or ambient completeness principle.

Theorem 8701.2 (Radius of convergence NameCert obligations)**.** *For every accepted* $\mathsf{RadiusOfConvergence}^{\uparrow}$ *carrier $R = (A, W, D, C, V, Q, E, H, T, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{RadiusOfConvergence}^{\uparrow}}$ *surface consists exactly of coefficient-source exposure, finite power-series window exposure, dyadic candidate-radius ledger exposure, convergence-side budget exposure, divergence-side budget exposure,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback,* $\mathsf{Real}^{\uparrow}$ *sealing, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. Every power-series or analytic-function consumer must read*

$$A, W, D, C, V, Q, E, H, T, P, N$$

before treating the packet as radius evidence.

Proof. Project the carrier of Definition 8701.1. The rows $A, W, D, C, V, Q, E, H, T, P, N$ are exactly the displayed coordinates available to the local certificate.

The coefficient source and finite window rows fix the visible power-series data. The dyadic ledger then lists candidate radii, while the convergence and divergence budgets record only finite tests attached to that ledger.

Next read the regular rational and Real-facing rows. The $\mathsf{RegSeqRat}^{\uparrow}$ row translates the displayed candidate-radius comparisons into regular readback data, and the $\mathsf{Real}^{\uparrow}$ seal is reached only after those rows have been exposed.

Finally transport, replay, provenance, and local naming preserve the same finite route. Since the carrier lacks coordinates for a host supremum, analytic continuation, quotient real equality, trichotomy, selected limits, or ambient completeness, no NameCert obligation can export those objects. □

Closure status for $\mathsf{NameCert}_{\mathsf{RadiusOfConvergence}^{\uparrow}}$.

Constructive story: A $\mathsf{RadiusOfConvergence}^{\uparrow}$ packet is generated from coefficient source data, finite power-series windows, dyadic candidate-radius ledgers, convergence-side and divergence-side budgets, RegSeqRat readback, Real sealing, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert evidence.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{RadiusOfConvergence}^{\uparrow}}$, seed)

Scope closed: Definition 8701.1 and Definition 8701.2 seed the finite radius-of-convergence interface over coefficient windows, dyadic candidate ledgers, convergence and divergence budgets, regular rational readback, Real sealing, transport, replay, provenance, and naming.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{RadiusOfConvergence}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close Lean verification, host suprema, analytic continuation, quotient real equality, trichotomy, selected limits, ambient completeness, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, coefficient source exposure, finite window routing, dyadic candidate-radius ledger exposure, convergence and divergence budget routing, RegSeqRat readback, Real sealing, transport, provenance, and local naming for BEDC.Derived.RadiusOfConvergenceUp.

Chapter 8702

A Concrete Naming Certificate for $\mathsf{FrechetUrysohnSpace}^{\uparrow}$

Following Frechet, Urysohn, Kelley, and Engelking, the $\mathsf{FrechetUrysohnSpace}^{\uparrow}$ packet records the classical sequential closure criterion as finite BEDC naming data. It sits after the indexed-open topology surface of chapter 88, the sequence-indexed convergence interface of chapter 4112, and the finite observation rows of chapter 126. Completion-facing consumers read its numeric convergence rows through $\mathsf{RegSeqRat}^{\uparrow}$ and the terminal $\mathsf{Real}^{\uparrow}$ seal; the packet does not assert quotient sequence spaces, selected subsequences, countable choice, open-cover compactness, or ambient completeness.

Definition 8702.1 (Frechet–Urysohn space carrier)**.** *A* $\mathsf{FrechetUrysohnSpace}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$F = (T, S, W, R, E, A, H, C, P, N)$$

with the following rows:

1. *T is the* $\mathsf{Topology}^{\uparrow}$ *source row, carrying indexed open rows, closed-row vocabulary, point membership reads, and neighbourhood tests.*
2. *S is the* $\mathsf{SequentialSpace}^{\uparrow}$ *source row, exposing the sequence-indexed convergence interface over the same topology surface.*
3. *W is the* $\mathsf{StreamName}^{\uparrow}$ *observation-window row for the sequence names used by a closure request.*
4. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *convergence-readback row for numeric or completion-facing sequence observations.*
5. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row, available only after T, S, W, R have been displayed.*
6. *A is the sequential-closure admission row: for each displayed closed-row request and point-window request, it records the finite route by which a topological closure read may be witnessed by a displayed sequence window.*
7. *H records componentwise* hsame *transport for $T, S, W, R, E, A, C, P, N$.*
8. *C records displayed* Cont *replay of the route*

$$T, S, W, R \longmapsto E, A, H, P, N.$$

9. *P is the* Pkg *provenance over* $\mathsf{FrechetUrysohnSpace}^{\uparrow}$, $\mathsf{Topology}^{\uparrow}$, $\mathsf{SequentialSpace}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.

10. N is the local $\mathsf{NameCert}_{\mathsf{FrechetUrysohnSpace}^{\uparrow}}$ *row.*
The classifier compares accepted packets only through $T, S, W, R, E, A, H, C, P, N$. It has no coordinate for quotient sequence equality, a host-selected subsequence, countable choice, arbitrary filters, open-cover compactness, host point equality, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 8702.2 (Frechet–Urysohn space NameCert obligations)**.** *For every accepted* $\mathsf{FrechetUrysohnSpace}^{\uparrow}$ *carrier*

$$F = (T, S, W, R, E, A, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{FrechetUrysohnSpace}^{\uparrow}}$ *surface consists exactly of topology-source admission through T, sequential-source admission through S, finite stream-window exposure through W, regular rational convergence readback through R, terminal Real-seal ordering through E, sequential-closure admission through A, componentwise transport through H, displayed replay through C, provenance through P, and local naming through N.*

Proof. Project the carrier rows of Definition 8702.1. The topology source, sequential source, stream windows, regular rational readback, Real seal, and closure-admission row are the only data visible before transport and provenance are read.

Read the closure request in dependency order. The topology row supplies the open and closed vocabulary; the sequential row supplies the sequence-indexed convergence interface; the stream and regular-rational rows expose finite windows and convergence readback before the terminal Real seal can be consumed.

Finally replay A, H, C, P, N. The admission row binds topological closure reads to displayed sequence windows, while transport, continuation, provenance, and local naming preserve the same route. Since no excluded quotient, selector, choice, filter, compactness, host equality, or completeness row is present, the listed rows exhaust the local certificate. □

Theorem 8702.3 (Frechet–Urysohn sequential-closure route)**.** *Every topological closure read exported by an accepted* $\mathsf{FrechetUrysohnSpace}^{\uparrow}$ *carrier must pass through*

$$T, S, W, R \longmapsto E, A, H, C, P, N.$$

Thus a $\mathsf{Topology}^{\uparrow}$ *consumer may use the packet as a sequential-closure route only after the* $\mathsf{SequentialSpace}^{\uparrow}$ *source,* $\mathsf{StreamName}^{\uparrow}$ *windows,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback, and* $\mathsf{Real}^{\uparrow}$ *seal rows have been displayed. The route is not a quotient sequence space, not a host subsequence selector, not countable choice, and not ambient completeness of* $\mathsf{Real}^{\uparrow}$*.*

Proof. Begin with a closure-facing consumer. The carrier exposes only the topology row T for open and closed vocabulary, so the closure request cannot bypass the displayed topology source.

Next inspect S, W, R, E. The sequential-space row supplies the convergence interface, the stream row supplies finite observation windows, and the regular-rational row supplies the convergence readback used by completion-facing readers before the Real seal is reached.

Finally apply A, H, C, P, N. The sequential-closure admission row names the route from topological closure to sequence windows, and the structural rows preserve that route componentwise. Since the carrier has no coordinate for quotient sequence spaces, selected subsequences, countable choice, filters, compactness, or ambient Real completeness, none is exported by the handoff. □

Closure status for $\mathsf{NameCert}_{\mathsf{FrechetUrysohnSpace}^{\uparrow}}$**.**

Constructive story: A $\mathsf{FrechetUrysohnSpace}^{\uparrow}$ packet is generated from a Topology source row, a SequentialSpace source row, StreamName observation windows, RegSeqRat convergence readback, a Real seal, sequential-closure admission, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\mathsf{FrechetUrysohnSpace}^{\uparrow}}$, seed)

Scope closed: Definition 8702.1, Definition 8702.2, and Definition 8702.3 seed the Frechet–Urysohn carrier over topology, sequential-space, StreamName, RegSeqRat, Real-seal, admission, transport, replay, provenance, and local naming rows.

Formal verification: FormalStatus(NameCert$_{\mathsf{FrechetUrysohnSpace}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close quotient sequence spaces, selected subsequences, countable choice, arbitrary filters, open-cover compactness, host point equality, ambient Real$^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, topology-source routing, sequential-source routing, StreamName window coverage, RegSeqRat convergence readback, Real-seal ordering, sequential-closure admission, provenance, and local naming for BEDC.Derived.FrechetUrysohnSpaceUp.

Chapter 8703

Compact Uniform Barycentric Refinement NameCert Construction

Following Bishop and Bridges finite-cover refinement practice, the $\mathsf{CompactUniformBarycentricRefinement}^{\uparrow}$ packet records the compact-uniform-continuity use of dyadic barycentric subdivision as finite NameCert data. It consumes the subdivision primitive of chapter 8605, the compact source rows of chapter 129, the tolerance-only modulus surface of chapter 369, the finite interval-cell net of chapter 5966, and the sequence/readback route of chapter 126, chapter 301, and chapter 38. The packet is a compact-uniform consumer handoff; it does not assert open-cover compactness, selected finite subcovers, quotient stream equality, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 8703.1 (Compact uniform barycentric refinement carrier)**.** *A* $\mathsf{CompactUniformBarycentricRefinement}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$U = (B, K, M, I, S, R, E, H, C, P, N)$$

with the following rows:

1. *B is the* $\mathsf{DyadicBarycentricRefinement}^{\uparrow}$ *source row, exposing parent cells, barycenters, child cells, and mesh-decrease data.*
2. *K is the* $\mathsf{CompactMetric}^{\uparrow}$ *source row that supplies the compact finite-net boundary read by the uniform-continuity consumer.*
3. *M is the* $\mathsf{UniformModulus}^{\uparrow}$ *handoff row, recording the tolerance-only modulus produced after the compact source and subdivision rows are inspected.*
4. *I is the* $\mathsf{DyadicIntervalNet}^{\uparrow}$ *interval-cell row used to align parent cells, child cells, and compact finite-net probes.*
5. *S is the* $\mathsf{StreamName}^{\uparrow}$ *observation-window row for endpoint, barycenter, and finite-net probe reads.*
6. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for child-cell radii, compact-net tolerances, and modulus budgets.*
7. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row, available only after B, K, M, I, S, R have been displayed.*
8. *H records componentwise* hsame *transport for all displayed refinement, compact, modulus, interval, window, readback, seal, provenance, and local naming rows.*

9. *C records displayed* Cont *replay of the compact-uniform route*

$$B, K, I, S, R \longmapsto M, E, H, P, N.$$

10. *P is the* Pkg *provenance over* CompactUniformBarycentricRefinement$^{\uparrow}$, DyadicBarycentricRefinement$^{\uparrow}$, CompactMetric$^{\uparrow}$, UniformModulus$^{\uparrow}$, DyadicIntervalNet$^{\uparrow}$, StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, Real$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

11. *N is the local* NameCert$_{\text{CompactUniformBarycentricRefinement}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $B, K, M, I, S, R, E, H, C, P, N$. It has no coordinate for arbitrary open covers, selected finite subcovers, host compactness, quotient stream equality, selected limits, countable choice, or ambient Real$^{\uparrow}$ *completeness.*

Theorem 8703.2 (Compact uniform barycentric refinement NameCert obligations)**.** *For every accepted* CompactUniformBarycentricRefinement$^{\uparrow}$ *carrier*

$$U = (B, K, M, I, S, R, E, H, C, P, N),$$

the local NameCert$_{\text{CompactUniformBarycentricRefinement}^{\uparrow}}$ *surface consists exactly of barycentric-refinement source admission through B, compact-metric source admission through K, uniform-modulus handoff through M, dyadic interval-cell alignment through I, finite observation through S, regular rational readback through R, terminal Real-seal ordering through E, componentwise transport through H, displayed replay through C, provenance through P, and local naming through N.*

Proof. Project the carrier of Definition 8703.1. The accepted packet displays the dyadic barycentric source, compact metric source, uniform-modulus handoff, interval-cell alignment, observation windows, readback row, and Real seal before the structural rows are inspected.

Read the compact-uniform route in order. The barycentric row supplies parent and child cells, the compact row supplies finite-net source data, and the interval-cell row aligns the subdivision with the compact probes. The StreamName and RegSeqRat rows then expose finite endpoint windows and tolerance budgets before the terminal Real seal is available.

Finally replay M, H, C, P, N. The modulus row is a tolerance-only handoff generated inside the displayed route, while transport, continuation, provenance, and local naming preserve the same finite rows. Since no open-cover, selected-subcover, quotient, selected-limit, choice, host-compactness, or completeness coordinate is present, none is exported by the certificate. □

Theorem 8703.3 (Compact uniform barycentric refinement modulus route)**.** *Every compact-uniform-continuity consumer of an accepted* CompactUniformBarycentricRefinement$^{\uparrow}$ *packet must read*

$$B, K, I, S, R \longmapsto M, E, H, C, P, N.$$

Thus the UniformModulus$^{\uparrow}$ *row is available only after the* DyadicBarycentricRefinement$^{\uparrow}$, CompactMetric$^{\uparrow}$, DyadicIntervalNet$^{\uparrow}$, StreamName$^{\uparrow}$, *and* RegSeqRat$^{\uparrow}$ *rows have been displayed, and the* Real$^{\uparrow}$ *seal remains downstream of the same finite route.*

Proof. Begin with the barycentric and compact source rows. The row B exposes the parent cells, barycenters, child cells, and mesh-decrease data, while K supplies only the compact finite-net boundary used by the consumer.

Next align the source rows through I, S, R. The dyadic interval-cell row ties the subdivision cells to compact probes; the stream row exposes finite endpoint and barycenter windows; and the regular-rational row records the tolerance budgets consumed by the modulus handoff.

Only then may the consumer read M and E. The UniformModulus row is produced as a tolerance-only consumer row, and the terminal Real seal remains downstream of the displayed readback. The structural rows H, C, P, N preserve that order, excluding open-cover compactness, selected subcovers, quotient stream equality, selected limits, countable choice, and ambient Real completeness. □

Closure status for $\mathsf{NameCert}_{\mathsf{CompactUniformBarycentricRefinement}^{\uparrow}}$.

Constructive story: A $\mathsf{CompactUniformBarycentricRefinement}^{\uparrow}$ packet is generated from a DyadicBarycentricRefinement source row, a CompactMetric source row, a UniformModulus handoff row, a DyadicIntervalNet alignment row, StreamName windows, RegSeqRat readback, a Real seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CompactUniformBarycentricRefinement}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8703.1, Definition 8703.2, and Definition 8703.3 seed the compact-uniform barycentric refinement carrier over dyadic subdivision, compact source, uniform modulus, interval-cell, StreamName, RegSeqRat, Real-seal, transport, replay, provenance, and local naming rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CompactUniformBarycentricRefinement}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close open-cover compactness, selected finite subcovers, quotient stream equality, selected limits, countable choice, host compactness, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked barycentric-refinement admission, compact-source admission, interval-cell alignment, StreamName window coverage, RegSeqRat tolerance readback, UniformModulus handoff, Real-seal ordering, provenance, and local naming for BEDC.Derived.CompactUniformBarycentricRefinementUp.

Chapter 8704

A Concrete Naming Certificate for $\mathsf{BishopContinuityTheorem}^{\uparrow}$

Following Bishop and Bridges, constructive continuity theorems are read here as finite modulus-producing routes over displayed names rather than as host statements about arbitrary functions. The $\mathsf{BishopContinuityTheorem}^{\uparrow}$ packet sits between the fan-continuity route of chapter 2027, the bar-induction continuity route of chapter 6028, the local modulus handoff of chapter 6998, the finite observation surface of chapter 126, the regular rational readback of chapter 301, and the terminal real-name seal of chapter 38. The chapter names the theorem surface by which fan or bar continuity evidence is routed into a Bishop local modulus for Real and RegSeqRat consumers; it does not assert choice, weak limited principle of omniscience, quotient equality of real names, a selected host functional, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 8704.1 (Bishop continuity theorem carrier)**.** *A* $\mathsf{BishopContinuityTheorem}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$T = (F, B, M, S, R, E, H, C, P, N)$$

with the following displayed rows:

1. *F is the* $\mathsf{FanContinuityPrinciple}^{\uparrow}$ *route, when the theorem is read through a fan-continuity source.*
2. *B is the* $\mathsf{BarInductionContinuity}^{\uparrow}$ *route, when the theorem is read through a bar-induction source.*
3. *M is the* $\mathsf{BishopContinuityModulus}^{\uparrow}$ *handoff row produced by the selected displayed source route.*
4. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row used to inspect the source and image names before the modulus is consumed.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row obtained from those finite windows and the modulus-controlled tolerance ledger.*
6. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal read only after F or B, M, S, and R have been displayed.*
7. *H records componentwise* hsame *transport for the fan route, bar route, modulus row, window row, readback row, real seal, and local certificate row.*
8. *C records displayed* Cont *replay from the chosen continuity source through M, S, R, E.*
9. *P is the* Pkg *provenance over* $\mathsf{BishopContinuityTheorem}^{\uparrow}$, $\mathsf{FanContinuityPrinciple}^{\uparrow}$, $\mathsf{BarInductionContinuity}^{\uparrow}$, $\mathsf{BishopContinuityModulus}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*

10. N is the local $\mathsf{NameCert}_{\mathsf{BishopContinuityTheorem}^{\uparrow}}$ *row.*
The classifier compares accepted packets only through $F, B, M, S, R, E, H, C, P, N$ and the displayed choice of continuity source. It has no coordinate for a choice principle, weak limited principle of omniscience, quotient equality of real names, selected host functional, detached semantic continuity theorem, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 8704.2 (Bishop continuity theorem NameCert obligations)**.** *For the carrier of Definition 8704.1, the local* $\mathsf{NameCert}_{\mathsf{BishopContinuityTheorem}^{\uparrow}}$ *surface consists exactly of carrier admission for $T = (F, B, M, S, R, E, H, C, P, N)$, continuity-source exposure through F or B, local modulus handoff through M, finite observation through S, regular rational readback through R, terminal real seal through E, componentwise transport through H, displayed replay through C, provenance through P, and local naming through N.*

Proof. Project the accepted carrier to its displayed rows. The theorem source is either the fan-continuity row F or the bar-induction continuity row B, and no third continuity-source coordinate is available.

Read the modulus row next. The local handoff M is the $\mathsf{BishopContinuityModulus}^{\uparrow}$ surface consumed by the theorem, so the source route can affect downstream Real or RegSeqRat consumers only by producing that displayed modulus row.

Finally route the numeric observations through S, R, E. The $\mathsf{StreamName}^{\uparrow}$ row supplies finite windows, the $\mathsf{RegSeqRat}^{\uparrow}$ row reads them back as regular rational data, and the $\mathsf{Real}^{\uparrow}$ seal is reached only after those rows are displayed. The structural rows H, C, P, N transport, replay, source, and name the same finite packet, so the listed rows exhaust the NameCert obligations. □

Theorem 8704.3 (Bishop continuity theorem fan-modulus handoff)**.** *Whenever an accepted* BishopContinuityTheor *packet uses the* $\mathsf{FanContinuityPrinciple}^{\uparrow}$ *source row F, its downstream continuity output factors through the* $\mathsf{BishopContinuityModulus}^{\uparrow}$ *row M before any* $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *or* $\mathsf{Real}^{\uparrow}$ *consumer can read the theorem. The handoff is the finite route*

$$F \longmapsto M \longmapsto S \longmapsto R \longmapsto E,$$

with transport, replay, provenance, and local naming confined to H, C, P, N.

Proof. Start with the source row F in Definition 8704.1. It carries the fan-continuity evidence only as the displayed packet of chapter 2027.

Apply the NameCert obligations of Definition 8704.2. They require the theorem output to pass through M before the finite observation and readback rows S, R, E are visible.

The route is then fixed by the continuation row C. It replays the fan source into the local modulus, then into the stream windows, regular rational readback, and terminal real seal. Since H, C, P, N are the only structural rows, no choice selector, quotient equality, host functional, or completeness principle can enter the handoff. □

Theorem 8704.4 (Bishop continuity theorem nonescape boundary)**.** *Every* $\mathsf{RegSeqRat}^{\uparrow}$ *or* $\mathsf{Real}^{\uparrow}$ *consumer of an accepted* $\mathsf{BishopContinuityTheorem}^{\uparrow}$ *packet receives only the displayed continuity-source row F or B, the local modulus row M, the finite* $\mathsf{StreamName}^{\uparrow}$ *windows S, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback R, the terminal* $\mathsf{Real}^{\uparrow}$ *seal E, and the structural rows H, C, P, N. Such a consumer cannot extract choice, weak limited principle of omniscience, quotient equality of real names, a selected host functional, detached semantic continuity, a general compactness theorem, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness from the packet.*

Proof. Read the consumer request through Definition 8704.2. The only numeric-facing route reaches R and E after one displayed continuity source and the local modulus row have already been exposed.

If the source is fan continuity, use Definition 8704.3. If the source is bar-induction continuity, the same carrier projection replaces F by B and still routes through M, S, R, E before the consumer can read any endpoint data.

The excluded principles are absent from the carrier inventory. Transport by H, replay by C, provenance by P, and local naming by N preserve the displayed finite rows; they do not create choice, WLPO, quotient equality, host functional selection, semantic continuity outside the packet, compactness, or real completeness. □

Falsifiable prediction: Any accepted BishopContinuityTheoremUp packet that exports a RegSeqRat or Real continuity read without displaying a FanContinuityPrinciple or BarInductionContinuity source, a BishopContinuityModulus row, StreamName windows, RegSeqRat readback, and Real seal fails the carrier classifier.

Independence witness: fancontinuityprinciple, barinductioncontinuity, bishopcontinuitymodulus, streamname, regseqrat, real: none is bijective with $\mathsf{BishopContinuityTheorem}^{\uparrow}$ because this carrier jointly records the theorem source, local modulus handoff, finite observation windows, regular rational readback, terminal real seal, transport, replay, provenance, and one local NameCert row while refusing choice, WLPO, quotient equality, host function selection, and ambient Real completeness.

Closure status for $\mathsf{NameCert}_{\mathsf{BishopContinuityTheorem}^{\uparrow}}$.

Constructive story: A $\mathsf{BishopContinuityTheorem}^{\uparrow}$ packet is generated from a FanContinuityPrinciple or BarInductionContinuity source row, a BishopContinuityModulus handoff row, StreamName windows, RegSeqRat readback, terminal RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BishopContinuityTheorem}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8704.1, Definition 8704.2, Definition 8704.3, Definition 8704.4, the falsifiable prediction, and the independence witness seed the constructive L10 continuity-theorem surface.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BishopContinuityTheorem}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close choice, WLPO, quotient equality of real names, selected host functionals, detached semantic continuity, general compactness, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, fan and bar source exposure, BishopContinuityModulus handoff, StreamName windows, RegSeqRat readback, Real seal nonescape, transport, replay, provenance, and local NameCert rows for BEDC.Derived.BishopContinuityTheoremUp.

Chapter 8705

A Concrete Naming Certificate for $\mathsf{CompletionReflectorKleisliExtension}^{\uparrow}$

Following Mac Lane on Kleisli categories and monads, and Bishop–Bridges/Kelley on metric completion, the $\mathsf{CompletionReflectorKleisliExtension}^{\uparrow}$ packet records the finite service boundary where a completion-facing map is extended along the completion reflector monad without becoming a host function on completed representatives. It sits after the reflector monad of chapter 8693, the separated reflector unit of chapter 8694, and the real-number terminal seal of chapter 38. The packet names a Kleisli extension carrier, the bind and join compatibility rows that make the extension public, and the separated uniqueness row that prevents hidden quotient or choice data from entering the route.

Definition 8705.1 (Completion reflector Kleisli extension carrier)**.** *A* $\mathsf{CompletionReflectorKleisliExtension}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (S, R, U, K, J, E, H, C, P, N)$$

with the following displayed rows:

1. *S is the source metric row, exposing point admission, distance readback, zero-distance inspection, symmetry, triangle, and source transport before any completion-valued extension is read.*
2. *R is the completion reflector monad row, recording the completion object, reflector handoff, unit interface, bind interface, and join interface consumed from the* $\mathsf{CompletionReflectorMonad}^{\uparrow}$ *packet.*
3. *U is the separated unit row, read through* $\mathsf{MetricSeparatedReflectorUnit}^{\uparrow}$*, which identifies exactly which zero-distance witnesses are allowed to pass from the source metric surface into the separated completion-facing target.*
4. *K is the Kleisli-extension schedule. It records the finite graph of inspected source names, the completion-valued target requests attached to them, and the order in which those requests are extended along the reflector unit.*
5. *J is the bind and join compatibility row, requiring the extension schedule K to pass through the monad bind and join rows of R before a nested completion request is flattened.*
6. *E is the separated uniqueness row. It states that two extension reads with the same S, R, U, K, J rows expose the same public route only through the separated comparison named by the reflector boundary.*

7. *H records componentwise* hsame *transport for the source metric row, reflector monad row, separated unit row, Kleisli schedule, bind and join compatibility, separated uniqueness, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from a source metric request through R, U, K, J, E, H, P, N.*
9. *P is the* Pkg *provenance over* $\mathsf{CompletionReflectorKleisliExtension}^{\uparrow}$, $\mathsf{CompletionReflectorMonad}^{\uparrow}$, $\mathsf{MetricSeparatedReflectorUnit}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* NameCert *rows.*
10. *N is the local* $\mathsf{NameCert}_{\mathsf{CompletionReflectorKleisliExtension}^{\uparrow}}$ *row.*

The carrier has no coordinate for selected representatives, quotient completion, host equality of completed objects, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 8705.2 (Completion reflector Kleisli extension NameCert obligations)**.** *For every accepted* $\mathsf{CompletionReflectorKleisliExtension}^{\uparrow}$ *carrier*

$$L = (S, R, U, K, J, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{CompletionReflectorKleisliExtension}^{\uparrow}}$ *surface consists exactly of source metric admission through S, completion reflector monad exposure through R, separated unit exposure through U, Kleisli extension scheduling through K, bind and join compatibility through J, separated uniqueness through E, componentwise transport through H, displayed replay through C, provenance through P, and local naming through N.*

Proof. Project the carrier of Definition 8705.1. The source metric information is confined to S, the completion reflector monad interface is confined to R, and the separated reflector unit information is confined to U.

The Kleisli extension route is not a host operation on completed objects. It is the finite schedule K together with the bind and join compatibility row J, so every completion-valued extension request must pass through the reflector monad rows named in chapter 8693.

Separated uniqueness is read only through E, with the separated unit boundary supplied by chapter 8694 and the real terminal seal supplied by chapter 38. The rows H, C, P, N then transport, replay, source, and name the same finite packet. Since no excluded principle has a row in L, the listed coordinates exhaust the local NameCert obligations. □

Theorem 8705.3 (Completion reflector Kleisli extension nonescape)**.** *Every completion-facing consumer of an accepted* $\mathsf{CompletionReflectorKleisliExtension}^{\uparrow}$ *carrier reads only the displayed finite route*

$$S, R, U, K, J, E, H, C, P, N.$$

In particular, the packet exports no selected representatives, no quotient completion, no host equality of completed objects, no countable choice, and no ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Apply Definition 8705.2. It identifies the public route as the source metric row, reflector monad row, separated unit row, Kleisli extension schedule, bind and join compatibility row, separated uniqueness row, transport row, replay row, provenance row, and local naming row.

The consumer can read completion-facing behavior only after those rows have been displayed. The reflector monad row supplies the bind and join surface, the separated unit row supplies the zero-distance boundary, and the Kleisli schedule records the finite extension order.

The carrier has no slot for representatives, quotient completion, host equality, choice, or ambient completeness. A request for any of those principles therefore remains outside the carrier instead of being replayed through H, C, P, N. □

Closure status for $\mathsf{NameCert}_{\mathsf{CompletionReflectorKleisliExtension}^{\uparrow}}$.

Constructive story: A $\mathsf{CompletionReflectorKleisliExtension}^{\uparrow}$ packet is generated from source metric rows, a completion reflector monad row, a separated unit row, a Kleisli extension schedule, bind and join compatibility, separated uniqueness, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CompletionReflectorKleisliExtension}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8705.1, Definition 8705.2, and Definition 8705.3 seed the finite Kleisli extension service boundary over source metric, completion reflector monad, separated unit, bind and join compatibility, separated uniqueness, transport, replay, provenance, and local naming rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CompletionReflectorKleisliExtension}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim selected representatives, quotient completion, host equality, countable choice, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, Kleisli extension scheduling, bind and join compatibility, separated uniqueness, transport, replay, provenance, and local naming for BEDC.Derived.CompletionReflectorKleisliExtensionUp.

Chapter 8706

A Concrete Naming Certificate for $\mathsf{BishopCauchyDiagonal}^{\uparrow}$

Following Bishop and Bridges on constructive Cauchy real names, the $\mathsf{BishopCauchyDiagonal}^{\uparrow}$ packet records the finite diagonal window used when a Cauchy family is read as a regular rational name and then sealed as a real-name boundary. It sits between the finite stream windows of chapter 126, the dyadic tolerance arithmetic of chapter 291, the regular rational readback of chapter 301, and the terminal real-name seal of chapter 38. The packet is a finite L10 Real and Completion object; it does not import host limits, quotient real equality, countable choice, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 8706.1 (Bishop Cauchy diagonal carrier)**.** *A* $\mathsf{BishopCauchyDiagonal}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (S, A, D, W, R, E, H, C, P, N)$$

with the following displayed rows:

1. *S is the source Cauchy window row, recording the finite family of rational names and the inspected Cauchy bounds.*
2. *A is the diagonal schedule row, listing the finite index and precision pairs actually selected for the diagonal read.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger attached to the source window and diagonal schedule.*
4. *W is the* $\mathsf{StreamName}^{\uparrow}$ *window readback generated by the displayed diagonal schedule.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff row, exposing the regular rational readback only after S, A, D, W have been displayed.*
6. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row for the regular name presented by the diagonal read.*
7. *H records componentwise* hsame *transport for the source window, diagonal schedule, dyadic ledger, StreamName window, RegSeqRat handoff, Real seal, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from a finite diagonal request through $S, A, D, W, R, E, H, P, N$.*
9. *P is the* Pkg *provenance over* $\mathsf{BishopCauchyDiagonal}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{BishopCauchyDiagonal}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $S, A, D, W, R, E, H, C, P, N$. No coordinate stores a host limit, quotient stream equality, selected representative, countable-choice sequence, trichotomy branch, or ambient $\mathsf{Real}^{\uparrow}$ *completeness theorem.*

Theorem 8706.2 (Bishop Cauchy diagonal NameCert obligations)**.** *For every accepted* $\mathsf{BishopCauchyDiagonal}^{\uparrow}$ *carrier*

$$B = (S, A, D, W, R, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{BishopCauchyDiagonal}^{\uparrow}}$ *surface consists exactly of source Cauchy window admission, finite diagonal schedule exposure, dyadic tolerance ledger visibility,* $\mathsf{StreamName}^{\uparrow}$ *window readback,* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff, terminal* $\mathsf{Real}^{\uparrow}$ *seal, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. A Real-facing consumer may read the diagonal packet only after all ten rows have been displayed.*

Proof. Project the carrier of Definition 8706.1. The displayed inventory is the finite source window S, diagonal schedule A, dyadic ledger D, StreamName readback W, regular rational handoff R, Real seal E, and the structural rows H, C, P, N.

The analytic rows are ordered. The schedule A is meaningful only against the source Cauchy window S; the dyadic ledger D attaches the requested tolerances to that finite schedule; and the StreamName row W records the actual window read from those displayed entries.

The completion-facing rows are downstream. The $\mathsf{RegSeqRat}^{\uparrow}$ handoff R and terminal $\mathsf{Real}^{\uparrow}$ seal E may be consumed only after the finite window and dyadic ledger have been exposed.

Finally H, C, P, N preserve and name the same route. Since the carrier has no coordinate for host limits, quotient real equality, countable choice, trichotomy, or ambient Real completeness, the listed rows exhaust the local NameCert obligation surface. □

Theorem 8706.3 (Bishop Cauchy diagonal Real handoff)**.** *Every* $\mathsf{Real}^{\uparrow}$ *consumer of an accepted* $\mathsf{BishopCauchyDiagonal}^{\uparrow}$ *packet must factor through the finite route*

$$S, A, D, W, R, E, H, C, P, N.$$

The route first displays the source Cauchy window and diagonal schedule, then reads the $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, the* $\mathsf{StreamName}^{\uparrow}$ *window, and the* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff before the terminal* $\mathsf{Real}^{\uparrow}$ *seal is public. It exports a named finite diagonal packet, not a host limit, a quotient real representative, countable choice, trichotomy, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start from the NameCert obligations of Definition 8706.2. They force a Real-facing read to expose $S, A, D, W, R, E, H, C, P, N$ as the accepted packet surface.

The finite diagonal schedule is read through the same completion corridor as the sibling chapters. The stream window agrees with the $\mathsf{StreamName}^{\uparrow}$ route of chapter 126, the precision ledger agrees with the $\mathsf{DyadicRatCore}^{\uparrow}$ route of chapter 291, and the regular rational handoff agrees with the $\mathsf{RegSeqRat}^{\uparrow}$ route of chapter 301.

Only after these rows are displayed may the terminal seal of chapter 38 be consumed. Thus the handoff remains a finite BEDC certificate for a diagonal read, with the excluded completeness, choice, quotient, and host-limit coordinates absent from the packet. □

Falsifiable prediction: Every accepted $\mathsf{BishopCauchyDiagonal}^{\uparrow}$ read is refuted if it reaches a $\mathsf{Real}^{\uparrow}$ consumer without displaying the source Cauchy window, diagonal schedule, dyadic tolerance ledger, StreamName window readback, RegSeqRat handoff, Real seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local $\mathsf{NameCert}$ row.

Independence witness: streamname, dyadicratcore, regseqrat, real: $\mathsf{BishopCauchyDiagonal}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries a source Cauchy window, finite diagonal schedule, dyadic tolerance ledger, StreamName window readback, RegSeqRat handoff, Real seal, transport, replay, provenance, and local naming as one finite diagonal packet.

Closure status for $\mathsf{NameCert}_{\mathsf{BishopCauchyDiagonal}^{\uparrow}}$.

Constructive story: A $\mathsf{BishopCauchyDiagonal}^{\uparrow}$ packet is generated from a source Cauchy window, finite diagonal schedule, DyadicRatCore tolerance ledger, StreamName window readback, RegSeqRat handoff, Real seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BishopCauchyDiagonal}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8706.1, Definition 8706.2, and Definition 8706.3 seed the finite diagonal route from Cauchy windows to Real-facing regular rational seals.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BishopCauchyDiagonal}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host limits, quotient real equality, selected representatives, countable choice, trichotomy, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked source-window admission, diagonal schedule exactness, dyadic tolerance visibility, StreamName readback, RegSeqRat handoff, Real seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.BishopCauchyDiagonalUp.

Chapter 8707

A Concrete Naming Certificate for $\mathsf{RieszSchauderTheory}^{\uparrow}$

Following Riesz and Schauder on compact operators in normed spaces, the $\mathsf{RieszSchauderTheory}^{\uparrow}$ packet records the finite BEDC route by which a displayed compact linear operator exposes spectral-window and Fredholm-facing obligations. It reads the Banach endpoint rows of chapter 90, the bounded operator action of chapter 1644, the compact-operator certificate of chapter 1952, the spectral-radius boundary of chapter 2352, and the compact-perturbation alternative of chapter 3425. The packet names only this displayed compact-operator spectral route; it does not import a host spectrum, quotient operator algebra, selected eigenbasis, closed-range complement, or analytic Fredholm theorem.

Definition 8707.1 (Riesz–Schauder theory carrier)**.** *A* $\mathsf{RieszSchauderTheory}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$R = (X, Y, B, K, S, F, H, C, P, N)$$

with the following displayed rows:

1. X *is the* $\mathsf{Banach}^{\uparrow}$ *source endpoint row.*
2. Y *is the* $\mathsf{Banach}^{\uparrow}$ *target endpoint row, or the same endpoint when the compact operator is read endomorphically.*
3. B *is the* $\mathsf{BoundedLinearOperator}^{\uparrow}$ *row naming the displayed linear action and norm-bound ledger between the endpoints.*
4. K *is the* $\mathsf{CompactOperator}^{\uparrow}$ *row naming compactness by finite image-net schedules, tail moduli, and replay data.*
5. S *is the* $\mathsf{SpectralRadius}^{\uparrow}$ *window row used by spectral consumers that inspect finite power-growth and resolvent-test data.*
6. F *is the* $\mathsf{FredholmAlternative}^{\uparrow}$ *handoff row used by range-obstruction and kernel-facing consumers.*
7. H *records componentwise* hsame *transport for the endpoint, bounded-action, compactness, spectral-window, and Fredholm-handoff rows.*
8. C *records displayed* Cont *replay through the same rows.*
9. P *is the* Pkg *provenance over* $\mathsf{RieszSchauderTheory}^{\uparrow}$, $\mathsf{Banach}^{\uparrow}$, $\mathsf{BoundedLinearOperator}^{\uparrow}$, $\mathsf{CompactOperator}^{\uparrow}$, $\mathsf{SpectralRadius}^{\uparrow}$, $\mathsf{FredholmAlternative}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* $\mathsf{NameCert}$.

10. N is the local $\mathsf{NameCert}_{\mathsf{RieszSchauderTheory}^{\uparrow}}$ *row.*
The classifier compares accepted packets only through these rows. It has no coordinate for a completed spectrum, quotient operator, selected eigenvector chain, algebraic multiplicity, closed-range complement, or host Fredholm determinant.

Lean4 (statement) `BEDC.Derived.RieszSchauderTheoryUp`

Theorem 8707.2 (Riesz–Schauder theory NameCert obligations)**.** *For an accepted* $\mathsf{RieszSchauderTheory}^{\uparrow}$ *carrier $R = (X, Y, B, K, S, F, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{RieszSchauderTheory}^{\uparrow}}$ *surface consists exactly of endpoint admission through X, Y, bounded-action admission through B, compact-operator admission through K, spectral-window exposure through S, Fredholm-handoff exposure through F, componentwise transport through H, displayed replay through C, package provenance through P, and local naming through N.*

Proof. Project the carrier of Definition 8707.1. The tuple $X, Y, B, K, S, F, H, C, P, N$ is the full visible inventory, so endpoint, action, compactness, spectral-window, Fredholm-handoff, transport, replay, provenance, and naming obligations cannot be enlarged by an external operator object.

Read the analytic dependencies in order. The Banach rows provide the endpoints, the bounded-operator row provides the displayed action, and the compact-operator row supplies the finite compactness witness before any spectral or Fredholm consumer can inspect the packet.

The spectral and Fredholm rows are then handoffs rather than ambient theorems. The row S points only to finite power-growth and resolvent windows from $\mathsf{SpectralRadius}^{\uparrow}$, while F points only to the kernel or range-obstruction boundary already named by $\mathsf{FredholmAlternative}^{\uparrow}$.

Finally H, C, P, N preserve, replay, source, and name those same rows. Since the carrier contains no completed spectrum, quotient operator, selected eigenbasis, multiplicity ledger, closed-range complement, or determinant coordinate, the listed obligations exhaust the local certificate surface. □

Theorem 8707.3 (Riesz–Schauder compact Fredholm route)**.** *Every consumer that reads a Riesz–Schauder spectral or Fredholm conclusion from an accepted* $\mathsf{RieszSchauderTheory}^{\uparrow}$ *packet must pass through the displayed route*

$$\mathsf{Banach}^{\uparrow}, \mathsf{BoundedLinearOperator}^{\uparrow} \longmapsto \mathsf{CompactOperator}^{\uparrow} \longmapsto \mathsf{SpectralRadius}^{\uparrow}, \mathsf{FredholmAlternative}^{\uparrow} \longmapsto \mathsf{RieszSchau}$$

The route exposes compactness through finite image-net schedules and exposes spectral or range-obstruction data only through the sibling windows S and F. It does not export a host spectrum, quotient operator algebra, selected eigenspace chain, algebraic multiplicity theorem, or analytic Fredholm determinant.

Proof. Begin with the NameCert obligations of Definition 8707.2. They force every accepted read to expose the Banach endpoints, bounded action, compactness row, spectral window, Fredholm handoff, and structural rows before any conclusion is public.

The compactness step is the central gate. A consumer cannot enter S or F until K has displayed the finite compact-operator schedules certified by chapter 1952. The bounded action B remains attached to the same endpoints throughout this replay.

Once the compact row is visible, the spectral side may inspect only the finite resolvent and power-growth windows of chapter 2352. The Fredholm side may inspect only the kernel-facing or range-obstruction handoff of chapter 3425.

Repack the route through H, C, P, N. These rows preserve and name the displayed packet, but they do not add a spectrum object, quotient operator algebra, selected eigenvectors, multiplicities,

complements, or determinants. Hence every exported Riesz–Schauder read factors through the finite compact-Fredholm route above. □

Closure status for $\mathsf{NameCert}_{\mathsf{RieszSchauderTheory}^{\uparrow}}$.

Constructive story: A $\mathsf{RieszSchauderTheory}^{\uparrow}$ packet is generated from Banach endpoint rows, a BoundedLinearOperatorUp action row, a CompactOperatorUp compactness row, SpectralRadiusUp finite spectral windows, a FredholmAlternativeUp kernel or range-obstruction handoff, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RieszSchauderTheory}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8707.1, Definition 8707.2, and Definition 8707.3 seed the compact-operator spectral route over BanachUp, BoundedLinearOperatorUp, CompactOperatorUp, SpectralRadiusUp, FredholmAlternativeUp, BHist, hsame, Cont, Pkg, and NameCert rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RieszSchauderTheory}^{\uparrow}}, \mathsf{formalTarget})$

Bridge status: none

Not claimed: This chapter does not close a host Riesz–Schauder theorem, completed spectrum, quotient operator algebra, eigenbasis selection, algebraic multiplicity, closed-range complement, Lean theorem verification, or bridge checking.

Upgrade path: Obligation closure requires checked endpoint admission, bounded-action admission, compactness admission, spectral-window exposure, Fredholm-handoff exposure, transport, replay, provenance, and local naming for BEDC.Derived.RieszSchauderTheoryUp.

Chapter 8708

A Concrete Naming Certificate for $\mathsf{CompactOpenExponentialLaw}^{\uparrow}$

Following Kelley, the $\mathsf{CompactOpenExponentialLaw}^{\uparrow}$ packet records the classical compact-open exponential law as finite NameCert data: a continuous map out of a product is compared with its curried continuous map into a compact-open function space only through displayed compact-open subbasic rows, continuity rows, Kelleyfication boundary rows, transport, replay, provenance, and local naming. It sits after the compact-open topology surface of chapter 4138, the Kelleyfication boundary of chapter 6830, and the continuous-map interface of chapter 130. The chapter names the finite topology-facing adjunction packet; it is not host cartesian closedness, a global mapping-space equality, selected compactly generated replacement, quotient function equality, countable choice, or Lean bridge verification.

Definition 8708.1 (Compact-open exponential law carrier)**.** *A* $\mathsf{CompactOpenExponentialLaw}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (X, Y, Z, P, E, U, V, K, A, H, C, Q, N)$$

with the following displayed rows:

1. *X, Y, Z are the source, exponent, and target space rows inspected by the law.*
2. *P is the finite product-window row, recording the displayed reads of $X \times Y$ before any curried map is exposed.*
3. *E is the evaluation row, naming the comparison between a map $X \times Y \to Z$ and a map $X \to Z^Y$ through finite observations.*
4. *U is the* $\mathsf{CompactOpenTopology}^{\uparrow}$ *row, listing the compact-open subbasic windows used on the function-space side.*
5. *V is the* $\mathsf{ContinuousMap}^{\uparrow}$ *row, recording continuity for the uncurried and curried maps only through the public continuous-map interface.*
6. *K is the* $\mathsf{Kelleyfication}^{\uparrow}$ *boundary row, recording the compactly generated read when the compact-open topology must be sealed before the adjunction is public.*
7. *A is the adjunction comparison row, storing the two displayed directions of the compact-open exponential law.*

8. *H records componentwise* hsame *transport for spaces, product windows, evaluation, compact-open rows, continuous-map rows, Kelleyfication rows, adjunction rows, replay, provenance, and local naming.*
9. *C records displayed* Cont *replay from any law-facing read through $P, E, U, V, K, A, H, Q, N$ in that order.*
10. *Q is the* Pkg *provenance over* $\mathsf{CompactOpenExponentialLaw}^{\uparrow}$, $\mathsf{CompactOpenTopology}^{\uparrow}$, $\mathsf{Kelleyfication}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{CompactOpenExponentialLaw}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $X, Y, Z, P, E, U, V, K, A, H, C, Q, N$. It has no coordinate for host cartesian closedness, quotient function equality, selected compactly generated replacements, global mapping-space equality, countable choice, or bridge verification.

Theorem 8708.2 (Compact-open exponential law NameCert obligations)**.** *For every accepted* $\mathsf{CompactOpenExponentialLaw}^{\uparrow}$ *carrier*

$$L = (X, Y, Z, P, E, U, V, K, A, H, C, Q, N),$$

the local $\mathsf{NameCert}_{\mathsf{CompactOpenExponentialLaw}^{\uparrow}}$ *surface consists exactly of the following finite obligations:*

1. *carrier admission for the three displayed space rows, product-window row, evaluation row, compact-open row, continuous-map row, Kelleyfication boundary row, adjunction row, transport, replay, provenance, and local naming;*
2. *compact-open exposure through U, requiring every function-space observation to be read through the compact-open subbasic rows of chapter 4138;*
3. *continuous-map compatibility through V, requiring the uncurried and curried reads to use the public continuous-map interface of chapter 130;*
4. *Kelleyfication nonescape through K, requiring the compactly generated boundary of chapter 6830 before a topology-facing adjunction read is exported;*
5. *adjunction exactness through A, requiring both directions of the exponential-law comparison to preserve the same product, evaluation, compact-open, continuous-map, Kelleyfication, transport, replay, provenance, and local naming rows.*

No compact-open exponential-law obligation is stored outside these rows.

Proof. Project the carrier in Definition 8708.1. The accepted packet exposes exactly the rows $X, Y, Z, P, E, U, V, K, A, H, C, Q, N$, so carrier admission and local naming attach to those rows and to no hidden function-space object.

The compact-open obligation is read through U. Its subbasic windows are the only function-space topology coordinates available to the packet, and they are already routed through chapter 4138.

The continuity obligation is read through V. Both the uncurried and curried sides use the same public continuous-map interface, so the packet does not introduce host continuity or quotient equality of maps.

The Kelleyfication row K is the boundary before the adjunction becomes topology-facing. It records the compactly generated read supplied by chapter 6830 without selecting an external replacement.

Finally the adjunction row A compares the two displayed directions and the structural rows H, C, Q, N preserve that comparison under transport, replay, provenance, and local naming. Since the refused host endpoints have no carrier coordinate, the listed obligations exhaust the local NameCert surface. □

Theorem 8708.3 (Compact-open exponential law Kelley adjunction)**.** *Let* $L = (X, Y, Z, P, E, U, V, K, A, H, C, Q, N$ *be an accepted* $\mathsf{CompactOpenExponentialLaw}^{\uparrow}$ *carrier. Any law-facing read that exports the compact-open exponential comparison must first pass through the finite route*

$$P \longrightarrow E \longrightarrow U \longrightarrow V \longrightarrow K \longrightarrow A.$$

Thus the packet presents the Kelley-style adjunction only as a displayed compact-open and continuous-map route sealed by the Kelleyfication boundary; it exports no host cartesian-closed structure, global mapping-space equality, selected compactly generated replacement, quotient function equality, countable choice, or bridge credential.

Proof. Start with a law-facing consumer of the accepted carrier. By Definition 8708.2, the consumer can inspect the law only through the visible rows of L.

The route begins with the finite product and evaluation rows P and E. These rows display the uncurried input and the evaluation comparison before any function-space topology is available.

The compact-open and continuous-map rows come next. The row U supplies the subbasic topology observations, and V records that both sides of the comparison are read through the continuous-map interface.

The Kelleyfication boundary K then seals the topology-facing read. Only after that boundary is present may A expose the two directions of the compact-open exponential comparison.

The structural rows H, C, Q, N transport, replay, source, and name the same route. Because no host cartesian closedness, global mapping-space equality, selected replacement, quotient function equality, countable-choice schedule, or bridge credential appears in the carrier, the exported adjunction is exactly the displayed route. □

Falsifiable prediction: Every public $\mathsf{CompactOpenExponentialLaw}^{\uparrow}$ read factors through displayed product-window, evaluation, $\mathsf{CompactOpenTopology}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{Kelleyfication}^{\uparrow}$, adjunction, hsame, Cont, Pkg, and local NameCert rows. A public read that exports host cartesian closedness, global mapping-space equality, selected compactly generated replacement, quotient function equality, countable choice, or bridge verification from this packet refutes the carrier boundary.

Independence witness: compact-open-topology, kelleyfication, continuousmap: $\mathsf{CompactOpenExponentialLaw}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries product-window, evaluation, compact-open, continuous-map, Kelleyfication, adjunction, transport, replay, provenance, and local naming rows, while the siblings isolate topology generation, compactly generated sealing, or the continuous-map interface without the exponential-law comparison.

Closure status for $\mathsf{NameCert}_{\mathsf{CompactOpenExponentialLaw}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CompactOpenExponentialLaw}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8708.1 and Definition 8708.2 seed the finite compact-open exponential-law packet over product windows, evaluation, compact-open topology, continuous-map compatibility, Kelleyfication boundary, adjunction, transport, replay, provenance, and local naming rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CompactOpenExponentialLaw}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim host cartesian closedness, global mapping-space equality, selected compactly generated replacement, quotient function equality, countable choice, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, compact-open exposure, continuous-map compatibility, Kelleyfication nonescape, adjunction exactness, transport, replay, provenance, and local naming for BEDC.Derived.CompactOpenExp

Constructive story: A CompactOpenExponentialLaw$^{\uparrow}$ packet is generated from source, exponent, target, finite product-window, evaluation, CompactOpenTopology, ContinuousMap, Kelleyfication, adjunction comparison, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert rows.

Chapter 8709

A Concrete Naming Certificate for EilenbergVariety$^{\uparrow}$

Following Eilenberg's variety theorem for regular languages, the EilenbergVariety$^{\uparrow}$ packet records the finite NameCert surface where a family of regular-language rows and their syntactic-monoid classifiers are read together under boolean closure, quotient closure, and inverse-morphism closure. It sits beside the accepted-word packet of chapter 351, the right-congruence classifier of chapter 5729, the canonical deterministic presentation of chapter 6188, the finite classifier monoid of chapter 6302, and the finite-control surface of chapter 2364. The chapter names the displayed handoff between language families and finite syntactic monoid rows; it does not import a host powerset of all languages, arbitrary quotient languages, infinite alphabets, or an ambient pseudovariety theorem.

Definition 8709.1 (Eilenberg variety carrier)**.** *An* EilenbergVariety$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$V = (A, L, M, C, Q, I, H, R, P, N)$$

with the following displayed rows:

1. *A is the finite alphabet-family row, naming the displayed alphabets and finite alphabet morphisms available to the packet.*
2. *L is the regular-language family row, whose entries are accepted* RegularLanguage$^{\uparrow}$ *observations over the alphabets named by A.*
3. *M is the syntactic-monoid family row, assigning to each displayed language row its finite* SyntacticMonoid$^{\uparrow}$ *classifier.*
4. *C is the closure ledger for finite union, finite intersection, and complement inside the displayed language rows.*
5. *Q is the quotient ledger for displayed left and right word quotients, read through the finite right-congruence rows of* MyhillNerode$^{\uparrow}$ *and the canonical presentations of* MinimalDfa$^{\uparrow}$.
6. *I is the inverse-morphism ledger, recording how a displayed finite alphabet morphism pulls a displayed regular-language row back to another displayed regular-language row.*
7. *H records componentwise* hsame *transport for alphabet-family, regular-language, syntactic-monoid, boolean-closure, quotient, inverse-morphism, replay, provenance, and local naming rows.*

8. *R records displayed* Cont *replay from accepted-word observations through the Myhill–Nerode, minimal-DFA, finite-automaton, and syntactic-monoid handoff rows.*
9. *P is the* Pkg *provenance over* $\mathsf{EilenbergVariety}^{\uparrow}$, $\mathsf{RegularLanguage}^{\uparrow}$, $\mathsf{MyhillNerode}^{\uparrow}$, $\mathsf{MinimalDfa}^{\uparrow}$, $\mathsf{SyntacticMonoid}^{\uparrow}$, $\mathsf{FiniteAutomaton}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{EilenbergVariety}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $A, L, M, C, Q, I, H, R, P, N$. It has no coordinate for a host language powerset, arbitrary infinite alphabet family, selected quotient representatives outside the displayed ledgers, external monoid pseudovariety, or global star-free equivalence claim.

Theorem 8709.2 (Eilenberg variety NameCert obligations)**.** *For every accepted* $\mathsf{EilenbergVariety}^{\uparrow}$ *carrier $V = (A, L, M, C, Q, I, H, R, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{EilenbergVariety}^{\uparrow}}$ *surface consists exactly of finite alphabet-family exposure, regular-language row exposure, syntactic-monoid classifier exposure, boolean-closure replay, left and right quotient replay, inverse-morphism replay, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming.*

Proof. Project the carrier of Definition 8709.1. The rows A, L, M expose the finite alphabet family, the displayed regular-language observations, and the finite syntactic monoid classifiers attached to those observations.

Read C, Q, I next. The boolean ledger C records only finite union, finite intersection, and complement among displayed rows; the quotient ledger Q uses the Myhill–Nerode and minimal-DFA rows to name left and right quotient replay; the inverse-morphism ledger I follows displayed finite alphabet morphisms back to displayed language rows.

The structural rows H, R, P, N transport, replay, source, and name the same finite packet. Since the carrier has no coordinate for a host language powerset, infinite alphabet family, external quotient representative, pseudovariety oracle, or global star-free theorem, the listed rows exhaust the NameCert obligations. □

Theorem 8709.3 (Eilenberg variety syntactic-monoid handoff)**.** *Every* $\mathsf{SyntacticMonoid}^{\uparrow}$, $\mathsf{MyhillNerode}^{\uparrow}$, $\mathsf{MinimalDfa}^{\uparrow}$, $\mathsf{FiniteAutomaton}^{\uparrow}$, *or* $\mathsf{RegularLanguage}^{\uparrow}$ *consumer of an accepted* $\mathsf{EilenbergVariety}^{\uparrow}$ *packet first reads the displayed alphabet-family row, regular-language family row, syntactic-monoid family row, boolean-closure ledger, quotient ledger, and inverse-morphism ledger. The handoff through chapter 351, chapter 5729, chapter 6188, chapter 6302, and chapter 2364 therefore exports only the finite regular-language and classifier-monoid route.*

Proof. Start with an accepted packet $V = (A, L, M, C, Q, I, H, R, P, N)$. A regular-language consumer reads each language row from L only after the finite alphabet-family row A has fixed the displayed alphabet.

The Myhill–Nerode and minimal-DFA consumers then read the quotient ledger Q as a finite classifier replay boundary. The finite-automaton consumer receives only the displayed deterministic presentations already licensed by those right-congruence and accepted-word rows.

Finally, the syntactic-monoid consumer reads M as the finite classifier-monoid family attached to L, with C and I describing only displayed closure and inverse-morphism replay. Thus the packet supplies the Eilenberg handoff as finite BEDC rows, not as a host powerset of languages, a selected family of all quotients, or an external pseudovariety theorem. □

Closure status for $\mathsf{NameCert}_{\mathsf{EilenbergVariety}^{\uparrow}}$**.**

Constructive story: An EilenbergVariety$^{\uparrow}$ packet is generated from finite alphabet-family rows, regular-language family rows, syntactic-monoid classifier rows, boolean-closure ledgers, quotient ledgers, inverse-morphism ledgers, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert rows.

Theory closure: TheoryGate(NameCert$_{\text{EilenbergVariety}\uparrow}$, seed)

Scope closed: Definition 8709.1, Definition 8709.2, and Definition 8709.3 seed the finite regular-language variety handoff across RegularLanguageUp, MyhillNerodeUp, MinimalDfaUp, SyntacticMonoidUp, and FiniteAutomatonUp rows.

Formal verification: FormalStatus(NameCert$_{\text{EilenbergVariety}\uparrow}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close Lean verification, a host variety theorem over all regular languages, star-free or aperiodic classification, external monoid pseudovarieties, infinite alphabet families, arbitrary quotient representatives, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, regular-language family exposure, syntactic-monoid classifier exposure, boolean closure, quotient replay, inverse-morphism replay, sibling handoff, transport, replay, provenance, and local naming for BEDC.Derived.EilenbergVarietyUp.

Chapter 8710

A Concrete Naming Certificate for $\mathsf{BishopRegularCompletion}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{BishopRegularCompletion}^{\uparrow}$ packet records the base regular-completion boundary for rational names as finite BEDC NameCert data. It sits before the reflector route of chapter 6545, the functor handoff of chapter 7003, and the modulus refinement of chapter 8393; it reads dyadic tolerances from chapter 291, finite observation windows from chapter 126, regular rational readback from chapter 301, and the terminal real-name seal from chapter 38. The packet names the shared L10 completion surface refined by those siblings; it does not quotient Cauchy streams, select limits, use countable choice, assert host real equality, or claim ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 8710.1 (Bishop regular completion carrier)**.** *A* $\mathsf{BishopRegularCompletion}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (D, S, R, E, H, C, P, N)$$

with the following displayed rows:

1. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, listing the dyadic radii, comparison budgets, and triangle slack inspected by a regular completion request.*
2. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row, exposing exactly the stream entries visible at the requested precision.*
3. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row obtained from the same windows and dyadic tolerance ledger.*
4. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row, available only after D, S, R have all been displayed.*
5. *H records componentwise* hsame *transport for the dyadic ledger, finite windows, regular readback, Real seal, replay, provenance, and local naming rows.*
6. *C records displayed* Cont *replay from a precision request through*

$$D, S \longmapsto R \longmapsto E \longmapsto H, P, N.$$

7. *P is the* Pkg *provenance over* $\mathsf{BishopRegularCompletion}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
8. *N is the local* $\mathsf{NameCert}_{\mathsf{BishopRegularCompletion}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through D, S, R, E, H, C, P, N. It has no coordinate for quotient stream equality, a selected representative in a host completion, countable choice, trichotomy, host real equality, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 8710.2 (Bishop regular completion NameCert obligations)**.** *For every accepted* $\mathsf{BishopRegularCompletion}$ *carrier*

$$B = (D, S, R, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{BishopRegularCompletion}^{\uparrow}}$ *surface consists exactly of the following obligation rows:*

1. *carrier admission for the dyadic tolerance ledger, finite stream windows, regular rational readback, terminal Real seal, transport, replay, provenance, and local naming rows;*
2. *finite-window exposure, requiring every completion-facing request to inspect S before the readback row R is consumed;*
3. *dyadic tolerance exactness, requiring D to supply the same budget used by the stream-window comparison and the regular rational readback;*
4. *Real seal nonescape, requiring E to be read only after D, S, R have been displayed and replayed through H, C, P, N;*
5. *exclusion of quotient stream equality, selected limits, countable choice, trichotomy, host real equality, and ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the carrier of Definition 8710.1. Its analytic rows are exactly D, S, R, E, with H, C, P, N supplying transport, replay, provenance, and local naming.

The source side begins with D and S. The dyadic ledger fixes the tolerance budget for the request, while the stream-window row fixes the finite observations allowed at that budget.

The regular readback row R is downstream of those source rows. Thus a completion-facing consumer receives regular rational data only through the displayed dyadic and stream evidence.

Finally, the terminal seal E is reached only after the same route has been replayed and named. Since the carrier contains no coordinate for quotient equality, a selected host limit, countable choice, trichotomy, host equality, or ambient completeness, those principles are outside the local certificate. □

Theorem 8710.3 (Bishop regular completion RegSeqRat seal)**.** *Every accepted* $\mathsf{BishopRegularCompletion}^{\uparrow}$ *packet reads its regular rational input through the finite route*

$$\mathsf{DyadicRatCore}^{\uparrow}, \quad \mathsf{StreamName}^{\uparrow}, \quad \mathsf{RegSeqRat}^{\uparrow}$$

displayed by D, S, R, H, C, P, N. The row R may be consumed as a regular rational readback for completion-facing arguments only after the dyadic tolerance ledger and finite stream window have been exposed.

Proof. Apply Definition 8710.2. The finite-window exposure clause places S before R, and the dyadic tolerance exactness clause places D before both the window comparison and the readback.

Rows H, C, P, N then transport, replay, source, and name the same route. They do not add a quotient of streams or a selected representative, so the RegSeqRat seal remains the displayed finite handoff from dyadic tolerance and stream-window data to regular rational readback. □

Theorem 8710.4 (Bishop regular completion Real handoff)**.** *Every* $\mathsf{Real}^{\uparrow}$ *consumer of an accepted* $\mathsf{BishopRegularCompletion}^{\uparrow}$ *carrier reads the route*

$$\mathsf{DyadicRatCore}^{\uparrow}, \quad \mathsf{StreamName}^{\uparrow}, \quad \mathsf{RegSeqRat}^{\uparrow}, \quad \mathsf{Real}^{\uparrow}$$

through the displayed rows D, S, R, E, H, C, P, N. This handoff is the base boundary refined by chapter 6545, chapter 7003, and chapter 8393; it exports no quotient completion, selected limit, countable-choice functional, host real equality, trichotomy, or ambient completeness theorem.

Proof. Use Definition 8710.3. The Real-facing route already passes through dyadic tolerance, finite stream inspection, and regular rational readback.

The Real seal nonescape clause of Definition 8710.2 places E after those rows and after replay through H, C, P, N. The reflector, functor, and modulus chapters may refine this handoff by adding their own rows, but they still consume the same displayed base boundary.

Hence a Real-facing consumer receives only the finite Bishop regular completion packet. Any claim about quotient completions, selected limits, countable choice, host real equality, trichotomy, or ambient completeness is absent from the carrier. □

Falsifiable prediction: Every accepted $\mathsf{BishopRegularCompletion}^{\uparrow}$ read exposes a DyadicRatCore tolerance ledger, StreamName finite-window row, RegSeqRat readback row, RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert row before any reflector, functor, or modulus refinement is consumed.

Independence witness: dyadicratcore, streamname, regseqrat, real, bishop-regular-completion-reflector, bishop-regular-completion-functor, bishop-regular-completion-modulus: $\mathsf{BishopRegularCompletion}^{\uparrow}$ is not bijective to any listed sibling because it binds dyadic tolerance, finite windows, regular rational readback, terminal Real sealing, transport, replay, provenance, and local naming as the shared base completion boundary.

Closure status for $\mathsf{NameCert}_{\mathsf{BishopRegularCompletion}^{\uparrow}}$.

Constructive story: A $\mathsf{BishopRegularCompletion}^{\uparrow}$ packet is generated from a DyadicRatCore tolerance ledger, StreamName finite windows, RegSeqRat readback, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BishopRegularCompletion}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8710.1, Definition 8710.2, Definition 8710.3, and Definition 8710.4 seed the base Bishop regular completion boundary refined by the reflector, functor, and modulus siblings.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BishopRegularCompletion}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim quotient completion equality, selected limits, countable choice, host real equality, trichotomy, ambient RealUp completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, finite-window exposure, dyadic tolerance exactness, RegSeqRat readback, RealUp seal nonescape, replay, provenance, and local naming for BEDC.Derived.BishopRegularCompletionUp.

Chapter 8711

A Concrete Naming Certificate for CompactUniformModulusExtraction$^{\uparrow}$

Following Bishop and Bridges on compact metric uniform continuity, the CompactUniformModulusExtraction$^{\uparrow}$ packet records the finite extraction route from compact nets and pointwise continuity data to a tolerance-only uniform-modulus readback. It sits over the compact metric source of chapter 60, the continuous-map local-radius surface of chapter 59, the dyadic tolerance ledger of chapter 291, the regular rational readback of chapter 301, and the terminal Real seal of chapter 38. The packet is the concrete NameCert handoff for chapter 9237; it does not choose a global modulus from outside the displayed finite data.

Definition 8711.1 (Compact uniform modulus extraction carrier)**.** *A* CompactUniformModulusExtraction$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$U = (K, L, D, F, Q, R, H, C, P, N)$$

with the following displayed rows:

1. *K is the compact-net row, carrying the finite* ProbeBundle *centers, coverage witnesses, and compact-metric source data used by the extraction.*
2. *L is the* CFun$^{\uparrow}$ *local-radius row, recording the pointwise radius data and graph certificate consumed at each displayed center.*
3. *D is the* DyadicRatCore$^{\uparrow}$ *tolerance row, carrying the requested output tolerance, radius slack, and finite lower-bound comparisons.*
4. *F is the finite fold row over the compact net, retaining the minimum positive radius ledger obtained from the displayed centers.*
5. *Q is the* RegSeqRat$^{\uparrow}$ *readback row for the folded precision and the local regular-rational comparisons.*
6. *R is the terminal* Real$^{\uparrow}$ *seal row, available only after K, L, D, F, Q have all been displayed.*
7. *H records componentwise* hsame *transport for the compact-net, local-radius, dyadic, fold, readback, Real seal, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from a tolerance request through the compact-net fold and into the uniform-modulus readback.*

9. *P is the* Pkg *provenance over* $\mathsf{CompactUniformModulusExtraction}^{\uparrow}$, $\mathsf{Compact}^{\uparrow}$, $\mathsf{CFun}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*
10. *N is the local* $\mathsf{NameCert}_{\mathsf{CompactUniformModulusExtraction}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through $K, L, D, F, Q, R, H, C, P, N$. It has no coordinate for open-cover choice, selected external moduli, quotient equality of real names, trichotomy, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 8711.2 (Compact uniform modulus extraction obligations)**.** *For every accepted* CompactUniformModulus *carrier $U = (K, L, D, F, Q, R, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{CompactUniformModulusExtraction}^{\uparrow}}$ *surface consists exactly of compact-net admission through K, local-radius exposure through L, dyadic tolerance and slack readback through D, finite lower-bound folding through F, regular rational readback through Q, Real sealing through R, componentwise transport through H, displayed replay through C, provenance through P, and local naming through N. A uniform-modulus consumer therefore receives only the finite route*

$$K, L, D \longmapsto F \longmapsto Q \longmapsto R, H, C, P, N.$$

Proof. Project the carrier of Definition 8711.1. The compact-net row K supplies the finite center family and coverage witnesses, while L supplies the local continuous-map radius data attached to those centers.

Read the dyadic tolerance row D. It is the only tolerance budget available to the extraction, and the finite fold row F records the lower-bound ledger obtained by comparing the displayed positive radii.

The regular rational readback Q and terminal Real seal R are downstream of that fold. Transport, replay, provenance, and local naming through H, C, P, N preserve the same displayed packet.

Since no row stores open-cover choice, an external modulus selector, quotient equality, trichotomy, countable choice, or ambient Real completeness, the listed coordinates exhaust the NameCert obligations. □

Theorem 8711.3 (Compact uniform modulus Real-seal route)**.** *Every Real-facing read from an accepted* $\mathsf{CompactUniformModulusExtraction}^{\uparrow}$ *packet must expose the compact-net row K, continuous-map local-radius row L,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row D, finite lower-bound fold F, and* $\mathsf{RegSeqRat}^{\uparrow}$ *readback Q before the terminal* $\mathsf{Real}^{\uparrow}$ *seal R is consumed. The route exports a displayed uniform-modulus handoff and no open-cover choice principle, selected external modulus, quotient real equality, countable-choice schedule, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness theorem.*

Proof. Apply the obligation theorem Definition 8711.2. It places K, L, D before the fold row F, and places F before the regular rational readback Q.

The Real seal R is therefore downstream of compact-net coverage, local continuity radii, dyadic tolerance comparison, and folded precision readback. A Real-facing consumer cannot inspect the terminal seal before those rows have been displayed in the same packet.

Finally replay H, C, P, N. These rows transport, replay, source, and name the finite route but do not add open-cover choice, external modulus selection, quotient equality, countable choice, or ambient completeness. The Real-facing handoff is exactly the displayed compact-net extraction route. □

Falsifiable prediction: Every accepted $\mathsf{CompactUniformModulusExtraction}^{\uparrow}$ consumer must display compact-net rows, ContinuousFunction local-radius rows, DyadicRatCore tolerance rows, finite lower-bound fold rows, RegSeqRat readback, a RealUp seal, componentwise hsame transport,

displayed Cont replay, Pkg provenance, and a local NameCert row before a uniform-modulus readback is public.

Independence witness: compact, continuous, dyadicratcore, regseqrat, real: $\mathsf{CompactUniformModulusExtraction}^{\uparrow}$ is not bijective to any listed sibling because it binds compact-net coverage, local continuous radii, dyadic tolerance comparison, finite lower-bound folding, regular rational readback, terminal Real sealing, transport, replay, provenance, and local naming as one extraction carrier.

Closure status for $\mathsf{NameCert}_{\mathsf{CompactUniformModulusExtraction}^{\uparrow}}$.

Constructive story: A $\mathsf{CompactUniformModulusExtraction}^{\uparrow}$ packet is generated from compact-net coverage, ContinuousFunction local-radius rows, DyadicRatCore tolerance comparison, finite lower-bound folding, RegSeqRat readback, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CompactUniformModulusExtraction}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8711.1, Definition 8711.2, and Definition 8711.3 seed the finite extraction route from compact nets and local continuity radii to a uniform-modulus readback.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CompactUniformModulusExtraction}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim open-cover choice, an external modulus selector, quotient equality of Real names, trichotomy, countable choice, ambient RealUp completeness, Lean theorem checking, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, compact-net coverage, local-radius exposure, dyadic tolerance exactness, finite fold stability, RegSeqRat readback, Real seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.CompactUniformModulusExtractionUp.

Chapter 8712

A Concrete Naming Certificate for $\mathsf{CauchyProductUniformCompletion}^{\uparrow}$

Following Bishop and Bridges on products of regular Cauchy names and uniform completions, the $\mathsf{CauchyProductUniformCompletion}^{\uparrow}$ packet records the finite route by which paired Cauchy-product rows are transported into the current L10 uniform-completion boundary. It sits after the product source of chapter 464, the regular product route of chapter 461, the product-completion fusion of chapter 7495, the uniform completion handoff of chapter 6282, and the Bishop regular completion boundary of chapter 8710. The packet exposes product-uniform completion transport without quotient pairs, selected limits, host product equality, or ambient completeness.

Definition 8712.1 (Cauchy product uniform completion carrier)**.** *A* $\mathsf{CauchyProductUniformCompletion}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$P = (A, B, J, U, D, S, Q, R, H, C, G, N)$$

with the following displayed rows:

1. *A is the* $\mathsf{CauchyProduct}^{\uparrow}$ *source row carrying the paired Cauchy product data.*
2. *B is the* $\mathsf{RegularCauchyProduct}^{\uparrow}$ *regularity row, recording the product-facing regular Cauchy witness before completion transport.*
3. *J is the* $\mathsf{CauchyProductCompletionFusion}^{\uparrow}$ *row that synchronizes product-completion and projection data.*
4. *U is the* $\mathsf{UniformCompletionReflector}^{\uparrow}$ *handoff row, read only after A, B, J have exposed the product route.*
5. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger attached to the product and uniform-completion comparisons.*
6. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row for the paired product observations.*
7. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row attached to the same windows and dyadic tolerance budget.*
8. *R is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row for completion-facing product reads.*
9. *H records componentwise* hsame *transport for the product, regularity, fusion, uniform-completion, tolerance, window, readback, Real seal, replay, provenance, and local naming rows.*
10. *C records displayed* Cont *replay from a product-completion request through $A, B, J, U, D, S, Q, R, H$.*

11. *G is the* Pkg *provenance over* CauchyProductUniformCompletion$^{\uparrow}$, CauchyProduct$^{\uparrow}$, RegularCauchyProduct$^{\uparrow}$, CauchyProductCompletionFusion$^{\uparrow}$, UniformCompletionReflector$^{\uparrow}$, BishopRegularCompletion$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, Real$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*
12. *N is the local* NameCert$_{\text{CauchyProductUniformCompletion}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through $A, B, J, U, D, S, Q, R, H, C, G, N$. It has no coordinate for quotient pair representatives, selected completion limits, host product equality, countable choice, trichotomy, or ambient Real$^{\uparrow}$ *completeness.*

Theorem 8712.2 (Cauchy product uniform completion obligations)**.** *For every accepted* CauchyProductUniformCor *carrier $P = (A, B, J, U, D, S, Q, R, H, C, G, N)$, the local* NameCert$_{\text{CauchyProductUniformCompletion}^{\uparrow}}$ *surface consists exactly of Cauchy product admission through A, regular product exposure through B, product-completion fusion through J, uniform-completion handoff through U, dyadic tolerance readback through D, finite product windows through S, regular rational readback through Q, terminal Real sealing through R, componentwise transport through H, displayed replay through C, provenance through G, and local naming through N.*

Proof. Project the carrier of Definition 8712.1. The product rows A, B, J expose the Cauchy product source, regularity witness, and product-completion fusion before any uniform-completion handoff is visible.

Read U, D, S, Q next. The uniform-completion reflector row is tied to the same dyadic tolerance ledger, finite product windows, and regular rational readback, so the transport is not a host-side map between completed quotient pairs.

The terminal Real seal R is downstream of those displayed rows. Transport, replay, provenance, and local naming through H, C, G, N preserve the same finite packet.

Since the classifier has no coordinate for quotient pair representatives, selected completion limits, host product equality, countable choice, trichotomy, or ambient completeness, the listed rows exhaust the local NameCert obligations. □

Theorem 8712.3 (Cauchy product uniform-completion product route)**.** *Every completion-facing product read from an accepted* CauchyProductUniformCompletion$^{\uparrow}$ *carrier factors through the finite route*

CauchyProduct$^{\uparrow}$, RegularCauchyProduct$^{\uparrow}$, CauchyProductCompletionFusion$^{\uparrow}$, UniformCompletionReflector$^{\uparrow}$, DyadicR

The route transports paired Cauchy-product rows to the uniform-completion handoff before the Real seal is public, and it exports no quotient pair, selected product limit, host product equality, countable-choice schedule, or ambient completeness theorem.

Proof. Use the obligation theorem Definition 8712.2. It places the Cauchy product row, regular product row, and product-completion fusion row before the uniform-completion handoff.

Apply the sibling completion boundary of chapter 8710. The dyadic tolerance, StreamName window, RegSeqRat readback, and Real-seal order used there is the same L10 order consumed by the product route.

Now read the product-completion fusion sibling of chapter 7495. It synchronizes product-completion and projection data before any component or product-facing completion consumer can inspect the terminal seal.

Finally replay H, C, G, N. These rows keep the uniform-completion transport attached to the displayed product rows, so the public read is the finite product-uniform route rather than a quotient pair, selected limit, host product equality, choice schedule, or ambient-completeness claim. □

Theorem 8712.4 (Cauchy product uniform completion sibling compatibility)**.** *The* CauchyProductUniformComplet *carrier is compatible with the finite-data product-window route of chapter 34 and the regular sequence common-window route of chapter 5965. Any sibling consumer must keep the product rows A, B, J, the uniform-completion row U, the tolerance and window rows D, S, Q, and the Real seal row R visible before it uses transport, replay, provenance, or local naming.*

Proof. Project the product route theorem Definition 8712.3. It already fixes the order from Cauchy product rows through uniform completion, dyadic tolerances, finite windows, RegSeqRat readback, and the terminal Real seal.

Read the product finite-data route through chapter 34. Its paired-window surface supplies product data only as displayed finite rows, not as hidden host tuples or selected projections.

Read the common-window completion route through chapter 5965. That route keeps StreamName windows, RegSeqRat readback, DyadicRatCore tolerances, and Real seals public before completion-facing comparisons are consumed.

The rows H, C, G, N then transport and name the same packet. Hence every sibling consumer must preserve A, B, J, U, D, S, Q, R before structural replay, and no sibling can replace the route by quotient pairs, selected limits, host product equality, countable choice, or ambient completeness. □

Falsifiable prediction: Every accepted CauchyProductUniformCompletion$^{\uparrow}$ consumer must display CauchyProduct, RegularCauchyProduct, CauchyProductCompletionFusion, UniformCompletionReflector, DyadicRatCore, StreamName, RegSeqRat, RealUp, hsame, Cont, Pkg, and local NameCert rows before a product-uniform-completion read is public.

Independence witness: cauchyproduct, regularcauchyproduct, cauchy-product-completion-fusion, uniform-completion-reflector, bishop-regular-completion, prod, regular-sequence-space: CauchyProductUniformCom is not bijective to any listed sibling because it binds paired Cauchy product rows, product-completion fusion, uniform-completion transport, dyadic tolerances, finite windows, regular rational readback, Real sealing, transport, replay, provenance, and local naming as one product-uniform carrier.

Closure status for NameCert$_{\text{CauchyProductUniformCompletion}^{\uparrow}}$.

Constructive story: A CauchyProductUniformCompletion$^{\uparrow}$ packet is generated from CauchyProduct rows, RegularCauchyProduct regularity, CauchyProductCompletionFusion synchronization, UniformCompletionReflector handoff, DyadicRatCore tolerances, StreamName windows, RegSeqRat readback, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\text{CauchyProductUniformCompletion}^{\uparrow}}$, seed)

Scope closed: Definition 8712.1, Definition 8712.2, Definition 8712.3, and Definition 8712.4 seed the finite product-uniform-completion route for L10 completion consumers.

Formal verification: FormalStatus(NameCert$_{\text{CauchyProductUniformCompletion}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim quotient pair representatives, selected product limits, host product equality, countable choice, trichotomy, ambient RealUp completeness, Lean theorem checking, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, product-row exposure, product-completion fusion, uniform-completion handoff, dyadic tolerance exactness, finite-window readback, RegSeqRat handoff, Real seal nonescape, sibling compatibility, transport, replay, provenance, and local naming for BEDC.Derived.CauchyProductUniformCompletionUp.

Chapter 8713

A Concrete Naming Certificate for $\mathsf{BishopRegularCauchyCofinalStability}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{BishopRegularCauchyCofinalStability}^{\uparrow}$ packet records the finite route by which a regular Cauchy rational name remains stable after a cofinal reindexing of its observation schedule. It sits over the regular rational sequence carrier of chapter 301, the finite stream observations of chapter 126, the dyadic tolerance ledger of chapter 291, the terminal real-name boundary of chapter 38, and the interleaving comparison route of chapter 414. The packet exposes cofinal schedule stability as finite NameCert data; it does not import quotient stream equality, selected subsequences, countable choice, host real equality, or ambient completeness of $\mathsf{Real}^{\uparrow}$.

Definition 8713.1 (Bishop regular Cauchy cofinal stability carrier)**.** *A* $\mathsf{BishopRegularCauchyCofinalStability}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (R, K, D, W, I, E, H, C, P, N)$$

with the following displayed rows:

1. *R is the source* $\mathsf{RegSeqRat}^{\uparrow}$ *regular rational name row.*
2. *K is the cofinal schedule row, recording the finite monotone reindexing windows through which the same tail of R is inspected.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row that fixes the dyadic budget before and after the cofinal schedule is read.*
4. *W is the* $\mathsf{StreamName}^{\uparrow}$ *finite-observation row opened along the schedule K.*
5. *I is the* $\mathsf{RegularCauchyInterleaving}^{\uparrow}$ *comparison row, displaying the interleaving route between the original schedule and the cofinal schedule.*
6. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row reached only after R, K, D, W, I have been exposed.*
7. *H records componentwise* hsame *transport for the source name, cofinal schedule, dyadic budget, finite window, interleaving route, Real seal, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from a Real-facing tolerance request through R, K, D, W, I and then into the terminal seal row E.*
9. *P is the* Pkg *provenance over* $\mathsf{BishopRegularCauchyCofinalStability}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{RegularCauchyInterleaving}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

10. *N is the local* $\mathsf{NameCert}_{\mathsf{BishopRegularCauchyCofinalStability}^{\uparrow}}$ *row.*
The classifier compares accepted packets only through $R, K, D, W, I, E, H, C, P, N$. It has no coordinate for quotient equality of streams, a selected cofinal subsequence, countable-choice schedules, host real equality, or completeness of $\mathsf{Real}^{\uparrow}$.

Lean4 (statement) BEDC.Derived.BishopRegularCauchyCofinalStabilityUp

Theorem 8713.2 (Bishop regular Cauchy cofinal NameCert obligations)**.** *For every accepted* $\mathsf{BishopRegularCauchyCofinalStability}^{\uparrow}$ *carrier $S = (R, K, D, W, I, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{BishopRegularCauchy}}$ *surface consists exactly of carrier admission for the source* $\mathsf{RegSeqRat}^{\uparrow}$ *row R; cofinal schedule exposure through K; dyadic tolerance exposure through D; finite stream-window exposure through W; interleaving comparison through I; Real-seal handoff through E; componentwise* hsame *transport through H; displayed* Cont *replay through C; provenance through P; and local naming through N.*

Proof. Project the carrier in Definition 8713.1. Its displayed packet lists exactly the rows $R, K, D, W, I, E, H, C, P, N$ so any accepted cofinal read begins with the regular rational name, the cofinal schedule, the dyadic budget, and the finite stream window.

The interleaving row gives the comparison surface. It records how the original regular Cauchy schedule and the cofinal schedule are read through the same dyadic tolerance ledger before either route reaches the terminal $\mathsf{Real}^{\uparrow}$ seal.

The support rows preserve that inventory. Componentwise hsame transport, displayed Cont replay, package provenance, and local naming can only replay the displayed rows; since no quotient stream equality, selected subsequence, countable-choice schedule, host real equality, or ambient completeness coordinate occurs in the carrier, the listed rows exhaust the NameCert obligations. □

Theorem 8713.3 (Bishop regular Cauchy cofinal Real seal)**.** *Every* $\mathsf{Real}^{\uparrow}$*-facing read of an accepted* $\mathsf{BishopRegularCauchyCofinalStability}^{\uparrow}$ *carrier $S = (R, K, D, W, I, E, H, C, P, N)$ factors through the finite route*

$$\mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{BishopRegularCauchyCofinalStability}^{\uparrow} \longmapsto \mathsf{RegularCauchyInterleaving}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}.$$

The read exposes the same source regular rational name, cofinal schedule, dyadic tolerance budget, finite StreamName observations, and interleaving route before the terminal Real seal is available. It exports no quotient stream equality, selected cofinal subsequence, countable choice, host real equality, or ambient $\mathsf{Real}^{\uparrow}$ *completeness row.*

Proof. Read the rows R, K, D, W, I, E from the carrier. The source regular rational name R supplies the tail data, K scopes the cofinal reindexing schedule, D fixes the dyadic tolerance, and W exposes only finite observations of that schedule.

Next use the interleaving row I. It places the original and cofinal observations in one finite comparison route before the seal row E is exposed, so a Real-facing consumer cannot read a completed real independently of the displayed schedule.

Finally apply the structural rows H, C, P, N. Transport and replay preserve the same route, while provenance and local naming bind the packet as a $\mathsf{BishopRegularCauchyCofinalStability}^{\uparrow}$ certificate. Because the carrier lacks any quotient, choice-selected, host-equality, or completeness coordinate, the terminal $\mathsf{Real}^{\uparrow}$ seal cannot be reached by an escaping read. □

Closure status for $\mathsf{NameCert}_{\mathsf{BishopRegularCauchyCofinalStability}^{\uparrow}}$.

Constructive story: A BishopRegularCauchyCofinalStability$^{\uparrow}$ packet is generated from a regular rational sequence row, a cofinal schedule row, a dyadic tolerance ledger, finite StreamName observations, a RegularCauchyInterleaving comparison row, a terminal Real seal, componentwise hsame transport, displayed Cont replay, package provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\text{BishopRegularCauchyCofinalStability}^{\uparrow}}$, seed)

Scope closed: Definition 8713.1, Definition 8713.2, and Definition 8713.3 seed the quotient-free cofinal reindexing route for regular Cauchy rational names.

Formal verification: FormalStatus(NameCert$_{\text{BishopRegularCauchyCofinalStability}^{\uparrow}}$, formalTarget)

Lean target: `BEDC.Derived.BishopRegularCauchyCofinalStabilityUp`

Bridge status: none

Not claimed: This chapter does not close quotient stream equality, selected cofinal subsequences, countable-choice schedules, host real equality, ambient Real completeness, theorem-level Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, cofinal schedule exposure, dyadic budget preservation, interleaving route stability, Real-seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.BishopRegularCauch

Chapter 8714

A Concrete Naming Certificate for $\mathsf{CauchyRootTest}^{\uparrow}$

Following Cauchy and Bishop–Bridges constructive analysis, the $\mathsf{CauchyRootTest}^{\uparrow}$ packet records a finite root-test convergence surface for Real-series and Completion-facing consumers. It sits beside the Real-series source of chapter 1581, the Cauchy-series criterion of chapter 2015, the dyadic tolerance ledger of chapter 291, the regular rational readback of chapter 301, the finite stream-window carrier of chapter 126, and the terminal real-name seal of chapter 38. The packet names a displayed root-bound discipline; it does not assert a selected sum, a host limit, countable choice, quotient stream equality, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 8714.1 (Cauchy root test carrier)**.** *A* $\mathsf{CauchyRootTest}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$T = (A, Q, W, D, S, R, E, H, C, P, N)$$

with the following displayed rows:

1. *A is the* $\mathsf{RealSeries}^{\uparrow}$ *source row whose terms are read only through finite probes.*
2. *Q is the root-bound witness row, displaying a dyadic bound below the unit scale and an entry index beyond which the bound applies.*
3. *W is the* $\mathsf{StreamName}^{\uparrow}$ *tail-window row that exposes the finite segment inspected by a precision request.*
4. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger comparing the displayed root bound with the requested tail budget.*
5. *S is the* $\mathsf{CauchySeriesCriterion}^{\uparrow}$ *handoff row certifying that the finite root-bound data supplies the required Cauchy-series tail route.*
6. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row obtained only after the source, root-bound, window, tolerance, and Cauchy-series rows have been exposed.*
7. *E is the* $\mathsf{Real}^{\uparrow}$ *seal reached from the displayed regular rational readback row.*
8. *H records componentwise* hsame *transport for source, root-bound, window, tolerance, Cauchy-series, readback, seal, replay, provenance, and local naming rows.*
9. *C records displayed* Cont *replay from a root-test request through $A, Q, W, D, S, R, E, H, P, N$.*

10. *P is the* Pkg *provenance over* $\mathsf{CauchyRootTest}^{\uparrow}$, $\mathsf{RealSeries}^{\uparrow}$, $\mathsf{CauchySeriesCriterion}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

11. *N is the local* $\mathsf{NameCert}_{\mathsf{CauchyRootTest}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through these rows. It has no coordinate for selected infinite sums, host completeness, quotient stream equality, countable-choice tail selectors, or detached limit objects.

Theorem 8714.2 (Cauchy root test NameCert obligations)**.** *For every accepted* $\mathsf{CauchyRootTest}^{\uparrow}$ *carrier* $T = (A, Q, W, D, S, R, E, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{CauchyRootTest}^{\uparrow}}$ *surface consists exactly of carrier admission for the displayed eleven-row packet,* $\mathsf{RealSeries}^{\uparrow}$ *source exposure, root-bound witness exposure, finite* $\mathsf{StreamName}^{\uparrow}$ *tail-window admission,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance exactness,* $\mathsf{CauchySeriesCriterion}^{\uparrow}$ *handoff,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback,* $\mathsf{Real}^{\uparrow}$ *seal non-escape, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming.*

Proof. Project the carrier of Definition 8714.1. The displayed rows are exactly $A, Q, W, D, S, R, E, H, C, P, N$, so every local obligation must be read from one of those rows.

The convergence read begins with A, Q, W, D. The series source gives the inspected terms, the root-bound row gives the subunit dyadic bound and entry index, the stream row gives the finite tail window, and the dyadic ledger records the tolerance comparisons used by the request.

The handoff row S is then forced through $\mathsf{CauchySeriesCriterion}^{\uparrow}$. It consumes the same source, root-bound, window, and dyadic rows before any regular rational endpoint can be exposed.

Rows R and E terminate the route through $\mathsf{RegSeqRat}^{\uparrow}$ and $\mathsf{Real}^{\uparrow}$. Transport, replay, provenance, and local naming preserve this order, and the carrier contains no row for selected sums, host limits, quotient streams, countable-choice selectors, or ambient completeness. Hence the listed rows exhaust the local NameCert surface. □

Falsifiable prediction: Every accepted $\mathsf{CauchyRootTest}^{\uparrow}$ endpoint read factors through a RealSeries source row, root-bound witness, finite StreamName tail window, DyadicRatCore tolerance ledger, CauchySeriesCriterion handoff, RegSeqRat readback, RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert row.

Independence witness: realseries, cauchy-series-criterion, dyadicratcore, regseqrat, streamname, real: no listed sibling supplies the whole eleven-row packet $T = (A, Q, W, D, S, R, E, H, C, P, N)$, because each sibling contributes only the source series, Cauchy handoff, dyadic tolerance, regular readback, finite stream windows, or endpoint seal while this packet binds them into one finite root-test route.

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyRootTest}^{\uparrow}}$**.**

Constructive story: A $\mathsf{CauchyRootTest}^{\uparrow}$ packet is generated from a RealSeries source row, root-bound witness, finite StreamName tail window, DyadicRatCore tolerance ledger, CauchySeriesCriterion handoff, RegSeqRat readback, RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{CauchyRootTest}^{\uparrow}}$, seed)

Scope closed: Definition 8714.1 and Definition 8714.2 seed the finite root-test convergence route from displayed RealSeries source data through Cauchy-series handoff, regular rational readback, and Real sealing.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{CauchyRootTest}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close selected sums, host limits, quotient stream equality, countable-choice tail selectors, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, source exposure, root-bound exactness, stream-window admission, dyadic tolerance exactness, Cauchy-series handoff, RegSeqRat readback, Real seal non-escape, transport, replay, provenance, and local naming for BEDC.Derived.CauchyRootTestUp.

Chapter 8715

A Concrete Naming Certificate for HyperbolicIdealPentagon$^{\uparrow}$

The HyperbolicIdealPentagon$^{\uparrow}$ packet realizes the five-end boundary-cycle branch of chapter 9463 as finite NameCert data. It sits beside the Poincare-disk geodesic triangle packet of chapter 7891, the boundary-geodesic carrier of chapter 3491, the cross-ratio packet of chapter 3948, the ideal quadrilateral of chapter 7659, and the metric row of chapter 3474. The packet names five displayed boundary endpoints, cyclic side-geodesic incidence, hyperbolic metric comparison, cross-ratio readback, Real-seal rows, TasteGate-facing nontriviality and field-faithfulness requirements, transport, replay, provenance, and local naming; it does not complete an ideal boundary, choose global geodesic representatives, import a host Poincare model theorem, or identify observer expansion with physical spacetime.

Definition 8715.1 (Hyperbolic ideal pentagon carrier)**.** *A* HyperbolicIdealPentagon$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$G = (T, B, S, M, X, Q, R, E, F, H, C, P, N)$$

with the following displayed rows:

1. *T is the* PoincareDiskGeodesicTriangle$^{\uparrow}$ *comparison row used for finite triangular subreads inside the pentagon cycle.*
2. *B is the* HyperbolicGeodesicBoundary$^{\uparrow}$ *row naming five cyclically ordered boundary endpoints.*
3. *S records the five side-geodesic incidence rows and the finite adjacency ledger for the boundary cycle.*
4. *M is the* HyperbolicMetric$^{\uparrow}$ *metric-comparison row over the displayed side and diagonal probes.*
5. *X is the* HyperbolicCrossRatio$^{\uparrow}$ *readback row for the boundary quadruples selected from adjacent pentagon windows.*
6. *Q is the* HyperbolicIdealQuadrilateral$^{\uparrow}$ *compatibility row recording the four-end subcycles used by the same pentagon data.*
7. *R is the* RegSeqRat$^{\uparrow}$ *readback row for finite metric and cross-ratio comparisons.*
8. *E is the* Real$^{\uparrow}$ *seal reached only from the displayed regular rational readback row.*
9. *F records the TasteGate-facing requirements that the ambient scalar rows supply* Nontrivial *and* FieldFaithful *instances before the metric and cross-ratio comparisons are exported.*

10. *H records componentwise* hsame *transport for boundary endpoints, side incidence, metric comparison, cross-ratio readback, quadrilateral compatibility, readback, seal, TasteGate requirements, replay, provenance, and local naming rows.*
11. *C records displayed* Cont *replay from a pentagon-cycle request through $T, B, S, M, X, Q, R, E, F, H, P, N$.*
12. *P is the* Pkg *provenance over* HyperbolicIdealPentagon$^{\uparrow}$, PoincareDiskGeodesicTriangle$^{\uparrow}$, HyperbolicGeodesicBound HyperbolicCrossRatio$^{\uparrow}$, HyperbolicIdealQuadrilateral$^{\uparrow}$, HyperbolicMetric$^{\uparrow}$, RegSeqRat$^{\uparrow}$, Real$^{\uparrow}$, Nontrivial, FieldFaithful, BHist, hsame, Cont, *and* NameCert.
13. *N is the local* NameCert$_{\text{HyperbolicIdealPentagon}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these rows. It has no coordinate for completed boundary quotients, selected geodesic representatives, host Poincare disk theorems, global analytic flow, or physical observer substance.

Theorem 8715.2 (Hyperbolic ideal pentagon NameCert obligations)**.** *For every accepted* HyperbolicIdealPentagon$^{\uparrow}$ *carrier $G = (T, B, S, M, X, Q, R, E, F, H, C, P, N)$, the local* NameCert$_{\text{HyperbolicIdealPentagon}^{\uparrow}}$ *surface is exhausted by triangular subread admission, five-end boundary incidence, side-geodesic visibility, hyperbolic metric comparison, cross-ratio readback, ideal-quadrilateral compatibility, regular rational readback, Real seal non-escape, TasteGate-facing* Nontrivial *and* FieldFaithful *instance requirements, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming.*

Proof. Project the carrier of Definition 8715.1. The rows $T, B, S, M, X, Q, R, E, F, H, C, P, N$ are the only displayed coordinates available to the local certificate.

The boundary-cycle read begins with T, B, S. The triangular row supplies the finite subread discipline, while the boundary row and side-incidence row expose exactly five cyclic endpoints and their adjacent geodesic sides.

Rows M, X, Q supply the geometric comparisons. The metric row reads only the displayed side and diagonal probes, the cross-ratio row reads boundary quadruples selected from finite adjacent windows, and the quadrilateral row checks compatibility with the four-end subcycle surface.

The endpoint readback then passes through R and E, and the TasteGate row F records that nontriviality and field-faithfulness are required before exporting the metric and cross-ratio comparisons. Transport, replay, provenance, and local naming preserve the same route. Since no row stores completed boundary quotients, selected geodesics, host Poincare theorems, global analytic flows, or physical observer substance, the listed rows exhaust the local NameCert surface. □

Falsifiable prediction: Any accepted HyperbolicIdealPentagon$^{\uparrow}$ consumer that exports a five-end boundary-cycle comparison without the side-geodesic incidence row S, the metric row M, the cross-ratio row X, the Real seal E, and the TasteGate-facing row F refutes the carrier surface.

Independence witness: poincare-disk-geodesic-triangle, hyperbolic-geodesic-boundary, hyperbolic-cross-ratio, hyperbolic-ideal-quadrilateral, hyperbolic-metric: no listed sibling is bijective to HyperbolicIdealPentago because this packet alone binds five boundary endpoints, side-geodesic incidence, metric comparison, cross-ratio readback, ideal-quadrilateral compatibility, Real sealing, TasteGate-facing nontriviality and field-faithfulness requirements, transport, replay, provenance, and local naming.

Closure status for NameCert$_{\text{HyperbolicIdealPentagon}^{\uparrow}}$.

Constructive story: A HyperbolicIdealPentagon$^{\uparrow}$ packet is generated from PoincareDiskGeodesicTriangle subreads, HyperbolicGeodesicBoundary five-end incidence, side-geodesic rows, HyperbolicMetric comparisons, HyperbolicCrossRatio readback, HyperbolicIdealQuadrilateral compatibility, RegSeqRat readback, RealUp seal, TasteGate-facing Nontrivial and FieldFaithful requirements, hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\text{HyperbolicIdealPentagon}\uparrow}$, seed)

Scope closed: Definition 8715.1 and Definition 8715.2 seed the finite five-end boundary-cycle route over triangular subreads, boundary incidence, side geodesics, metric comparison, cross-ratio readback, quadrilateral compatibility, Real sealing, TasteGate requirements, transport, provenance, and naming rows.

Formal verification: FormalStatus(NameCert$_{\text{HyperbolicIdealPentagon}\uparrow}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close completed ideal boundaries, quotient endpoint equality, selected global geodesics, host Poincare disk theorems, physical observer dynamics, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked triangular subread admission, five-end boundary incidence, side-geodesic visibility, metric comparison, cross-ratio readback, quadrilateral compatibility, RegSeqRat readback, Real seal non-escape, TasteGate-facing instance requirements, transport, replay, provenance, and local naming for BEDC.Derived.HyperbolicIdealPentagonUp

Chapter 8716

A Concrete Naming Certificate for $\mathsf{ConstructiveCauchyCompletionSelector}^{\uparrow}$

Bishop and Bridges constructive completion practice reads a completed real endpoint through regular Cauchy rational data, finite observation windows, and displayed moduli rather than through quotient streams or selected limits. The $\mathsf{ConstructiveCauchyCompletionSelector}^{\uparrow}$ packet records that selector surface as finite BEDC NameCert data over the regular rational source of chapter 301, the finite stream windows of chapter 126, the dyadic tolerance ledger of chapter 291, the terminal real-name seal of chapter 38, and the equality route of chapter 1874. It names the handoff by which a completion-facing consumer can inspect a regular Cauchy input and its equality discipline without importing quotient stream equality, countable choice, a host limit selector, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 8716.1 (Constructive Cauchy completion selector carrier)**.** *A* $\mathsf{ConstructiveCauchyCompletionSelector}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (R, S, D, E, Q, H, C, P, N)$$

with the following displayed rows:

1. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *source row whose regular rational observations are to be sealed as a completion-facing real name.*
2. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row exposing exactly the inspected source entries at the requested precision.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, including the dyadic radii, slack comparisons, and modulus budgets used by the window read.*
4. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row, reachable only after R, S, D have been displayed.*
5. *Q is the* $\mathsf{CauchyDifferenceCriterion}^{\uparrow}$ *equality route used when two selector packets with displayed regular sources are compared.*
6. *H records componentwise* hsame *transport for the regular source, windows, dyadic ledger, Real seal, equality route, continuation, provenance, and local naming rows.*
7. *C records displayed* Cont *replay from a completion request through*

$$R, S, D \longrightarrow E \longrightarrow Q \longrightarrow H, P, N.$$

8. *P is the* Pkg *provenance over* ConstructiveCauchyCompletionSelector$^{\uparrow}$, RegSeqRat$^{\uparrow}$, StreamName$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, Real$^{\uparrow}$, CauchyDifferenceCriterion$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
9. *N is the local* NameCert$_{\text{ConstructiveCauchyCompletionSelector}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $R, S, D, E, Q, H, C, P, N$. It has no coordinate for quotient stream equality, a selected host limit, countable choice, trichotomy, host real equality, or ambient Real$^{\uparrow}$ *completeness.*

Theorem 8716.2 (Constructive Cauchy completion selector NameCert obligations)**.** *For every accepted* ConstructiveCauchyCompletionSelector$^{\uparrow}$ *carrier $K = (R, S, D, E, Q, H, C, P, N)$, the local* NameCert$_{\text{ConstructiveCauchyCompletionSelector}^{\uparrow}}$ *surface consists exactly of these finite obligations:*

1. *carrier admission for the* RegSeqRat$^{\uparrow}$ *source row,* StreamName$^{\uparrow}$ *finite-window row,* DyadicRatCore$^{\uparrow}$ *tolerance ledger,* Real$^{\uparrow}$ *seal,* CauchyDifferenceCriterion$^{\uparrow}$ *equality route, transport, replay, provenance, and local naming rows;*
2. *source-window exactness, requiring every completion-facing read to expose S as the finite inspection window for R;*
3. *tolerance-ledger exactness, requiring D to supply the dyadic budget consumed by the window read and the terminal seal;*
4. *Real-seal nonescape, requiring E to be read only after R, S, D have been displayed and replayed through H, C, P, N;*
5. *equality-route discipline, requiring any comparison of accepted selector packets to factor through the displayed* CauchyDifferenceCriterion$^{\uparrow}$ *row Q rather than through quotient streams or host real equality.*

No completion selector obligation is stored outside these rows.

Proof. Project the carrier of Definition 8716.1. The source row is R, its finite observations are S, its precision budget is D, and its terminal seal is E.

The source-window and tolerance clauses are row projections. A completion-facing consumer receives the source only through the displayed window and dyadic ledger, so no unbounded stream representative or selected limit can enter the local certificate.

The equality clause is supplied by the CauchyDifferenceCriterion$^{\uparrow}$ row Q. When two accepted selector packets are compared, Q routes the comparison through displayed regular sources, difference data, null evidence, zero-distance handoff, and the Real seal boundary.

Finally replay H, C, P, N. These structural rows preserve the displayed packet componentwise and record its provenance and local name; they do not add quotient stream equality, countable choice, trichotomy, host real equality, or ambient completeness. □

Theorem 8716.3 (Constructive Cauchy completion selector RegSeqRat–Real handoff)**.** *Every* Real$^{\uparrow}$ *consumer of an accepted* ConstructiveCauchyCompletionSelector$^{\uparrow}$ *carrier reads the completion-facing route*

$$\mathsf{RegSeqRat}^{\uparrow}, \quad \mathsf{StreamName}^{\uparrow}, \quad \mathsf{DyadicRatCore}^{\uparrow}, \quad \mathsf{Real}^{\uparrow}$$

through the displayed rows R, S, D, E, H, C, P, N. If the consumer compares two such routes, it must additionally read the CauchyDifferenceCriterion$^{\uparrow}$ *row Q before treating the terminal seals as the same completion endpoint.*

Proof. Start with the NameCert obligations of Definition 8716.2. They place the finite window row S and dyadic tolerance ledger D before the terminal seal E, with R as the only regular rational source.

The handoff to $\mathsf{Real}^{\uparrow}$ is therefore the displayed route R, S, D, E. The transport, replay, provenance, and naming rows keep the same route visible to downstream Real and Completion consumers.

For equality-facing reads, apply the equality-route discipline from the same obligation theorem. The row Q is the only coordinate that compares accepted selector packets, and it is precisely the $\mathsf{CauchyDifferenceCriterion}^{\uparrow}$ route of chapter 1874. Thus the handoff reaches $\mathsf{Real}^{\uparrow}$ without quotient stream equality, selected limits, countable choice, trichotomy, host real equality, or ambient completeness. □

Closure status for $\mathsf{NameCert}_{\mathsf{ConstructiveCauchyCompletionSelector}^{\uparrow}}$.

Constructive story: A $\mathsf{ConstructiveCauchyCompletionSelector}^{\uparrow}$ packet is generated from one RegSeqRat source row, finite StreamName windows, a DyadicRatCore tolerance ledger, one RealUp seal, one CauchyDifferenceCriterion equality route, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{ConstructiveCauchyCompletionSelector}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8716.1, Definition 8716.2, and Definition 8716.3 seed the completion selector route from RegSeqRat through StreamName, DyadicRatCore, Real, CauchyDifferenceCriterion, transport, replay, provenance, and local naming rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{ConstructiveCauchyCompletionSelector}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim quotient stream equality, selected limits, countable choice, trichotomy, host real equality, ambient RealUp completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, source-window exactness, tolerance-ledger exactness, RealUp seal nonescape, equality-route discipline, replay, provenance, and local naming for BEDC.Derived.ConstructiveCauchyCompleti

Chapter 8717

A Concrete Naming Certificate for $\mathsf{HartmanGrobman}^{\uparrow}$

Following Hartman and Grobman on local hyperbolic dynamics, the $\mathsf{HartmanGrobman}^{\uparrow}$ packet records the finite BEDC surface by which a nonlinear local flow near a hyperbolic fixed point is compared with its linearized flow on a displayed conjugacy window. It sits after the ODE source of chapter 193, the local-flow endpoint packet of chapter 1899, the Gronwall comparison surface of chapter 2034, the metric carrier of chapter 57, and the terminal real-name seal of chapter 38. The packet names local linearization data only as finite NameCert rows; it is not a global conjugacy theorem, a selected stable manifold, a host solution operator, or a quotient equality of paths.

Definition 8717.1 (Hartman–Grobman carrier)**.** *A* $\mathsf{HartmanGrobman}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$G = (F, A, L, U, W, O, H, C, P, N)$$

with the following displayed rows:

1. *F is the nonlinear local-flow row, read from the displayed* $\mathsf{Ode}^{\uparrow}$ *source and the* $\mathsf{PicardLindelofLocalFlow}^{\uparrow}$ *endpoint packet on one local time window.*
2. *A is the hyperbolic fixed-point row, recording the fixed point, the local chart basepoint, and the finite spectral separation ledger used by the comparison.*
3. *L is the linearized-flow row, displaying the derivative or linear comparison row on the same chart window.*
4. *U is the local chart row, carrying the metric neighbourhood, coordinate window, and real endpoint reads through* $\mathsf{Met}^{\uparrow}$ *and* $\mathsf{Real}^{\uparrow}$ *rows.*
5. *W is the conjugacy-window row, naming the finite domain on which nonlinear and linear orbit segments are compared.*
6. *O is the orbit-comparison ledger, with the* $\mathsf{GronwallInequality}^{\uparrow}$ *row and tolerance budget used to compare the nonlinear and linear segment reads.*
7. *H records componentwise* hsame *transport for nonlinear flow, hyperbolic fixed point, linearized flow, local chart, conjugacy window, orbit-comparison ledger, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from the ODE source through local flow, linearization, chart restriction, Gronwall comparison, and endpoint sealing.*

9. *P is the* Pkg *provenance over* $\mathsf{HartmanGrobman}^{\uparrow}$, $\mathsf{Ode}^{\uparrow}$, $\mathsf{PicardLindelofLocalFlow}^{\uparrow}$, $\mathsf{GronwallInequality}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

10. *N is the local* $\mathsf{NameCert}_{\mathsf{HartmanGrobman}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $F, A, L, U, W, O, H, C, P, N$. It has no coordinate for global conjugacy, arbitrary invariant manifolds, selected stable or unstable foliations, host solution operators, quotient path equality, or ambient completeness.

Theorem 8717.2 (Hartman–Grobman NameCert obligations)**.** *For every accepted* $\mathsf{HartmanGrobman}^{\uparrow}$ *carrier $G = (F, A, L, U, W, O, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{HartmanGrobman}^{\uparrow}}$ *surface consists exactly of carrier admission; nonlinear local-flow exposure through F; hyperbolic fixed-point exposure through A; linearized-flow exposure through L; local chart exposure through U; conjugacy-window exposure through W; orbit-comparison exactness through O; componentwise transport through H; displayed replay through C; provenance through P; and local naming through N.*

Proof. Project the carrier of Definition 8717.1. The rows $F, A, L, U, W, O, H, C, P, N$ are the complete finite inventory of an accepted packet.

The dynamic rows come first. The nonlinear local-flow row F and linearized-flow row L are read on the same chart row U, while the hyperbolic fixed-point row A supplies the finite separation ledger needed before the two flows can be compared.

The conjugacy-window and orbit-comparison obligations are then exactly W and O. The latter is the only place where Gronwall-style comparison and tolerance data enter the packet.

Finally H, C, P, N transport, replay, source, and name the same displayed rows. Since the carrier has no coordinate for global conjugacy, arbitrary invariant manifolds, selected stable or unstable foliations, host solution operators, quotient path equality, or ambient completeness, none of those objects can become a local NameCert obligation. □

Theorem 8717.3 (Hartman–Grobman linearization window)**.** *Every accepted* $\mathsf{HartmanGrobman}^{\uparrow}$ *local linearization read factors through the finite route*

$$\mathsf{Ode}^{\uparrow} \longmapsto \mathsf{PicardLindelofLocalFlow}^{\uparrow} \longmapsto (A, L, U, W) \longmapsto \mathsf{GronwallInequality}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}.$$

The route exposes the nonlinear local flow, hyperbolic fixed point, linearized flow, chart window, conjugacy window, orbit-comparison ledger, transport, replay, provenance, and local NameCert rows before any downstream stability consumer may treat nonlinear and linear orbit segments as locally conjugate.

Proof. Start with the ODE and local-flow rows. The nonlinear flow read is not a host solution operator; it is the displayed local endpoint route named by F.

Read the fixed-point and chart rows next. The hyperbolic separation ledger A and chart window U place both the nonlinear and linearized rows in the same finite coordinate neighbourhood.

The linearized-flow row L and conjugacy-window row W then delimit the comparison. The orbit-comparison ledger O sends the finite segment estimates through the Gronwall surface before the Real endpoint seal is exposed.

The structural rows H, C, P, N preserve this same route under transport, replay, provenance, and local naming. Thus a stability consumer receives only the displayed local linearization window, not a global conjugacy, selected invariant manifold, quotient path equality, or ambient solution theory. □

Theorem 8717.4 (Hartman–Grobman hyperbolic scope)**.** *Any* $\mathsf{HartmanGrobman}^{\uparrow}$ *consumer that reaches a conjugacy-window row must first expose the hyperbolic fixed-point row* A*, the local chart row* U*, the linearized-flow row* L*, and the orbit-comparison ledger* O*. Consequently the packet supports only local hyperbolic scope: it names a finite comparison window between displayed nonlinear and linear orbit segments and exports no global dynamics, arbitrary invariant manifolds, host solution operators, quotient path equality, or selected stable-manifold data.*

Proof. Project an accepted carrier. The row W is not independent; it is a conjugacy-window coordinate inside the packet $G = (F, A, L, U, W, O, H, C, P, N)$.

The fixed-point and chart rows A, U bind the window to a hyperbolic local neighbourhood. The linearized-flow row L supplies the comparison target, and O supplies the orbit ledger through which the nonlinear and linear segments are compared.

After these rows are visible, H, C, P, N keep the packet stable under transport, replay, provenance, and local naming. No remaining coordinate can extend the read to global dynamics, arbitrary invariant manifolds, host solution operators, quotient path equality, or selected stable-manifold data. □

Falsifiable prediction: An accepted $\mathsf{HartmanGrobman}^{\uparrow}$ read cannot expose a conjugacy-window row without displaying the hyperbolic fixed-point row, local chart row, linearized-flow row, orbit-comparison ledger, transport row, replay row, provenance row, and local NameCert row.

Independence witness: ode, picard-lindelof-local-flow, gronwall-inequality, metric, real

Closure status for $\mathsf{NameCert}_{\mathsf{HartmanGrobman}^{\uparrow}}$.

Constructive story: A $\mathsf{HartmanGrobman}^{\uparrow}$ packet is generated from a nonlinear local-flow row, hyperbolic fixed-point row, linearized-flow row, local chart row, conjugacy-window row, orbit-comparison ledger, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{HartmanGrobman}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8717.1, Definition 8717.2, Definition 8717.3, and Definition 8717.4 seed the finite local hyperbolic linearization packet over nonlinear flow, fixed point, linearized flow, chart, conjugacy window, orbit comparison, transport, replay, provenance, and naming rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{HartmanGrobman}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close global dynamics, arbitrary invariant manifolds, selected stable or unstable manifolds, host solution operators, quotient path equality, Lean verification, axiom-clean audit, or bridge checking.

Upgrade path: Formalization requires a Lean carrier and checked NameCert obligations for BEDC.Derived.HartmanGrobmanUp over local flow, hyperbolic fixed-point, linearized-flow, chart, conjugacy-window, orbit-comparison, transport, replay, provenance, and naming rows.

Chapter 8718

A Concrete Naming Certificate for $\mathsf{MetricPartitionOfUnity}^{\uparrow}$

Following Bourbaki and Bishop–Bridges on metric covers and locally finite analytic gluing, the $\mathsf{MetricPartitionOfUnity}^{\uparrow}$ packet records the finite BEDC route by which a metric-source cover is read as a locally finite subordinate partition certificate. It sits after the metric carrier of chapter 57, the topology carrier of chapter 88, the locally finite cover surface of chapter 7245, the paracompact refinement ledger of chapter 1963, and the partition surface of chapter 3369. The packet names only displayed metric-cover, support, finite-weight, normalization, transport, replay, provenance, and local naming rows; it does not select arbitrary host functions, choose subcovers, import open-cover compactness, or identify analytic functions extensionally.

Definition 8718.1 (Metric partition of unity carrier)**.** *A* $\mathsf{MetricPartitionOfUnity}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$U = (M, T, L, Q, S, W, Z, H, C, P, N)$$

with the following displayed rows:

1. *M is the* $\mathsf{Met}^{\uparrow}$ *source row, exposing the displayed distance, ball, and metric-cover requests whose subordinate weights are being named.*
2. *T is the* $\mathsf{Topology}^{\uparrow}$ *handoff row induced by the metric balls, recording the open-set interpretation used by every cover and support read.*
3. *L is the* $\mathsf{LocallyFiniteCover}^{\uparrow}$ *row, recording the locally finite cover cells, finite neighbourhood witnesses, and assignment back to the metric-cover request.*
4. *Q is the* $\mathsf{Paracompact}^{\uparrow}$ *refinement ledger that keeps the locally finite cover route visible without selecting an arbitrary host subcover.*
5. *S is the subordinate support row, listing for each displayed cover cell the support window in which the corresponding weight row may be nonzero.*
6. *W is the finite weight row, listing the finitely many nonzero weights visible at each displayed metric neighbourhood read.*
7. *Z is the normalization row, recording that the displayed finite weights sum to the unit row on the covered metric region.*
8. *H is componentwise* hsame *transport for $M, T, L, Q, S, W, Z, C, P, N$.*

9. *C is displayed* Cont *replay from the metric-cover request through the locally finite cover, support, weight, and normalization rows.*
10. *P is the* Pkg *provenance over* $\mathsf{MetricPartitionOfUnity}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{Topology}^{\uparrow}$, $\mathsf{LocallyFiniteCover}^{\uparrow}$, $\mathsf{Paracompact}^{\uparrow}$, $\mathsf{PartitionOfUnity}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{MetricPartitionOfUnity}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $M, T, L, Q, S, W, Z, H, C, P, N$. It has no coordinate for a host-selected function family, arbitrary subcover selection, open-cover compactness, unlogged support choice, or extensional equality of real-valued functions.

Theorem 8718.2 (Metric partition of unity NameCert obligations)**.** *For every accepted* $\mathsf{MetricPartitionOfUnity}^{\uparrow}$ *carrier*

$$U = (M, T, L, Q, S, W, Z, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{MetricPartitionOfUnity}^{\uparrow}}$ *surface consists exactly of carrier admission for the metric source row, topology handoff, locally finite cover row, paracompact refinement ledger, subordinate support rows, finite weight rows, normalization row, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. Every partition consumer must read the finite route*

$$M \longmapsto T \longmapsto L, Q \longmapsto S, W, Z \longmapsto H, C, P, N$$

before it treats subordinate weights as metric analytic data.

Proof. Project the carrier of Definition 8718.1. The accepted packet displays exactly the metric source, topology handoff, locally finite cover, paracompact refinement, support, weight, normalization, transport, replay, provenance, and local naming rows.

The metric source row M is read first, and T records the open-set interpretation of the displayed metric balls. The locally finite cover row L and paracompact refinement row Q then supply the cover cells and finite neighbourhood witnesses without adding a host subcover selector.

The subordinate support, weight, and normalization rows are S, W, Z. They expose support containment, the finite list of nonzero weights visible at a displayed metric neighbourhood, and the corresponding sum-to-one row on the covered region.

Finally H, C, P, N transport, replay, source, and name the same finite packet. Since the carrier has no coordinate for arbitrary function selection, open-cover compactness, or extensional equality of functions, the listed rows exhaust the local NameCert surface. □

Theorem 8718.3 (Metric cover partition route)**.** *Every* $\mathsf{PartitionOfUnity}^{\uparrow}$ *or metric-analysis consumer of an accepted* $\mathsf{MetricPartitionOfUnity}^{\uparrow}$ *packet must pass through the* $\mathsf{Met}^{\uparrow}$ *source row, the* $\mathsf{Topology}^{\uparrow}$ *handoff, the* $\mathsf{LocallyFiniteCover}^{\uparrow}$ *row, and the* $\mathsf{Paracompact}^{\uparrow}$ *refinement ledger before reading subordinate supports, finite weights, or normalization data. Thus the metric partition certificate is a finite cover route, not a host construction of real-valued functions.*

Proof. Read the dependency route in Definition 8718.2. It places the metric source M and topology handoff T before the locally finite and refinement rows L, Q.

The rows S, W, Z are downstream of that cover route. A support row is subordinate to a displayed cover cell, a weight row is visible only through the finite neighbourhood witnesses, and the normalization row sums only the displayed finite support.

The final rows H, C, P, N authenticate the same route. Therefore a consumer reaches the partition surface only through the metric and topological cover ledger already named by the packet, with no hidden function family or subcover selection. □

Falsifiable prediction: Every accepted $\mathsf{MetricPartitionOfUnity}^{\uparrow}$ read exposes a MetricSpace source row, Topology handoff, LocallyFiniteCover row, Paracompact refinement ledger, subordinate support rows, finite weight rows, normalization row, hsame transport, Cont replay, Pkg provenance, and local NameCert row before any partition or metric-analysis consumer reads it.

Independence witness: metricspace, topology, locally-finite-cover, paracompact, partition-of-unity: $\mathsf{MetricPartitionOfUnity}^{\uparrow}$ is not bijective to any listed sibling because it jointly binds a metric-source cover, topology handoff, locally finite cover cells, refinement ledger, subordinate support rows, finite weight rows, normalization, transport, replay, provenance, and local naming in one finite certificate.

Closure status for $\mathsf{NameCert}_{\mathsf{MetricPartitionOfUnity}^{\uparrow}}$.

Constructive story: A $\mathsf{MetricPartitionOfUnity}^{\uparrow}$ packet is generated from a MetricSpace source row, Topology handoff, LocallyFiniteCover row, Paracompact refinement ledger, subordinate support rows, finite weight rows, normalization row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{MetricPartitionOfUnity}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8718.1, Definition 8718.2, and Definition 8718.3 seed the finite metric-cover route from metric balls and topological opens to subordinate partition weights.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{MetricPartitionOfUnity}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host-selected function families, arbitrary subcover selection, open-cover compactness, analytic function extensionality, theorem-level Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, metric-source exactness, topology handoff exactness, locally finite cover exactness, subordinate support exactness, finite weight normalization, transport, replay, provenance, and local naming for BEDC.Derived.MetricPartitionOfUnityUp.

Chapter 8719

Bishop Apartness Field Envelope NameCert Construction

Following Bishop and Bridges, the $\mathsf{BishopApartnessFieldEnvelope}^{\uparrow}$ packet records the finite envelope by which a regular real-name surface is admitted to constructive apartness-field use without turning the ambient Real object into a quotient field or a trichotomous ordered field. It sits after the terminal real-name seal of chapter 38, the regular rational readback of chapter 301, and the apartness-real interface of chapter 304. The envelope also exposes the neighboring apartness-budget discipline used by $\mathsf{RegularCauchyApartnessBudget}^{\uparrow}$ consumers, but it names only the finite handoff rows visible to BEDC.

Definition 8719.1 (Bishop apartness field envelope carrier)**.** *A* $\mathsf{BishopApartnessFieldEnvelope}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$E = (Q, R, A, B, F, M, T, C, P, N)$$

with the following displayed rows:

1. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *source row, carrying the regular rational name that later field-facing consumers inspect.*
2. *R is the* $\mathsf{Real}^{\uparrow}$ *seal row, available only after the regular rational readback route has been displayed.*
3. *A is the* $\mathsf{ApartnessReal}^{\uparrow}$ *positive-separation row used when nonzero or inequality evidence is consumed constructively.*
4. *B is the finite apartness-budget row, recording the dyadic or regular-Cauchy tolerance window required before A may be read.*
5. *F is the field-operation envelope row for addition, multiplication, negation, and reciprocal requests that already carry displayed apartness evidence for the reciprocal case.*
6. *M is the mixed handoff row joining regular names, Real seals, apartness evidence, and field-operation requests.*
7. *T records componentwise* hsame *transport for source names, Real seals, apartness evidence, budgets, field-operation rows, mixed handoff rows, continuation rows, provenance, and local naming.*
8. *C records displayed* Cont *replay from a regular name and a positive apartness budget through R, A, B, F, M, T.*

9. *P is the* Pkg *provenance over* $\mathsf{BishopApartnessFieldEnvelope}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{ApartnessReal}^{\uparrow}$, $\mathsf{RegularCauchyApartnessBudget}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{BishopApartnessFieldEnvelope}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $Q, R, A, B, F, M, T, C, P, N$. It has no coordinate for trichotomy, quotient fields, selected reciprocal representatives, host field equality, countable choice, or full $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 (statement) `BEDC.Derived.BishopApartnessFieldEnvelopeUp`

Theorem 8719.2 (Bishop apartness field envelope NameCert obligations)**.** *For every accepted* $\mathsf{BishopApartnessFieldEnvelope}^{\uparrow}$ *carrier $E = (Q, R, A, B, F, M, T, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{BishopApartnessFieldEnvelope}}$ *surface consists exactly of carrier admission, regular rational source readback, Real seal nonescape, apartness-positive evidence, finite apartness-budget exactness, field-operation envelope admission, mixed handoff replay, componentwise transport, package provenance, and local naming.*

Proof. Carrier admission is projection from Definition 8719.1. The source row Q is read first, and the Real seal R remains downstream of the regular rational route.

The apartness row A is not a global order decision. It can be consumed only together with the finite budget B, so reciprocal and inequality-facing uses enter through displayed positive-separation evidence rather than trichotomy or host real equality.

The field-operation row F and mixed handoff row M collect only the operations whose inputs have already exposed the required regular and apartness rows. The structural rows T, C, P, N transport, replay, source, and name the same finite packet. Since no other coordinate is present, the certificate has exactly the stated obligations. □

Theorem 8719.3 (Bishop apartness field envelope regular real handoff)**.** *Every regular-real consumer of an accepted* $\mathsf{BishopApartnessFieldEnvelope}^{\uparrow}$ *carrier reaches the* $\mathsf{Real}^{\uparrow}$ *seal only through the displayed route*

$$Q \longmapsto R \longmapsto M, T, C, P, N.$$

Thus Real and Completion consumers receive a regular rational source row and a finite replay route before the Real-facing seal is visible, and they receive no quotient-field equality, selected representative, countable-choice schedule, or full $\mathsf{Real}^{\uparrow}$ *completeness principle.*

Proof. Start with an accepted carrier $E = (Q, R, A, B, F, M, T, C, P, N)$. The row Q is the only regular rational source coordinate, and R is the only Real seal coordinate.

The mixed handoff row M records how the Real-facing read is joined to the field and apartness envelope, while T and C transport and replay that same route. Provenance and local naming are carried by P and N.

Because no quotient-field object, selected representative, choice schedule, or completeness witness is a coordinate of the carrier, every regular-real handoff reaches the seal only through the displayed finite rows. □

Theorem 8719.4 (Bishop apartness field envelope apartness-field handoff)**.** *Every apartness-field use of an accepted* $\mathsf{BishopApartnessFieldEnvelope}^{\uparrow}$ *carrier must expose the route*

$$A, B, F \longmapsto M, T, C, P, N.$$

In particular, reciprocal-facing field requests are admitted only when the finite apartness-budget row has supplied positive-separation evidence. The envelope does not assert trichotomy, quotient fields, global decidable equality, selected inverses, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the accepted carrier. The apartness-positive row A and finite budget row B are the only coordinates that license a nonzero or inequality read.

The field-operation row F can therefore be consumed only after that apartness evidence is displayed. The mixed handoff row M joins the operation request back to the regular and Real-name route, and T, C, P, N preserve the same finite evidence through transport, replay, provenance, and local naming.

The carrier contains no trichotomy coordinate, quotient-field row, global equality decision, selected inverse, or completeness witness. Apartness-field consumers therefore receive only the displayed constructive handoff. □

Falsifiable prediction: Every $\mathsf{BishopApartnessFieldEnvelope}^{\uparrow}$ consumer factors through one RegSeqRat source row, one RealUp seal row, one ApartnessReal positive-separation row, one finite apartness-budget row, one field-operation envelope row, one mixed handoff row, componentwise hsame transport, Cont replay, Pkg provenance, and local naming.

Independence witness: regseqrat, real, apartnessreal, regular-cauchy-apartness-budget: BishopApartnessFieldEnv is not bijective to any listed sibling because it jointly carries regular rational readback, Real sealing, apartness-positive evidence, finite budget data, field-operation admission, mixed handoff, transport, replay, provenance, and local naming in one envelope.

Closure status for $\mathsf{NameCert}_{\mathsf{BishopApartnessFieldEnvelope}^{\uparrow}}$.

Constructive story: A $\mathsf{BishopApartnessFieldEnvelope}^{\uparrow}$ packet is generated from a RegSeqRat source row, a RealUp seal row, an ApartnessReal positive-separation row, a finite apartness budget, a field-operation envelope, a mixed handoff row, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BishopApartnessFieldEnvelope}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8719.1, Definition 8719.2, Definition 8719.3, and Definition 8719.4 seed the finite constructive bridge from regular real names to apartness-field consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BishopApartnessFieldEnvelope}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close trichotomy, quotient fields, global decidable equality, selected inverses, selected reciprocal representatives, host field equality, countable choice, full RealUp completeness, Lean theorem checking, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, regular rational source readback, Real seal nonescape, apartness-positive evidence, finite apartness-budget exactness, field-operation envelope admission, mixed handoff replay, transport, provenance, and local naming for BEDC.Derived.BishopApartnessFieldEnvelopeUp.

Chapter 8720

A Concrete Naming Certificate for RegularCauchySeparatedFilter$^{\uparrow}$

Following Bishop–Bridges constructive analysis and the Bourbaki separation discipline for uniform completions, the RegularCauchySeparatedFilter$^{\uparrow}$ packet records the finite filter object that sits between regular Cauchy readback and separated completion. It is a neighbor of the CauchyFilterBasis$^{\uparrow}$ route of chapter 1501, the RegularCauchyFilterBasis$^{\uparrow}$ route of chapter 7853, and the separated-completion surface of chapter 1612. The packet keeps window schedules, rational readback, dyadic tolerances, basis observations, separated comparison, Real sealing, transport, replay, provenance, and local naming as displayed rows; it does not introduce quotient filters, selected limits, ambient real equality, countable choice, or host completeness.

Definition 8720.1 (RegularCauchySeparatedFilter carrier)**.** *A* RegularCauchySeparatedFilter$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Q = (S, R, D, B, E, L, H, C, P, N)$$

with the following displayed rows:

1. *S is the* StreamName$^{\uparrow}$ *finite-window schedule naming the regular Cauchy observations that may be read.*
2. *R is the* RegSeqRat$^{\uparrow}$ *readback row attached to the displayed windows.*
3. *D is the* DyadicRatCore$^{\uparrow}$ *tolerance ledger for the same windows and regular-rational reads.*
4. *B is the* CauchyFilterBasis$^{\uparrow}$ *basis-window row whose observations are indexed by S and whose tolerances are supplied by D.*
5. *E is the* SeparatedCompletion$^{\uparrow}$ *comparison row, identifying when two displayed basis windows have zero separated distance inside the completion route.*
6. *L is the terminal* Real$^{\uparrow}$ *seal row reached only after S, R, D, B, E have been displayed.*
7. *H records componentwise* hsame *transport for windows, readback, tolerance, basis windows, separated comparison, Real seal, replay, provenance, and local naming.*
8. *C records displayed* Cont *replay from a filter-window request through regular readback, dyadic tolerance, basis exposure, separated comparison, and Real sealing.*
9. *P records* Pkg *provenance over* RegularCauchySeparatedFilter$^{\uparrow}$, StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, CauchyFilterBasis$^{\uparrow}$, SeparatedCompletion$^{\uparrow}$, Real$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*

10. N is the local $\mathsf{NameCert}_{\mathsf{RegularCauchySeparatedFilter}^{\uparrow}}$ *row.*

The classifier accepts packets only through the ten displayed rows $S, R, D, B, E, L, H, C, P, N$. No coordinate stores a quotient filter, a hidden cofinal family, a selected completion point, host real equality, countable-choice selector, or ambient completeness witness.

Theorem 8720.2 (RegularCauchySeparatedFilter NameCert obligations)**.** *For every accepted* $\mathsf{RegularCauchySeparatedFilter}^{\uparrow}$ *carrier*

$$Q = (S, R, D, B, E, L, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{RegularCauchySeparatedFilter}^{\uparrow}}$ *surface consists exactly of carrier admission for StreamName windows, RegSeqRat readback, DyadicRatCore tolerance, CauchyFilterBasis basis windows, SeparatedCompletion comparison, Real sealing, componentwise transport, displayed replay, package provenance, and local naming. Every completion-facing consumer must first read S, then R and D, then B and E, and only then the structural rows L, H, C, P, N.*

Proof. Project the carrier of Definition 8720.1. The visible source of the packet is the finite window schedule S together with its regular-rational readback R and dyadic tolerance ledger D.

Read the filter-basis and separation rows next. The row B contains exactly the basis observations licensed by the displayed windows, while E records the separated-completion comparison for the same observations. This is the handoff to the separated-completion route of chapter 1612.

Finally consume the Real seal and structural rows. The row L is downstream from S, R, D, B, E, and H, C, P, N only transport, replay, source, and name that same route. Since no excluded quotient, selector, host-equality, choice, or completeness coordinate is present, the listed rows exhaust the local NameCert obligations. □

Closure status for $\mathsf{NameCert}_{\mathsf{RegularCauchySeparatedFilter}^{\uparrow}}$**.**

Constructive story: A $\mathsf{RegularCauchySeparatedFilter}^{\uparrow}$ packet is generated from finite StreamName windows, RegSeqRat readback, a DyadicRatCore tolerance ledger, CauchyFilterBasis basis windows, a SeparatedCompletion comparison row, a RealUp seal, componentwise transport, displayed replay, package provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{RegularCauchySeparatedFilter}^{\uparrow}}$, seed)

Scope closed: Definition 8720.1 and Definition 8720.2 seed the finite regular Cauchy separated-filter route between basis windows and separated completion.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{RegularCauchySeparatedFilter}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close quotient filters, selected completion points, host real equality, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, separated-comparison preservation, readback preservation, Real-seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.RegularCauchySeparatedFilterUp.

Chapter 8721

A Concrete Naming Certificate for $\mathsf{HyperbolicCrossRatioPhase}^{\uparrow}$

The $\mathsf{HyperbolicCrossRatioPhase}^{\uparrow}$ packet realizes the boundary cross-ratio phase branch of chapter 9463 as one finite NameCert surface. It sits after the hyperbolic metric packet of chapter 3474, the visual-boundary route of chapter 4181, the Busemann boundary route of chapter 3732, the boundary-shadow route of chapter 3813, and the Real seal of chapter 38. The packet records phase as finite boundary cross-ratio data with displayed metric, boundary, shadow, transport, replay, provenance, and local naming rows; it is not a selected ideal endpoint, quotient boundary equality, host Mobius geometry, or ambient real-valued phase theory.

Falsifiable prediction: An accepted $\mathsf{HyperbolicCrossRatioPhase}^{\uparrow}$ read is refuted if a consumer exports a boundary cross-ratio phase without first displaying HyperbolicMetric, visual-boundary, Busemann-boundary, boundary-shadow, Real-seal, transport, replay, provenance, and local NameCert rows.

Independence witness: hyperbolicmetric, hyperbolicvisualboundary, hyperbolicbusemannboundary, hyperbolicboundaryshadow, real: none is bijective to $\mathsf{HyperbolicCrossRatioPhase}^{\uparrow}$ because this packet jointly records metric scale, visual-boundary endpoints, Busemann calibration, shadow incidence, phase readback, Real sealing, transport, replay, provenance, and local NameCert rows.

Definition 8721.1 (Hyperbolic cross-ratio phase carrier)**.** *A* $\mathsf{HyperbolicCrossRatioPhase}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$X = (M, V, B, S, Q, R, H, C, P, N)$$

with the following displayed rows:

1. *M is the* $\mathsf{HyperbolicMetric}^{\uparrow}$ *row, naming the finite metric-read surface used by the boundary comparison.*
2. *V is the* $\mathsf{HyperbolicVisualBoundary}^{\uparrow}$ *row, naming the displayed visual-boundary points visible to the packet.*
3. *B is the* $\mathsf{HyperbolicBusemannBoundary}^{\uparrow}$ *row, calibrating the boundary reads through Busemann data.*
4. *S is the* $\mathsf{HyperbolicBoundaryShadow}^{\uparrow}$ *row, recording the shadow incidence attached to the same boundary data.*
5. *Q is the finite cross-ratio phase row, recording the ordered boundary quadruple and its phase readback.*

6. *R is the* $\mathsf{Real}^{\uparrow}$ *seal row reached only after M, V, B, S, Q have been displayed.*
7. *H records componentwise* hsame *transport for metric, visual-boundary, Busemann, shadow, phase, Real seal, replay, provenance, and local naming.*
8. *C records displayed* Cont *replay from a boundary-phase request through metric readback, visual-boundary exposure, Busemann calibration, shadow incidence, phase readback, and Real sealing.*
9. *P records* Pkg *provenance over* $\mathsf{HyperbolicCrossRatioPhase}^{\uparrow}$, $\mathsf{HyperbolicMetric}^{\uparrow}$, $\mathsf{HyperbolicVisualBoundary}^{\uparrow}$, $\mathsf{HyperbolicBusemannBoundary}^{\uparrow}$, $\mathsf{HyperbolicBoundaryShadow}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*
10. *N is the local* $\mathsf{NameCert}_{\mathsf{HyperbolicCrossRatioPhase}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $M, V, B, S, Q, R, H, C, P, N$. It has no coordinate for selected ideal endpoints, quotient boundary equality, host Mobius transformations, hidden phase normalization, or ambient real-valued geometry.

Theorem 8721.2 (Hyperbolic cross-ratio phase NameCert obligations)**.** *For the carrier of Definition 8721.1, the local* $\mathsf{NameCert}_{\mathsf{HyperbolicCrossRatioPhase}^{\uparrow}}$ *surface consists exactly of carrier admission for*

$$X = (M, V, B, S, Q, R, H, C, P, N),$$

metric-read exposure through M, visual-boundary exposure through V, Busemann calibration through B, shadow incidence through S, cross-ratio phase readback through Q, Real sealing through R, componentwise transport through H, displayed continuation replay through C, package provenance through P, and local naming through N.

Proof. Project the carrier of Definition 8721.1. Its visible rows are exactly $M, V, B, S, Q, R, H, C, P, N$.

The boundary comparison side is read through M, V, B, S, Q. The metric row fixes the finite scale surface, the visual-boundary row names the boundary entries, the Busemann row calibrates them, the shadow row records incidence, and the phase row reads the ordered cross-ratio datum.

The Real seal and structural rows are downstream. The row R seals the displayed phase readback, while H, C, P, N preserve, replay, source, and name the same route. Since the carrier has no coordinate for selected endpoints, quotient boundary equality, host Mobius transformations, hidden phase normalization, or ambient real-valued geometry, the listed rows exhaust the obligations. □

The Lean `TasteGate.lean` development for $\mathsf{HyperbolicCrossRatioPhase}^{\uparrow}$ must include explicit Nontrivial $\mathsf{HyperbolicCrossRatioPhase}^{\uparrow}$ and FieldFaithful $\mathsf{HyperbolicCrossRatioPhase}^{\uparrow}$ instances. These instances must preserve the hyperbolic metric, visual-boundary, Busemann-boundary, boundary-shadow, cross-ratio phase, Real-seal, transport, replay, provenance, and local naming rows.

Closure status for $\mathsf{NameCert}_{\mathsf{HyperbolicCrossRatioPhase}^{\uparrow}}$.

Constructive story: A $\mathsf{HyperbolicCrossRatioPhase}^{\uparrow}$ packet is generated from HyperbolicMetric rows, visual-boundary rows, Busemann-boundary calibration, boundary-shadow incidence, cross-ratio phase readback, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{HyperbolicCrossRatioPhase}^{\uparrow}}$, seed)

Scope closed: Definition 8721.1 and Definition 8721.2 seed the finite boundary cross-ratio phase route for hyperbolic observer-expansion consumers.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{HyperbolicCrossRatioPhase}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close Lean verification, bridge checking, selected ideal endpoints, quotient boundary equality, host Mobius geometry, hidden phase normalization, or ambient real-valued geometry.

Upgrade path: Obligation closure requires checked carrier admission, metric exposure, visual-boundary exposure, Busemann calibration, shadow incidence, phase readback, Real-seal nonescape, nontriviality, and field faithfulness for BEDC.Derived.HyperbolicCrossRatioPhaseUp.

Chapter 8722

A Concrete Naming Certificate for $\mathsf{FiniteLipschitzDifferentiability}^{\uparrow}$

Following Rademacher's differentiability theorem for Lipschitz maps, the $\mathsf{FiniteLipschitzDifferentiability}^{\uparrow}$ packet records the BEDC-finite interface at which derivative-candidate evidence may be consumed without importing a measure-theoretic almost-everywhere theorem. It refines the finite derivative-candidate route of chapter 5146 by reading the Lipschitz graph and bound of chapter 3762, the Real base and output seals of chapter 38, the dyadic radius ledger of chapter 291, the metric-neighbourhood rows of chapter 57, and the finite variation control of chapter 3361. The packet is a named finite-window differentiability interface; it is not a Lebesgue a.e. differentiability theorem and it selects no derivative outside the displayed windows.

Definition 8722.1 (Finite Lipschitz differentiability carrier)**.** *A* $\mathsf{FiniteLipschitzDifferentiability}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$F = (L, E, D, M, A, H, C, P, N)$$

with the following displayed rows:

1. *L is the* $\mathsf{LipschitzFunction}^{\uparrow}$ *graph-and-bound row, exposing the source metric, target metric, graph ledger, Lipschitz constant, and finite distance-inequality route used by the derivative-candidate read.*
2. *E is the pair of* $\mathsf{Real}^{\uparrow}$ *base and output seal rows, recording the base-point seal, endpoint output seals, and finite difference-quotient values visible to Real-facing consumers.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *radius and difference-quotient ledger, listing the inspected dyadic radii, endpoint offsets, halved-window refinements, tolerance comparisons, and displayed quotient windows.*
4. *M is the* $\mathsf{Met}^{\uparrow}$ *neighbourhood row for the source and target distance requests used to read the Lipschitz and quotient comparisons.*
5. *A is the* $\mathsf{AbsolutelyContinuousFunction}^{\uparrow}$ *control row, bounding only the displayed finite variation window consumed by the derivative-candidate route.*
6. *H records componentwise* hsame *transport for the Lipschitz row, Real seals, dyadic radius ledger, metric neighbourhoods, absolute-continuity control, replay row, provenance row, and local naming row.*

7. *C records displayed* Cont *replay from a finite differentiability request through D, M, L, A and then into the terminal Real seal row E.*
8. *P is the* Pkg *provenance over* FiniteLipschitzDifferentiability$^{\uparrow}$, Rademacher$^{\uparrow}$, LipschitzFunction$^{\uparrow}$, Real$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, Met$^{\uparrow}$, AbsolutelyContinuousFunction$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
9. *N is the local* NameCert$_{\text{FiniteLipschitzDifferentiability}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $L, E, D, M, A, H, C, P, N$. It has no coordinate for measurable exceptional sets, selected derivatives outside the finite windows, Lebesgue measure algebra, quotient equality, countable choice, host real equality, or a completed derivative space.

Theorem 8722.2 (Finite Lipschitz differentiability NameCert obligations)**.** *For every accepted* FiniteLipschitzDifferentiability$^{\uparrow}$ *carrier*

$$F = (L, E, D, M, A, H, C, P, N),$$

the local NameCert$_{\text{FiniteLipschitzDifferentiability}^{\uparrow}}$ *surface consists exactly of Lipschitz graph-and-bound exposure, Real base and output seal routing, dyadic radius and difference-quotient accounting, metric-neighbourhood inspection, absolute-continuity finite-window control, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, local naming, and non-escape from the displayed rows.*

Consequently the packet excludes measurable exceptional sets, selected derivatives outside the finite windows, Lebesgue measure algebra, quotient equality, countable choice, host real equality, and completed derivative-space data.

Lean4 (statement) `BEDC.Derived.FiniteLipschitzDifferentiabilityUp`

Proof. Carrier exposure is projection from Definition 8722.1. The visible analytic rows are L, E, D, M, A, and the visible structural rows are H, C, P, N.

The differentiability read is finite. The Lipschitz row supplies the graph and bound, the dyadic ledger supplies the inspected radii and quotient windows, and the metric row supplies the neighbourhoods in which those finite requests are compared. The absolute-continuity row bounds only the displayed variation window attached to those requests.

The Real row seals the base, endpoint, and quotient values reached by that finite route. Transport and replay preserve the same coordinates, while provenance and local naming source the packet without adding analytic rows.

Since no other coordinate occurs in the carrier, the NameCert surface exports none of the excluded measurable, derivative-selection, quotient, choice, host-equality, or completion data. □

Closure status for NameCert$_{\text{FiniteLipschitzDifferentiability}^{\uparrow}}$.

Theory closure: TheoryGate(NameCert$_{\text{FiniteLipschitzDifferentiability}^{\uparrow}}$, seed)

Scope closed: Definition 8722.1 and Definition 8722.2 seed the finite Lipschitz differentiability interface over Lipschitz graph-and-bound, Real seal, dyadic radius, metric-neighbourhood, absolute-continuity, transport, replay, provenance, and naming rows.

Formal verification: FormalStatus(NameCert$_{\text{FiniteLipschitzDifferentiability}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close Lebesgue almost-everywhere differentiability, measurable exceptional sets, selected derivatives outside finite windows, Lebesgue measure algebra, quotient equality, countable choice, host real equality, completed derivative spaces, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, Lipschitz graph-and-bound exposure, Real seal routing, dyadic radius and quotient accounting, metric-neighbourhood inspection, absolute-continuity finite-window control, transport stability, replay stability, provenance, local naming, and non-escape for BEDC.Derived.FiniteLipschitzDifferentiabilityUp.

Constructive story: A FiniteLipschitzDifferentiability$^{\uparrow}$ packet is generated from a LipschitzFunction row, RealUp base and output seals, DyadicRatCore radius and difference-quotient ledger, MetricSpace neighbourhood row, AbsolutelyContinuousFunction finite-window control row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 8723

A Concrete Naming Certificate for $\mathsf{CofinalTailSelectorBudget}^{\uparrow}$

Following Bishop and Bridges on constructive Cauchy convergence, the $\mathsf{CofinalTailSelectorBudget}^{\uparrow}$ packet records the finite tail-selection budget through which a regular Cauchy stream exposes cofinal tail data before any real-name consumer may read it. It sits after the finite stream naming surface of chapter 126, the dyadic tolerance carrier of chapter 291, the regular rational sequence route of chapter 301, the real-name seal of chapter 38, and the Cauchy tail-equivalence boundary of chapter 1738. The packet names a choice-free cofinal selector budget; it does not select limits, quotient streams, countable-choice subsequences, trichotomy witnesses, or ambient Real completeness.

Definition 8723.1 (Cofinal tail-selector budget carrier)**.** *A* $\mathsf{CofinalTailSelectorBudget}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (S, T, W, D, R, E, H, C, P, N)$$

with the following displayed rows:

1. *S is the* $\mathsf{StreamName}^{\uparrow}$ *source row, exposing the finite stream-name windows on which tail requests are made.*
2. *T is the cofinal tail-selector budget row, recording a finite budget for moving from an inspected window to a later tail window without choosing a global subsequence.*
3. *W is the finite window row, listing the source indices and later indices visible to the local selector budget.*
4. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row, recording the dyadic precision request used by the tail comparison.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff row through which regular rational sequence consumers read the selected tail window.*
6. *E is the* $\mathsf{Real}^{\uparrow}$ *seal, available only after the StreamName, dyadic tolerance, and RegSeqRat rows have been exposed.*
7. *H records componentwise* hsame *transport for the stream source, selector budget, windows, tolerance, handoff, seal, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay of the same selector route.*

9. *P is the* Pkg *provenance over* $\mathsf{CofinalTailSelectorBudget}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{CauchyTailEquivalence}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{CofinalTailSelectorBudget}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $S, T, W, D, R, E, H, C, P, N$. It has no coordinate for a selected limit, quotient-stream equality, an infinite choice function, trichotomy, or completeness of an ambient real line.

Theorem 8723.2 (Cofinal tail-selector budget NameCert obligations)**.** *For every accepted* CofinalTailSelectorBudge *carrier $B = (S, T, W, D, R, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{CofinalTailSelectorBudget}^{\uparrow}}$ *surface consists exactly of carrier admission for the StreamName source, cofinal selector budget, finite window, dyadic tolerance, RegSeqRat handoff, Real seal, componentwise transport, displayed replay, provenance, and local naming; cofinal selector exposure through S, T, W; dyadic tolerance readback through D; RegSeqRat handoff through R; and Real-seal nonescape through E.*

Proof. Project the carrier of Definition 8723.1. Its rows are precisely $S, T, W, D, R, E, H, C, P, N$, so carrier admission gives the complete local inventory.

The cofinal selector is not a global choice function. It is read from the StreamName source S, the finite selector budget T, and the displayed window row W, so each accepted tail request names only a finite later-window obligation.

The analytic readback is then forced through D, R, E. The dyadic tolerance row supplies the precision request, the RegSeqRat row supplies the regular rational handoff, and the Real row seals the read without adding a selected limit.

Finally H, C, P, N transport, replay, source, and name the same finite packet. Since no quotient stream, choice sequence, trichotomy witness, or ambient completeness coordinate occurs in the carrier, the listed rows exhaust the NameCert obligations. □

Theorem 8723.3 (Cofinal selector RegSeqRat handoff)**.** *Every* $\mathsf{Real}^{\uparrow}$*-facing consumer of an accepted* $\mathsf{CofinalTailSelectorBudget}^{\uparrow}$ *packet reads the cofinal selector through*

$$S \longmapsto T, W \longmapsto D \longmapsto R \longmapsto E$$

before the Real seal is visible. Thus the consumer first reads the $\mathsf{StreamName}^{\uparrow}$ *source, the finite cofinal selector budget and window rows, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row, and the* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff row; it cannot bypass them through quotient streams, selected limits, countable choice, trichotomy, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start with a Real-facing consumer. The carrier exposes the Real row only as E, and E is downstream of the dyadic tolerance and regular-rational handoff rows.

The selector route begins with the StreamName source S. The finite budget and window rows T, W record the cofinal tail request before any tolerance or regular sequence handoff is opened.

The rows D and R then supply the dyadic precision and RegSeqRat readback required by the consumer. Componentwise transport, displayed replay, provenance, and local naming preserve the same route through H, C, P, N.

Because the packet has no coordinate for selected limits, quotient streams, countable choice, trichotomy, or ambient Real completeness, every Real-facing read remains on the displayed chain before the seal E is consumed. □

Falsifiable prediction: Every $\mathsf{CofinalTailSelectorBudget}^{\uparrow}$ read consumed by a Real-facing completion route factors through StreamName source, finite cofinal selector budget, finite window, DyadicRatCore tolerance, RegSeqRat handoff, Real seal, hsame transport, Cont replay, Pkg provenance, and local NameCert rows.

Independence witness: streamname, regseqrat, dyadicratcore, real, cauchy-tail-equivalence: $\mathsf{CofinalTailSelectorBudget}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries a finite cofinal selector budget between StreamName windows, dyadic tolerance readback, RegSeqRat handoff, Real sealing, transport, replay, provenance, and local naming while refusing selected limits, quotient streams, countable choice, trichotomy, and ambient completeness.

Closure status for $\mathsf{NameCert}_{\mathsf{CofinalTailSelectorBudget}^{\uparrow}}$.

Constructive story: A $\mathsf{CofinalTailSelectorBudget}^{\uparrow}$ packet is generated from a StreamName source row, a finite cofinal tail-selector budget, finite windows, a DyadicRatCore tolerance row, a RegSeqRat handoff row, a Real seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CofinalTailSelectorBudget}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8723.1, Definition 8723.2, and Definition 8723.3 seed the finite choice-free cofinal tail-selector route from StreamName windows to RegSeqRat and Real-facing consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CofinalTailSelectorBudget}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close selected limits, quotient streams, countable choice, trichotomy, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, cofinal selector exposure, dyadic tolerance readback, RegSeqRat handoff, Real-seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.CofinalTailSelectorBudgetUp

Chapter 8724

A Concrete Naming Certificate for MetaCICNormalizationCounterexampleBudget$^{\uparrow}$

The MetaCICNormalizationCounterexampleBudget$^{\uparrow}$ packet realizes the finite obstruction row of the MetaCIC normalization audit map of chapter 9383. It packages a bounded counterexample budget for candidate-mediated normalization checks: a consumer may inspect typed terms, candidate evidence, bounded residual traces, normal-form consistency seals, and obstruction rows, but it cannot promote the packet into global strong normalization, subject reduction, evaluator equality, quotient term equality, or kernel consistency. The Lean follow-up supplies Nontrivial and FieldFaithful instances for the finite packet interface.

The bounded counterexample budget consumes the candidate surface of chapter 5994 and the local-join surface of chapter 4238; its budget row refines those sibling frontier packets by adding residual-checker, obstruction, and normal-form-seal rows.

It is also a consumer of the normalization-frontier packet of chapter 892 and the MetaCIC critical-path route: the candidate evidence, residual checker, join envelope, and obstruction row refine the frontier budget before any read reaches kernel primitives.

Definition 8724.1 (MetaCIC normalization counterexample budget carrier)**.** *A* MetaCICNormalizationCounterexam *carrier is a finite* BHist *packet*

$$M = (T, K, B, R, J, F, O, H, C, P, N)$$

with the following displayed rows:

1. *T is the MetaCIC typed-term source row, exposing the closed fragment and typing boundary under audit.*
2. *K is the candidate-evidence row used to mediate strong-normalization reads.*
3. *B is the bounded counterexample budget row, recording the finite number of residual traces, redex windows, or obstruction candidates inspected by the audit.*
4. *R is the residual-checker row, carrying the bounded redex and residual observations.*
5. *J is the local join-envelope row, recording the finite confluence-facing data visible to the counterexample search.*
6. *F is the normal-form consistency seal row, available only after the candidate, budget, residual, and join rows have been read.*

7. *O is the obstruction row, recording failed budget discharge without turning it into a global normalization theorem.*
8. *H records componentwise* hsame *transport for the typed-term, candidate, budget, residual, join, seal, obstruction, replay, provenance, and local naming rows.*
9. *C records displayed* Cont *replay of the same bounded audit route.*
10. *P is the* Pkg *provenance over* $\mathsf{MetaCICNormalizationCounterexampleBudget}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{MetaCICNormalizationCounterexampleBudget}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $T, K, B, R, J, F, O, H, C, P, N$. It has no coordinate for global strong normalization, subject reduction, evaluator equality, quotient term equality, or kernel consistency.

Theorem 8724.2 (MetaCIC normalization counterexample budget obligations)**.** *For every accepted* $\mathsf{MetaCICNormalizationCounterexampleBudget}^{\uparrow}$ *carrier $M = (T, K, B, R, J, F, O, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{MetaCICNormalizationCounterexampleBudget}^{\uparrow}}$ *surface consists exactly of carrier admission for the typed-term source, candidate evidence, bounded counterexample budget, residual checker, local join envelope, normal-form consistency seal, obstruction row, componentwise transport, displayed replay, provenance, and local naming. Every normalization-audit consumer must read candidate evidence and bounded obstruction data before the seal F is visible, and every failed budget discharge remains confined to the obstruction row O.*

Proof. Project the carrier of Definition 8724.1. Its rows are exactly $T, K, B, R, J, F, O, H, C, P, N$, so accepted packets expose no normalization evidence outside the displayed inventory.

The candidate-mediated route is finite. The typed-term row T and candidate row K must be read before the bounded budget row B can expose residual observations through R and local join data through J.

The normal-form consistency seal F is downstream of those finite rows. A failed bounded search is recorded in O, but O is an obstruction row rather than a proof of subject reduction, evaluator equality, quotient term equality, or global strong normalization.

Finally H, C, P, N transport, replay, source, and name the same audit packet. Since no carrier coordinate names kernel consistency or an ambient evaluator equality, the obligations cannot escape the bounded counterexample budget. □

Falsifiable prediction: Every $\mathsf{MetaCICNormalizationCounterexampleBudget}^{\uparrow}$ normalization-audit read factors through typed-term source, candidate evidence, bounded counterexample budget, residual-checker, local join-envelope, normal-form consistency seal, obstruction, hsame transport, Cont replay, Pkg provenance, and local NameCert rows before any bounded obstruction result is exported.

Independence witness: metacic-parallel-diamond-frontier, normalization-candidate-frontier, normal-form-consistency-seal, metacic-residual-join-envelope: $\mathsf{MetaCICNormalizationCounterexampleBudget}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries a bounded counterexample budget, residual-checker route, local join envelope, normal-form consistency seal, obstruction row, transport, replay, provenance, and local naming while refusing global strong normalization, subject reduction, evaluator equality, quotient term equality, and kernel consistency.

Closure status for $\mathsf{NameCert}_{\mathsf{MetaCICNormalizationCounterexampleBudget}^{\uparrow}}$.

Constructive story: A MetaCICNormalizationCounterexampleBudget$^{\uparrow}$ packet is generated from a typed-term source row, candidate evidence, a bounded counterexample budget, residual-checker data, a local join envelope, a normal-form consistency seal, an obstruction row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\text{MetaCICNormalizationCounterexampleBudget}^{\uparrow}}$, seed)

Scope closed: Definition 8724.1 and Definition 8724.2 seed the bounded obstruction route for the MetaCIC normalization audit map.

Formal verification: FormalStatus(NameCert$_{\text{MetaCICNormalizationCounterexampleBudget}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close global strong normalization, subject reduction, evaluator equality, quotient term equality, kernel consistency, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, candidate-mediated budget exposure, residual-checker readback, local join-envelope routing, normal-form seal nonescape, obstruction confinement, transport, replay, provenance, and local naming for BEDC.Derived.MetaCICNormalizationCounterexampleBudgetUp.

Chapter 8725

A Concrete Naming Certificate for $\mathsf{PuncturedInterval}^{\uparrow}$

Following Bishop and Bridges on deleted neighborhoods, the $\mathsf{PuncturedInterval}^{\uparrow}$ packet records a finite interval read around a displayed center while retaining a positive deleted-radius row. It sits after the located interval surface of chapter 394, the real interval surface of chapter 4111, and the dyadic-to-real spine of chapter 291, chapter 126, chapter 301, and chapter 38. The packet names deleted-neighborhood finite interval reads for later limit and derivative consumers; it is not full calculus, a host topology on real numbers, a selected real representative, or ambient order completeness.

Definition 8725.1 (PuncturedInterval carrier)**.** *A* $\mathsf{PuncturedInterval}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$J = (I, X, R, D, W, Q, S, H, C, P, N)$$

with the following displayed rows:

1. *I is the* $\mathsf{RealInterval}^{\uparrow}$ *source interval row, already carrying endpoint-and-enclosure data.*
2. *X is the center row, read as a* $\mathsf{Real}^{\uparrow}$ *name inside the interval surface.*
3. *R is the deleted-radius row, carrying a positive dyadic or regular rational radius around X.*
4. *D is the dyadic comparison row, comparing endpoint windows, the center row, and the deleted radius at a displayed tolerance.*
5. *W is the* $\mathsf{StreamName}^{\uparrow}$ *window row for interval endpoints, center reads, and radius reads.*
6. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row that turns the windows and dyadic comparison budget into finite rational observations.*
7. *S is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row for interval, center, and deleted-neighborhood consumers.*
8. *H records componentwise* hsame *transport for source interval, center, radius, dyadic comparison, windows, readback, seal, replay, provenance, and local naming rows.*
9. *C records displayed* Cont *replay from a deleted-neighborhood request through $I, X, R, D, W, Q, S, H, P, N$.*
10. *P is the* Pkg *provenance over* $\mathsf{PuncturedInterval}^{\uparrow}$, $\mathsf{LocatedInterval}^{\uparrow}$, $\mathsf{RealInterval}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{PuncturedInterval}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these rows. It has no coordinate for a host deleted-neighborhood topology, selected real representatives, derivative data, limit laws, trichotomy, countable choice, compactness, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 (statement) `BEDC.Derived.PuncturedIntervalUp`

Theorem 8725.2 (PuncturedInterval NameCert obligations)**.** *For every accepted* $\mathsf{PuncturedInterval}^{\uparrow}$ *carrier* $J = (I, X, R, D, W, Q, S, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{PuncturedInterval}^{\uparrow}}$ *surface consists exactly of carrier admission, interval-source readback, center readback, deleted-radius positivity, dyadic comparison exactness, StreamName window exposure, RegSeqRat finite readback, Real seal nonescape, componentwise transport, displayed replay, package provenance, and local naming. No obligation is stored outside the displayed packet rows.*

Proof. Carrier admission is projection from Definition 8725.1. The projection exposes the interval source row I, center row X, positive deleted-radius row R, dyadic comparison row D, and the finite window, readback, and seal rows W, Q, S.

The deleted-neighborhood condition is read through R and D. The radius row supplies the positive exclusion around the center, while the dyadic comparison row is the only place where endpoint windows, center windows, and the deleted radius are compared.

The finite real-name route is $D \mapsto W \mapsto Q \mapsto S$. A consumer first fixes a displayed tolerance, then reads finite stream windows, then obtains regular rational readback, and only then reaches the Real seal.

Finally H, C, P, N transport, replay, source, and locally name the same route. Since the carrier contains no topology object, derivative object, limit law, selected representative, trichotomy decision, choice schedule, compactness theorem, or completeness principle, the listed rows exhaust the NameCert obligations. □

Theorem 8725.3 (PuncturedInterval deleted-neighborhood scope)**.** *Every deleted-neighborhood read of an accepted* $\mathsf{PuncturedInterval}^{\uparrow}$ *carrier reaches an interval or* $\mathsf{Real}^{\uparrow}$ *consumer only through the displayed route*

$$I, X, R \longmapsto D, W, Q \longmapsto S, H, C, P, N.$$

Thus the read exposes the source interval, center, positive deleted radius, dyadic comparison budget, StreamName windows, RegSeqRat readback, Real seal, transport, replay, provenance, and local NameCert before any downstream limit or derivative consumer can inspect the interval. The scope does not include full calculus, host real topology, quotient real equality, selected endpoint representatives, or ambient completeness.

Proof. Start with an accepted carrier $J = (I, X, R, D, W, Q, S, H, C, P, N)$. The interval row I and center row X identify the displayed source and center, while R is the only coordinate that records the deleted positive radius.

Read the dyadic comparison route next. The comparison row D attaches the radius exclusion to finite endpoint and center windows; the window row W and readback row Q keep this comparison inside StreamName and RegSeqRat data.

Only after this finite comparison route may the Real seal S be consumed. The structural rows H, C, P, N preserve the same deleted-neighborhood read through transport, replay, provenance, and local naming.

Because the carrier has no coordinate for calculus rules, a host topology, quotient equality, selected real representatives, or completeness, any later limit or derivative consumer receives only the scoped deleted-neighborhood packet described above. □

Closure status for $\mathsf{NameCert}_{\mathsf{PuncturedInterval}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{PuncturedInterval}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8725.1, Definition 8725.2, and Definition 8725.3 seed the finite deleted-neighborhood interval surface over $\mathsf{LocatedInterval}^{\uparrow}$, $\mathsf{RealInterval}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ rows.

Constructive story: A $\mathsf{PuncturedInterval}^{\uparrow}$ packet is generated from a RealInterval source row, a RealUp center row, a positive deleted-radius row, a dyadic comparison row, StreamName windows, RegSeqRat readback, a Real seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{PuncturedInterval}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close full calculus, host real topology, derivative rules, limit laws, quotient real equality, selected real representatives, trichotomy, countable choice, compactness, ambient RealUp completeness, Lean theorem checking, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, center readback, deleted-radius positivity, dyadic comparison exactness, StreamName window exposure, RegSeqRat readback, Real seal nonescape, transport, provenance, and local naming for BEDC.Derived.PuncturedIntervalUp.

Chapter 8726

A Concrete Naming Certificate for $\mathsf{DyadicIntervalIntersectionLedger}^{\uparrow}$

Following Bishop and Bridges on finite interval reasoning over constructive real numbers, the $\mathsf{DyadicIntervalIntersectionLedger}^{\uparrow}$ packet records the displayed overlap ledger for two finite dyadic interval rows before any completion-facing consumer treats the overlap as a Real interval. It sits over the dyadic endpoint arithmetic of chapter 291, the finite endpoint-cell surface of chapter 306, the finite naming windows of chapter 126, the regular rational readback of chapter 301, and the terminal Real seal of chapter 38. The packet is a finite boundary ledger for nested-interval, finite-cover, and compactness consumers; it does not import trichotomy, quotient interval equality, selected points, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 8726.1 (Dyadic interval intersection ledger carrier)**.** *A* $\mathsf{DyadicIntervalIntersectionLedger}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (D, I_0, I_1, B, O, W, Q, E, H, C, P, N)$$

with the following displayed rows:

1. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *endpoint-arithmetic row, carrying lower and upper endpoint comparisons for the two inspected dyadic intervals.*
2. *I_0 and I_1 are the two* $\mathsf{DyadicInterval}^{\uparrow}$ *source rows whose overlap boundary is being recorded.*
3. *B is the finite boundary row, displaying the two candidate lower endpoints, the two candidate upper endpoints, and the endpoint comparisons needed to retain the intersection cell.*
4. *O is the overlap ledger row, recording the retained lower endpoint, retained upper endpoint, and the finite witness that the lower endpoint does not pass the upper endpoint.*
5. *W is the* $\mathsf{StreamName}^{\uparrow}$ *window row for the retained overlap endpoints.*
6. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the retained dyadic endpoint windows and tolerance requests.*
7. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row, available only after D, I_0, I_1, B, O, W, Q have been displayed.*
8. *H records componentwise* hsame *transport for the dyadic arithmetic, interval, boundary, overlap, window, readback, Real seal, replay, provenance, and local naming rows.*
9. *C records displayed* Cont *replay from the two source interval rows through the overlap ledger and into the Real-facing seal.*

10. *P is the* Pkg *provenance over* $\mathsf{DyadicIntervalIntersectionLedger}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{DyadicInterval}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*
11. *N is the local* $\mathsf{NameCert}_{\mathsf{DyadicIntervalIntersectionLedger}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through $D, I_0, I_1, B, O, W, Q, E, H, C, P, N$. It has no coordinate for host interval equality, quotient real equality, trichotomy of endpoints, selected overlap points, open-cover compactness, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 8726.2 (Dyadic interval intersection ledger NameCert obligations)**.** *For every accepted* $\mathsf{DyadicIntervalIntersectionLedger}^{\uparrow}$ *carrier $L = (D, I_0, I_1, B, O, W, Q, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{DyadicIntervalIntersectionLedger}^{\uparrow}}$ *surface consists exactly of dyadic endpoint arithmetic through D, the two source interval rows I_0, I_1, finite boundary comparison through B, retained-overlap exposure through O, stream-window exposure through W, regular rational readback through Q, terminal Real sealing through E, componentwise transport through H, displayed replay through C, provenance through P, and local naming through N. Thus every accepted interval-intersection consumer must read the finite route*

$$D, I_0, I_1 \longmapsto B \longmapsto O \longmapsto W, Q \longmapsto E, H, C, P, N.$$

Proof. Project the carrier of Definition 8726.1. The rows I_0 and I_1 name the two inspected dyadic intervals, while D supplies the endpoint arithmetic used to compare their displayed bounds.

The boundary row B records only finite comparisons among those endpoints. The overlap row O retains the displayed lower and upper endpoint selected by those comparisons together with the finite nonempty-cell witness.

The stream window row W and regular rational readback row Q are downstream of the retained overlap ledger, and the Real seal E is downstream of both. Transport, replay, provenance, and local naming through H, C, P, N preserve that same displayed route.

Since the carrier has no coordinate for host interval equality, quotient real equality, endpoint trichotomy, selected overlap points, open-cover compactness, or ambient Real completeness, the listed rows exhaust the NameCert obligations. □

Theorem 8726.3 (Dyadic interval intersection ledger Real-seal nonescape)**.** *Every Real-facing read from an accepted* $\mathsf{DyadicIntervalIntersectionLedger}^{\uparrow}$ *packet factors through the dyadic endpoint row D, the two* $\mathsf{DyadicInterval}^{\uparrow}$ *source rows I_0, I_1, the finite boundary row B, the retained overlap ledger O, the* $\mathsf{StreamName}^{\uparrow}$ *window row W, and the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row Q before the terminal* $\mathsf{Real}^{\uparrow}$ *seal E is consumed. The handoff exports a finite intersection boundary and no trichotomy principle, quotient interval equality, selected point, open-cover compactness theorem, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness row.*

Proof. Apply the NameCert obligations of Definition 8726.2. They place the two source interval rows and the dyadic endpoint arithmetic before the boundary comparison row.

The retained overlap ledger O is downstream of those finite comparisons, and the stream and regular-rational readback rows W, Q are downstream of the retained endpoints. A Real-facing consumer therefore reaches E only after the finite overlap route has been displayed.

Finally replay H, C, P, N. These rows transport, replay, source, and name the same packet without adding host interval equality, quotient Real equality, endpoint trichotomy, a selected point, open-cover compactness, or ambient completeness. The Real-facing handoff remains a finite BEDC ledger. □

Falsifiable prediction: Every accepted DyadicIntervalIntersectionLedgerUp consumer must display DyadicRatCore endpoint arithmetic, two DyadicInterval source rows, a finite boundary row, retained overlap ledger, StreamName windows, RegSeqRat readback, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert row before a Real-facing overlap read is public.

Independence witness: dyadicratcore, dyadicinterval, streamname, regseqrat, real: DyadicIntervalIntersectionLed is not bijective to any listed sibling because it binds two source intervals, finite endpoint comparisons, the retained overlap ledger, readback windows, terminal Real sealing, transport, replay, provenance, and local naming as one intersection-boundary carrier.

Closure status for $\mathsf{NameCert}_{\mathsf{DyadicIntervalIntersectionLedger}\uparrow}$.

Constructive story: A $\mathsf{DyadicIntervalIntersectionLedger}^{\uparrow}$ packet is generated from DyadicRatCore endpoint arithmetic, two DyadicInterval source rows, finite boundary comparison, retained overlap ledger, StreamName windows, RegSeqRat readback, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{DyadicIntervalIntersectionLedger}\uparrow}, \mathsf{seed})$

Scope closed: Definition 8726.1, Definition 8726.2, and Definition 8726.3 seed the finite interval-intersection boundary for DyadicRatCore, DyadicInterval, StreamName, RegSeqRat, and Real consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{DyadicIntervalIntersectionLedger}\uparrow}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim endpoint trichotomy, host interval equality, quotient Real equality, selected overlap points, open-cover compactness, ambient RealUp completeness, Lean theorem checking, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, dyadic endpoint comparisons, source-interval exposure, retained-overlap stability, StreamName windowing, RegSeqRat readback, Real seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.DyadicIntervalIntersectionLedgerUp.

Chapter 8727

A Concrete Naming Certificate for $\mathsf{ChoiceFreeFixedPointModulus}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{ChoiceFreeFixedPointModulus}^{\uparrow}$ packet records the finite modulus surface that turns a displayed interval contraction into fixed-point tolerances without selecting an ambient limit. It sits after the interval-contraction route of chapter 5867, the fixed-point interval packet of chapter 5811, the dyadic tolerance ledger of chapter 291, the finite name windows of chapter 126, the regular rational readback of chapter 301, and the terminal real-name seal of chapter 38. The packet is a finite L10 modulus for fixed-point consumers; it is not a selected limit, quotient real equality, countable choice, a host Picard theorem, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 8727.1 (Choice-free fixed-point modulus carrier)**.** *A* $\mathsf{ChoiceFreeFixedPointModulus}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M = (I, T, S, D, Q, W, R, E, H, C, P, N)$$

with the following displayed rows:

1. *I is the interval source row imported from the* $\mathsf{BishopIntervalContraction}^{\uparrow}$ *route, including the located endpoint and interval-admission data consumed by the fixed-point request.*
2. *T is the contraction self-map row, recording that the displayed map preserves the interval source and exposes its contraction witness.*
3. *S is the shrinkage modulus row, converting each requested fixed-point tolerance into a finite contraction-stage budget.*
4. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger used by the shrinkage row and by every downstream rational read.*
5. *Q is the dyadic comparison row that records the retained radius, error, and slack cells for the requested tolerance.*
6. *W is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row naming exactly which contraction stages are inspected.*
7. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row attached to those windows and the same dyadic tolerance ledger.*
8. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal reached only after I, T, S, D, Q, W, R have been displayed.*

9. *H records componentwise* hsame *transport for the interval source, self-map, shrinkage, dyadic, window, readback, real-seal, provenance, and local naming rows.*
10. *C records displayed* Cont *replay from each tolerance request through $I, T, S, D, Q, W, R, E, H, P, N$.*
11. *P is the* Pkg *provenance over* $\mathsf{ChoiceFreeFixedPointModulus}^{\uparrow}$, $\mathsf{BishopIntervalContraction}^{\uparrow}$, BishopFixedPointInterva $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
12. *N is the local* $\mathsf{NameCert}_{\mathsf{ChoiceFreeFixedPointModulus}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $I, T, S, D, Q, W, R, E, H, C, P, N$. It has no coordinate for a chosen fixed point, selected limit, quotient stream equality, countable choice, host completeness, or an ambient fixed-point theorem.

Theorem 8727.2 (Choice-free fixed-point modulus NameCert obligations)**.** *For every accepted* $\mathsf{ChoiceFreeFixedPointModulus}^{\uparrow}$ *carrier*

$$M = (I, T, S, D, Q, W, R, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{ChoiceFreeFixedPointModulus}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the interval source, contraction self-map, shrinkage modulus, dyadic tolerance, comparison, finite-window, regular readback, terminal real seal, transport, replay, provenance, and local naming rows;*
2. *interval compatibility, requiring each fixed-point tolerance request to read I and T before any shrinkage budget or window is exposed;*
3. *modulus exactness, requiring S, D, Q to be the sole source of contraction depth, tolerance, radius, error, and slack data;*
4. *finite readback, requiring W and R to be downstream of the same shrinkage and dyadic rows before the* $\mathsf{Real}^{\uparrow}$ *seal E can be consumed;*
5. *non-escape, requiring E, H, C, P, N to export no selected limit, quotient real equality, countable-choice schedule, host Picard theorem, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness principle.*

No choice-free fixed-point modulus obligation is stored outside these rows.

Proof. Carrier admission is projection from Definition 8727.1. The displayed tuple $I, T, S, D, Q, W, R, E, H, C, P, N$ is the entire public surface of the packet.

The interval and contraction rows are read first. A tolerance request cannot inspect a stage window until the interval source I and self-map row T have been displayed, so the packet inherits the interval-contraction route before any fixed-point modulus data is visible.

The modulus rows then determine the finite budget. The shrinkage row S reads the requested tolerance through the dyadic ledger D and comparison row Q, and these rows are the only place where contraction depth, radius, error, or slack data occur.

Finally, the readback and seal remain downstream. The finite windows W and $\mathsf{RegSeqRat}^{\uparrow}$ readback R are consumed before the terminal $\mathsf{Real}^{\uparrow}$ seal E, while H, C, P, N transport, replay, source, and name that same route. Since the carrier contains no selected limit, quotient equality, countable-choice row, host Picard theorem, or ambient completeness coordinate, the listed obligations exhaust the local NameCert surface. □

Falsifiable prediction: An accepted $\mathsf{ChoiceFreeFixedPointModulus}^{\uparrow}$ consumer that reaches a $\mathsf{RegSeqRat}^{\uparrow}$ readback or $\mathsf{Real}^{\uparrow}$ seal without reading the displayed rows $I, T, S, D, Q, W, R, E, H, C, P, N$ refutes the carrier surface.

Independence witness: bishop-interval-contraction, bishop-fixed-point-interval, dyadicratcore, streamname, regseqrat, real: no listed sibling supplies the joint packet containing an interval source, contraction self-map, shrinkage modulus, dyadic tolerance and comparison rows, finite windows, regular rational readback, terminal Real seal, transport, replay, provenance, and local NameCert row.

Closure status for $\mathsf{NameCert}_{\mathsf{ChoiceFreeFixedPointModulus}^{\uparrow}}$.

Constructive story: A $\mathsf{ChoiceFreeFixedPointModulus}^{\uparrow}$ packet is generated from an interval source row, contraction self-map row, shrinkage modulus row, dyadic tolerance and comparison rows, finite StreamName windows, RegSeqRat readback, a Real seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{ChoiceFreeFixedPointModulus}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8727.1 and Definition 8727.2 seed the finite choice-free modulus route from displayed interval contraction data to fixed-point Real-seal consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{ChoiceFreeFixedPointModulus}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close Lean verification, bridge checking, quotient real equality, selected limits, countable choice, a host Picard theorem, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Upgrade path: Obligation closure requires checked carrier admission, interval compatibility, modulus exactness, finite readback, terminal Real-seal non-escape, and local naming for BEDC.Derived.ChoiceFreeFixedPointModulusUp.

Chapter 8728

A Concrete Naming Certificate for $\mathsf{WarsawCircle}^{\uparrow}$

Following classical continuum theory, the $\mathsf{WarsawCircle}^{\uparrow}$ packet records the Warsaw circle as a compact metric continuum assembled from the topologist sine curve, a closing arc, and the displayed topology and real-coordinate carriers already present in the BEDC library. It sits beside the topologist sine curve of chapter 7316, the compact metric carrier of chapter 129, the topology carrier of chapter 88, the real-coordinate carrier of chapter 38, and the continuous-map carrier of chapter 130. The packet names the finite row surface by which a continuum-theory consumer reads the Warsaw circle; it does not assert planar embedding uniqueness, local connectedness, path connectedness, selected parametrizations, quotient equality of point names, or a Lean-checked standard bridge.

Definition 8728.1 (Warsaw circle carrier)**.** *A* $\mathsf{WarsawCircle}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$W = (S, A, T, M, R, F, H, C, P, N)$$

with the following rows:

1. *S is the* $\mathsf{TopologistSineCurve}^{\uparrow}$ *spine row naming the displayed sine-curve component.*
2. *A is the finite closing-arc row recording the added compact connector between the two endpoint sides of the displayed spine.*
3. *T is the* $\mathsf{Topology}^{\uparrow}$ *subspace-topology row on the assembled carrier.*
4. *M is the* $\mathsf{CompactMetric}^{\uparrow}$ *metric row for the closed bounded carrier surface.*
5. *R is the* $\mathsf{Real}^{\uparrow}$ *coordinate row used by the planar point names and endpoint witnesses.*
6. *F is the* $\mathsf{ContinuousMap}^{\uparrow}$ *inclusion-and-attachment row recording the displayed continuous maps from the sine spine and the closing arc into the assembled carrier.*
7. *H records componentwise* hsame *transport for the spine, arc, topology, compact metric, real coordinate, continuous-map, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from a Warsaw-circle request through the sine-curve spine, closing arc, topology, compact metric, real-coordinate, and continuous-map rows.*
9. *P is the* Pkg *provenance over* $\mathsf{WarsawCircle}^{\uparrow}$, $\mathsf{TopologistSineCurve}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{Topology}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$ *rows.*
10. *N is the local* $\mathsf{NameCert}_{\mathsf{WarsawCircle}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these rows. It has no coordinate for a selected parametrization of the continuum, planar embedding uniqueness, local connectedness, path connectedness, quotient equality of point names, or an ambient theorem of continuum theory.

Theorem 8728.2 (Warsaw circle NameCert obligations)**.** *For every accepted* $\mathsf{WarsawCircle}^{\uparrow}$ *carrier* $W = (S, A, T, M, R, F, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{WarsawCircle}^{\uparrow}}$ *surface consists exactly of sine-curve spine exposure through* S*, closing-arc exposure through* A*, topology exposure through* T*, compact metric exposure through* M*, real-coordinate exposure through* R*, continuous attachment exposure through* F*, componentwise* hsame *transport through* H*, displayed* Cont *replay through* C*,* Pkg *provenance through* P*, and local naming through* N*. A consumer therefore reads the Warsaw circle only through the finite route*

$$S, A, T, M, R, F \longmapsto H, C, P, N.$$

Proof. Project the accepted carrier of Definition 8728.1. The sine-curve row S and closing-arc row A display the two geometric pieces before any assembled continuum read is public.

The topology row T, compact metric row M, real-coordinate row R, and continuous attachment row F then expose the carrier surface used by a continuum-theory consumer. These rows are the only rows available before structural replay.

Finally replay H, C, P, N. Transport, continuation replay, provenance, and local naming preserve the same finite packet, so no selected parametrization, embedding uniqueness theorem, local connectedness claim, path connectedness claim, quotient equality of point names, or ambient continuum theorem enters the NameCert surface. □

Theorem 8728.3 (Warsaw circle sine-curve closure handoff)**.** *Every continuum-facing read from an accepted* $\mathsf{WarsawCircle}^{\uparrow}$ *carrier factors through the* $\mathsf{TopologistSineCurve}^{\uparrow}$ *spine row* S *before it may consume the closing arc* A*, topology row* T*, compact metric row* M*, real-coordinate row* R*, and continuous attachment row* F*. The handoff from the sine-curve carrier to the Warsaw-circle carrier is therefore the displayed finite route*

$$\mathsf{TopologistSineCurve}^{\uparrow} \longmapsto A, T, M, R, F, H, C, P, N,$$

not a new proof of local connectedness, path connectedness, selected planar parametrization, embedding uniqueness, quotient equality, or ambient continuum classification.

Proof. Start with the carrier of Definition 8728.1. Its first row is the displayed $\mathsf{TopologistSineCurve}^{\uparrow}$ spine, so any accepted Warsaw-circle read exposes the inherited sine-curve component before the closing arc or assembled surface is available.

Apply the NameCert obligations of Definition 8728.2. They place the closing arc, topology, compact metric, real-coordinate, and continuous-map rows downstream of that displayed spine and upstream of the structural rows.

The handoff is therefore finite and carrier-local. Since H, C, P, N only transport, replay, source, and name the same packet, the route cannot be reread as local connectedness, path connectedness, selected parametrization, planar embedding uniqueness, quotient equality of point names, or a general continuum-classification theorem. □

Falsifiable prediction: Every accepted $\mathsf{WarsawCircle}^{\uparrow}$ consumer must display the $\mathsf{TopologistSineCurve}^{\uparrow}$ spine row, closing-arc row, $\mathsf{Topology}^{\uparrow}$ row, $\mathsf{CompactMetric}^{\uparrow}$ row, $\mathsf{Real}^{\uparrow}$ coordinate row, $\mathsf{ContinuousMap}^{\uparrow}$ attachment row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local $\mathsf{NameCert}$ row before the Warsaw-circle certificate can be consumed.

Independence witness: topologist-sine-curve, compactmetric, topology, real, continuousmap: $\mathsf{WarsawCircle}^{\uparrow}$ is not bijective to any listed sibling because it carries the joint sine spine, closing arc, topology, compact metric, real-coordinate, continuous-attachment, transport, replay, provenance, and local naming rows. The sine-curve sibling lacks the closing arc and assembled compact-metric carrier; the compact metric sibling lacks the sine-spine and attachment rows; the topology sibling lacks compact-metric and continuum rows; the real sibling supplies only coordinate names; and the continuous-map sibling records maps without the named Warsaw-circle carrier.

Closure status for $\mathsf{NameCert}_{\mathsf{WarsawCircle}^{\uparrow}}$.

Constructive story: A $\mathsf{WarsawCircle}^{\uparrow}$ packet is generated from a topologist-sine-curve spine, a finite closing-arc row, topology and compact metric rows, real-coordinate rows, continuous attachment rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{WarsawCircle}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8728.1, Definition 8728.2, and Definition 8728.3 seed the finite Warsaw-circle carrier over the existing sine-curve, topology, compact metric, real-coordinate, and continuous-map anchors.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{WarsawCircle}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close local connectedness, path connectedness, planar embedding uniqueness, selected parametrizations, quotient equality of point names, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, sine-spine exposure, closing-arc exposure, topology and compact metric routing, real-coordinate exposure, continuous attachment routing, structural nonescape, and local naming for BEDC.Derived.WarsawCircleUp.

Chapter 8729

A Concrete Naming Certificate for $\mathsf{RegularCauchyLimitWitness}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{RegularCauchyLimitWitness}^{\uparrow}$ packet records the diagonal-limit witness of chapter 9238 as finite NameCert data. It consumes the diagonal representative and regularity theorem of Definition 9238.3 and Definition 9238.4, the dyadic tolerance ledger of chapter 291, the finite observation windows of chapter 126, the regular rational readback of chapter 301, the terminal real-name seal of chapter 38, and the completion-facing boundary of chapter 1639. The packet gives Real and Completion consumers a named diagonal-limit witness; it is not a quotient stream, a selected representative, countable choice, a host limit theorem, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 8729.1 (Regular Cauchy limit witness carrier)**.** *A* $\mathsf{RegularCauchyLimitWitness}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (X, M, D, W, R, E, B, H, C, P, N)$$

with the following displayed rows:

1. *X is the displayed regular-Cauchy source-family row whose members are read only through finite windows.*
2. *M is the diagonal modulus row, recording the primitive-recursive stage selector used by Definition 9238.3.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance, triangle, and slack ledger used by the diagonal regularity estimate.*
4. *W is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window family for the source reads, diagonal index reads, and output read.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the diagonal representative certified by the same modulus, tolerance, and window rows.*
6. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal exposed only after X, M, D, W, R have been displayed.*
7. *B is the* $\mathsf{BishopRegularCauchyCompletion}^{\uparrow}$ *boundary row, recording that the witness is completion-facing without selecting a completed host limit.*
8. *H records componentwise* hsame *transport for the source family, modulus, dyadic ledger, finite windows, readback, real seal, completion boundary, provenance, and local naming rows.*

9. *C records displayed* Cont *replay from each diagonal-limit request through* $X, M, D, W, R, E, B, H, P, N$.
10. *P is the* Pkg *provenance over* $\mathsf{RegularCauchyLimitWitness}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{BishopRegularCauchyCompletion}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyLimitWitness}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $X, M, D, W, R, E, B, H, C, P, N$. It has no coordinate for quotient streams, selected representatives, countable choice, host real equality, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 8729.2 (Regular Cauchy limit witness NameCert obligations)**.** *For every accepted* $\mathsf{RegularCauchyLimitWitness}^{\uparrow}$ *carrier*

$$L = (X, M, D, W, R, E, B, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{RegularCauchyLimitWitness}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the regular-Cauchy source family, diagonal modulus, dyadic tolerance and triangle ledger, finite windows, regular readback, terminal real seal, completion boundary, transport, replay, provenance, and local naming rows;*
2. *diagonal-stage exactness, requiring each output read to use the displayed modulus row M and no selected representative outside the packet;*
3. *finite-window coverage, requiring every source and output observation to be named by W and compared through the same dyadic ledger D;*
4. *RegSeqRat handoff, requiring R to be downstream of X, M, D, W and upstream of the terminal* $\mathsf{Real}^{\uparrow}$ *seal E;*
5. *completion boundary non-escape, requiring B, H, C, P, N to export no quotient streams, countable-choice selector, selected host limit, host real equality, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

No regular Cauchy limit-witness obligation is stored outside these rows.

Proof. Carrier admission is projection from Definition 8729.1. The displayed tuple $X, M, D, W, R, E, B, H, C, P, N$ is the entire public surface of the packet.

The diagonal-stage clause reads the source family through X and the stage selector through M. Because M is a displayed row, the output representative is obtained by the finite diagonal recipe rather than by choosing a representative from a host completion.

The window and dyadic clauses then control the estimate. Every source read and output read is named by W, while D supplies the tolerance, triangle, and slack data used by the diagonal regularity route of Definition 9238.4.

The regular readback row R is therefore downstream of X, M, D, W. The terminal seal E and completion boundary B can be consumed only after that route has been replayed and transported by H, C, P, N. Since the carrier contains no quotient-stream, selected-limit, countable-choice, host-equality, or ambient-completeness coordinate, the listed rows exhaust the local NameCert surface. □

Falsifiable prediction: Every accepted $\mathsf{RegularCauchyLimitWitness}^{\uparrow}$ Real-facing or Completion-facing read exposes a regular-Cauchy source family, displayed diagonal modulus, DyadicRatCore

tolerance ledger, StreamName finite windows, RegSeqRat readback, RealUp seal, BishopRegularCauchyCompletion boundary, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert row.

Independence witness: dyadicratcore, streamname, regseqrat, real, bishop-regular-cauchy-completion, regular-cauchy-diagonal-limit: no listed sibling supplies the joint packet containing the source family, diagonal modulus, dyadic triangle ledger, finite windows, regular readback, terminal Real seal, completion boundary, transport, replay, provenance, and local NameCert row.

Closure status for $\mathsf{NameCert}_{\mathsf{RegularCauchyLimitWitness}^{\uparrow}}$.

Constructive story: A $\mathsf{RegularCauchyLimitWitness}^{\uparrow}$ packet is generated from a regular-Cauchy source family, displayed diagonal modulus, DyadicRatCore tolerance and triangle ledger, StreamName finite windows, RegSeqRat readback, RealUp seal, BishopRegularCauchyCompletion boundary, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RegularCauchyLimitWitness}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8729.1 and Definition 8729.2 seed the finite diagonal-limit witness route from regular-Cauchy source data to Real and Completion consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RegularCauchyLimitWitness}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient stream equality, selected representatives, countable choice, host real equality, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, diagonal-stage exactness, finite-window coverage, RegSeqRat handoff, completion-boundary non-escape, and local naming for BEDC.Derived.RegularCauchyLimitWitnessUp.

Chapter 8730

A Concrete Naming Certificate for $\mathsf{BishopSpreadChoice}^{\uparrow}$

Following Bishop and Bridges and Troelstra–van Dalen on spreads, choice sequences, and finite observation, the $\mathsf{BishopSpreadChoice}^{\uparrow}$ packet records a finite choice-sequence prefix only after the displayed spread-law admission row has accepted it. It sits between the finite choice-sequence source of chapter 1482, the spread carrier of chapter 1677, the finite window interface of chapter 126, the regular rational readback of chapter 301, and the terminal real-name seal of chapter 38. The packet is a finite-prefix bridge for L10 Real and Completion consumers; it is not a completed branch, countable choice, quotient stream equality, fan compactness, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 8730.1 (Bishop spread-choice carrier)**.** *A* $\mathsf{BishopSpreadChoice}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (Q, S, W, R, E, H, C, P, N)$$

with the following displayed rows:

1. *Q is the* $\mathsf{ChoiceSequence}^{\uparrow}$ *finite-prefix row, exposing only the opened prefix entries and their displayed request order.*
2. *S is the* $\mathsf{SpreadLaw}^{\uparrow}$ *admission row. It records the finite spread-law decisions that admit the prefixes in Q.*
3. *W is the* $\mathsf{StreamName}^{\uparrow}$ *window row that displays the admitted prefix as the only stream window available to downstream readers.*
4. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row produced from the admitted window and its displayed rational requests.*
5. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached only after Q, S, W, R have been consumed.*
6. *H records componentwise* hsame *transport for the prefix, admission, window, readback, seal, replay, provenance, and local naming rows.*
7. *C records displayed* Cont *replay from a finite choice-sequence request through spread-law admission, window display, regular readback, and Real sealing.*
8. *P is the* Pkg *provenance over* $\mathsf{BishopSpreadChoice}^{\uparrow}$, $\mathsf{ChoiceSequence}^{\uparrow}$, $\mathsf{SpreadLaw}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
9. *N is the local* $\mathsf{NameCert}_{\mathsf{BishopSpreadChoice}^{\uparrow}}$ *row.*

The local classifier compares accepted packets only through $Q, S, W, R, E, H, C, P, N$. It has no coordinate for a completed infinite branch, a host function, quotient stream equality, countable choice, fan compactness, selected limits, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 8730.2 (Bishop spread-choice NameCert obligations)**.** *For every accepted* $\mathsf{BishopSpreadChoice}^{\uparrow}$ *carrier*

$$B = (Q, S, W, R, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{BishopSpreadChoice}^{\uparrow}}$ *surface consists exactly of finite choice-sequence prefix exposure, spread-law admission for that prefix, StreamName window display, regular rational readback, terminal Real sealing, componentwise transport, displayed replay, provenance, local naming, and non-escape from those rows.*

Proof. Project the carrier of Definition 8730.1. The visible analytic route begins with the prefix row Q, checks it through the spread-law row S, and then exposes the admitted window W.

The regular readback and Real seal are downstream. Row R reads only the admitted finite window, and row E is available only after Q, S, W, R have been displayed.

The structural rows preserve the same route. Transport H is componentwise, replay C follows the displayed admission and readback chain, and P, N source and name that packet. Since the carrier has no further coordinate, the listed rows exhaust the local NameCert surface. □

Theorem 8730.3 (Bishop spread-choice finite-prefix stability)**.** *Let $B = (Q, S, W, R, E, H, C, P, N)$ and $B' = (Q', S', W', R', E', H', C', P', N')$ be accepted* $\mathsf{BishopSpreadChoice}^{\uparrow}$ *carriers. If Q and Q' display the same finite choice-sequence prefix, S and S' give the same spread-law admission decisions for that prefix, and W and W' are componentwise* hsame *as admitted StreamName windows, then every finite derivative-free read exported through H, C, P, N and through H', C', P', N' displays the same W-window before reaching the regular readback and Real seal.*

Proof. Induct on the displayed prefix length. The empty prefix has no opened entry, so the only visible window is the root window admitted by the spread-law row.

For the successor step, assume the shorter prefix has the same admitted window in both carriers. The next displayed entry is read from the same finite choice-sequence prefix and is admitted by the same spread-law decision, so the extended StreamName row is componentwise hsame.

The readback cannot introduce a second window. By Definition 8730.2, every exported read must pass through Q, S, W before R and E. The transport, replay, provenance, and local naming rows therefore preserve the displayed finite row inventory rather than replacing it by a host stream, quotient representative, selected branch, countable-choice schedule, or ambient completion datum. □

Falsifiable prediction: Every accepted $\mathsf{BishopSpreadChoice}^{\uparrow}$ Real-facing read exposes one finite $\mathsf{ChoiceSequence}^{\uparrow}$ prefix row, one $\mathsf{SpreadLaw}^{\uparrow}$ admission row, one $\mathsf{StreamName}^{\uparrow}$ window, one $\mathsf{RegSeqRat}^{\uparrow}$ readback row, one terminal $\mathsf{Real}^{\uparrow}$ seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming.

Independence witness: choice-sequence, brouwer-spread, streamname, regseqrat, real: $\mathsf{BishopSpreadChoice}^{\uparrow}$ is not bijective to any listed sibling because it binds finite prefix data to spread-law admission before any StreamName, RegSeqRat, or Real row can be consumed.

Closure status for $\mathsf{NameCert}_{\mathsf{BishopSpreadChoice}^{\uparrow}}$**.**

Constructive story: A $\mathsf{BishopSpreadChoice}^{\uparrow}$ packet is generated from a finite ChoiceSequence prefix row, a SpreadLaw admission row, a StreamName window row, a RegSeqRat readback row, a terminal RealUp seal row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\mathsf{BishopSpreadChoice}^{\uparrow}}$, seed)

Scope closed: Definition 8730.1, Definition 8730.2, and Definition 8730.3 seed the finite-prefix bridge from choice-sequence observation through spread-law admission to StreamName, RegSeqRat, and Real-name handoff rows.

Formal verification: FormalStatus(NameCert$_{\mathsf{BishopSpreadChoice}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close completed infinite branches, countable choice, quotient stream equality, fan compactness, selected limits, ambient Real$^{\uparrow}$ completeness, Lean verification, or bridge checking for BishopSpreadChoice$^{\uparrow}$.

Upgrade path: Obligation closure requires checked carrier admission, spread-law admission stability, finite-prefix stability, readback handoff, Real seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.BishopSpreadChoiceUp.

Chapter 8731

A Concrete Naming Certificate for $\mathsf{SequentialOrderCompactness}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{SequentialOrderCompactness}^{\uparrow}$ packet records the finite order-window route by which a displayed real sequence in a compact interval can be inspected before any Real or Completion consumer reads an order-facing compactness claim. It sits beside the subsequence-window surface of chapter 2372, the interval boundary of chapter 3986, and the terminal real-name seal of chapter 38. The packet names only the local finite window used by an order-monotone read; it is not open-cover compactness, not a choice-selected subsequence, not trichotomy, not quotient real equality, and not ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 8731.1 (Sequential order compactness carrier)**.** *A* $\mathsf{SequentialOrderCompactness}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (A, I, O, R, W, D, H, C, P, N)$$

with the following displayed rows:

1. *A is the* $\mathsf{Real}^{\uparrow}$ *sequence source row whose inspected terms are offered only through displayed real-name seals.*
2. *I is the* $\mathsf{CompactInterval}^{\uparrow}$ *bracket row naming the interval boundary in which the sequence is read.*
3. *O is the finite monotone/order window. It records the inspected order comparisons and adjacent bracket witnesses visible inside the current window.*
4. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the sequence terms that appear in the order window.*
5. *W is the* $\mathsf{StreamName}^{\uparrow}$ *schedule row selecting the finite indices and readback windows being inspected.*
6. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row used to compare the displayed rational readbacks inside the compact interval bracket.*
7. *H records componentwise* hsame *transport for the source sequence, interval bracket, order window, readback, schedule, tolerance, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from an order-window request through A, I, O, R, W, D, H before any compactness-facing consumer reads the packet.*
9. *P is the* Pkg *provenance over* $\mathsf{SequentialOrderCompactness}^{\uparrow}$, $\mathsf{SequentialCompact}^{\uparrow}$, $\mathsf{CompactInterval}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

10. N is the local $\mathsf{NameCert}_{\mathsf{SequentialOrderCompactness}^{\uparrow}}$ *row.*
The classifier compares accepted carriers only through $A, I, O, R, W, D, H, C, P, N$. It has no coordinate for open-cover compactness, a selected infinite subsequence, trichotomy of real names, quotient real equality, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 8731.2 (Sequential order compactness NameCert obligations)**.** *For every accepted* $\mathsf{SequentialOrderCompactness}^{\uparrow}$ *carrier $S = (A, I, O, R, W, D, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{SequentialOrderCompactness}^{\uparrow}}$ *surface consists exactly of source-sequence exposure through A; compact-interval bracketing through I; finite monotone/order-window exposure through O; regular rational readback through R; finite schedule exposure through W; dyadic tolerance comparison through D; componentwise transport through H; displayed replay through C; provenance through P; and local naming through N. Every Real or Completion consumer must first pass through the sequential compactness sibling of chapter 2372, the compact-interval sibling of chapter 3986, and the real-name seal of chapter 38.*

Proof. Project the carrier in Definition 8731.1. The displayed rows are exactly $A, I, O, R, W, D, H, C, P, N$, so any accepted read begins with the source sequence, interval bracket, finite order window, readback, schedule, and dyadic tolerance rows.

The order-facing compactness information is local to the finite window. The compact interval row supplies the bracket, the StreamName row supplies the inspected indices, and the RegSeqRat and DyadicRatCore rows supply the finite rational comparison data used inside that bracket.

Transport and replay preserve the same rows componentwise. Provenance and local naming then bind the packet as a $\mathsf{SequentialOrderCompactness}^{\uparrow}$ certificate. Since the carrier contains no selected infinite subsequence, open-cover compactness witness, quotient real equality, trichotomy branch, countable-choice schedule, or ambient completeness row, the listed fields exhaust the local obligations. □

Theorem 8731.3 (Sequential order compactness finite-window extraction)**.** *Let $S = (A, I, O, R, W, D, H, C, P, N)$ be an accepted* $\mathsf{SequentialOrderCompactness}^{\uparrow}$ *carrier. Every order-facing compactness read exported by S factors through the finite route*

$$A \to I \to O \to R \to W \to D \to H \to C \to P \to N.$$

The extracted witness is a finite inspected order window over displayed real-name readbacks inside the compact interval bracket. It is not a selected convergent subsequence, not an open-cover compactness proof, not a quotient-real equality, not a trichotomy decision, and not an ambient completeness theorem for $\mathsf{Real}^{\uparrow}$*.*

Proof. Read the source sequence row A and compact-interval row I first. They determine which displayed real-name terms and which interval bracket are visible to the packet.

Next inspect the order window O through the readback and schedule rows R and W. The dyadic tolerance row D supplies the finite comparison budget for the displayed rational approximants, so the extracted information is a finite window rather than an infinite subsequence.

Finally replay the structural rows H, C, P, N. Componentwise transport and displayed continuation replay cannot create a selected limit point, a quotient equality, a trichotomy branch, or an open-cover witness. Thus the consumer receives exactly the finite order-window extraction over the compact interval route. □

Closure status for $\mathsf{NameCert}_{\mathsf{SequentialOrderCompactness}^{\uparrow}}$**.**

Constructive story: A $\mathsf{SequentialOrderCompactness}^{\uparrow}$ packet is generated from a displayed RealUp sequence source, a CompactInterval bracket, a finite monotone/order window, RegSeqRat readback, StreamName schedule, DyadicRatCore tolerance data, componentwise hsame transport, Cont replay, Pkg provenance, and local naming.

Theory closure: TheoryGate(NameCert$_{\mathsf{SequentialOrderCompactness}\uparrow}$, seed)

Scope closed: Definition 8731.1, Definition 8731.2, and Definition 8731.3 seed the finite order-window surface over displayed real sequences in compact interval brackets.

Formal verification: FormalStatus(NameCert$_{\mathsf{SequentialOrderCompactness}\uparrow}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close open-cover compactness, choice-selected subsequences, trichotomy, quotient real equality, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, interval-bracket exposure, finite order-window extraction, readback, schedule, tolerance, transport, replay, provenance, and local naming for BEDC.Derived.SequentialOrderCompactnessUp.

Chapter 8732

A Concrete Naming Certificate for $\mathsf{SequentialCompletionReflector}^{\uparrow}$

Following Bishop–Bridges constructive analysis, the $\mathsf{SequentialCompletionReflector}^{\uparrow}$ packet records the boundary where regular sequential completion data are reflected into a finite NameCert handoff. It sits after the completion schedule of $\mathsf{CauchyCompletionMonad}^{\uparrow}$ in chapter 378, the metric completion boundary of $\mathsf{MetricCompletion}^{\uparrow}$ in chapter 1506, the finite observation windows of $\mathsf{StreamName}^{\uparrow}$ in chapter 126, the regular rational readback of $\mathsf{RegSeqRat}^{\uparrow}$ in chapter 301, and the terminal real-name seal of $\mathsf{Real}^{\uparrow}$ in chapter 38. The reflector names how sequential Cauchy data are handed to Real and Completion consumers as displayed rows; it is not quotient equality, a host selected limit, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, or bridge checking.

Definition 8732.1 (Sequential completion reflector carrier)**.** *A* $\mathsf{SequentialCompletionReflector}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (M, K, W, R, E, H, C, P, N)$$

with the following displayed rows:

1. *M is the* $\mathsf{CauchyCompletionMonad}^{\uparrow}$ *schedule row, naming the unit and bind surface consumed by completion-facing reads.*
2. *K is the* $\mathsf{MetricCompletion}^{\uparrow}$ *boundary row, recording the source metric presentation and the completion target admitted by the reflector.*
3. *W is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row exposing only the inspected sequence entries and precision requests.*
4. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row attached to the same windows and dyadic tolerances.*
5. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row, available only after M, K, W, R have been displayed.*
6. *H records componentwise* hsame *transport for the schedule, completion boundary, finite windows, regular readback, terminal seal, provenance, and local naming rows.*
7. *C records displayed* Cont *replay from each sequential completion request through M, K, W, R, E, H, P, N.*
8. *P is the* Pkg *provenance over* $\mathsf{SequentialCompletionReflector}^{\uparrow}$, $\mathsf{CauchyCompletionMonad}^{\uparrow}$, $\mathsf{MetricCompletion}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
9. *N is the local* $\mathsf{NameCert}_{\mathsf{SequentialCompletionReflector}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $M, K, W, R, E, H, C, P, N$. It has no coordinate for quotient equality, host selected limits, countable choice, ambient $\mathsf{Real}^{\uparrow}$ *completeness, or checked bridge data.*

Theorem 8732.2 (Sequential completion reflector NameCert obligations)**.** *For every accepted* $\mathsf{SequentialCompletionReflector}^{\uparrow}$ *carrier*

$$S = (M, K, W, R, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{SequentialCompletionReflector}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the completion monad schedule, metric completion boundary, finite windows, regular rational readback, real seal, transport, replay, provenance, and local naming rows;*
2. *sequential-source exposure, requiring each completion request to pass through the* $\mathsf{StreamName}^{\uparrow}$ *window row W before any regular readback is consumed;*
3. *regular-readback handoff, requiring R to be downstream of M, K, W and upstream of the terminal* $\mathsf{Real}^{\uparrow}$ *seal E;*
4. *reflector non-escape, requiring H, C, P, N to replay only the displayed rows and to export no quotient completion, selected representative, countable-choice schedule, host limit, ambient* $\mathsf{Real}^{\uparrow}$ *completeness, or bridge credential.*

No sequential completion reflector obligation is stored outside these rows.

Proof. Carrier admission is projection from Definition 8732.1. The tuple $S = (M, K, W, R, E, H, C, P, N)$ is the whole surface exposed to a sequential completion consumer.

The sequential-source clause reads each requested stage through W. Since W is a finite $\mathsf{StreamName}^{\uparrow}$ window row, the consumer obtains only inspected entries and precision requests, not a chosen infinite representative.

The regular-readback clause then routes the same finite windows through R. The completion schedule M and metric completion boundary K remain visible before the terminal $\mathsf{Real}^{\uparrow}$ seal E is consumed, so the Real-facing handoff is a displayed regular-rational readback rather than a quotient completion.

Finally, H, C, P, N transport, replay, name, and package the same rows. Because the carrier contains no coordinate for quotient equality, selected limits, countable choice, ambient completeness, or bridge checking, the listed rows exhaust the local NameCert surface. □

Falsifiable prediction: Every accepted $\mathsf{SequentialCompletionReflector}^{\uparrow}$ consumer must display a CauchyCompletionMonad schedule row, a MetricCompletion boundary row, a StreamName finite-window row, a RegSeqRat readback row, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row before the reflector can be consumed.

Independence witness: cauchycompletionmonad, metriccompletion, streamname, regseqrat, real: no listed sibling supplies the joint reflector packet containing the completion schedule, metric boundary, finite windows, regular readback, terminal Real seal, transport, replay, provenance, and local NameCert row.

Closure status for $\mathsf{NameCert}_{\mathsf{SequentialCompletionReflector}^{\uparrow}}$**.**

Constructive story: A $\mathsf{SequentialCompletionReflector}^{\uparrow}$ packet is generated from a CauchyCompletionMonad schedule row, a MetricCompletion boundary row, StreamName finite windows, RegSeqRat readback, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\mathsf{SequentialCompletionReflector}\uparrow}$, seed)

Scope closed: Definition 8732.1 and Definition 8732.2 seed the finite reflector route from sequential Cauchy completion data to Real and Completion consumers.

Formal verification: FormalStatus(NameCert$_{\mathsf{SequentialCompletionReflector}\uparrow}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close quotient equality, host selected limits, countable choice, ambient Real$^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, sequential-source exposure, regular-readback handoff, reflector non-escape, and local naming for BEDC.Derived.SequentialCompletionReflectorUp.

Chapter 8733

A Concrete Naming Certificate for $\mathsf{DenseRationalEmbedding}^{\uparrow}$

Following Bishop–Bridges constructive analysis, the $\mathsf{DenseRationalEmbedding}^{\uparrow}$ packet records the finite handoff by which rational certificates are read as dense real-name data before completion consumers inspect a $\mathsf{Real}^{\uparrow}$ seal. It sits after the rational carrier of chapter 37, the dyadic comparison core of chapter 291, the regular rational sequence route of chapter 301, the finite stream-window interface of chapter 126, and the terminal real-name packet of chapter 38. The packet names a displayed density route from rational witnesses to real-name seals; it is not quotient real equality, trichotomy, selected limits, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 8733.1 (Dense rational embedding carrier)**.** *A* $\mathsf{DenseRationalEmbedding}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$D = (Q, Y, S, R, E, A, H, C, P, N)$$

with the following rows:

1. *Q is the* $\mathsf{Rat}^{\uparrow}$ *source row naming the rational witness to be embedded.*
2. *Y is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *comparison row, recording the dyadic tolerance and order checks used to locate Q inside a real-name window.*
3. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row that exposes the inspected real-name prefixes.*
4. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *regular rational sequence row used to transport the rational witness through completion-facing Cauchy data.*
5. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row for the terminal real name reached by the displayed embedding route.*
6. *A is the density-approximation row, recording that every inspected real-name window admits a rational witness read through Q, Y, S, R, E at the displayed tolerance.*
7. *H records componentwise* hsame *transport for the rational, dyadic, stream, regular-sequence, real-seal, density, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from a density request through the same rows.*
9. *P is the* Pkg *provenance over* $\mathsf{DenseRationalEmbedding}^{\uparrow}$, $\mathsf{Rat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{DenseRationalEmbedding}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $Q, Y, S, R, E, A, H, C, P, N$. It has no coordinate for quotient real equality, trichotomy, selected limit objects, countable choice, or ambient real completeness.

Theorem 8733.2 (Dense rational embedding NameCert obligations)**.** *For every accepted* $\mathsf{DenseRationalEmbedding}^{\uparrow}$ *carrier $D = (Q, Y, S, R, E, A, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{DenseRationalEmbedding}^{\uparrow}}$ *surface consists exactly of rational source admission, dyadic tolerance comparison, finite stream-window exposure, regular rational sequence readback, terminal real sealing, density-approximation exposure, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. Every density read is therefore confined to the finite route*

$$Q, Y, S, R, E, A \longmapsto H, C, P, N.$$

Proof. Project the accepted carrier of Definition 8733.1. The rows Q, Y, S, R, E, A are exactly the rational source, dyadic tolerance, stream-window, regular-sequence, real-seal, and density-approximation data available before structural replay.

The structural rows H, C, P, N transport, replay, source, and name the same finite packet. They add no quotient-real equality, no trichotomy branch, no selected limit, and no choice principle.

Thus the local NameCert surface is exhausted by the displayed rows. A completion-facing consumer can read density only through this finite route. □

Theorem 8733.3 (Dense rational embedding density window)**.** *Every real-name density request accepted by a* $\mathsf{DenseRationalEmbedding}^{\uparrow}$ *packet must display a finite stream window S, a regular rational readback row R, a dyadic tolerance row Y, and a rational witness row Q before the terminal* $\mathsf{Real}^{\uparrow}$ *seal E is consumed. The packet therefore supplies density as a finite window statement over rational certificates, not as an ambient completeness or selected-limit principle.*

Proof. Read the density-approximation row A. By the carrier definition, A is attached to the rows Q, Y, S, R, E and has no independent coordinate outside them.

The stream and regular-sequence rows determine what part of the real name is inspected. The dyadic row records the tolerance comparison, and the rational row supplies the witness used inside that tolerance.

Finally the real seal E authenticates the same inspected window. Since selected limits, quotient equality, trichotomy, choice, and ambient completeness are absent from the carrier, the density statement remains a finite rational-window handoff. □

Theorem 8733.4 (Dense rational embedding real seal)**.** *Every* $\mathsf{Real}^{\uparrow}$ *consumer of an accepted* $\mathsf{DenseRationalEmbedding}^{\uparrow}$ *packet receives the real-name seal only after the route*

$$\mathsf{Rat}^{\uparrow}, \mathsf{DyadicRatCore}^{\uparrow}, \mathsf{StreamName}^{\uparrow}, \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}$$

has been displayed and authenticated by A, H, C, P, N. Thus the handoff from rational certificates to real-name seals is a NameCert route for completion proofs, not a claim of quotient real equality, trichotomy, selected limits, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Begin with the rows of Definition 8733.1. The real seal E is downstream of the rational witness Q, dyadic comparison Y, stream window S, and regular rational readback R.

The density row A records that this route supplies the rational witness required by the inspected window. The transport and replay rows H, C preserve that route componentwise, and P, N source and name it.

No remaining coordinate can expose quotient equality of real names, a trichotomy decision, a selected limit object, choice, or ambient completeness. Hence the seal is exactly the displayed finite handoff from rational certificates into the real-name boundary. □

Falsifiable prediction: Every accepted $\mathsf{DenseRationalEmbedding}^{\uparrow}$ completion-facing read must display a $\mathsf{Rat}^{\uparrow}$ source row, $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance row, $\mathsf{StreamName}^{\uparrow}$ finite-window row, $\mathsf{RegSeqRat}^{\uparrow}$ readback row, $\mathsf{Real}^{\uparrow}$ seal row, density-approximation row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert row before the density handoff is consumed.

Independence witness: rat, dyadicratcore, regseqrat, streamname, real: $\mathsf{DenseRationalEmbedding}^{\uparrow}$ is not bijective to any listed sibling because it binds the rational witness, dyadic tolerance comparison, finite stream window, regular rational readback, terminal real seal, density row, transport, replay, provenance, and local naming into one completion-facing handoff.

Closure status for $\mathsf{NameCert}_{\mathsf{DenseRationalEmbedding}^{\uparrow}}$.

Constructive story: A $\mathsf{DenseRationalEmbedding}^{\uparrow}$ packet is generated from a RatUp source row, DyadicRatCoreUp tolerance row, StreamNameUp finite-window row, RegSeqRatUp readback row, RealUp seal row, density-approximation row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{DenseRationalEmbedding}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8733.1, Definition 8733.2, Definition 8733.3, and Definition 8733.4 seed the finite rational-to-real density handoff used by completion-facing consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{DenseRationalEmbedding}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient real equality, trichotomy, selected limits, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, rational source exposure, dyadic tolerance compatibility, stream-window exposure, regular rational readback, real sealing, density-row exactness, transport, replay, provenance, and local naming for BEDC.Derived.DenseRationalEmbeddingUp.

Chapter 8734

A Concrete Naming Certificate for $\mathsf{LocatedIntervalSeparation}^{\uparrow}$

Following Bishop and Bridges on located intervals and apartness-sensitive real construction, the $\mathsf{LocatedIntervalSeparation}^{\uparrow}$ packet records a finite positive separation boundary before a Real or Completion consumer treats two inspected interval faces as apart. It sits over the located endpoint carrier of chapter 394, the dyadic tolerance arithmetic of chapter 291, the finite observation windows of chapter 126, the regular rational readback of chapter 301, and the terminal real-name seal of chapter 38. The packet gives the L10 Real and Completion route a finite separation row; it is not trichotomy, quotient real equality, a selected endpoint representative, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Definition 8734.1 (Located interval separation carrier)**.** *A* $\mathsf{LocatedIntervalSeparation}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (J_0, J_1, G, D, W, R, E, H, C, P, N)$$

with the following displayed rows:

1. *J_0 and J_1 are the two* $\mathsf{LocatedInterval}^{\uparrow}$ *source rows whose exposed endpoint windows are being separated.*
2. *G is the dyadic positive-gap row. It displays a positive* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance together with the endpoint-side choice saying which visible face of J_0 lies at least that gap before the corresponding visible face of J_1.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *arithmetic ledger for positivity, subtraction, comparison, and slack retention used by the gap row.*
4. *W is the finite* $\mathsf{StreamName}^{\uparrow}$ *window family for the endpoint reads of J_0, the endpoint reads of J_1, and the gap-check observations.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the two endpoint windows and the dyadic gap tolerance.*
6. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row, exposed only after J_0, J_1, G, D, W, R have been displayed.*
7. *H records componentwise* hsame *transport for the source intervals, positive gap, dyadic arithmetic, finite windows, readback, real seal, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from each finite separation request through $J_0, J_1, G, D, W, R, E, H, P, N$.*
9. *P is the* Pkg *provenance over* $\mathsf{LocatedIntervalSeparation}^{\uparrow}$, $\mathsf{LocatedInterval}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

10. *N is the local* $\mathsf{NameCert}_{\mathsf{LocatedIntervalSeparation}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $J_0, J_1, G, D, W, R, E, H, C, P, N$. It has no coordinate for endpoint trichotomy, quotient real equality, selected representatives, countable choice, a host interval order, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 8734.2 (Located interval separation NameCert obligations)**.** *For every accepted* LocatedIntervalSeparatio *carrier*

$$S = (J_0, J_1, G, D, W, R, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{LocatedIntervalSeparation}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the two displayed* $\mathsf{LocatedInterval}^{\uparrow}$ *source rows, positive dyadic gap, dyadic arithmetic ledger, finite windows, regular readback, terminal real seal, transport, replay, provenance, and local naming rows;*
2. *source-row exposure, requiring every interval endpoint read to be projected from J_0 or J_1 as in Definition 394.1;*
3. *positive-gap exactness, requiring G to display a positive* $\mathsf{DyadicRatCore}^{\uparrow}$ *gap and D to display the arithmetic route that witnesses the retained separation;*
4. *finite-window coverage, requiring every endpoint and gap-check observation to be named by W and read back by R before the terminal* $\mathsf{Real}^{\uparrow}$ *seal E is consumed;*
5. *non-escape, requiring H, C, P, N to export no endpoint trichotomy, quotient real equality, selected representative, countable-choice schedule, host interval order, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

No located interval separation obligation is stored outside these rows.

Proof. Carrier admission is projection from Definition 8734.1. The displayed tuple $J_0, J_1, G, D, W, R, E, H, C, P, N$ is the whole packet surface.

The source-row clause first reads the two interval packets through the located interval carrier of chapter 394. Thus every endpoint row available to the separation test is already one of the finite endpoint-window rows of J_0 or J_1.

The positive-gap clause is then dyadic. Row G names the positive gap, and row D supplies the $\mathsf{DyadicRatCore}^{\uparrow}$ positivity, subtraction, comparison, and slack data needed to replay the displayed separation check.

The window and readback rows control the handoff. Every endpoint observation and every gap-check observation passes through W, then through the $\mathsf{RegSeqRat}^{\uparrow}$ readback row R, before the terminal real-name seal E can be consumed.

Finally H, C, P, N transport, replay, source, and name that same route. Since the carrier contains no further coordinate, the listed rows exhaust the local certificate surface and cannot export trichotomy, quotient real equality, selected representatives, countable choice, host interval order, or ambient Real completeness. □

Theorem 8734.3 (Located interval separation Real-completion handoff)**.** *Every Real-facing or Completion-facing read from an accepted* $\mathsf{LocatedIntervalSeparation}^{\uparrow}$ *packet factors through two displayed* $\mathsf{LocatedInterval}^{\uparrow}$ *source rows, a positive* $\mathsf{DyadicRatCore}^{\uparrow}$ *gap row, a finite* $\mathsf{StreamName}^{\uparrow}$ *window family, a* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row, and the terminal* $\mathsf{Real}^{\uparrow}$ *seal before any downstream consumer may cite the separation boundary.*

Consequently the handoff gives Real and Completion consumers a finite positive-gap boundary. It does not provide endpoint trichotomy, quotient real equality, selected representatives, countable choice, host interval order, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Apply Definition 8734.2. The obligations force a downstream read to begin with the two displayed source intervals J_0, J_1 and the displayed positive-gap row G.

The dyadic arithmetic is internal to the same packet. Row D supplies the positive-gap check, while W and R name and read back the finite endpoint and gap observations.

The terminal real-name seal E is therefore reached only after the finite separation route has been replayed. Transport H, replay C, provenance P, and the local certificate row N preserve that displayed route for Real and Completion consumers.

Because no carrier coordinate stores a host interval order, selected endpoint representative, quotient real equality, countable-choice schedule, endpoint trichotomy, or ambient completeness theorem, the handoff exports only the finite positive-gap boundary. □

Falsifiable prediction: Every accepted $\mathsf{LocatedIntervalSeparation}^{\uparrow}$ Real-facing or Completion-facing read exposes two $\mathsf{LocatedInterval}^{\uparrow}$ source rows, one positive $\mathsf{DyadicRatCore}^{\uparrow}$ gap row, one dyadic arithmetic ledger, finite $\mathsf{StreamName}^{\uparrow}$ windows, $\mathsf{RegSeqRat}^{\uparrow}$ readback, a terminal $\mathsf{Real}^{\uparrow}$ seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Independence witness: locatedinterval, dyadicratcore, streamname, regseqrat, real: $\mathsf{LocatedIntervalSeparation}^{\uparrow}$ is not bijective to any listed sibling because it binds two located interval source rows to a positive dyadic gap before any StreamName, RegSeqRat, or Real row can be consumed.

Closure status for $\mathsf{NameCert}_{\mathsf{LocatedIntervalSeparation}^{\uparrow}}$.

Constructive story: A $\mathsf{LocatedIntervalSeparation}^{\uparrow}$ packet is generated from two LocatedInterval source rows, a positive DyadicRatCore gap row, dyadic arithmetic, finite StreamName windows, RegSeqRat readback, a terminal RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{LocatedIntervalSeparation}^{\uparrow}}$, seed)

Scope closed: Definition 8734.1, Definition 8734.2, and Definition 8734.3 seed the finite positive-gap boundary for LocatedInterval, DyadicRatCore, StreamName, RegSeqRat, Real, and Completion consumers.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{LocatedIntervalSeparation}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close endpoint trichotomy, quotient real equality, selected representatives, countable choice, host interval order, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, source-row exposure, positive-gap exactness, finite-window coverage, RegSeqRat readback, Real seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.LocatedIntervalSeparationUp.

Chapter 8735

A Concrete Naming Certificate for DeLaValleePoussinCriterion$^{\uparrow}$

Following de la Vallee Poussin and Dunford–Schwartz on uniform integrability, the DeLaValleePoussinCriterion$^{\uparrow}$ packet records the finite convex-growth route by which a family of integrable rows is admitted to uniform-integrability consumers. It sits after the uniform-integrability surface of chapter 6228, the integral ledger of chapter 123, the measure carrier of chapter 92, the regular rational readback of chapter 301, and the terminal real seal of chapter 38. The packet names only displayed finite rows for a convex-growth test and its tail budget; it does not import measure completion, quotient equality almost everywhere, a selected dominating function, host convex analysis, countable choice, or ambient Real$^{\uparrow}$ completeness.

Definition 8735.1 (de la Vallee Poussin criterion carrier)**.** *A* DeLaValleePoussinCriterion$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$D = (M, I, U, G, T, R, E, H, C, P, N)$$

with the following rows:

1. *M is the* Measure$^{\uparrow}$ *row carrying the displayed measurable source, finite family window, and inspected set budget.*
2. *I is the* Integral$^{\uparrow}$ *row recording the integrable-row reads for the family over M.*
3. *U is the* UniformIntegrability$^{\uparrow}$ *handoff row reached only after the growth and tail rows have been exposed.*
4. *G is the convex-growth row, displaying the increasing convex gauge, its finite thresholds, and the inspected growth values used by the criterion.*
5. *T is the tail-budget row, recording the finite tail thresholds and the exact budget by which large values are handed to U.*
6. *R is the* RegSeqRat$^{\uparrow}$ *readback row for the rational budgets and growth thresholds.*
7. *E is the* Real$^{\uparrow}$ *seal row for the terminal real-valued comparison data.*
8. *H records componentwise* hsame *transport for $M, I, U, G, T, R, E, C, P, N$.*
9. *C records displayed* Cont *replay from the measure and integral rows through the growth, tail, readback, and seal rows.*

10. *P is the* Pkg *provenance over* $\mathsf{DeLaValleePoussinCriterion}^{\uparrow}$, $\mathsf{Measure}^{\uparrow}$, $\mathsf{Integral}^{\uparrow}$, $\mathsf{UniformIntegrability}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{DeLaValleePoussinCriterion}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $M, I, U, G, T, R, E, H, C, P, N$. It has no coordinate for a completed measure algebra, a quotient almost-everywhere class, a selected dominating function, an ambient family of all integrable functions, or host $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 (statement) `BEDC.Derived.DeLaValleePoussinCriterionUp`

Theorem 8735.2 (de la Vallee Poussin NameCert obligations)**.** *For every accepted* $\mathsf{DeLaValleePoussinCriterion}^{\uparrow}$ *carrier*

$$D = (M, I, U, G, T, R, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{DeLaValleePoussinCriterion}^{\uparrow}}$ *surface consists exactly of the following finite obligations:*

1. *carrier admission for the* $\mathsf{Measure}^{\uparrow}$ *row M, the* $\mathsf{Integral}^{\uparrow}$ *row I, and the family window inspected by the criterion;*
2. *growth-row exposure through G, requiring the convex gauge, finite thresholds, and growth reads to remain displayed before any uniform-integrability handoff;*
3. *tail-budget exactness through T, requiring each large-value tail read to carry its finite threshold and budget;*
4. *uniform-integrability handoff through U, requiring the public consumer to read* $\mathsf{UniformIntegrability}^{\uparrow}$ *only after M, I, G, T have remained visible;*
5. $\mathsf{RegSeqRat}^{\uparrow}$ *and* $\mathsf{Real}^{\uparrow}$ *seal nonescape through R, E, requiring rational budget readback and terminal real comparison to stay tied to the same measure, integral, growth, and tail rows;*
6. *structural stability through H, C, P, N, requiring componentwise transport, displayed replay, provenance, and local naming to preserve exactly the rows M, I, U, G, T, R, E.*

No obligation may be discharged by measure completion, quotient almost-everywhere equality, a hidden dominating function, host convex-duality data, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the carrier of Definition 8735.1. The measure and integral surface is M, I, the criterion data are G, T, U, the readback and seal are R, E, and the structural rows are H, C, P, N.

The growth row is exposed before the handoff row. Thus G supplies the displayed convex gauge and inspected thresholds used by the criterion, while T supplies the exact finite tail budget for large-value reads.

The uniform-integrability consumer receives U only through that displayed route. Since R and E read the rational budgets and real comparisons after M, I, G, T have remained visible, the terminal seal cannot be read from a completed measure algebra, quotient almost-everywhere class, selected dominating function, or ambient completeness principle.

Finally H, C, P, N transport, replay, source, and name the same finite rows. The listed obligations therefore exhaust the local NameCert surface. □

Theorem 8735.3 (de la Vallee Poussin uniform-integrability route)**.** *Every Vitali-facing or dominated-convergence-facing consumer of an accepted* $\mathsf{DeLaValleePoussinCriterion}^{\uparrow}$ *packet reads the criterion through the displayed route*

$$\mathsf{Measure}^{\uparrow}, \mathsf{Integral}^{\uparrow}, G, T \longmapsto \mathsf{UniformIntegrability}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow}, \mathsf{Real}^{\uparrow}.$$

Consequently the consumer sees a finite convex-growth row, an exact finite tail budget, regular rational readback, and a terminal real seal before any uniform-integrability conclusion is exported. It does not receive measure completion, quotient almost-everywhere equality, a host dominating function, countable choice, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start with the accepted carrier of Definition 8735.1. The measure and integral rows M, I provide the source family, while the growth and tail rows G, T display the finite criterion data.

Apply the NameCert obligations of Definition 8735.2. The row U is visible only after the measure, integral, growth, and tail-budget rows have been read.

The consumer route then passes through R, E. These rows convert the finite budgets and growth thresholds into regular rational readback and a real-valued seal, so Vitali and dominated-convergence consumers receive only the finite $\mathsf{UniformIntegrability}^{\uparrow}$ handoff route. □

Closure status for $\mathsf{NameCert}_{\mathsf{DeLaValleePoussinCriterion}^{\uparrow}}$.

Constructive story: A $\mathsf{DeLaValleePoussinCriterion}^{\uparrow}$ packet is generated from finite Measure rows, Integral rows, UniformIntegrability handoff rows, convex-growth rows, tail-budget rows, RegSeqRat readback rows, Real seal rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{DeLaValleePoussinCriterion}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8735.1, Definition 8735.2, and Definition 8735.3 seed the finite convex-growth and tail-budget route from Measure and Integral rows to UniformIntegrability, RegSeqRat, and Real consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{DeLaValleePoussinCriterion}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim the full host de la Vallee Poussin theorem, measure completion, quotient almost-everywhere equality, selected domination, host convex analysis, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, theorem-level Lean verification, axiom-clean audit, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, growth-row exposure, tail-budget exactness, uniform-integrability handoff, Real-seal nonescape, transport stability, and replay stability for BEDC.Derived.DeLaValleePoussinCriterionUp.

Chapter 8736

A Concrete Naming Certificate for $\mathsf{DyadicBallBase}^{\uparrow}$

Following Bishop and Bridges and Kelley-style metric bases, the $\mathsf{DyadicBallBase}^{\uparrow}$ packet records the finite dyadic ball-basis surface that a BEDC completion or topology consumer may inspect before any ambient compactness, choice of centers, or Real completeness theorem is visible. It sits over the dyadic ball source of chapter 311, the dyadic rational ledger of chapter 291, the metric-ball comparison route of chapter 1450, the finite stream window of chapter 126, the regular rational readback of chapter 301, and the Real seal of chapter 38. The packet names only a finite basis row for inspected center-radius windows; it does not assert completion, separability, total boundedness, a selected center enumeration, or an ambient topology basis theorem.

Definition 8736.1 (Dyadic ball base carrier)**.** *A* $\mathsf{DyadicBallBase}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (Y, Q, M, W, S, E, H, C, P, N)$$

with the following displayed rows:

1. *Y is the* $\mathsf{DyadicBall}^{\uparrow}$ *source row, exposing the finite center-radius ball request and its dyadic containment vocabulary.*
2. *Q is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *center and radius ledger, recording the inspected dyadic centers, positive dyadic radii, halved-radius comparisons, and finite refinement budgets.*
3. *M is the* $\mathsf{MetricBall}^{\uparrow}$ *comparison row, tying the dyadic ball request to the metric-ball inclusion and overlap checks that a later metric topology consumer may read.*
4. *W is the* $\mathsf{StreamName}^{\uparrow}$ *window row, displaying the finite name-window reads used to expose centers and endpoint requests without selecting an infinite enumeration.*
5. *S is the* $\mathsf{RegSeqRat}^{\uparrow}$ *tolerance readback row attached to the displayed StreamName windows and dyadic-radius ledger.*
6. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row for the inspected center and radius windows, reached only after Y, Q, M, W, S have been displayed.*
7. *H records componentwise* hsame *transport for the dyadic ball, dyadic rational ledger, metric-ball comparison, stream window, regular rational readback, Real seal, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from a dyadic-ball-basis request through $Y, Q, M, W, S, E, H, P, N$.*

9. *P is the* Pkg *provenance over* $\mathsf{DyadicBallBase}^{\uparrow}$, $\mathsf{DyadicBall}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{MetricBall}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{DyadicBallBase}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $Y, Q, M, W, S, E, H, C, P, N$. It has no coordinate for a selected dense enumeration, an ambient open-set lattice, host compactness, Real completeness, quotient equality of names, or choice of centers.

Theorem 8736.2 (Dyadic ball base NameCert obligations)**.** *For every accepted* $\mathsf{DyadicBallBase}^{\uparrow}$ *carrier*

$$B = (Y, Q, M, W, S, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{DyadicBallBase}^{\uparrow}}$ *surface consists exactly of five analytic rows followed by structural support: dyadic ball admission through Y; dyadic center-radius ledger exactness through Q; metric-ball comparison through M; finite StreamName window exposure through W; RegSeqRat tolerance readback through S; terminal Real sealing through E; componentwise* hsame *transport through H; displayed* Cont *replay through C; provenance through P; and local naming through N.*

Proof. Project the carrier of Definition 8736.1. The analytic surface is the finite row sequence Y, Q, M, W, S, E, and the structural surface is H, C, P, N.

The dyadic source row is read first. It supplies the ball request, while the dyadic rational ledger records the center and radius data that make the request finite and checkable.

The metric comparison row then places the same center-radius request inside the metric-ball vocabulary. The StreamName and RegSeqRat rows expose only finite windows and tolerance readbacks, so the packet does not select an infinite basis enumeration.

Finally the Real seal and structural rows preserve the displayed sequence. Since no other coordinate occurs in the carrier, the listed rows exhaust the local NameCert surface and no ambient basis, compactness, completeness, quotient, or choice datum is exported. □

Theorem 8736.3 (Dyadic ball base finite radius stability)**.** *Let*

$$B = (Y, Q, M, W, S, E, H, C, P, N)$$

and

$$B' = (Y', Q', M', W', S', E', H', C', P', N')$$

be accepted $\mathsf{DyadicBallBase}^{\uparrow}$ *carriers. If Y, Y', Q, Q', M, M', W, W', S, S', and E, E' are componentwise* hsame *as dyadic ball rows, dyadic center-radius ledgers, metric-ball comparison rows, StreamName windows, RegSeqRat readbacks, and Real seals, then every finite basis read exported through H, C, P, N and H', C', P', N' displays the same center-radius window and the same metric-ball comparison route.*

Proof. Project both accepted carriers. The only rows that can feed a basis read are Y, Q, M, W, S, E, with H, C, P, N and H', C', P', N' only transporting, replaying, sourcing, and naming the same packet shapes.

Apply the NameCert obligation surface of Definition 8736.2. It forces every consumer read through the dyadic ball source, dyadic rational center-radius ledger, metric-ball comparison, finite window, tolerance readback, and Real seal.

The componentwise hsame assumptions identify each analytic row in the two packets. Replay through C and C' therefore follows the same finite sequence, and transport through H and H'

preserves the displayed center-radius and comparison data. Provenance and naming add no new coordinate.

Thus the exported basis read is stable under the displayed finite radius data. The theorem does not assert an ambient topology basis, a chosen dense sequence, a compact net, Real completeness, or quotient equality of names. □

Theorem 8736.4 (Dyadic ball base non-escape)**.** *Every completion, metric-topology, or compact-net consumer of an accepted* $\mathsf{DyadicBallBase}^{\uparrow}$ *packet must read the route*

$$Y \to Q \to M \to W \to S \to E$$

before using the structural rows H, C, P, N*. The consumer receives a finite dyadic center-radius basis surface and cannot read a hidden modulus selector, selected dense enumeration, ambient open-set lattice, quotient stream equality, selected limit, host compactness proof, or Real completeness theorem from the packet.*

Proof. Start with the carrier and NameCert obligation surface, Definition 8736.1 and Definition 8736.2. They expose exactly the dyadic ball source, dyadic rational ledger, metric-ball comparison, finite window, tolerance readback, Real seal, and structural rows.

The route to a completion or topology consumer is ordered. The dyadic ball request is not public without the center-radius ledger, the metric comparison is not public before that ledger, and the window and tolerance rows are the only way the Real seal is reached.

Finally apply finite radius stability, Definition 8736.3. It shows that consumers can preserve the displayed center-radius window and metric comparison route, but only through the same finite rows. Since the carrier has no coordinate for the excluded selector, enumeration, lattice, quotient, limit, compactness, or completeness objects, no consumer can read them from the packet. □

Falsifiable prediction: Every accepted $\mathsf{DyadicBallBase}^{\uparrow}$ read exposes a $\mathsf{DyadicBall}^{\uparrow}$ source row, a $\mathsf{DyadicRatCore}^{\uparrow}$ center-radius ledger, a $\mathsf{MetricBall}^{\uparrow}$ comparison row, a $\mathsf{StreamName}^{\uparrow}$ finite window, a $\mathsf{RegSeqRat}^{\uparrow}$ tolerance readback, a $\mathsf{Real}^{\uparrow}$ seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming.

Independence witness: dyadicball, dyadicratcore, metricball, streamname, regseqrat, real: $\mathsf{DyadicBallBase}^{\uparrow}$ is not bijective to any listed sibling because it binds dyadic ball requests, dyadic center-radius ledgers, metric-ball comparisons, finite stream windows, regular rational tolerance readbacks, and Real seals into one finite basis packet.

Closure status for $\mathsf{NameCert}_{\mathsf{DyadicBallBase}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{DyadicBallBase}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8736.1, Definition 8736.2, Definition 8736.3, and Definition 8736.4 seed the finite dyadic ball-basis surface over dyadic ball, DyadicRatCore, MetricBall, StreamName, RegSeqRat, Real, transport, replay, provenance, and local naming rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{DyadicBallBase}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close Real completeness, compactness, total boundedness, selected dense enumerations, quotient equality of names, ambient topology-basis theorems, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked dyadic ball admission, center-radius ledger exactness, metric-ball comparison, finite window exposure, tolerance readback, Real seal routing, transport stability, replay stability, provenance, local naming, and non-escape for BEDC.Derived.DyadicBallBaseUp.

Constructive story: A $\mathsf{DyadicBallBase}^{\uparrow}$ packet is generated from a DyadicBall source row, a DyadicRatCore center-radius ledger, a MetricBall comparison row, a StreamName window row, a RegSeqRat tolerance readback row, a Real seal row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 8737

A Concrete Naming Certificate for $\mathsf{EgoroffFiniteMeasure}^{\uparrow}$

Following Egoroff and Bishop–Bridges constructive analysis, the $\mathsf{EgoroffFiniteMeasure}^{\uparrow}$ packet records the finite-measure convergence neighbour in which pointwise tail data are converted into a displayed uniform-tail window after paying an explicit exceptional-measure budget. It sits after the root measure rows of chapter 92, the finite event-value substrate of chapter 6127, the finite $\mathsf{StreamName}^{\uparrow}$ observation windows of chapter 126, the $\mathsf{RegSeqRat}^{\uparrow}$ readback of chapter 301, and the terminal $\mathsf{Real}^{\uparrow}$ seal of chapter 38. The packet records finite exceptional sets, finite tail thresholds, and uniform-window handoff rows only; it does not assert a full almost-everywhere quotient, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 8737.1 (Egoroff finite-measure carrier)**.** *An* $\mathsf{EgoroffFiniteMeasure}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$E = (M, F, S, B, W, R, U, H, C, P, N)$$

with the following displayed rows:

1. *M is the* $\mathsf{Measure}^{\uparrow}$ *source row, exposing the measurable domain and event-family route inspected by the convergence packet.*
2. *F is the* $\mathsf{FiniteMeasure}^{\uparrow}$ *row, giving the finite total-mass bound and the finite event-value ledger for exceptional sets.*
3. *S is the* $\mathsf{StreamName}^{\uparrow}$ *pointwise-observation row, listing the finite stream probes and tail requests read from the converging family.*
4. *B is the exceptional-budget row, assigning each requested precision a displayed finite event whose* $\mathsf{FiniteMeasure}^{\uparrow}$ *value is below the requested rational tolerance.*
5. *W is the uniform-tail window row, recording the finite tail index after the exceptional event has been removed.*
6. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row used to compare displayed values on the accepted tail window.*
7. *U is the uniform-window handoff row, binding B, W, R to the same measure source and stream observations.*
8. *H records componentwise* hsame *transport for the measure, finite-measure, stream, budget, window, readback, handoff, replay, provenance, and local naming rows.*

9. *C records displayed* Cont *replay from a convergence request through $M, F, S, B, W, R, U, H, P, N$.*
10. *P is the* Pkg *provenance over* $\mathsf{EgoroffFiniteMeasure}^{\uparrow}$, $\mathsf{Measure}^{\uparrow}$, $\mathsf{FiniteMeasure}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{EgoroffFiniteMeasure}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $M, F, S, B, W, R, U, H, C, P, N$. It has no coordinate for a countable exceptional-set union, quotient almost-everywhere equality, selected infinite subsequence, host measurable-function object, or ambient real-completeness principle.

Theorem 8737.2 (Egoroff finite-measure NameCert obligations)**.** *For every accepted* $\mathsf{EgoroffFiniteMeasure}^{\uparrow}$ *carrier*

$$E = (M, F, S, B, W, R, U, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{EgoroffFiniteMeasure}^{\uparrow}}$ *surface consists exactly of carrier admission for the measure source, finite-measure ledger, finite stream observations, exceptional-measure budget, uniform-tail window,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback, uniform-window handoff, componentwise transport, displayed replay, provenance, and local naming rows. No obligation is stored outside $M, F, S, B, W, R, U, H, C, P, N$.*

Proof. Project the carrier of Definition 8737.1. The analytic rows are M, F, S, B, W, R, U, while H, C, P, N are the structural certificate rows.

The measure source and finite-measure ledger are admitted first. The exceptional-budget row B can therefore speak only about displayed finite events and their recorded finite values, not about a hidden countable union or completed null ideal.

The stream row S supplies the inspected pointwise tails. The rows W and R then expose a finite tail index and a regular rational readback for the accepted request.

Finally U, H, C, P, N bind that budget and window to one public route. Since no excluded object is a carrier coordinate, none is a NameCert obligation of the packet. □

Theorem 8737.3 (Egoroff finite-measure uniform-window handoff)**.** *Every convergence consumer of an accepted* $\mathsf{EgoroffFiniteMeasure}^{\uparrow}$ *carrier must factor through the displayed route*

$$M, F, S \longmapsto B \longmapsto W, R \longmapsto U, H, C, P, N.$$

Thus the only public handoff is the finite BEDC route from a $\mathsf{Measure}^{\uparrow}$ *source and* $\mathsf{FiniteMeasure}^{\uparrow}$ *event-value ledger through* $\mathsf{StreamName}^{\uparrow}$ *observations, an exceptional-measure budget, a uniform-tail window,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback, and the terminal* $\mathsf{Real}^{\uparrow}$ *seal. It exports no almost-everywhere quotient, countable-choice selector, infinite exceptional-set union, hidden host limit, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Begin with the NameCert obligations of Definition 8737.2. They place the measure source M, finite-measure ledger F, and stream observations S before any uniform conclusion is visible.

The exceptional-budget row B is downstream of the finite-measure ledger. It records a displayed finite event and a displayed tolerance comparison for the current request, so the handoff cannot appeal to a countable null-set construction.

The uniform-tail window W and readback row R are then inspected on the remaining displayed route. The handoff row U ties the same budget, window, and readback to the source rows M, F, S.

Transport, replay, provenance, and local naming are carried by H, C, P, N. These rows preserve the same finite route and do not create an independent quotient or completeness boundary. □

Falsifiable prediction: Every accepted $\mathsf{EgoroffFiniteMeasure}^{\uparrow}$ read must expose a MeasureUp source, FiniteMeasureUp event-value ledger, finite StreamName observations, exceptional-measure budget, uniform-tail window, RegSeqRat readback, uniform-window handoff, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert row.

Independence witness: measure, finite-measure, streamname, regseqrat, real: $\mathsf{EgoroffFiniteMeasure}^{\uparrow}$ is not bijective to any listed sibling because it binds exceptional finite-measure budgets to uniform-tail windows and regular rational readback in one local NameCert carrier.

Closure status for $\mathsf{NameCert}_{\mathsf{EgoroffFiniteMeasure}^{\uparrow}}$.

Constructive story: An $\mathsf{EgoroffFiniteMeasure}^{\uparrow}$ packet is generated from a MeasureUp source row, a FiniteMeasureUp event-value ledger, finite StreamName observations, exceptional-measure budget rows, uniform-tail windows, RegSeqRat readback, a RealUp seal boundary, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{EgoroffFiniteMeasure}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8737.1, Definition 8737.2, and Definition 8737.3 seed the finite-measure Egoroff route from displayed exceptional budgets to uniform-tail windows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{EgoroffFiniteMeasure}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close Lean verification, bridge checking, countable exceptional-set unions, full almost-everywhere quotients, selected subsequences, host measurable-function equality, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Upgrade path: Obligation closure requires checked carrier admission, finite event-value exactness, exceptional-budget readback, uniform-tail window handoff, RegSeqRat and Real seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.EgoroffFiniteMeasureUp.

Chapter 8738

A Concrete Naming Certificate for $\mathsf{DyadicApartnessScale}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{DyadicApartnessScale}^{\uparrow}$ packet records the finite dyadic scale by which constructive real apartness is witnessed before any trichotomy or quotient real equality is available. It sits after the dyadic rational carrier of chapter 291, the regular rational readback of chapter 301, the located apartness route of chapter 7144, the RealMetric boundary of chapter 1638, and the terminal Real certificate of chapter 38. The packet is a finite scale witness for separation reads; it is not a comparison oracle, a selected real representative, an ambient completeness theorem, or a host equality principle.

Definition 8738.1 (Dyadic apartness scale carrier)**.** *A* $\mathsf{DyadicApartnessScale}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$A = (D, R, L, M, E, H, C, P, N)$$

with the following displayed rows:

1. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *scale row, carrying the positive dyadic tolerance and the two dyadic rational comparison endpoints inspected by the apartness read.*
2. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row, exposing the finite regular rational windows whose distance is compared against the dyadic scale.*
3. *L is the located-apartness row, recording that the apartness witness is displayed as positive separation data rather than as trichotomy.*
4. *M is the* $\mathsf{RealMetric}^{\uparrow}$ *metric row, naming the finite distance estimate consumed by separation-facing Real readers.*
5. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row, available only after D, R, L, M have been displayed.*
6. *H records componentwise* hsame *transport for the dyadic scale, regular readback, located-apartness, metric, Real seal, replay, provenance, and local naming rows.*
7. *C records displayed* Cont *replay from each Real-facing separation request through D, R, L, M, E, H, P, N.*
8. *P is the* Pkg *provenance over* $\mathsf{DyadicApartnessScale}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *located apartness,* $\mathsf{RealMetric}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
9. *N is the local* $\mathsf{NameCert}_{\mathsf{DyadicApartnessScale}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $D, R, L, M, E, H, C, P, N$. It has no coordinate for real trichotomy, quotient real equality, selected limits, host representatives, countable choice, ambient $\mathsf{Real}^{\uparrow}$ *completeness, or bridge checking.*

Theorem 8738.2 (Dyadic apartness scale NameCert obligations)**.** *For every accepted* $\mathsf{DyadicApartnessScale}^{\uparrow}$ *carrier*

$$A = (D, R, L, M, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{DyadicApartnessScale}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *dyadic-scale admission for the positive dyadic tolerance and inspected dyadic rational endpoints carried by D;*
2. *regular-window exposure requiring each separation read to pass through the* $\mathsf{RegSeqRat}^{\uparrow}$ *row R before the Real seal is consumed;*
3. *located-apartness exposure requiring L to display positive separation data and to refuse trichotomy as a public primitive;*
4. *metric handoff through M, recording only the finite distance estimate needed by RealMetric consumers;*
5. *Real-seal non-escape through E, followed by componentwise transport, displayed replay, provenance, and local naming through H, C, P, N.*

No accepted obligation row stores quotient real equality, selected limits, host real representatives, countable choice, ambient $\mathsf{Real}^{\uparrow}$ *completeness, or checked bridge data.*

Proof. Carrier admission is projection from Definition 8738.1. The tuple $A = (D, R, L, M, E, H, C, P, N)$ is the whole surface exposed to a separation-facing consumer.

The dyadic-scale and regular-window clauses force the apartness read to start from D and R. Thus the consumer sees a positive dyadic tolerance and finite regular rational windows, not an infinite representative or a quotient class.

The located-apartness and metric clauses then route the same data through L and M. The witness is positive separation at a displayed scale, and the RealMetric row records only the finite estimate needed for that separation.

Finally, E, H, C, P, N seal, transport, replay, package, and name the same finite rows. Since the carrier contains no coordinate for trichotomy, quotient equality, selected limits, choice, ambient completeness, or bridge checking, those objects cannot be exported by the NameCert surface. □

Theorem 8738.3 (Dyadic apartness scale Real separation handoff)**.** *Every Real-facing separation read of an accepted* $\mathsf{DyadicApartnessScale}^{\uparrow}$ *carrier factors through the finite route*

$$\mathsf{DyadicRatCore}^{\uparrow} \longrightarrow \mathsf{RegSeqRat}^{\uparrow} \longrightarrow \textit{located apartness} \longrightarrow \mathsf{RealMetric}^{\uparrow} \longrightarrow \mathsf{Real}^{\uparrow}$$

displayed by D, R, L, M, E. The handoff may witness that two Real reads are apart at a dyadic scale, but it does not decide equality, decide order, choose representatives, select limits, or supply ambient Real completeness.

Proof. Read the separation request through the dyadic scale row D and the finite regular windows in R. The only available comparison datum is a positive dyadic tolerance attached to displayed rational approximants.

Next pass the same datum through the located-apartness row L and the RealMetric row M. These rows state the finite positive-separation evidence consumed by the Real-facing read.

The terminal Real seal E is reached only after those rows are present, and the structural rows H, C, P, N replay exactly the same packet. Therefore the handoff supplies scale-indexed apartness evidence, not equality decision, order trichotomy, representative selection, selected limits, or ambient completeness. □

Falsifiable prediction: Every accepted $\mathsf{DyadicApartnessScale}^{\uparrow}$ consumer must display a DyadicRatCore scale row, a RegSeqRat finite-window readback row, a located-apartness row, a RealMetric estimate row, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row before Real-facing separation can be consumed.

Independence witness: dyadicratcore, regseqrat, located-apartness-field, realmetric, real: no listed sibling supplies the joint scale packet containing dyadic tolerance data, regular rational windows, located-apartness evidence, metric estimate, terminal Real seal, transport, replay, provenance, and local NameCert row.

Closure status for $\mathsf{NameCert}_{\mathsf{DyadicApartnessScale}^{\uparrow}}$.

Constructive story: A $\mathsf{DyadicApartnessScale}^{\uparrow}$ packet is generated from a DyadicRatCore scale row, RegSeqRat finite-window readback, located-apartness evidence, RealMetric estimate, Real seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{DyadicApartnessScale}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8738.1, Definition 8738.2, and Definition 8738.3 seed the finite dyadic scale route for constructive Real apartness.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{DyadicApartnessScale}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close trichotomy, quotient real equality, selected limits, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked dyadic-scale admission, regular-window exposure, located-apartness exposure, metric handoff, Real-seal non-escape, transport, replay, provenance, and local naming for BEDC.Derived.DyadicApartnessScaleUp.

Chapter 8739

A Concrete Naming Certificate for MetaCICResidualLocalConfluenceMatrix$^{\uparrow}$

The MetaCICResidualLocalConfluenceMatrix$^{\uparrow}$ packet realizes the bounded residual local-join frontier of chapter 9378 as finite matrix data. It sits beside the residual checker of chapter 3827, the residual local-join determinacy packet of chapter 5970, the residual-substitution boundary of chapter 2181, the parallel-diamond frontier of chapter 4238, and the confluence audit packet of chapter 735. The matrix records typed windows, residual pairs, bounded checkers, obstruction retention, transport, replay, provenance, and local naming before any confluence consumer may cite a local join.

Definition 8739.1 (MetaCIC residual local-confluence matrix carrier)**.** *A* MetaCICResidualLocalConfluenceMatrix$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M = (T, R, J, B, O, H, C, P, N)$$

with the following displayed rows:

1. *T is the typed-window row, naming the finite MetaCIC source terms and contexts inspected by the matrix.*
2. *R is the residual-pair row, recording the bounded residual branch pairs whose local join status is under inspection.*
3. *J is the candidate local-join row, displaying only the finite common-reduct candidates admitted by the checker.*
4. *B is the bounded-checker row, recording the finite checker outcome for each displayed residual pair.*
5. *O is the obstruction row, retaining residual-substitution compatibility, unrestricted closed parallel diamond, arbitrary closed Church–Rosser, subject-reduction discharge, evaluator equality, and kernel consistency as visible non-exports.*
6. *H records componentwise* hsame *transport for typed windows, residual pairs, candidate joins, checker outcomes, obstruction rows, replay, provenance, and local naming.*
7. *C records displayed* Cont *replay from each confluence-facing request through T, R, J, B, O, H, P, N.*
8. *P is the* Pkg *provenance over* MetaCICResidualLocalConfluenceMatrix$^{\uparrow}$*, the residual checker, residual local-join determinacy, residual-substitution boundary, parallel-diamond frontier, confluence audit packet,* BHist*,* hsame*,* Cont*, and* NameCert*.*

9. N is the local $\mathsf{NameCert}_{\mathsf{MetaCICResidualLocalConfluenceMatrix}^{\uparrow}}$ *row.*
The classifier compares accepted packets only through $T, R, J, B, O, H, C, P, N$. It has no coordinate for unrestricted substitution compatibility, arbitrary closed parallel diamond, arbitrary closed Church–Rosser, subject reduction, evaluator equality, kernel consistency, or bridge checking.

Theorem 8739.2 (MetaCIC residual local-confluence matrix NameCert obligations)**.** *For every accepted* $\mathsf{MetaCICResidualLocalConfluenceMatrix}^{\uparrow}$ *carrier*

$$M = (T, R, J, B, O, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{MetaCICResidualLocalConfluenceMatrix}^{\uparrow}}$ *surface consists exactly of typed-window exposure, residual-pair exposure, candidate local-join exposure, bounded-checker exactness, obstruction retention, componentwise transport, displayed replay, provenance, and local naming. Any accepted confluence-facing consumer must expose $T, R, J, B, O, H, C, P, N$ before treating a residual local join as available to the confluence audit route.*

Proof. Carrier admission is projection from Definition 8739.1. The typed windows, residual pairs, candidate joins, checker outcomes, and obstruction rows are all explicit coordinates of M.

The local-join read first displays T and R, so the matrix is tied to a bounded typed residual frontier. It then displays J and B, so candidate joins are available only through the finite checker row.

The obstruction row O remains visible after the checker outcome. Thus any missing residual-substitution compatibility or closed-diamond premise is retained as data rather than silently discharged.

Finally, H, C, P, N transport, replay, package, and name the same finite rows. Since no carrier coordinate stores an unrestricted confluence theorem, the NameCert surface cannot export arbitrary closed parallel diamond or Church–Rosser. □

Theorem 8739.3 (MetaCIC residual local-confluence matrix budget handoff)**.** *Every bounded local-join handoff exported by an accepted* $\mathsf{MetaCICResidualLocalConfluenceMatrix}^{\uparrow}$ *carrier factors through the finite route*

$$T \longrightarrow R \longrightarrow J \longrightarrow B \longrightarrow O$$

inside $M = (T, R, J, B, O, H, C, P, N)$. The route may pass checked residual-pair rows to the confluence audit map, but it must retain the obstruction row whenever residual-substitution compatibility, unrestricted closed parallel diamond, or arbitrary closed Church–Rosser has not been supplied.

Proof. The typed-window and residual-pair rows bound the source of every matrix entry. A handoff cannot name a candidate join until those finite source rows have been displayed.

The candidate local-join and bounded-checker rows then identify which entries passed the finite checker. These rows are budgeted by B, not by a global proof search or an unrestricted confluence theorem.

The obstruction row O remains part of the exported route. Therefore the handoff can support bounded local joins while still refusing arbitrary closed parallel diamond, Church–Rosser, unchecked substitution compatibility, subject reduction, evaluator equality, and kernel consistency. □

Falsifiable prediction: Every accepted $\mathsf{MetaCICResidualLocalConfluenceMatrix}^{\uparrow}$ consumer that cites a residual local join without first displaying typed-window, residual-pair, candidate local-join,

bounded-checker, obstruction, transport, replay, provenance, and local NameCert rows refutes the matrix surface.

Independence witness: metacic-confluence-residual-checker, metacic-residual-join-determinacy, metacic-residual-substitution-boundary, metacic-parallel-diamond-frontier, metacic-confluence-audit-packet: no listed sibling jointly carries typed windows, residual pairs, candidate local joins, bounded checker outcomes, obstruction retention, transport, replay, provenance, and local naming as one finite matrix packet.

Closure status for $\mathsf{NameCert}_{\mathsf{MetaCICResidualLocalConfluenceMatrix}^{\uparrow}}$.

Constructive story: A $\mathsf{MetaCICResidualLocalConfluenceMatrix}^{\uparrow}$ packet is generated from typed-window rows, residual-pair rows, candidate local-join rows, bounded-checker rows, obstruction rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{MetaCICResidualLocalConfluenceMatrix}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8739.1, Definition 8739.2, and Definition 8739.3 seed the finite matrix route for bounded residual local joins.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{MetaCICResidualLocalConfluenceMatrix}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close residual-substitution compatibility, arbitrary closed parallel diamond, arbitrary closed Church–Rosser, subject reduction, evaluator equality, kernel consistency, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked typed-window exposure, residual-pair exposure, candidate local-join exposure, bounded-checker exactness, obstruction retention, transport, replay, provenance, and local naming for BEDC.Derived.MetaCICResidualLocalConfluenceMatrixUp.

Chapter 8740

A Concrete Naming Certificate for $\mathsf{RegularCauchyRealizer}^{\uparrow}$

Following Bishop and Bridges on regular Cauchy real numbers, the $\mathsf{RegularCauchyRealizer}^{\uparrow}$ packet records the finite readback route by which regular Cauchy data answers precision requests before the terminal $\mathsf{Real}^{\uparrow}$ seal is exposed. It sits beside the general realizer route of chapter 1771, the finite observation windows of chapter 126, the regular rational readback of chapter 301, the dyadic tolerance ledger of chapter 291, and the Real carrier seal of chapter 38. The packet names a choice-free L10 Real and Completion readback surface; it is not quotient stream equality, a selected limit, countable choice, trichotomy, host real equality, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 8740.1 (Regular Cauchy realizer carrier)**.** *A* $\mathsf{RegularCauchyRealizer}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$R = (A, W, Q, D, E, H, C, P, N)$$

with the following displayed rows:

1. *A is the RegularCauchy source row, recording the request-to-tail discipline for the regular Cauchy name consumed by the realizer.*
2. *W is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row through which each precision request is inspected.*
3. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the regular rational values visible in the selected window.*
4. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row, recording the dyadic bound against which the readback is checked.*
5. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal available only after the source, window, readback, and tolerance rows have been displayed.*
6. *H records componentwise* hsame *transport for A, W, Q, D, E, C, P, N.*
7. *C records displayed* Cont *replay of the same request-to-window route.*
8. *P is the* Pkg *provenance over* $\mathsf{RegularCauchyRealizer}^{\uparrow}$, $\mathsf{CauchyRealizer}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
9. *N is the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyRealizer}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $A, W, Q, D, E, H, C, P, N$. It has no coordinate for quotient stream equality, selected host limits, ambient completeness, countable choice, trichotomy, or host real equality.

Theorem 8740.2 (Regular Cauchy realizer NameCert obligations)**.** *For every accepted* $\mathsf{RegularCauchyRealizer}^{\uparrow}$ *carrier* $R = (A, W, Q, D, E, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyRealizer}^{\uparrow}}$ *surface consists exactly of carrier admission for the RegularCauchy source row,* $\mathsf{StreamName}^{\uparrow}$ *windows,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance, terminal* $\mathsf{Real}^{\uparrow}$ *seal, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. Every consumer route must expose the same readback chain used by* $\mathsf{CauchyRealizer}^{\uparrow}$ *before it may cite the Real-facing seal.*

Proof. Project the carrier of Definition 8740.1. Its rows are exactly $A, W, Q, D, E, H, C, P, N$, so local naming has no source outside the finite packet.

The regular Cauchy source A answers a precision request only through the finite observation window W. The observed values are then read as regular rational data through Q and checked against the dyadic tolerance row D.

The terminal Real seal E is downstream of those rows. Transport H, replay C, provenance P, and local naming N preserve and name the same route. Since no quotient, selector, choice, trichotomy, or ambient-completeness coordinate occurs in the carrier, these rows exhaust the NameCert obligations. □

Theorem 8740.3 (Regular Cauchy realizer Real-seal route)**.** *Every* $\mathsf{Real}^{\uparrow}$ *seal exported by an accepted* $\mathsf{RegularCauchyRealizer}^{\uparrow}$ *carrier factors through the finite route*

$$A \to W \to Q \to D \to E \to H \to C \to P \to N.$$

Thus a Real or Completion consumer reads the RegularCauchy source, $\mathsf{StreamName}^{\uparrow}$ *window,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance, terminal Real seal, componentwise transport, replay, provenance, and local* NameCert *rows before it treats the packet as a realizer. The route does not claim completeness of* $\mathsf{Real}^{\uparrow}$ *or equality with a host quotient real.*

Proof. Open the exported Real seal row E. By Definition 8740.1, that row is available only inside the same finite packet as the RegularCauchy source, StreamName window, RegSeqRat readback, and DyadicRatCore tolerance rows.

Apply Definition 8740.2. It forces every consumer read to pass through A, W, Q, D before the seal and then through transport, replay, provenance, and local naming.

The sibling $\mathsf{CauchyRealizer}^{\uparrow}$ chapter supplies the general realizer pattern, while this packet narrows the read to regular Cauchy data. Because neither carrier contains host quotient equality, selected limits, countable choice, or ambient Real completeness, the displayed row route is the full Real-seal route. □

Falsifiable prediction: Every accepted RegularCauchyRealizerUp Real or Completion read exposes a RegularCauchy source row, StreamName finite window, RegSeqRat readback, DyadicRatCore tolerance row, terminal RealUp seal, hsame transport, Cont replay, Pkg provenance, and local NameCert row before a consumer receives the seal.

Independence witness: cauchy-realizer, streamname, regseqrat, dyadicratcore, real: $\mathsf{RegularCauchyRealizer}^{\uparrow}$ is not bijective to any listed sibling because it jointly binds regular Cauchy source data, finite windows, rational readback, dyadic tolerance, Real sealing, transport, replay, provenance, and local naming while refusing quotient equality and selected limits.

Closure status for $\mathsf{NameCert}_{\mathsf{RegularCauchyRealizer}^{\uparrow}}$**.**

Constructive story: A $\mathsf{RegularCauchyRealizer}^{\uparrow}$ packet is generated from a RegularCauchy source row, finite StreamName windows, RegSeqRat readback, DyadicRatCore tolerance, a terminal Real seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\mathsf{RegularCauchyRealizer}\uparrow}$, seed)

Scope closed: Definition 8740.1, Definition 8740.2, and Definition 8740.3 seed the finite regular Cauchy readback route into the Real seal.

Formal verification: FormalStatus(NameCert$_{\mathsf{RegularCauchyRealizer}\uparrow}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close quotient stream equality, selected limits, countable choice, trichotomy, host real equality, ambient Real$^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, finite-window readback, dyadic tolerance accounting, Real-seal factorization, transport, replay, provenance, and local naming for BEDC.Derived.RegularCauchyRealizerUp.

Chapter 8741

A Concrete Naming Certificate for $\mathsf{LocatedIntervalModulusPartition}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{LocatedIntervalModulusPartition}^{\uparrow}$ packet records the finite partition and mesh-modulus surface by which a located interval is handed to dyadic and real-name consumers. It sits after the located interval boundary of chapter 394, the dyadic interval net of chapter 5966, the dyadic rational core of chapter 291, the finite stream windows of chapter 126, the regular rational readback of chapter 301, and the terminal real-name seal of chapter 38. The packet gives L10 Real and Completion consumers a named finite-means partition/modulus object; it is not host interval equality, selected representatives, trichotomy, choice, compactness, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 8741.1 (Located interval modulus partition carrier)**.** *A* $\mathsf{LocatedIntervalModulusPartition}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M = (L, U, A, Q, D, K, W, R, S, H, C, P, N)$$

with the following displayed rows:

1. *L and U are the located interval endpoint rows inherited from* $\mathsf{LocatedInterval}^{\uparrow}$*.*
2. *A is the locatedness and endpoint-order row, binding the endpoints before any interval partition is read.*
3. *Q is the finite dyadic partition-cell row supplied by* $\mathsf{DyadicIntervalNet}^{\uparrow}$*.*
4. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row used to express cell endpoints, mesh bounds, and outward rounding budgets.*
5. *K is the mesh-modulus row, recording the finite precision request that bounds the displayed partition cells.*
6. *W is the* $\mathsf{StreamName}^{\uparrow}$ *window row for endpoint and cell reads at the displayed mesh.*
7. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the dyadic and stream-window observations.*
8. *S is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row for partition and endpoint consumers.*
9. *H records componentwise* hsame *transport for endpoint, locatedness, partition, tolerance, modulus, window, readback, seal, replay, provenance, and local naming rows.*
10. *C records displayed* Cont *replay of the same partition/modulus route.*

11. *P is the* Pkg *provenance over* $\mathsf{LocatedIntervalModulusPartition}^{\uparrow}$, $\mathsf{LocatedInterval}^{\uparrow}$, $\mathsf{DyadicIntervalNet}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
12. *N is the local* $\mathsf{NameCert}_{\mathsf{LocatedIntervalModulusPartition}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $L, U, A, Q, D, K, W, R, S, H, C, P, N$. It has no coordinate for host interval equality, selected endpoint or cell representatives, trichotomy, countable choice, compactness, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 8741.2 (Located interval modulus partition carrier obligations)**.** *For every accepted* $\mathsf{LocatedIntervalModulusPartition}^{\uparrow}$ *carrier*

$$M = (L, U, A, Q, D, K, W, R, S, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{LocatedIntervalModulusPartition}^{\uparrow}}$ *surface exposes exactly located interval endpoints, finite dyadic partition cells, mesh-modulus data,* $\mathsf{StreamName}^{\uparrow}$ *windows,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback, the* $\mathsf{Real}^{\uparrow}$ *seal, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. Every partition read must pass through $A, Q, D, K, W, R, S, H, C, P, N$ after the endpoints are displayed, and the packet exports no host interval equality, selected representatives, trichotomy, choice, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the carrier of Definition 8741.1. Its rows are exactly $L, U, A, Q, D, K, W, R, S, H, C, P, N$, so accepted packets expose endpoint, locatedness, partition, tolerance, modulus, window, readback, seal, transport, replay, provenance, and naming data and no further host interval coordinate.

The finite partition route begins with the located interval endpoint rows and the locatedness row A. The dyadic cells Q are then read through the tolerance row D and mesh-modulus row K, which fixes the finite precision at which the partition is visible.

The real-name handoff is downstream of the finite rows. Stream windows W and regular rational readback R mediate the dyadic observations before the terminal seal S can be consumed.

Finally H, C, P, N transport, replay, source, and name the same finite packet. Since the carrier has no row for host interval equality, selected representatives, trichotomy, choice, compactness, or ambient $\mathsf{Real}^{\uparrow}$ completeness, none of those endpoints is exported. □

Falsifiable prediction: Every accepted $\mathsf{LocatedIntervalModulusPartition}^{\uparrow}$ consumer that reads a partition cell must expose located endpoints, dyadic partition cells, mesh modulus, stream windows, regular rational readback, Real seal, transport, replay, provenance, and local NameCert rows before exporting the read.

Closure status for $\mathsf{NameCert}_{\mathsf{LocatedIntervalModulusPartition}^{\uparrow}}$.

Constructive story: A $\mathsf{LocatedIntervalModulusPartition}^{\uparrow}$ packet is generated from located interval endpoints, an endpoint-order row, finite dyadic partition cells, a dyadic tolerance row, a mesh-modulus row, StreamName windows, RegSeqRat readback, a Real seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{LocatedIntervalModulusPartition}^{\uparrow}}$, seed)

Scope closed: Definition 8741.1 and Definition 8741.2 seed the finite partition/modulus route from located intervals to dyadic nets and regular real readback.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{LocatedIntervalModulusPartition}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close host interval equality, selected representatives, trichotomy, choice, compactness, ambient RealUp completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, endpoint-order preservation, dyadic partition-cell visibility, mesh-modulus readback, StreamName windows, RegSeqRat handoff, Real seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.LocatedIntervalModulusPartitionUp.

Chapter 8742

A Concrete Naming Certificate for PerfectlyNormalSpace$^{\uparrow}$

Following Engelking and Munkres on perfectly normal spaces, the PerfectlyNormalSpace$^{\uparrow}$ packet records the classical separation surface where every displayed closed row is presented as a zero set and every displayed open row is presented as the complementary cozero set. It sits above the topology carrier of chapter 88, the closed-pair separation route of chapter 1866, the separation-function route of **??**, the zero/cozero boundary of chapter 1858 and chapter 1857, and the continuous-map surface of chapter 130. The packet names only finite displayed rows for this traditional point-set condition; it does not import host powersets, arbitrary function spaces, selected complements, quotient equality of functions, or ambient real completeness.

Definition 8742.1 (Perfectly normal space carrier)**.** *A* PerfectlyNormalSpace$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$P = (T, N, F, Z, O, U, M, H, C, K, L)$$

with the following displayed rows:

1. *T is the* Topology$^{\uparrow}$ *source row, carrying the open-set and closed-set observation surface.*
2. *N is the* NormalSpace$^{\uparrow}$ *row, exposing the closed-pair neighborhood separation route already named in chapter 1866.*
3. *F is the finite ledger of displayed closed rows that the packet will expose as zero sets.*
4. *Z assigns to each closed row in F a* ZeroSet$^{\uparrow}$ *witness and the corresponding continuous real-valued function row.*
5. *O is the open/cozero handoff row, recording that the complement of each displayed closed row in F is consumed as a* CozeroSet$^{\uparrow}$ *row.*
6. *U is the* UrysohnLemma$^{\uparrow}$ *boundary row, tying the zero-set and cozero-set witnesses to the separation-function route of* **??**.
7. *M is the* ContinuousMap$^{\uparrow}$ *row for the displayed real-valued functions used by Z and O.*
8. *H records componentwise* hsame *transport for the topology, normal-space, closed-row, zero-set, cozero-set, Urysohn-boundary, continuous-map, replay, provenance, and local naming rows.*
9. *C records displayed* Cont *replay from a closed-row request through T, N, F, Z, O, U, M.*

10. *K is the* Pkg *provenance over* PerfectlyNormalSpace$^\uparrow$, Topology$^\uparrow$, NormalSpace$^\uparrow$, ZeroSet$^\uparrow$, CozeroSet$^\uparrow$, UrysohnLemma$^\uparrow$, ContinuousMap$^\uparrow$, BHist, hsame, Cont, *and* NameCert.
11. *L is the local* NameCert$_{\text{PerfectlyNormalSpace}^\uparrow}$ *row.*

The carrier contains no coordinate for a host powerset of closed subsets, arbitrary complement selection, unrestricted function-space equality, choice over separating maps, or ambient Real$^\uparrow$ *completeness.*

Theorem 8742.2 (Perfectly normal space NameCert obligations)**.** *For every accepted* PerfectlyNormalSpace$^\uparrow$ *carrier*

$$P = (T, N, F, Z, O, U, M, H, C, K, L),$$

the local NameCert$_{\text{PerfectlyNormalSpace}^\uparrow}$ *surface consists exactly of the finite rows that admit the topology source, the normal-space closed-pair route, the displayed closed rows, their zero-set witnesses, the complementary cozero-set handoff, the Urysohn function boundary, the continuous-map rows, componentwise* hsame*, displayed* Cont*,* Pkg *provenance, and local naming. Every public read of perfect normality must pass through these rows before exporting a perfectly normal space name.*

Proof. Carrier admission is projection from Definition 8742.1. The accepted packet displays the topology source T, normal-space route N, closed-row ledger F, zero-set witnesses Z, cozero handoff O, Urysohn boundary U, continuous-map row M, and the structural rows H, C, K, L.

Closed-as-zero-set exposure is read through F and Z. Each displayed closed row has its zero-set witness before any consumer may treat the closed row as part of the perfectly normal surface.

The open/cozero handoff is read through O. Since O is attached to the same closed rows and the same continuous-map data, an open-row consumer receives only the displayed complementary cozero route, not an ambient complement selector.

The Urysohn and Tietze-facing nonescape condition is enforced by U and M. A downstream separation-function or extension reader must pass through the normal-space row of chapter 1866, the Urysohn route of **??**, and the displayed ContinuousMap$^\uparrow$ row before using the zero/cozero certificate.

Finally the componentwise hsame row, displayed Cont replay, provenance, and local naming rows preserve this finite route. They provide stability, source accounting, and local naming, while adding no host powerset, choice principle, quotient function equality, or ambient completeness datum. □

Closure status for NameCert$_{\text{PerfectlyNormalSpace}^\uparrow}$.

Constructive story: A PerfectlyNormalSpace$^\uparrow$ packet is generated from a Topology$^\uparrow$ source row, a NormalSpace$^\uparrow$ closed-pair route, displayed closed rows, ZeroSet$^\uparrow$ witnesses, complementary CozeroSet$^\uparrow$ rows, a UrysohnLemma$^\uparrow$ boundary row, ContinuousMap$^\uparrow$ real-valued function rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\text{PerfectlyNormalSpace}^\uparrow}$, seed)

Scope closed: Definition 8742.1 and Definition 8742.2 name the finite carrier and seed obligation surface for closed-as-zero-set and open-as-cozero reads over Topology$^\uparrow$, NormalSpace$^\uparrow$, ZeroSet$^\uparrow$, CozeroSet$^\uparrow$, UrysohnLemma$^\uparrow$, ContinuousMap$^\uparrow$, BHist, hsame, Cont, Pkg, and NameCert rows.

Formal verification: FormalStatus(NameCert$_{\text{PerfectlyNormalSpace}^\uparrow}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim checked Lean realization, public closure, Tietze extension closure, quotient equality of functions, host powersets, choice over separators, or a completed bridge.

Upgrade path: Obligation closure requires checked carrier admission, closed-as-zero-set exposure, open/cozero handoff, Urysohn and continuous-map boundary stability, transport stability, provenance, and local naming for BEDC.Derived.PerfectlyNormalSpace

Chapter 8743

A Concrete Naming Certificate for $\mathsf{PerronMethodFiniteBarrier}^{\uparrow}$

Following Perron and the classical barrier method for the Dirichlet problem, the $\mathsf{PerronMethodFiniteBarrier}^{\uparrow}$ packet records a finite BEDC surface for local boundary barriers used by a Perron upper-envelope route. It sits between the integral precedent of chapter 6378, the endpoint and order rows of chapter 38, and the metric-facing boundary data of chapter 57. The packet is a finite barrier ledger; it does not select a harmonic solution, solve the full Dirichlet problem, complete a measure space, quotient real equality, choose from a family of candidates, or assert ambient completeness.

Definition 8743.1 (Perron finite barrier carrier)**.** *A* $\mathsf{PerronMethodFiniteBarrier}^{\uparrow}$ *carrier is a finite tuple*

$$B = (\Omega, \partial\Omega, x_0, U, R, M, W, L, H, C, P, N)$$

whose rows have the following displayed meanings.

1. Ω *is the inspected domain row, and* $\partial\Omega$ *is the finite boundary-window row.*
2. x_0 *is the boundary point under inspection, with all endpoint comparisons read through* $\mathsf{Real}^{\uparrow}$ *rows.*
3. U *is a finite neighborhood ledger around* x_0*.*
4. R *is the ordered real-value row used for barrier inequalities.*
5. M *is the metric-distance row that relates* U *and the boundary window.*
6. W *is the finite barrier-witness list.*
7. L *is the Perron ledger recording which displayed upper and lower comparison rows are available.*
8. H, C, P, N *are componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local* $\mathsf{NameCert}_{\mathsf{PerronMethodFiniteBarrier}^{\uparrow}}$ *rows.*

The carrier contains no coordinate for a selected harmonic function, no completed boundary measure, no quotient real equality, no countable choice selector, and no ambient complete metric space.

Theorem 8743.2 (Perron finite barrier NameCert obligations)**.** *For an accepted* $\mathsf{PerronMethodFiniteBarrier}^{\uparrow}$ *packet, the local* $\mathsf{NameCert}$ *surface consists exactly of carrier admission for the domain row, boundary-window row, inspected boundary point, finite neighborhood ledger, ordered* $\mathsf{Real}^{\uparrow}$ *value row,* $\mathsf{Met}^{\uparrow}$ *distance row, finite barrier-witness list, Perron comparison ledger, componentwise transport, displayed replay, provenance, and local naming rows. Every barrier comparison exported by*

the packet must read a witness from W, an order comparison from R, and a neighborhood-distance request from M and U before it can be used by a downstream Perron or boundary-value consumer.

Proof. Project the carrier of Definition 8743.1. The available rows are precisely $\Omega, \partial\Omega, x_0, U, R, M, W, L, H, C, P, N$, so every accepted read begins with the displayed domain, boundary, point, neighborhood, real-order, metric, witness, and comparison-ledger data.

The NameCert row N names only those projected rows. The transport row H preserves them componentwise under hsame, the replay row C replays the displayed comparison requests, and the provenance row P records the finite source of each witness.

Thus no consumer can replace the finite witness list by a selected harmonic solution, a boundary measure completion, quotient equality of real values, choice over candidate functions, or ambient completeness. The packet exports exactly the finite barrier data listed in the statement. □

Theorem 8743.3 (Perron finite barrier harmonic route)**.** *Every boundary-value consumer that reads a* PerronMethodFiniteBarrier$^{\uparrow}$ *packet toward a harmonic Perron route must first pass through the finite barrier NameCert obligations of Definition 8743.2. Consequently the route can expose a local barrier inequality and a Perron comparison ledger, but it cannot claim a selected harmonic solution, the full Dirichlet problem, measure completion, quotient real equality, choice, or ambient completeness.*

Proof. Start with the NameCert obligations. They force the consumer to inspect the finite boundary window, the boundary point, the neighborhood ledger, the real-order row, the metric-distance row, the finite barrier-witness list, and the Perron comparison ledger before any harmonic-facing read is exported.

The Perron comparison ledger may then be passed to downstream chapters in the same sense that chapter 6378 passes finite Perron data through an integration route, while the Real$^{\uparrow}$ and Met$^{\uparrow}$ rows keep endpoint and distance evidence explicit. This supplies a constructive barrier route rather than a solved boundary-value problem.

Because the carrier has no coordinate for a chosen harmonic function, completed measure, quotient equality, choice selector, or complete ambient space, none of those objects can be produced by this route. The exported data are exactly the local barrier inequality and its finite comparison provenance. □

Falsifiable prediction: Every accepted PerronMethodFiniteBarrier$^{\uparrow}$ read must expose a finite boundary window, inspected boundary point, neighborhood ledger, ordered Real$^{\uparrow}$ value row, Met$^{\uparrow}$ distance row, finite barrier-witness list, Perron comparison ledger, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming before any harmonic-facing consumer can use it.

Independence witness: perron-integral, real, metric: no listed sibling jointly carries the finite boundary-window, local barrier-witness, Perron comparison-ledger, real-order, metric-distance, transport, replay, provenance, and local NameCert rows of $B = (\Omega, \partial\Omega, x_0, U, R, M, W, L, H, C, P, N)$.

Closure status for NameCert$_{\text{PerronMethodFiniteBarrier}^{\uparrow}}$.

Constructive story: A PerronMethodFiniteBarrier$^{\uparrow}$ packet is generated from domain and boundary-window rows, an inspected boundary point, finite neighborhood rows, Real order rows, Metric distance rows, a finite barrier-witness list, a Perron comparison ledger, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\text{PerronMethodFiniteBarrier}^{\uparrow}}$, seed)

Scope closed: Definition 8743.1, Definition 8743.2, and Definition 8743.3 seed the finite barrier packet for Perron-method boundary consumers.

Formal verification: FormalStatus(NameCert$_{\text{PerronMethodFiniteBarrier}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close a selected harmonic solution, the full Dirichlet problem, measure completion, quotient equality, choice, ambient completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires a checked carrier, barrier-comparison ledger, transport and replay stability, and local NameCert rows for BEDC.Derived.PerronMethodFiniteBarrierUp.

Chapter 8744

A Concrete Naming Certificate for $\mathsf{CauchySequenceModulusChain}^{\uparrow}$

Following Bishop and Bridges on regular Cauchy moduli, the $\mathsf{CauchySequenceModulusChain}^{\uparrow}$ packet names the finite chain of displayed precision refinements by which a regular sequence read becomes available to Real-facing completion consumers. It sits after the stream-window carrier of chapter 126, the regular rational readback of chapter 301, the dyadic tolerance core of chapter 291, the terminal real seal of chapter 38, and the regular completion route of chapter 1639. The packet records a finite modulus-chain surface; it does not assert quotient stream equality, selected limits, ambient completeness, countable choice, or host real equality.

Definition 8744.1 (Cauchy sequence modulus-chain carrier)**.** *A* $\mathsf{CauchySequenceModulusChain}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M = (S, R, D, C, E, H, T, P, N)$$

with the following displayed rows:

1. *S is the finite* $\mathsf{StreamName}^{\uparrow}$ *window row whose requests determine which sequence entries are visible.*
2. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row attached to those displayed windows.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row used to state every comparison budget in the chain.*
4. *C is the displayed chain of Cauchy-modulus refinements, ordered so that each later row refines the tolerance requested by the previous row.*
5. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row for Real-facing completion reads.*
6. *H records componentwise* hsame *transport for the window, readback, tolerance, chain, seal, replay, provenance, and naming rows.*
7. *T records displayed* Cont *replay of the same finite chain.*
8. *P is the* Pkg *provenance over* $\mathsf{CauchySequenceModulusChain}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{BishopRegularCauchyCompletion}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
9. *N is the local* $\mathsf{NameCert}_{\mathsf{CauchySequenceModulusChain}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $S, R, D, C, E, H, T, P, N$. It has no coordinate for quotient stream equality, a selected limit, countable choice, host real equality, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.CauchySequenceModulusChainUp.CauchySequenceModulusChainTasteGate single carrier alignment`

Theorem 8744.2 (Cauchy sequence modulus-chain NameCert obligations)**.** *For every accepted* $\mathsf{CauchySequenceModulusChain}^{\uparrow}$ *carrier*

$$M = (S, R, D, C, E, H, T, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{CauchySequenceModulusChain}^{\uparrow}}$ *surface consists exactly of carrier admission, chain coherence, tolerance monotonicity, readback visibility, Real-seal discipline, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. Every row of the displayed chain* C *must read its tolerance through* D*, expose its observations through* S *and* R*, and reach* E *only after the finite refinement chain has been displayed.*

Proof. Project the carrier of Definition 8744.1. Its visible rows are exactly $S, R, D, C, E, H, T, P, N$, so the local certificate has no hidden coordinate from which quotient stream equality, selected limits, choice, or ambient completeness can be recovered.

Read the analytic rows in order. The finite windows S expose the requested sequence entries, R records the regular rational readback, and D supplies the dyadic tolerance language in which each refinement in C is stated.

The chain row C is then checked for coherence and monotonicity: later requests may refine earlier tolerances, but they cannot bypass the displayed tolerance ledger. The terminal seal E is available only after that finite chain has been read.

Finally H, T, P, N transport, replay, source, and name the same finite packet. Since these structural rows preserve only the displayed route, the NameCert obligations are exhausted by the stated rows. □

Theorem 8744.3 (Cauchy sequence modulus-chain regular handoff)**.** *Every Real-facing completion read sourced from an accepted* $\mathsf{CauchySequenceModulusChain}^{\uparrow}$ *packet factors through the displayed finite chain*

$$\mathsf{StreamName}^{\uparrow},\ \mathsf{RegSeqRat}^{\uparrow},\ \mathsf{DyadicRatCore}^{\uparrow},\ C,\ \mathsf{Real}^{\uparrow}$$

before the terminal Real seal is consumed. The handoff exports no quotient stream equality, selected limit, countable-choice schedule, host real equality, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start with the accepted carrier $M = (S, R, D, C, E, H, T, P, N)$. The only observation windows are S, the only regular rational readback row is R, and the only tolerance language for the completion request is D.

The completion-facing read must therefore pass through the chain row C before it reaches the terminal seal E. A consumer that tries to inspect E without C omits the displayed modulus-refinement route and is not reading the accepted packet.

The transport, replay, provenance, and naming rows preserve the same order. Thus every Real-facing read factors through the finite chain before the Real seal, and none of the excluded host-level or choice-level data is exported. □

Falsifiable prediction: Every accepted $\mathsf{CauchySequenceModulusChain}^{\uparrow}$ completion read exposes finite StreamName windows, RegSeqRat readback, DyadicRatCore tolerances, a displayed Cauchy-modulus refinement chain, a terminal Real seal, transport, replay, provenance, and local NameCert rows before exporting the read.

Closure status for $\mathsf{NameCert}_{\mathsf{CauchySequenceModulusChain}^{\uparrow}}$.

Constructive story: A $\mathsf{CauchySequenceModulusChain}^{\uparrow}$ packet is generated from StreamName windows, RegSeqRat readback, DyadicRatCore tolerances, a displayed Cauchy-modulus refinement chain, a terminal Real seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CauchySequenceModulusChain}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8744.1, Definition 8744.2, and Definition 8744.3 seed the finite modulus-chain route from regular rational windows to the Real seal.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CauchySequenceModulusChain}^{\uparrow}}, \mathsf{unformalized})$

Lean target: `BEDC.Derived.CauchySequenceModulusChainUp`

Bridge status: none

Not claimed: This chapter does not close quotient stream equality, selected limits, countable choice, host real equality, ambient $\mathsf{Real}^{\uparrow}$ completeness, theorem-level Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, chain coherence, tolerance monotonicity, readback visibility, Real-seal discipline, transport, replay, provenance, and local naming for BEDC.Derived.CauchySequenceModulusChainUp.

Chapter 8745

A Concrete Naming Certificate for $\mathsf{GeneticCodeDeformationLedger}^{\uparrow}$

The $\mathsf{GeneticCodeDeformationLedger}^{\uparrow}$ packet realizes the comparative genetic-code deformation ledger of Definition 9462.1905 as finite BEDC NameCert data. It sits after the stop-codon suffix bridge of chapter 1374, the six-bit codon source window of chapter 2234, the finite state graph surface of chapter 2306, and the partition incidence carrier of chapter 4017. The packet records table-wise stop/sense deformation from the standard stop boundary; it does not derive genetic-code universality, biological dynamics, amino-acid chemistry, or empirical reassignment likelihoods.

Definition 8745.1 (Genetic-code deformation ledger carrier)**.** *A* $\mathsf{GeneticCodeDeformationLedger}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$G = (T, S, E, A, U, V, W, L, \Delta, H, C, P, N)$$

with the following displayed rows:

1. T *is the external genetic-code table row under comparison.*
2. S *is the displayed stop-set row for* T*.*
3. E *is the displayed sense-set row for* T*.*
4. A, U, V, W *are the role rows for* UAA*,* UAG*,* UGA*, and* UGG*.*
5. L *is the standard* L*-shaped stop-boundary row* $\{\mathrm{UAA}, \mathrm{UAG}, \mathrm{UGA}\}$ *read through* $\mathsf{StopCodonZeckendorfSuffix}^{\uparrow}$ *and* $\mathsf{CodonSixBitWindow}^{\uparrow}$*.*
6. Δ *is the symmetric-difference witness row comparing* S *with the standard stop boundary* L*.*
7. H *records componentwise* hsame *transport for the table, stop-set, sense-set, role, boundary, difference, replay, provenance, and naming rows.*
8. C *records displayed* Cont *replay of the same finite comparison route.*
9. P *is the* Pkg *provenance over* $\mathsf{GeneticCodeDeformationLedger}^{\uparrow}$*,* $\mathsf{StopCodonZeckendorfSuffix}^{\uparrow}$*,* $\mathsf{CodonSixBitWindow}$ $\mathsf{CoreStateGraph}^{\uparrow}$*,* $\mathsf{PartitionCoreIncidence}^{\uparrow}$*, the codon-cube boundary program,* BHist*,* hsame*,* Cont*, and* $\mathsf{NameCert}$*.*
10. N *is the local* $\mathsf{NameCert}_{\mathsf{GeneticCodeDeformationLedger}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $T, S, E, A, U, V, W, L, \Delta, H, C, P, N$. It has no coordinate for genetic-code necessity, all-code universality, release-factor dynamics, amino-acid chemistry, or stochastic readthrough data.

Lean4 ✓ `BEDC.Derived.GeneticCodeDeformationLedgerUp.GeneticCodeDeformationLedgerTasteGate single carrier alignment`

Theorem 8745.2 (Genetic-code deformation ledger NameCert obligations)**.** *For every accepted* $\mathsf{GeneticCodeDeformationLedger}^{\uparrow}$ *carrier*

$$G = (T, S, E, A, U, V, W, L, \Delta, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{GeneticCodeDeformationLedger}^{\uparrow}}$ *surface consists exactly of carrier admission, genetic-code table exposure, StopSet and SenseSet visibility, role-row exactness for* UAA*,* UAG*,* UGA*, and* UGG*, standard L-boundary exposure, symmetric-difference witness visibility, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. No ledger obligation is stored outside those rows.*

Proof. Project the carrier of Definition 8745.1. Its visible rows are exactly $T, S, E, A, U, V, W, L, \Delta, H, C, P, N$, so the NameCert surface cannot add an unlisted biological or empirical coordinate.

The table row T anchors the comparison. The rows S and E expose which codons are recorded as stops and senses, while A, U, V, W display the four boundary roles inspected by the ledger.

The standard boundary is read through L, and the deformation is read only through Δ. Thus preserving the local certificate requires preserving the displayed stop/sense and role rows together with the stated symmetric difference.

Finally H, C, P, N transport, replay, source, and name the same finite route. Since those structural rows carry no empirical dynamics or amino-acid semantics, the listed obligations exhaust the packet. □

Theorem 8745.3 (Genetic-code deformation boundary classification)**.** *Every accepted* GeneticCodeDeformationLed *packet classifies a table row T as standard-boundary preserving exactly when the displayed symmetric-difference row Δ is empty, and as a stop-boundary deformation exactly when Δ is displayed as nonempty. The classification factors through S, L, Δ after the four role rows A, U, V, W are visible, and it exports no claim of genetic-code necessity, all-code universality, or biological dynamics.*

Proof. Start with the stop-set row S and the standard L-shaped row L. These are the only stop-boundary sets available to the accepted packet.

The symmetric-difference row Δ is the sole classifier for deformation. If it is empty, the packet records preservation of the standard boundary; if it is nonempty, the packet records precisely the displayed boundary displacement.

The role rows A, U, V, W make the four inspected codon roles visible before the classification is exported. The structural rows H, C, P, N preserve that finite comparison route and do not add genetic-code necessity, all-code universality, release-factor dynamics, or readthrough probabilities. □

Falsifiable prediction: Every accepted $\mathsf{GeneticCodeDeformationLedger}^{\uparrow}$ comparison exposes a table row, StopSet, SenseSet, four boundary role rows, the standard L-shaped stop boundary, a symmetric-difference witness, transport, replay, provenance, and local NameCert rows before classifying the table as boundary-preserving or boundary-deforming.

Closure status for $\mathsf{NameCert}_{\mathsf{GeneticCodeDeformationLedger}^{\uparrow}}$.

Constructive story: A GeneticCodeDeformationLedger$^{\uparrow}$ packet is generated from a genetic-code table row, StopSet and SenseSet rows, UAA/UAG/UGA/UGG role rows, the standard L-shaped stop-boundary row, a symmetric-difference witness, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\text{GeneticCodeDeformationLedger}^{\uparrow}}$, seed)

Scope closed: Definition 8745.1, Definition 8745.2, and Definition 8745.3 seed the finite comparative deformation ledger for genetic-code table rows.

Formal verification: FormalStatus(NameCert$_{\text{GeneticCodeDeformationLedger}^{\uparrow}}$, unformalized)

Lean target: `BEDC.Derived.GeneticCodeDeformationLedgerUp`

Bridge status: none

Not claimed: This chapter does not close genetic-code universality, biological dynamics, amino-acid chemistry, empirical reassignment likelihoods, Lean theorem verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, stop/sense visibility, four-role exactness, standard boundary exposure, symmetric-difference classification, transport, replay, provenance, and local naming for BEDC.Derived.GeneticCodeDeformationLedgerUp.

Chapter 8746

A Concrete Naming Certificate for RegularCauchyModulusOfConvergence$^{\uparrow}$

Following Bishop and Bridges constructive analysis, the RegularCauchyModulusOfConvergence$^{\uparrow}$ packet records the finite convergence-modulus service attached to a regular Cauchy rational name before any quotient real equality, selected limit, or ambient completeness theorem is available. It sits over the regular sequence route of chapter 301, the finite window service of chapter 126, the dyadic tolerance ledger of chapter 291, the Cauchy difference export of chapter 1874, and the terminal real-name seal of chapter 38. The packet gives later Real$^{\uparrow}$ equality and completion consumers a visible modulus row rather than a hidden choice schedule.

Definition 8746.1 (Regular Cauchy modulus of convergence carrier)**.** *A* RegularCauchyModulusOfConvergence$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (X, M, W, T, R, E, H, C, P, N)$$

with the following displayed rows:

1. *X is the* RegSeqRat$^{\uparrow}$ *source row whose rational observations are read only through finite requests.*
2. *M is the modulus row assigning each requested dyadic precision to a visible tail threshold for X.*
3. *W is the* StreamName$^{\uparrow}$ *window row exposing exactly the finite source observations used after the threshold row M is read.*
4. *T is the* DyadicRatCore$^{\uparrow}$ *tolerance row against which the requested precision and tail comparisons are checked.*
5. *R is the regular convergence row recording that all displayed tail reads of X beyond the threshold supplied by M are controlled by the same T tolerance.*
6. *E is the terminal* Real$^{\uparrow}$ *seal row available to a Real equality or completion consumer only after X, M, W, T, R have been read.*
7. *H records componentwise* hsame *transport for the source, modulus, window, tolerance, convergence, Real seal, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay of the route from the source and precision request through the modulus, finite window, tolerance, convergence, and Real seal rows.*

9. *P is the* Pkg *provenance over* $\mathsf{RegularCauchyModulusOfConvergence}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyModulusOfConvergence}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $X, M, W, T, R, E, H, C, P, N$. It has no coordinate for quotient stream equality, selected limits, countable choice, trichotomy, host real equality, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 8746.2 (Regular Cauchy modulus of convergence NameCert obligations)**.** *For every accepted* $\mathsf{RegularCauchyModulusOfConvergence}^{\uparrow}$ *carrier $K = (X, M, W, T, R, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyModulusOfConvergence}^{\uparrow}}$ *surface consists exactly of carrier admission for the regular rational source, displayed modulus row, finite StreamName window, dyadic tolerance ledger, regular convergence row, terminal Real seal, componentwise transport, displayed replay, provenance, and local naming.*

Every Real equality or completion consumer using the modulus must read

$$X \longmapsto M \longmapsto W \longmapsto T \longmapsto R \longmapsto E$$

together with H, C, P, N, and receives no quotient stream equality, selected representative, countable-choice schedule, trichotomy, host real equality, or ambient completeness theorem.

Proof. Project the carrier of Definition 8746.1. The only analytic source is the $\mathsf{RegSeqRat}^{\uparrow}$ row X, and the only precision-to-tail service is the displayed modulus row M.

The window row W exposes the finite observations available after M is read. The dyadic tolerance row T is the sole tolerance ledger for those observations, so the convergence row R can record tail control only through X, M, W, T.

The terminal Real seal E is downstream of the same finite route. The structural rows H, C, P, N transport, replay, source, and name that route without adding quotient equality, selected limits, choice schedules, trichotomy, host real equality, or ambient completeness. □

Theorem 8746.3 (Regular Cauchy modulus of convergence tail stability)**.** *If an accepted* RegularCauchyModulusOf
carrier $K = (X, M, W, T, R, E, H, C, P, N)$ is read at a requested dyadic precision, then every visible tail comparison exported beyond the threshold row M is stable under the same finite route

$$X, M, W, T, R, H, C, P, N.$$

Consequently any $\mathsf{CauchyDifferenceCriterion}^{\uparrow}$ *or* $\mathsf{Real}^{\uparrow}$ *consumer may cite the modulus only as a displayed tail-stability service over* $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, *and* $\mathsf{DyadicRatCore}^{\uparrow}$ *rows, not as a quotient stream equality, selected limit, trichotomy, countable choice, host real equality, or ambient completeness principle.*

Proof. Begin with the obligation surface of Definition 8746.2. It places every accepted modulus read on the displayed route through $X, M, W, T, R, E, H, C, P, N$.

For a tail comparison, the Real seal E is not needed until the consumer asks for the terminal equality-facing handoff. The stability claim is already carried by R after the source, modulus, finite window, and dyadic tolerance rows have been consumed.

Now apply the public export route of Definition 1874.14. A difference-criterion consumer can use the same $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, and $\mathsf{DyadicRatCore}^{\uparrow}$ rows as visible inputs before reaching a $\mathsf{Real}^{\uparrow}$ seal, so the modulus remains a displayed finite service rather than a hidden quotient or choice object. □

Falsifiable prediction: Every $\mathsf{RegularCauchyModulusOfConvergence}^{\uparrow}$ read factors through one RegSeqRat source row, a displayed modulus row, finite StreamName windows, a DyadicRatCore tolerance ledger, a regular convergence row, a terminal RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming.

Independence witness: regseqrat, streamname, dyadicratcore, cauchy-difference-criterion, real: $\mathsf{RegularCauchyModulusOfConvergence}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries a source row, precision-to-tail modulus row, finite window row, dyadic tolerance ledger, convergence row, terminal Real seal, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{RegularCauchyModulusOfConvergence}^{\uparrow}}$.

Constructive story: A $\mathsf{RegularCauchyModulusOfConvergence}^{\uparrow}$ packet is generated from a RegSeqRat source row, displayed convergence-modulus row, StreamName window row, DyadicRatCore tolerance row, regular convergence row, terminal RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RegularCauchyModulusOfConvergence}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8746.1, Definition 8746.2, and Definition 8746.3 seed the finite convergence-modulus route consumed by Real equality and Cauchy-difference readers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RegularCauchyModulusOfConvergence}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient stream equality, selected limits, trichotomy, countable choice, host real equality, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, modulus exactness, finite-window exposure, dyadic tolerance compatibility, convergence-row stability, Real sealing, transport, replay, provenance, and local naming for BEDC.Derived.RegularCauchyModulusOfConvergenceUp.

Chapter 8747

A Concrete Naming Certificate for BishopDyadicLocatedIntervalSelection$^{\uparrow}$

Following Bishop and Bridges, the BishopDyadicLocatedIntervalSelection$^{\uparrow}$ packet records the finite act of selecting a dyadic located interval from displayed endpoint and tolerance data. It sits after the dyadic rational surface of chapter 291, the real interval surface of chapter 4111, the located interval surface of chapter 394, and the completion handoff through chapter 301, chapter 126, and chapter 38. The packet supplies a choice-free interval-selection interface for Real and Completion consumers; it is not a Heine–Borel theorem, an open-cover compactness principle, a quotient-real equality rule, or a host choice operator.

Definition 8747.1 (Bishop dyadic located-interval selection carrier)**.** *A* BishopDyadicLocatedIntervalSelection$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (Q, D, M, R, E, H, C, P, N)$$

with the following displayed rows:

1. *Q is the located request row, recording the requested interval predicate, endpoint side, positive tolerance, and locatedness evidence read from* LocatedInterval$^{\uparrow}$ *and* RealInterval$^{\uparrow}$*.*
2. *D is the dyadic bracket row supplied by* DyadicRatCore$^{\uparrow}$*; it stores the lower and upper dyadic rationals, their outward rounding checks, and the finite bracket evidence for the request row.*
3. *M is the midpoint and refinement budget row, recording the dyadic midpoint reads, the requested refinement depth, and the finite comparison rows used to keep the bracket located.*
4. *R is the regular-Cauchy handoff row from the selected dyadic bracket to* StreamName$^{\uparrow}$ *windows and* RegSeqRat$^{\uparrow}$ *readback at the requested precision.*
5. *E is the terminal* Real$^{\uparrow}$ *seal row for the selected interval endpoints and the interval-selection consumer.*
6. *H records componentwise* hsame *transport for the request, bracket, midpoint, handoff, Real seal, replay, provenance, and local naming rows.*
7. *C records displayed* Cont *replay for located requests, dyadic bracket inspection, midpoint refinement, regular-Cauchy handoff, and Real-seal consumption.*
8. *P is the* Pkg *provenance over* BishopDyadicLocatedIntervalSelection$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, RealInterval$^{\uparrow}$, LocatedInterval$^{\uparrow}$, RegSeqRat$^{\uparrow}$, StreamName$^{\uparrow}$, Real$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*

9. *N is the local* $\mathsf{NameCert}_{\mathsf{BishopDyadicLocatedIntervalSelection}^{\uparrow}}$ *row.*

The carrier predicate says exactly that these rows form one finite located-interval selection packet. It contains no coordinate for open-cover compactness, host endpoint choice, quotient equality of reals, excluded middle over cuts, or an ambient completeness theorem.

Theorem 8747.2 (Bishop dyadic located-interval selection obligations)**.** *For every accepted* BishopDyadicLocatedIn *carrier $S = (Q, D, M, R, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{BishopDyadicLocatedIntervalSelection}^{\uparrow}}$ *surface consists exactly of:*

1. *carrier admission for the finite packet of Definition 8747.1;*
2. *located-request admission through the displayed* $\mathsf{LocatedInterval}^{\uparrow}$ *and* $\mathsf{RealInterval}^{\uparrow}$ *rows in Q;*
3. *dyadic bracket admission through the outward rounding and endpoint comparison rows of D;*
4. *midpoint and refinement-budget admission through the finite dyadic midpoint and comparison rows of M;*
5. *regular-Cauchy handoff through the* $\mathsf{StreamName}^{\uparrow}$ *and* $\mathsf{RegSeqRat}^{\uparrow}$ *rows in R;*
6. *Real-seal non-escape through E after the request, bracket, midpoint, and handoff rows have been displayed;*
7. *componentwise transport, replay, provenance, and naming through H, C, P, N.*

No obligation for Heine–Borel compactness, open-cover selection, quotient-real equality, host choice, or a hidden real representative is part of the packet.

Proof. Project the carrier of Definition 8747.1. The request row Q supplies only displayed locatedness and endpoint data, while D supplies only finite dyadic bracket evidence.

The midpoint row M refines that bracket by finite dyadic comparisons. It neither selects a host real endpoint nor appeals to an open-cover argument; each refinement step is one displayed midpoint or comparison row.

The handoff row R then exposes the selected bracket as stream windows and regular rational readback, and E seals the resulting endpoint reads as $\mathsf{Real}^{\uparrow}$ data. The structural rows H, C, P, N preserve the same finite route under transport, replay, provenance, and local naming.

Since every consumer read factors through those rows, the local NameCert has no remaining coordinate from which compactness, quotient equality, host choice, or hidden endpoint representatives could be exported. □

Theorem 8747.3 (Bishop dyadic located-interval selection sibling lattice)**.** *Every accepted* BishopDyadicLocatedInt *consumer must read the sibling lattice*

$$\mathsf{DyadicRatCore}^{\uparrow},\ \mathsf{LocatedInterval}^{\uparrow},\ \mathsf{RealInterval}^{\uparrow},\ \mathsf{StreamName}^{\uparrow},\ \mathsf{RegSeqRat}^{\uparrow},\ \mathsf{Real}^{\uparrow}$$

through the displayed rows $Q, D, M, R, E, H, C, P, N$ before treating the result as an interval-selection surface. The dyadic rational sibling supplies bracket arithmetic, the located and real interval siblings supply request and endpoint admission, the stream and regular-rational siblings supply completion-facing readback, and the Real sibling supplies only the terminal seal. No sibling may be bypassed by a host root, host endpoint, quotient representative, compactness theorem, or choice functional.

Proof. Begin with the obligation theorem Definition 8747.2. It places request admission in Q, dyadic bracket admission in D, midpoint refinement in M, completion handoff in R, and Real-seal reads in E.

Thus $\mathsf{DyadicRatCore}^{\uparrow}$ is read only as bracket arithmetic and midpoint refinement, while $\mathsf{LocatedInterval}^{\uparrow}$ and $\mathsf{RealInterval}^{\uparrow}$ are read only through the request and endpoint rows. The handoff to $\mathsf{StreamName}^{\uparrow}$ and $\mathsf{RegSeqRat}^{\uparrow}$ occurs after those rows, not before them.

Finally the $\mathsf{Real}^{\uparrow}$ seal is downstream of the same displayed path. Componentwise hsame transport, Cont replay, Pkg provenance, and local NameCert naming keep the route inside the finite packet, so no sibling can be replaced by a host endpoint, quotient representative, compactness theorem, or choice functional. □

Closure status for $\mathsf{NameCert}_{\mathsf{BishopDyadicLocatedIntervalSelection}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BishopDyadicLocatedIntervalSelection}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8747.1, Definition 8747.2, and Definition 8747.3 seed the finite located-request, dyadic-bracket, midpoint-refinement, regular-Cauchy handoff, Real-seal, transport, replay, provenance, and local NameCert rows for choice-free interval selection.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BishopDyadicLocatedIntervalSelection}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close Heine–Borel compactness, open-cover compactness, quotient-real equality, host endpoint choice, excluded middle over cuts, Lean verification, or a public standard bridge.

Upgrade path: Obligation closure requires checked carrier admission, bracket exactness, midpoint refinement stability, regular-Cauchy handoff, Real seal non-escape, and sibling-lattice non-bypass for BEDC.Derived.BishopDyadicLocatedIntervalSelectionUp.

Constructive story: A $\mathsf{BishopDyadicLocatedIntervalSelection}^{\uparrow}$ packet is generated from a located request row, dyadic bracket row, midpoint and refinement budget row, StreamNameUp and RegSeqRatUp handoff, RealUp seal, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Chapter 8748

A Concrete Naming Certificate for $\mathsf{LocatedRealLimit}^{\uparrow}$

Following Bishop and Bridges on located real numbers and limits of regular Cauchy data, the $\mathsf{LocatedRealLimit}^{\uparrow}$ packet records the finite boundary at which a regular rational name, a stream name, and a Real seal are allowed to present a located limit without importing host limits or countable choice. It reads the Real carrier of chapter 38, the regular rational sequence route of chapter 301, the finite observation windows of chapter 126, and the dyadic tolerance discipline of chapter 291. The packet names a choice-free limit boundary: approximants are admitted through displayed rows, tolerance coverage is local, uniqueness is separated by the Real carrier, and the ledger contains no coordinate for an external limit object.

Definition 8748.1 (Located real limit carrier)**.** *A* $\mathsf{LocatedRealLimit}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (R, Q, W, T, U, H, C, P, N)$$

with the following displayed rows:

1. *R is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row for the named located limit.*
2. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *tail row whose rational approximants supply the displayed limit data.*
3. *W is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row through which requests for an index and tolerance are inspected.*
4. *T is the located tolerance coverage row, recording that every positive dyadic tolerance has a finite tail window in which the displayed rational approximants are compatible with R.*
5. *U is the separated uniqueness row for the* $\mathsf{Real}^{\uparrow}$ *seal, identifying two accepted limit packets only through Real separatedness and the shared tail coverage data.*
6. *H records componentwise* hsame *transport for R, Q, W, T, U, C, P, N.*
7. *C records displayed* Cont *replay of the same request-to-tail route.*
8. *P is the* Pkg *provenance over* $\mathsf{LocatedRealLimit}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
9. *N is the local* $\mathsf{NameCert}_{\mathsf{LocatedRealLimit}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $R, Q, W, T, U, H, C, P, N$. It has no coordinate for a host limit, selected subsequence, quotient representative, ambient completeness of $\mathsf{Real}^{\uparrow}$*, countable choice, or classical trichotomy.*

Theorem 8748.2 (Located real limit NameCert obligations)**.** *For every accepted* $\mathsf{LocatedRealLimit}^{\uparrow}$ *carrier* $L = (R, Q, W, T, U, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{LocatedRealLimit}^{\uparrow}}$ *surface consists exactly of carrier admission for the terminal* $\mathsf{Real}^{\uparrow}$ *seal,* $\mathsf{RegSeqRat}^{\uparrow}$ *tail data,* $\mathsf{StreamName}^{\uparrow}$ *finite windows, located tolerance coverage, separated Real uniqueness, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. In particular:*

1. *carrier admission exposes only the displayed rows* $R, Q, W, T, U, H, C, P, N$*;*
2. *located tolerance coverage is witnessed by the finite tail window row* W *and the tolerance row* T*;*
3. $\mathsf{RegSeqRat}^{\uparrow}$ *tail compatibility is read through the same tail row* Q *before the Real seal* R *may be consumed;*
4. *uniqueness of the named limit is separated by* U *and the* $\mathsf{Real}^{\uparrow}$ *carrier, not by host equality;*
5. *the provenance ledger has no escape to host limits, selected representatives, countable choice, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the carrier of Definition 8748.1. The only visible rows are $R, Q, W, T, U, H, C, P, N$, so admission and naming are finite and local to the packet.

Given a positive tolerance request, the finite window row W supplies the inspected tail segment and the tolerance row T records the corresponding located coverage. The regular rational tail row Q is the only source of approximants used by the Real seal R.

If two accepted packets present the same tail coverage, the separated uniqueness row U compares their terminal Real seals through the $\mathsf{Real}^{\uparrow}$ boundary. Transport, replay, provenance, and local naming preserve that route. Since no host-limit, selector, quotient representative, choice, trichotomy, or ambient-completeness coordinate appears in the carrier, the listed rows exhaust the local NameCert obligations. □

Theorem 8748.3 (Located real limit tail route)**.** *Every Real or Completion consumer of an accepted* $\mathsf{LocatedRealLimit}^{\uparrow}$ *carrier factors its limit read through the finite route*

$$Q \to W \to T \to R \to U \to H \to C \to P \to N.$$

Thus the consumer reads $\mathsf{RegSeqRat}^{\uparrow}$ *tail data,* $\mathsf{StreamName}^{\uparrow}$ *finite windows, located tolerance coverage, the terminal* $\mathsf{Real}^{\uparrow}$ *seal, separated uniqueness, transport, replay, provenance, and local naming before treating the packet as a located real limit.*

Proof. Open the terminal Real seal row R. By Definition 8748.1, that row is packaged with the regular rational tail row, the finite observation window row, and the located tolerance row.

Apply Definition 8748.2. It forces each consumer read to expose Q, W, T before the seal and then the separated uniqueness, transport, replay, provenance, and local naming rows.

The sibling Real and regular rational chapters supply the carrier boundaries cited above, while this packet records their joint limit-facing handoff. Because the route contains no coordinate for host limits, selected representatives, countable choice, quotient equality, or ambient completeness, the displayed finite path is the complete consumer boundary. □

Falsifiable prediction: Every accepted LocatedRealLimitUp read exposes RegSeqRat tail data, StreamName finite windows, located tolerance coverage, a RealUp seal, separated uniqueness, hsame transport, Cont replay, Pkg provenance, and local NameCert before a consumer receives the limit boundary.

Independence witness: real, regseqrat, streamname, dyadicratcore: $\mathsf{LocatedRealLimit}^{\uparrow}$ is not bijective to any listed sibling because it jointly binds terminal Real sealing, regular rational tails, finite observation windows, located tolerance coverage, separated uniqueness, transport, replay, provenance, and local naming while refusing host limits and choice.

Closure status for $\mathsf{NameCert}_{\mathsf{LocatedRealLimit}^{\uparrow}}$.

Constructive story: A $\mathsf{LocatedRealLimit}^{\uparrow}$ packet is generated from a terminal Real seal, RegSeqRat tail data, StreamName finite windows, located tolerance coverage, separated Real uniqueness, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{LocatedRealLimit}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8748.1, Definition 8748.2, and Definition 8748.3 seed the finite located-limit boundary over Real, RegSeqRat, and StreamName rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{LocatedRealLimit}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host limits, selected representatives, countable choice, quotient equality, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, located tolerance coverage, RegSeqRat tail compatibility, separated Real uniqueness, ledger non-escape, transport, replay, provenance, and local naming for BEDC.Derived.LocatedRealLimitUp

Chapter 8749

A Concrete Naming Certificate for $\mathsf{CauchyFilterSubsequence}^{\uparrow}$

Following Bishop and Bridges on regular Cauchy sequences and Bourbaki–Kelley on filters, the $\mathsf{CauchyFilterSubsequence}^{\uparrow}$ packet records the finite route by which Cauchy-filter convergence evidence is read as subsequence windows without invoking countable choice. It sits between the Cauchy-filter surface of chapter 333, the regular-filter handoff of chapter 1445, the finite observation schedule of chapter 126, the regular rational readback of chapter 301, and the terminal real-name seal of chapter 38. The packet names only displayed extraction windows: it is not a quotient filter, not a selected infinite subsequence, not a countable-choice schedule, and not an appeal to ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 8749.1 (CauchyFilterSubsequence carrier)**.** *A* $\mathsf{CauchyFilterSubsequence}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (F, R, W, Q, E, H, C, P, N)$$

with the following displayed rows:

1. *F is the source* $\mathsf{CauchyFilter}^{\uparrow}$ *convergence row, including the finite filter witnesses and directed refinement data visible to the packet.*
2. *R is the* $\mathsf{RegularCauchyFilter}^{\uparrow}$ *handoff row that regularizes the filter evidence before any sequence-facing read is exposed.*
3. *W is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row naming the inspected subsequence requests and their displayed positions.*
4. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the rational tolerance windows opened by W.*
5. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached only after F, R, W, Q have been displayed.*
6. *H records componentwise* hsame *transport for the filter, regular-filter, window, readback, seal, replay, provenance, and local naming rows.*
7. *C records displayed* Cont *replay from a filter tolerance request through the same finite rows.*
8. *P is the* Pkg *provenance over* $\mathsf{CauchyFilterSubsequence}^{\uparrow}$, $\mathsf{CauchyFilter}^{\uparrow}$, $\mathsf{RegularCauchyFilter}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
9. *N is the local* $\mathsf{NameCert}_{\mathsf{CauchyFilterSubsequence}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $F, R, W, Q, E, H, C, P, N$. It has no coordinate for a chosen infinite subsequence, quotient filter equality, host sequence equality, countable choice, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 8749.2 (CauchyFilterSubsequence NameCert obligations)**.** *For every accepted* $\mathsf{CauchyFilterSubsequence}^{\uparrow}$ *carrier $S = (F, R, W, Q, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{CauchyFilterSubsequence}^{\uparrow}}$ *surface consists exactly of carrier admission for the source* $\mathsf{CauchyFilter}^{\uparrow}$ *row F, the regular-filter handoff row R, the finite* $\mathsf{StreamName}^{\uparrow}$ *extraction windows W, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row Q, the terminal* $\mathsf{Real}^{\uparrow}$ *seal E, componentwise* hsame *transport H, displayed* Cont *replay C, provenance P, and local naming N.*

Proof. Project the carrier of Definition 8749.1. The analytic rows are precisely the Cauchy-filter source, regular-filter handoff, stream-window extraction surface, regular rational readback, and terminal real-name seal.

The structural rows H, C, P, N transport, replay, source, and name that same finite tuple. Since the carrier contains no slot for a selected infinite subsequence, quotient filter equality, host sequence equality, countable choice, trichotomy, or ambient completeness, the listed rows exhaust the local certificate surface. □

Theorem 8749.3 (CauchyFilterSubsequence finite-window route)**.** *Every* $\mathsf{CauchyFilterSubsequence}^{\uparrow}$ *consumer that extracts sequence-facing evidence from a Cauchy filter must factor through the displayed route*

$$\mathsf{CauchyFilter}^{\uparrow} \longmapsto \mathsf{RegularCauchyFilter}^{\uparrow} \longmapsto \mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}.$$

The route exposes finite subsequence windows and tolerance readback, but it never exports a selected infinite subsequence, quotient filter, countable-choice schedule, host equality of streams, or ambient $\mathsf{Real}^{\uparrow}$ *completeness row.*

Proof. Start with the source row F. It supplies only displayed filter convergence evidence, so a sequence-facing consumer must first read the regular-filter handoff R.

The handoff R opens the finite window row W. The regular rational readback Q can then inspect the tolerance windows named by W, and the terminal seal E is reached only after those rows have been displayed.

Transport, replay, provenance, and local naming preserve the same route through H, C, P, N. No row of the carrier can replace the route by a chosen infinite sequence or by quotient equality of filters or streams. □

Theorem 8749.4 (CauchyFilterSubsequence nonescape)**.** *Let $S = (F, R, W, Q, E, H, C, P, N)$ be an accepted* $\mathsf{CauchyFilterSubsequence}^{\uparrow}$ *carrier. Every downstream Real or Completion consumer that reads subsequence evidence from S can read only the displayed rows $F, R, W, Q, E, H, C, P, N$ and their sibling chapter surfaces. In particular, no consumer can escape to a hidden selector, quotient filter equality, host stream equality, countable choice, trichotomy, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Apply the NameCert obligations of Definition 8749.2. They bind the local certificate to the nine displayed rows and leave no extra consumer coordinate.

Apply the finite-window route of Definition 8749.3. It places every sequence-facing read on the path from the Cauchy-filter row through regular-filter, stream-window, regular-rational, and Real-seal rows.

Thus a Real or Completion consumer sees exactly the visible route named by the packet. Hidden selectors, quotient equalities, countable-choice schedules, trichotomy, and ambient completeness are outside the carrier and cannot be read from it. □

Falsifiable prediction: Every accepted $\mathsf{CauchyFilterSubsequence}^{\uparrow}$ read displays a CauchyFilter row, a RegularCauchyFilter handoff, StreamName finite windows, RegSeqRat readback, a RealUp seal, componentwise hsame transport, Cont replay, Pkg provenance, and local NameCert row before any Real or Completion consumer extracts subsequence evidence.

Independence witness: cauchyfilter, regularcauchyfilter, streamname, regseqrat, real: $\mathsf{CauchyFilterSubsequence}^{\uparrow}$ is not bijective to any listed sibling because it jointly binds filter convergence evidence, regular-filter handoff, finite subsequence windows, regular rational readback, terminal real sealing, transport, replay, provenance, and local naming while refusing selected infinite subsequences and countable choice.

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyFilterSubsequence}^{\uparrow}}$.

Constructive story: A $\mathsf{CauchyFilterSubsequence}^{\uparrow}$ packet is generated from CauchyFilter convergence rows, RegularCauchyFilter handoff rows, StreamName finite subsequence windows, RegSeqRat readback, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CauchyFilterSubsequence}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8749.1, Definition 8749.2, Definition 8749.3, and Definition 8749.4 seed the finite bridge from Cauchy-filter convergence evidence to visible subsequence windows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CauchyFilterSubsequence}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim selected infinite subsequences, quotient filters, quotient streams, countable choice, trichotomy, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, filter-source admission, regular-filter handoff, finite window extraction, regular rational readback, seal nonescape, transport, replay, provenance, and local naming for the same packet.

Chapter 8750

A Concrete Naming Certificate for $\mathsf{LusinFiniteContinuityWindow}^{\uparrow}$

Following Lusin and Bishop–Bridges constructive measure theory, the $\mathsf{LusinFiniteContinuityWindow}^{\uparrow}$ packet records the finite continuity-window route by which a measurable real-valued source is read on a displayed large set through a continuous representative row. It sits after the measure ledger of chapter 92, the continuous-map carrier of chapter 130, the approximation packet of chapter 4147, the finite exceptional-window discipline of chapter 2204, the regular-rational readback route of chapter 301, and the terminal real seal of chapter 38. The packet names only a finite BHist continuity-window handoff; it does not claim full measure completion, quotient almost-everywhere equality, a selected null representative, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 8750.1 (Lusin finite-continuity-window carrier)**.** *A* $\mathsf{LusinFiniteContinuityWindow}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$W = (M, L, C, E, R, S, H, Q, P, N)$$

with the following displayed rows:

1. *M is the measurable source row, exposing the finite* $\mathsf{Measure}^{\uparrow}$ *ledger, the inspected measurable real-valued row, and the measurable-set boundary on which the window is read.*
2. *L is the large-set ledger row, carrying the displayed subset, its finite complement budget, and the containment checks used by the continuity-window read.*
3. *C is the* $\mathsf{ContinuousMap}^{\uparrow}$ *representative row, naming the continuous representative on the displayed large set rather than an ambient function-space element.*
4. *E is the exceptional-set budget row, recording the finite exceptional window inherited from the* $\mathsf{Egorov}^{\uparrow}$ *and* $\mathsf{LusinApproximation}^{\uparrow}$ *routes.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row, turning the measured values and representative values inside the window into regular-rational comparison data.*
6. *S is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row, available only after M, L, C, E, R have been displayed.*
7. *H records componentwise* hsame *transport for the measurable source, large-set ledger, continuous representative, exceptional-set budget, regular-rational readback, Real seal, replay, provenance, and local-name rows.*

8. *Q records displayed* Cont *replay of the finite route*

$$M, L, C, E, R, S \longmapsto H, P, N.$$

9. *P is the* Pkg *provenance over* $\mathsf{LusinFiniteContinuityWindow}^{\uparrow}$, $\mathsf{Measure}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{LusinApproximation}^{\uparrow}$, $\mathsf{Egorov}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

10. *N is the local* $\mathsf{NameCert}_{\mathsf{LusinFiniteContinuityWindow}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $M, L, C, E, R, S, H, Q, P, N$. It has no coordinate for completed measure algebras, host measurable-function quotients, selected null representatives, countable choice, quotient almost-everywhere equality, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 8750.2 (Lusin finite-continuity-window NameCert obligations)**.** *For every accepted* $\mathsf{LusinFiniteContinuityWindow}^{\uparrow}$ *carrier*

$$W = (M, L, C, E, R, S, H, Q, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{LusinFiniteContinuityWindow}^{\uparrow}}$ *surface consists exactly of the following obligation rows:*

1. *carrier admission for the measurable source row M, the large-set ledger row L, and the* $\mathsf{ContinuousMap}^{\uparrow}$ *representative row C;*
2. *large-set exactness through L, requiring the displayed subset and complement budget to be read in the same finite* $\mathsf{Measure}^{\uparrow}$ *ledger as M;*
3. *exceptional-set budget exposure through E, requiring every continuity-window read to preserve the same finite exceptional row;*
4. *regular-rational readback through R, requiring measured and representative values inside the window to pass through the displayed* $\mathsf{RegSeqRat}^{\uparrow}$ *comparison surface;*
5. $\mathsf{Real}^{\uparrow}$ *seal non-escape through S, requiring real-valued comparison to remain downstream of M, L, C, E, R;*
6. *structural stability through H, Q, P, N, requiring componentwise transport, displayed replay, provenance, and local naming to preserve exactly the rows M, L, C, E, R, S.*

No obligation may be discharged by completing the measure algebra, quotienting by almost-everywhere equality, selecting a null representative, importing a host Lusin theorem, or appealing to countable choice.

Proof. Project the carrier of Definition 8750.1. The measure-facing rows are M, L, E, the representative-facing row is C, the regular-rational readback row is R, and the terminal real seal is S.

The large-set ledger is read before any continuity verdict is exported. Thus the representative in C is attached to the displayed subset and complement budget in L, while the exceptional row E records the finite window inherited from the Egorov and Lusin-approximation routes.

The real-valued comparison is sealed only after regular-rational readback has been displayed. The row R fixes the inspected rational windows for the measured source and the continuous representative, and S exposes only the downstream $\mathsf{Real}^{\uparrow}$ comparison route.

Finally H, Q, P, N transport, replay, source, and name only those displayed rows. Since the excluded completed measure algebra, quotient almost-everywhere equality, selected null representative, host theorem, choice, and ambient completeness coordinates are absent, the listed rows exhaust the local NameCert obligations. □

Theorem 8750.3 (Lusin finite-continuity-window measure handoff)**.** *Every* $\mathsf{Measure}^{\uparrow}$ *or* $\mathsf{ContinuousMap}^{\uparrow}$ *consumer of an accepted* $\mathsf{LusinFiniteContinuityWindow}^{\uparrow}$ *packet reaches the terminal* $\mathsf{Real}^{\uparrow}$ *seal only through the finite route*

$$\mathsf{Measure}^{\uparrow} \longmapsto \mathsf{LusinApproximation}^{\uparrow} \longmapsto \mathsf{Egorov}^{\uparrow} \longmapsto \mathsf{ContinuousMap}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}$$

as displayed by the rows $M, L, E, C, R, S, H, Q, P, N$*. The handoff exports no completed measure algebra, host measurable-function quotient, selected null set, quotient almost-everywhere equality, countable-choice schedule, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness row.*

Proof. Read the packet through Definition 8750.1. The source row M fixes the finite measure ledger, while L and E expose the large-set and exceptional-set budgets before the representative row C is available.

The regular-rational comparison then passes through R. Only after this readback can the terminal seal S be consumed, so every Real-facing handoff factors through the displayed measure, approximation, exceptional-window, continuous-representative, and regular-rational rows.

The structural rows H, Q, P, N preserve that same finite route under transport, replay, provenance, and local naming. No excluded coordinate is present from which a consumer could read a completed measure algebra, quotient almost-everywhere equality, selected null set, countable-choice schedule, or ambient Real completeness. □

Closure status for $\mathsf{NameCert}_{\mathsf{LusinFiniteContinuityWindow}^{\uparrow}}$.

Constructive story: A $\mathsf{LusinFiniteContinuityWindow}^{\uparrow}$ packet is generated from finite Measure source rows, large-set ledger rows, ContinuousMap representative rows, exceptional-set budget rows, RegSeqRat readback rows, Real seal rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{LusinFiniteContinuityWindow}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8750.1, Definition 8750.2, and Definition 8750.3 seed the finite large-set continuity-window route from Measure and LusinApproximation rows to ContinuousMap, RegSeqRat, and Real consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{LusinFiniteContinuityWindow}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim full measure completion, host measurable-function quotients, selected null representatives, quotient almost-everywhere equality, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, axiom-clean audit, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, large-set ledger exactness, continuous representative admission, exceptional-set budget exposure, regular-rational readback, Real seal non-escape, transport stability, and replay stability for BEDC.Derived.LusinFiniteContinuityWindowUp.

Lean4 (statement) `BEDC.Derived.LusinFiniteContinuityWindowUp`

Chapter 8751

A Concrete Naming Certificate for $\mathsf{FiniteOpenCoverNumber}^{\uparrow}$

Following Bishop and Bridges on compact metric arguments by finite covers, the $\mathsf{FiniteOpenCoverNumber}^{\uparrow}$ packet records the finite numerical boundary used when a compact cover is consumed through a displayed ProbeBundle rather than through an external enumeration. It realizes the finite-cover route of chapter 9237: compactness supplies finitely many cover rows, the $\mathsf{Rat}^{\uparrow}$ and $\mathsf{DyadicRatCore}^{\uparrow}$ ledgers record positive radius comparisons, and the resulting number row is consumed by uniform-modulus arguments without choosing a host finite set. The packet sits beside the compact carrier of chapter 60, the finite-net route of chapter 4760, and the rational lower-bound fold of chapter 4118.

Definition 8751.1 (Finite open-cover number carrier)**.** *A* $\mathsf{FiniteOpenCoverNumber}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$O = (K, B, R, L, U, H, C, P, N)$$

with the following displayed rows:

1. *K is the compact source row whose cover is being read.*
2. *B is the* ProbeBundle *row carrying the finite cover names.*
3. *R is the* $\mathsf{Rat}^{\uparrow}$ *radius row attached to each bundled cover element.*
4. *L is the lower-bound ledger row recording a positive rational number below the displayed cover radii.*
5. *U is the uniform-modulus handoff row consumed by compact-uniform-continuity arguments.*
6. *H records componentwise* hsame *transport for K, B, R, L, U, C, P, N.*
7. *C records displayed* Cont *replay of the same finite-cover read.*
8. *P is the* Pkg *provenance over* $\mathsf{FiniteOpenCoverNumber}^{\uparrow}$, $\mathsf{Compact}^{\uparrow}$, ProbeBundle, $\mathsf{Rat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{UniformModulus}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
9. *N is the local* $\mathsf{NameCert}_{\mathsf{FiniteOpenCoverNumber}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $K, B, R, L, U, H, C, P, N$. It has no coordinate for an externally numbered cover, a host finite set, a selected minimum, open-cover compactness outside the displayed compact row, countable choice, or ambient Real completeness.

Theorem 8751.2 (Finite open-cover number NameCert obligations)**.** *For every accepted* $\mathsf{FiniteOpenCoverNumber}^{\uparrow}$ *carrier* $O = (K, B, R, L, U, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{FiniteOpenCoverNumber}^{\uparrow}}$ *surface consists exactly of carrier admission for the compact source row,* $\mathsf{ProbeBundle}$ *finite cover row,* $\mathsf{Rat}^{\uparrow}$ *radius rows, positive lower-bound ledger, uniform-modulus handoff, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. Every consumer route must expose the finite cover through* B *and the rational radius ledger through* R, L *before it may read the uniform-modulus row* U*.*

Proof. Project the carrier of Definition 8751.1. The only rows available to the local classifier are $K, B, R, L, U, H, C, P, N$, so the cover number is named by finite packet data.

The compact row K supplies the source of the cover, while B supplies the displayed finite $\mathsf{ProbeBundle}$ cover names. The radius row R and lower-bound ledger L are the only numerical rows from which the cover number can be read.

The uniform-modulus handoff U is downstream of those cover and radius rows. Transport, replay, provenance, and local naming preserve that route. Since the carrier contains no external enumeration, host finite set, selected minimum, choice coordinate, open-cover compactness outside K, or ambient Real completeness, these rows exhaust the local $\mathsf{NameCert}$ obligations. □

Theorem 8751.3 (Finite open-cover number compact-uniform route)**.** *Every compact-uniform-continuity consumer of an accepted* $\mathsf{FiniteOpenCoverNumber}^{\uparrow}$ *carrier factors its finite-cover read through*

$$K \to B \to R \to L \to U \to H \to C \to P \to N.$$

Thus the consumer reads the compact source, $\mathsf{ProbeBundle}$ *finite cover, rational radius rows, positive lower-bound ledger, uniform-modulus handoff, transport, replay, provenance, and local naming before treating the packet as a finite open-cover number.*

Proof. Open the handoff row U. By Definition 8751.1, it appears only after the compact source row, finite cover bundle row, rational radius row, and lower-bound ledger row have been displayed.

Apply Definition 8751.2. It forces any compact-uniform consumer to read the finite cover as $\mathsf{ProbeBundle}$ data and the numerical cover bound as a $\mathsf{Rat}^{\uparrow}$ ledger before using the handoff.

The compact-uniform-continuity vision cited above consumes exactly this finite-cover route. Because the carrier has no external numbering, selected minimum, host finite set, countable choice, ambient completeness, or open-cover compactness outside the displayed compact row, the finite BEDC route is the complete boundary. □

Falsifiable prediction: Every accepted FiniteOpenCoverNumberUp compact-uniform read exposes a compact source row, ProbeBundle finite cover, RatUp radius rows, positive lower-bound ledger, UniformModulus handoff, hsame transport, Cont replay, Pkg provenance, and local NameCert before a consumer receives the cover number.

Independence witness: compact, compact-uniform-finite-net, probe-bundle-finite-minimum-fold: $\mathsf{FiniteOpenCoverNumber}^{\uparrow}$ is not bijective to any listed sibling because it jointly binds compact cover source data, finite ProbeBundle cover rows, rational radius ledgers, a positive lower-bound number, uniform-modulus handoff, transport, replay, provenance, and local naming while refusing external enumerations and selected minima.

Closure status for $\mathsf{NameCert}_{\mathsf{FiniteOpenCoverNumber}^{\uparrow}}$**.**

Constructive story: A $\mathsf{FiniteOpenCoverNumber}^{\uparrow}$ packet is generated from a compact source row, ProbeBundle finite cover row, RatUp radius rows, a positive lower-bound ledger, a UniformModulus handoff, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\text{FiniteOpenCoverNumber}\uparrow}$, seed)

Scope closed: Definition 8751.1, Definition 8751.2, and Definition 8751.3 seed the finite cover-number boundary consumed by compact-uniform-continuity routes.

Formal verification: FormalStatus(NameCert$_{\text{FiniteOpenCoverNumber}\uparrow}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close externally numbered covers, host finite sets, selected minima, countable choice, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, ProbeBundle cover rows, RatUp radius ledgers, lower-bound number accounting, uniform-modulus handoff, transport, replay, provenance, and local naming for BEDC.Derived.FiniteOpenCove

Chapter 8752

A Concrete Naming Certificate for $\mathsf{BrouwerFixedPointTwoD}^{\uparrow}$

Following Brouwer and constructive finite-dimensional fixed-point presentations, the $\mathsf{BrouwerFixedPointTwoD}^{\uparrow}$ packet records a finite compact-convex certificate for a two-dimensional self-map before any fixed-point-facing read is allowed. It consumes the compact metric source of chapter 129, the convex carrier of chapter 208, the continuous self-map surface of chapter 130, the dyadic rational ledger of chapter 291, the stream window discipline of chapter 126, the regular sequence readback of chapter 301, and the terminal real-name seal of chapter 38. The packet names only the finite mesh, labelling, tolerance, readback, transport, replay, provenance, and local naming route; it does not assert the unrestricted host theorem.

Definition 8752.1 (Brouwer fixed-point two-dimensional carrier)**.** *A* $\mathsf{BrouwerFixedPointTwoD}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (K, V, F, M, L, D, S, R, E, H, C, P, N)$$

with the following displayed rows:

1. *K is the* $\mathsf{CompactMetric}^{\uparrow}$ *source row, recording the compact two-dimensional metric carrier and the finite cover data used by the certificate.*
2. *V is the* $\mathsf{ConvexSet}^{\uparrow}$ *row, recording convex membership, boundary faces, and admitted convex-combination operations for the displayed source.*
3. *F is the continuous self-map row, read through* $\mathsf{ContinuousMap}^{\uparrow}$*, exposing only the displayed modulus and finite image windows used on the mesh.*
4. *M is the finite vertex and mesh ledger, recording the triangulation cells, adjacency, boundary flags, and mesh-scale index.*
5. *L is the finite labelling ledger, assigning each boundary and interior mesh vertex the displacement label read from F.*
6. *D is the dyadic tolerance ledger, read through* $\mathsf{DyadicRatCore}^{\uparrow}$*, recording mesh diameter, residual budgets, and label-comparison margins.*
7. *S is the Sperner witness row, carrying the fully labelled simplex and its finite induction trace inside the mesh ledger.*

8. *R is the readback row through* $\mathsf{StreamName}^{\uparrow}$ *and* $\mathsf{RegSeqRat}^{\uparrow}$*, exposing finite windows of the approximate fixed-simplex coordinates.*
9. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row, reached only after K, V, F, M, L, D, S, R are displayed and used only to keep the readback inside the named compact-convex source.*
10. *H records componentwise* hsame *transport for the compact, convex, self-map, mesh, labelling, tolerance, witness, readback, seal, replay, provenance, and naming rows.*
11. *C records displayed* Cont *replay for every consumer route through $K, V, F, M, L, D, S, R, E, H$.*
12. *P is the* Pkg *provenance over* $\mathsf{BrouwerFixedPointTwoD}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{ConvexSet}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
13. *N is the local* $\mathsf{NameCert}_{\mathsf{BrouwerFixedPointTwoD}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $K, V, F, M, L, D, S, R, E, H, C, P, N$. It has no coordinate for full classical Brouwer fixed point, open-cover compactness, quotient point equality, choice-selected limits, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 8752.2 (Brouwer fixed-point two-dimensional NameCert obligations)**.** *For every accepted* $\mathsf{BrouwerFixedPointTwoD}^{\uparrow}$ *carrier*

$$B = (K, V, F, M, L, D, S, R, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{BrouwerFixedPointTwoD}^{\uparrow}}$ *obligation surface consists exactly of compact-convex source exposure through K, V; continuous self-map exposure through F; finite vertex and mesh exposure through M; labelling exposure through L; dyadic tolerance exposure through D; Sperner witness exposure through S; StreamName and RegSeqRat readback through R; Real sealing through E; componentwise transport through H; displayed replay through C; provenance through P; and local naming through N. Every fixed-point-facing read must pass through that finite route before it can cite the two-dimensional certificate.*

Proof. Project the carrier of Definition 8752.1. The compact-convex source is visible only through K, V, and the self-map is visible only through F.

The mesh part is finite. Induct on the displayed mesh ledger M: the boundary clauses read their labels from L and their dyadic margins from D, while each subdivision step preserves the same vertex, adjacency, and tolerance rows. The Sperner witness row S is therefore reached by finite mesh induction rather than by open-cover compactness.

The readback part is downstream. The StreamName and RegSeqRat row R exposes only finite coordinate windows of the simplex selected by S, and the Real seal E records that this readback remains inside the displayed compact-convex source.

Finally H, C, P, N transport, replay, source, and name the same packet. Since the carrier contains no row for full classical Brouwer fixed point, open-cover compactness, quotient point equality, choice-selected limits, or ambient $\mathsf{Real}^{\uparrow}$ completeness, the listed rows exhaust the finite NameCert obligation surface. □

Closure status for $\mathsf{NameCert}_{\mathsf{BrouwerFixedPointTwoD}^{\uparrow}}$**.**

Constructive story: A $\mathsf{BrouwerFixedPointTwoD}^{\uparrow}$ packet is generated from compact metric rows, convex source rows, continuous self-map rows, finite vertex and mesh rows, finite labelling and Sperner witness rows, dyadic tolerance rows, StreamName and RegSeqRat readback rows, a Real seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{BrouwerFixedPointTwoD}^{\uparrow}}$, seed)

Scope closed: Definition 8752.1 and Definition 8752.2 seed the finite compact-convex fixed-point certificate over compact metric, convex, continuous-map, dyadic tolerance, stream readback, regular sequence, Real seal, transport, replay, provenance, and local naming rows.

Formal verification: FormalStatus(NameCert$_{\mathsf{BrouwerFixedPointTwoD}\uparrow}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close full classical Brouwer fixed point, open-cover compactness, quotient point equality, choice-selected limits, ambient RealUp completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, finite mesh induction, labelling exactness, dyadic tolerance readback, StreamName and RegSeqRat window stability, Real seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.BrouwerFixedPointTwoDUp.

Chapter 8753

A Concrete Naming Certificate for $\mathsf{ProperMetricCompletionBoundary}^{\uparrow}$

Following Bourbaki and Kelley on proper metric spaces, completions, and compact exhaustions, the $\mathsf{ProperMetricCompletionBoundary}^{\uparrow}$ packet names the finite boundary by which a proper metric closed-ball ledger can be consumed by completion-facing and compactification-facing readers. It is a NameCert reconstruction of the classical fact that proper metric data supplies compact bounded windows around a completion boundary; it is not a quotient completion, not a selected representative scheme, not a countable-choice selector, not an open-cover compactness theorem, and not an ambient $\mathsf{Real}^{\uparrow}$ completeness principle.

The sibling surface is explicit. The packet reads proper-radius windows from **??**, closed-ball membership from chapter 1451, compact-window witnesses from chapter 129, completion-facing boundary rows from chapter 1506, and terminal real readback from chapter 38. These siblings are consumed only as displayed BEDC rows, so the packet can hand compact-ball information to completion and one-point compactification corridors without importing host compactness, selected completion points, or ambient real completeness.

Definition 8753.1 (Proper metric completion boundary carrier)**.** *A* $\mathsf{ProperMetricCompletionBoundary}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (M, R, C, K, Q, W, E, H, T, P, N)$$

with the following displayed rows:

1. *M is the source* $\mathsf{ProperMetric}^{\uparrow}$ *row, exposing the proper metric radius-window ledger.*
2. *R is the* $\mathsf{MetricClosedBall}^{\uparrow}$ *row, exposing center-radius non-strict membership for each displayed window.*
3. *C is the* $\mathsf{CompactMetric}^{\uparrow}$ *row attached to the closed-ball window.*
4. *K is the compact-ball handoff row, recording that compact-window consumers read R and C together over the same source metric.*
5. *Q is the* $\mathsf{MetricCompletion}^{\uparrow}$ *boundary row, exposing only the completion-facing request that consumes the displayed compact windows.*
6. *W is the finite window row that aligns the proper-radius ledger with the completion request.*
7. *E is the* $\mathsf{Real}^{\uparrow}$ *readback seal for the radius and tolerance comparisons used by R, W, Q.*

8. *H records componentwise* hsame *transport for $M, R, C, K, Q, W, E, T, P, N$.*
9. *T records displayed* Cont *replay from the proper-radius request through closed balls, compact windows, the completion boundary, and the Real seal.*
10. *P is the* Pkg *provenance over* $\mathsf{ProperMetricCompletionBoundary}^{\uparrow}$, $\mathsf{ProperMetric}^{\uparrow}$, $\mathsf{MetricClosedBall}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{MetricCompletion}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{ProperMetricCompletionBoundary}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $M, R, C, K, Q, W, E, H, T, P, N$. There is no coordinate for quotient completion points, selected representatives, countable choice, open-cover compactness, host equality, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 8753.2 (Proper metric completion boundary NameCert obligations)**.** *For every accepted* $\mathsf{ProperMetricCompletionBoundary}^{\uparrow}$ *carrier $B = (M, R, C, K, Q, W, E, H, T, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{ProperMetricCompletionBoundary}^{\uparrow}}$ *surface consists exactly of proper-metric radius admission, closed-ball membership admission, compact-window handoff, completion-boundary request admission, finite-window alignment, Real readback sealing, componentwise* hsame *transport, displayed* Cont *replay, provenance, and local naming.*

No NameCert obligation is stored outside those rows, and no accepted read can recover a quotient completion, a selected representative, a countable-choice selector, an open-cover compactness principle, host equality, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the accepted carrier of Definition 8753.1. The rows M, R, C, K, Q, W, E are the only mathematical data rows, and the support rows H, T, P, N only transport, replay, source, and name that displayed packet.

The proper metric route is finite. The source row M supplies a radius-window ledger, R records the corresponding closed-ball membership, and C records the compact-metric witness attached to that same window.

The completion-facing row is downstream of those windows. The boundary request Q can be read only after the compact-ball handoff K and the alignment row W are exposed, and its radius comparisons are sealed by E through the displayed Real readback.

Finally, H, T, P, N preserve this same route. Since the carrier has no coordinate for quotient completion points, selected representatives, countable choice, open-cover compactness, host equality, or ambient completeness, the local NameCert surface cannot export any of those principles. □

Theorem 8753.3 (Proper metric compact-ball handoff)**.** *Every completion-facing or compactification-facing consumer of an accepted* $\mathsf{ProperMetricCompletionBoundary}^{\uparrow}$ *carrier must read the compact-ball handoff through*

$$M \longmapsto R \longmapsto C \longmapsto K \longmapsto W \longmapsto Q \longmapsto E \longmapsto H, T, P, N.$$

Thus the consumer receives proper metric closed-ball data, a compact-metric witness for the displayed ball, and a completion-boundary request only as one finite BEDC route. It receives no quotient completion point, selected representative, countable-choice schedule, open-cover compactness theorem, host equality, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start with the proper metric source. The row M names the finite radius-window surface, and the closed-ball row R reads membership for that displayed window.

Next read the compact witness. The compact-metric row C and handoff row K bind the witness to the same closed-ball window, so a consumer cannot substitute an independent compact object or an open-cover compactness theorem.

Now expose the completion side. The alignment row W matches the radius window with the completion-boundary request Q, and the Real seal E records only the displayed tolerance readback needed by that request.

The support rows H, T, P, N replay and name the same path. Therefore every completion-facing or compactification-facing read is confined to the stated carrier route and cannot escape into quotient completions, selected representatives, countable choice, host equality, or ambient Real completeness. □

Closure status for $\mathsf{NameCert}_{\mathsf{ProperMetricCompletionBoundary}^{\uparrow}}$.

Constructive story: A $\mathsf{ProperMetricCompletionBoundary}^{\uparrow}$ packet is generated from a ProperMetricUp radius-window row, a MetricClosedBallUp membership row, a CompactMetricUp witness row, a compact-ball handoff, a MetricCompletionUp boundary request, finite window alignment, a RealUp readback seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{ProperMetricCompletionBoundary}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8753.1, Definition 8753.2, and Definition 8753.3 seed the finite NameCert surface for proper metric compact-ball data consumed by completion-boundary readers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{ProperMetricCompletionBoundary}^{\uparrow}}, \mathsf{formalTarget})$

Bridge status: none

Not claimed: This chapter does not close quotient completion, selected representatives, countable choice, open-cover compactness, host equality, ambient Real completeness, Lean verification, or a public standard bridge.

Upgrade path: Obligation closure requires checked carrier admission, compact-ball handoff exactness, completion-boundary readback, transport, replay, provenance exhaustion, and ledger non-escape for BEDC.Derived.ProperMetricCompletionBoundaryUp.

Chapter 8754

A Concrete Naming Certificate for $\mathsf{ClosedIntervalFiniteNetSelector}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{ClosedIntervalFiniteNetSelector}^{\uparrow}$ packet records the finite selector boundary needed when a closed real interval is read through constructive finite data. It sits after the interval carrier of chapter 4111, the located finite-net rows of chapter 1808, the finite-net witness surface of chapter 3471, the dyadic mesh route of chapter 5966, the stream-name surface of chapter 126, the regular rational readback of chapter 301, and the terminal real seal of chapter 38. The chapter gives compact-interval consumers a named finite selection packet without asserting open-cover compactness, arbitrary subcover choice, quotient real equality, trichotomy, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 8754.1 (ClosedIntervalFiniteNetSelector carrier)**.** *A* $\mathsf{ClosedIntervalFiniteNetSelector}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Q = (L, U, M, F, V, W, R, S, H, C, P, N)$$

with the following displayed rows:

1. *L and U are the lower and upper endpoint rows read from a* $\mathsf{RealInterval}^{\uparrow}$ *packet, including the displayed endpoint-order and enclosure data.*
2. *M is the dyadic mesh-depth row. It records the positive precision request, mesh denominator, and outward rounding budget used by the selector.*
3. *F is the located finite-net row from* $\mathsf{LocatedClosedIntervalFiniteNet}^{\uparrow}$*; it displays the finite list of mesh cells, endpoint coverage checks, and locatedness witnesses visible at depth M.*
4. *V is the finite-net witness row routed through* $\mathsf{HeineBorelFiniteNet}^{\uparrow}$ *and* $\mathsf{DyadicIntervalNet}^{\uparrow}$*; it records the exact finite candidate rows retained by the selector, not an arbitrary subcover.*
5. *W is the* $\mathsf{StreamName}^{\uparrow}$ *window row for the endpoint streams and the selected mesh cells.*
6. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row turning those windows and the mesh budget into regular rational observations.*
7. *S is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row for every Real-facing endpoint or selected-net output.*
8. *H records componentwise* hsame *transport for endpoints, mesh depth, located finite-net rows, witness rows, stream windows, readback, Real seal, replay, provenance, and local naming.*

9. *C records displayed* Cont *replay for finite selector reads through* $L, U, M, F, V, W, R, S, H, P, N$.
10. *P is the* Pkg *provenance over* ClosedIntervalFiniteNetSelector$^{\uparrow}$, RealInterval$^{\uparrow}$, LocatedClosedIntervalFiniteNet$^{\uparrow}$, HeineBorelFiniteNet$^{\uparrow}$, DyadicIntervalNet$^{\uparrow}$, StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, Real$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* NameCert$_{\text{ClosedIntervalFiniteNetSelector}^{\uparrow}}$ *row.*

The carrier predicate asserts exactly that these rows form one finite selector history for a displayed closed real interval. It has no coordinate for open-cover compactness, selected arbitrary subcovers, quotient real equality, trichotomy, countable choice, or ambient Real$^{\uparrow}$ *completeness.*

Theorem 8754.2 (ClosedIntervalFiniteNetSelector NameCert obligations)**.** *For every accepted* ClosedIntervalFiniteNetSelector$^{\uparrow}$ *carrier* $Q = (L, U, M, F, V, W, R, S, H, C, P, N)$*, the local* NameCert$_{\text{ClosedIntervalFiniteN}}$ *surface consists exactly of endpoint admission, dyadic mesh-depth admission, located finite-net exposure, finite-net witness retention, stream-window exposure, regular rational readback, Real seal nonescape, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. No finite selector obligation is stored outside those rows.*

Proof. Project the carrier of Definition 8754.1. The endpoint rows L, U, mesh row M, located finite-net row F, and witness row V are the only selection data in the packet.

Read the sibling finite-net route next. The located finite-net row F supplies finite mesh-cell and endpoint-coverage data, while V records the retained witness rows through HeineBorelFiniteNet$^{\uparrow}$ and DyadicIntervalNet$^{\uparrow}$. These rows name finite candidates; they do not choose an arbitrary subcover.

Finally route every Real-facing output through W, R, S and every structural read through H, C, P, N. Since the excluded compactness, quotient equality, trichotomy, countable-choice, and completeness principles are not coordinates of the carrier, the local NameCert obligations are exhausted by the displayed rows. □

Theorem 8754.3 (ClosedIntervalFiniteNetSelector choice-free retention)**.** *Every accepted* ClosedIntervalFiniteNetS *packet retains finite selector data only through the displayed route*

$$L, U \longmapsto M, F, V \longmapsto W, R, S, H, C, P, N.$$

Consequently downstream compact-interval consumers may cite a finite net selected at a displayed dyadic depth, but they receive no open-cover compactness theorem, no selected arbitrary subcover, no quotient real equality, no order trichotomy, no countable-choice schedule, and no ambient Real$^{\uparrow}$ *completeness principle.*

Proof. Start from the endpoint rows. The interval boundary is read from L, U together with the order and enclosure discipline of RealInterval$^{\uparrow}$, so the selector never replaces the endpoints by host representatives.

Use the dyadic mesh-depth row M to enter the finite-net siblings. The located finite-net row F exposes finite mesh coverage at that depth, and the witness row V retains exactly the finite candidates routed through LocatedClosedIntervalFiniteNet$^{\uparrow}$, HeineBorelFiniteNet$^{\uparrow}$, and DyadicIntervalNet$^{\uparrow}$.

The stream windows, regular rational readback, and Real seal are then read through W, R, S. Componentwise hsame transport, displayed Cont replay, Pkg provenance, and the local NameCert row preserve the same finite route. Since no carrier row stores the refused global principles, every consumer receives only the choice-free finite selector retained by the displayed packet. □

Closure status for $\mathsf{NameCert}_{\mathsf{ClosedIntervalFiniteNetSelector}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{ClosedIntervalFiniteNetSelector}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8754.1, Definition 8754.2, and Definition 8754.3 seed the finite selector surface over $\mathsf{RealInterval}^{\uparrow}$, $\mathsf{LocatedClosedIntervalFiniteNet}^{\uparrow}$, $\mathsf{HeineBorelFiniteNet}^{\uparrow}$, $\mathsf{DyadicIntervalNet}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{ClosedIntervalFiniteNetSelector}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close open-cover compactness, selected arbitrary subcovers, quotient real equality, trichotomy, countable choice, ambient RealUp completeness, Lean verification, or a public standard bridge.

Upgrade path: Obligation closure requires checked carrier admission, finite-net witness retention, Real seal nonescape, choice-free routing, and ledger refusal for BEDC.Derived.ClosedIntervalFiniteNetSelectorUp.

Constructive story: A $\mathsf{ClosedIntervalFiniteNetSelector}^{\uparrow}$ packet is generated from closed interval endpoints, a dyadic mesh depth, located finite-net rows, finite witness rows, StreamName windows, RegSeqRat readback, a Real seal, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Chapter 8755

A Concrete Naming Certificate for $\mathsf{SignedDyadicRootBracket}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{SignedDyadicRootBracket}^{\uparrow}$ packet records a finite dyadic interval whose endpoint signs bracket a root before any completion-facing consumer may read it. It sits over the dyadic rational ledger of chapter 291, the finite window discipline of chapter 126, the regular rational readback route of chapter 301, the interval surface of chapter 4111, and the terminal real-name seal of chapter 38. The packet names only the displayed signed endpoints, tolerance ledger, windowed function reads, bisection row, transport, replay, provenance, and local naming route.

Definition 8755.1 (Signed dyadic root-bracket carrier)**.** *A* $\mathsf{SignedDyadicRootBracket}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (I, a, b, L, R, D, W, F, S, Q, E, H, C, P, N)$$

with the following displayed rows:

1. *I is the* $\mathsf{RealInterval}^{\uparrow}$ *row naming the inspected interval.*
2. *a, b are the displayed dyadic endpoints read through* $\mathsf{DyadicRatCore}^{\uparrow}$*.*
3. *L and R are the endpoint sign rows, recording opposite signs for the windowed reads at a and b.*
4. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger controlling endpoint arithmetic, midpoint arithmetic, and sign-margin comparisons.*
5. *W is the* $\mathsf{StreamName}^{\uparrow}$ *window row exposing exactly the finite function observations used at the two endpoints and at later bisection midpoints.*
6. *F is the function-read row, available only through the displayed finite windows and dyadic tolerances.*
7. *S is the signed bracket row tying I, a, b, L, R, D, W, F into one admitted bracket.*
8. *Q is the bisection row recording the inspected midpoint, the retained dyadic subinterval, and the retained endpoint-sign witness.*
9. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row reached only after the interval, endpoint, sign, tolerance, window, function-read, bracket, and bisection rows have been displayed.*
10. *H records componentwise* hsame *transport for the interval, endpoint, sign, tolerance, window, function-read, bracket, bisection, seal, replay, provenance, and naming rows.*

11. *C records displayed* Cont *replay of every consumer route through* $I, a, b, L, R, D, W, F, S, Q, E, H$.
12. *P is the* Pkg *provenance over* $\mathsf{SignedDyadicRootBracket}^{\uparrow}$, $\mathsf{RealInterval}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
13. *N is the local* $\mathsf{NameCert}_{\mathsf{SignedDyadicRootBracket}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $I, a, b, L, R, D, W, F, S, Q, E, H, C, P, N$. It has no coordinate for host trichotomy, selected roots, quotient real equality, unrestricted intermediate-value reasoning, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 8755.2 (Signed dyadic root-bracket NameCert obligations)**.** *For every accepted* SignedDyadicRootBracke *carrier*

$$B = (I, a, b, L, R, D, W, F, S, Q, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{SignedDyadicRootBracket}^{\uparrow}}$ *surface consists exactly of interval exposure through I; dyadic endpoint exposure through a, b; endpoint-sign exposure through L, R; dyadic tolerance exposure through D; finite observation exposure through W; function-read exposure through F; signed bracket exposure through S; bisection exposure through Q; terminal real sealing through E; componentwise transport through H; displayed replay through C; provenance through P; and local naming through N.*

Proof. Project the carrier of Definition 8755.1. The interval row, two dyadic endpoints, and two sign rows are the only endpoint data available to a consumer.

The analytic read is finite. The window row W exposes only the observations used by the function-read row F, and the tolerance ledger D is the sole ledger for endpoint arithmetic, midpoint arithmetic, and sign margins.

The bracket and bisection rows are downstream of those finite observations. The row S records the accepted signed bracket, while Q records only one displayed midpoint inspection and the retained dyadic subinterval.

Finally E, H, C, P, N seal, transport, replay, source, and name the same route. Since the carrier contains no row for host trichotomy, selected roots, quotient real equality, unrestricted intermediate-value reasoning, or ambient completeness, the listed rows exhaust the local NameCert surface. □

Theorem 8755.3 (Signed dyadic root-bracket bisection stability)**.** *If an accepted* $\mathsf{SignedDyadicRootBracket}^{\uparrow}$ *carrier $B = (I, a, b, L, R, D, W, F, S, Q, E, H, C, P, N)$ is read by a bisection-facing consumer, the retained subinterval in Q must expose the same* $\mathsf{RealInterval}^{\uparrow}$ *source, dyadic endpoint ledger,* $\mathsf{StreamName}^{\uparrow}$ *window row,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback discipline, and terminal* $\mathsf{Real}^{\uparrow}$ *seal route before the consumer sees the retained bracket. The read exports a finite signed dyadic sub-bracket, not a selected root, quotient real equality, host trichotomy, or ambient completeness witness.*

Proof. Begin with the NameCert obligations of Definition 8755.2. They force every accepted bracket read through $I, a, b, L, R, D, W, F, S, Q, E, H, C, P, N$.

For a bisection read, inspect the row Q. Its midpoint and retained endpoint rows are admitted only through the same dyadic tolerance ledger D and the same finite observation window W used by the original signed bracket row S.

The retained subinterval is sealed only after the displayed readback and terminal real-name boundary are exposed. Componentwise transport and displayed replay keep the retained bracket on the same finite route, so no selected limit, host trichotomy, quotient real equality, or ambient completeness row is exported. □

Closure status for $\mathsf{NameCert}_{\mathsf{SignedDyadicRootBracket}^{\uparrow}}$.

Constructive story: A $\mathsf{SignedDyadicRootBracket}^{\uparrow}$ packet is generated from a RealInterval row, dyadic endpoint rows, endpoint-sign rows, a DyadicRatCore tolerance ledger, finite StreamName observation windows, RegSeqRat readback discipline, a function-read row, a signed bracket row, one bisection row, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{SignedDyadicRootBracket}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8755.1, Definition 8755.2, and Definition 8755.3 seed the finite signed dyadic root-bracket route consumed by later bisection and Real or Completion readers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{SignedDyadicRootBracket}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close a host intermediate value theorem, host trichotomy, selected roots or limits, quotient real equality, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, endpoint sign exactness, dyadic midpoint stability, finite-window function reads, RegSeqRat readback, Real sealing, transport, replay, provenance, and local naming for BEDC.Derived.SignedDyadicRootBracketUp.

Chapter 8756

A Concrete Naming Certificate for $\mathsf{OmegaGenerationBody}^{\uparrow}$

Following Lawvere and Mac Lane on categorical diagrams and Bishop-style certified data, the $\mathsf{OmegaGenerationBody}^{\uparrow}$ packet records the licensed generation body interface of chapter 9361 as finite NameCert data. It sits after the stream-display discipline of chapter 126, the product packet of chapter 34, and the local naming carrier surface of chapter 1366. The packet names only the displayed diagram body, legal stream display, code/readback, pairing, generation-order, transport, replay, provenance, and local naming rows; it is not a host tower object, an unlicensed external encoding, a global pairing axiom, or an ambient completeness principle.

Definition 8756.1 (Omega generation body carrier)**.** *An* $\mathsf{OmegaGenerationBody}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$G = (D, L, K, J, O, H, C, P, N)$$

with the following displayed rows:

1. *D is the licensed diagram body row. It records the finite coordinate list for the Ω generation diagram, the accepted object interfaces, and the readback arrows between coordinate rows.*
2. *L is the legal stream display row, read through* $\mathsf{StreamName}^{\uparrow}$*, exposing the public stream window used to display a body without replacing the body by a raw code string.*
3. *K is the code/readback row. It records a faithful readable code morphism together with the displayed decode witness that returns each public stream row to the body row it names.*
4. *J is the pairing involution row. It records the licensed endomorphism on each layer that claims paired behavior, its double-application classifier law, and the fixed-row or apart-pair branch.*
5. *O is the generation-order row. It records the finite forward route generated by displayed history extension and continuation rows before any body read may be consumed.*
6. *H records componentwise* hsame *transport for D, L, K, J, O and the structural rows.*
7. *C records displayed* Cont *replay for every consumer route through the diagram body, stream display, code/readback, pairing, and generation-order rows.*
8. *P is the* Pkg *provenance over* $\mathsf{OmegaGenerationBody}^{\uparrow}$*, the licensed interface rows of chapter 9361,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{Prod}^{\uparrow}$*,* $\mathsf{NameCert}^{\uparrow}$*,* BHist*,* hsame*,* Cont*, and* $\mathsf{NameCert}$*.*
9. *N is the local* $\mathsf{NameCert}_{\mathsf{OmegaGenerationBody}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $D, L, K, J, O, H, C, P, N$. It has no coordinate for an unlicensed tower carrier, a raw bit-string encoding, an involution unsupported by a named layer, a backward time map, quotient body equality, countable choice, or ambient completion.

Theorem 8756.2 (Omega generation body display NameCert obligations)**.** *For every accepted* $\mathsf{OmegaGenerationBody}^{\uparrow}$ *carrier*

$$G = (D, L, K, J, O, H, C, P, N),$$

every body read consumed through the local $\mathsf{NameCert}_{\mathsf{OmegaGenerationBody}^{\uparrow}}$ *must first expose the licensed diagram body row D, the legal stream display row L, the code/readback row K, the pairing involution row J, the generation-order route O, componentwise* hsame *transport H, displayed* Cont *replay C,* Pkg *provenance P, and the local naming row N. Thus the body interface is consumed only as the finite row sequence*

$$D, L, K, J, O \longmapsto H, C, P, N,$$

with no hidden body coordinate outside the accepted carrier.

Proof. Project the carrier of Definition 8756.1. The rows D, L, K, J, O are the only interface-facing data: D supplies the licensed generation diagram body, L supplies the public stream display, K supplies faithful readable code and decode witnesses, J supplies typed pairing by involution, and O supplies the finite generation-order route.

The display cannot be read as a raw external encoding. The stream row is licensed through $\mathsf{StreamName}^{\uparrow}$, the code/readback row carries its own decode witness, and the product-shaped body data remains tied to the coordinate rows named by chapter 34.

The pairing and order rows remain separate. The row J authorizes paired behavior only where a licensed involution is present, while O records the forward generation route through history extension and continuation replay. Neither row supplies a global inverse time map or an untyped pairing principle.

Finally replay H, C, P, N. Componentwise transport, displayed continuation replay, provenance, and local naming preserve exactly the same finite route. Since the carrier contains no unlicensed tower coordinate, raw code row, unsupported pairing, quotient body equality, choice schedule, or ambient completion row, every body read must expose the listed NameCert rows before it can be consumed. □

Closure status for $\mathsf{NameCert}_{\mathsf{OmegaGenerationBody}^{\uparrow}}$.

Constructive story: An $\mathsf{OmegaGenerationBody}^{\uparrow}$ packet is generated from a licensed diagram body row, a legal StreamName display row, a faithful readable code and decode row, a pairing involution row, a finite generation-order route, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{OmegaGenerationBody}^{\uparrow}}$, seed)

Scope closed: Definition 8756.1 and Definition 8756.2 seed the finite Omega generation body surface over licensed interface, StreamName, Prod, NameCert, history, transport, replay, provenance, and local naming rows.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{OmegaGenerationBody}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close unlicensed tower carriers, raw external encodings, global pairing axioms, backward time maps, quotient body equality, countable choice, ambient completion, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, licensed diagram-body exposure, legal stream display, faithful readable code, pairing involution typing, generation-order routing, transport, replay, provenance, and local naming for BEDC.Derived.OmegaGenerationBodyUp.

Chapter 8757

A Concrete Naming Certificate for $\mathsf{ToeplitzOperator}^{\uparrow}$

Following Toeplitz's Hilbert-space operator construction and the classical matrix reading of constant diagonals, the $\mathsf{ToeplitzOperator}^{\uparrow}$ packet records the finite BEDC surface on which a bounded operator is named by displayed sequence windows and a diagonal-constant matrix row. It sits beside the Hankel-shadow carrier of chapter 6634, the finite matrix carrier of chapter 49, the bounded-operator and operator-norm surfaces of chapter 1644 and chapter 3603, the regular sequence-space route of chapter 5965, and the scalar seal of chapter 38. The chapter names only the finite Toeplitz carrier; it does not assert the spectral theorem, host infinite matrices, quotient operator equality, selected completions, or host Hilbert-space equality.

Definition 8757.1 (Toeplitz operator carrier)**.** *A* $\mathsf{ToeplitzOperator}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$T = (S, U, M, D, B, L, R, H, C, P, N)$$

with the following displayed rows:

1. *S is the finite source sequence-window row, recording the visible source indices, values, and tail request read through* $\mathsf{RegularSequenceSpace}^{\uparrow}$*.*
2. *U is the finite target sequence-window row, recording the visible target indices and values produced by the same displayed action.*
3. *M is the* $\mathsf{Mat}^{\uparrow}$ *row whose displayed entries are available only on the finite source-target rectangle named by S and U.*
4. *D is the diagonal-constancy row, requiring every displayed entry M_{ij} to be read from the same scalar row when the visible difference $i - j$ agrees.*
5. *B is the* $\mathsf{BoundedLinearOperator}^{\uparrow}$ *row recording the finite operator action and linearity ledger on the displayed windows.*
6. *L is the boundedness and* $\mathsf{OperatorNorm}^{\uparrow}$ *ledger, carrying the scalar bound used by consumers of B.*
7. *R is the* $\mathsf{Real}^{\uparrow}$ *scalar seal for the diagonal coefficients and norm-bound endpoints.*
8. *H records componentwise* hsame *transport for S, U, M, D, B, L, R and the structural rows.*
9. *C records displayed* Cont *replay of the route*

$$S, U \longmapsto M, D \longmapsto B, L, R.$$

10. *P is the* Pkg *provenance over* $\mathsf{ToeplitzOperator}^{\uparrow}$, $\mathsf{HankelOperator}^{\uparrow}$, $\mathsf{Mat}^{\uparrow}$, $\mathsf{BoundedLinearOperator}^{\uparrow}$, $\mathsf{OperatorNorm}^{\uparrow}$, $\mathsf{RegularSequenceSpace}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{ToeplitzOperator}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these rows. It has no coordinate for a host infinite matrix, spectral measure, quotient operator equality, chosen completion, or host Hilbert-space equality.

Theorem 8757.2 (Toeplitz operator NameCert obligations)**.** *For every accepted* $\mathsf{ToeplitzOperator}^{\uparrow}$ *carrier*

$$T = (S, U, M, D, B, L, R, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{ToeplitzOperator}^{\uparrow}}$ *surface consists exactly of carrier admission for the source and target sequence windows, finite* $\mathsf{Mat}^{\uparrow}$ *admission, diagonal-constancy exactness, bounded-linear-operator compatibility, operator-norm ledger exposure,* $\mathsf{Real}^{\uparrow}$ *scalar sealing, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. A consumer therefore reads a Toeplitz operator only through the finite route*

$\mathsf{RegularSequenceSpace}^{\uparrow}$, $\mathsf{Mat}^{\uparrow}$, $\mathsf{BoundedLinearOperator}^{\uparrow}$, $\mathsf{OperatorNorm}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, Pkg, NameCe

Proof. Project the carrier of Definition 8757.1. The visible analytic rows are exactly the source window S, target window U, matrix row M, diagonal-constancy row D, bounded-operator row B, norm ledger L, and scalar seal R.

Diagonal-constancy exactness reads M and D together. The matrix row is admitted only on the displayed finite rectangle, and D compares entries only by the visible difference index already named by S and U.

Bounded-operator compatibility is the route through B, L, R. The bounded action is exposed before the operator-norm ledger, and the scalar bound is sealed through $\mathsf{Real}^{\uparrow}$ without adding a host supremum or selected norm-attaining vector.

Finally replay H, C, P, N. These rows transport, replay, source, and name only the same finite packet, so the listed rows exhaust the local NameCert surface and leave spectral data, infinite matrices, quotient operator equality, selected completions, and host Hilbert equality outside the carrier. □

Theorem 8757.3 (Toeplitz operator diagonal-constancy route)**.** *Every diagonal read of an accepted* $\mathsf{ToeplitzOperator}^{\uparrow}$ *carrier factors through the finite source window S, finite target window U,* $\mathsf{Mat}^{\uparrow}$ *row M, diagonal-constancy row D, bounded operator row B,* $\mathsf{OperatorNorm}^{\uparrow}$ *ledger L,* $\mathsf{Real}^{\uparrow}$ *scalar seal R, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and the local* $\mathsf{NameCert}_{\mathsf{ToeplitzOperator}^{\uparrow}}$ *row. The route is a Toeplitz certificate-level boundary parallel to the anti-diagonal boundary of* $\mathsf{HankelOperator}^{\uparrow}$*, not a host equality of infinite operators.*

Proof. Start from the NameCert obligations of Definition 8757.2. They require a diagonal consumer to expose S, U, M, D before any bounded-operator or scalar-bound read is available.

Use the diagonal-constancy row. If two displayed pairs have the same visible difference index, the packet reads them through the same scalar coefficient row; if the difference is not named by the finite windows, the carrier exports no entry.

Next consume the boundedness route through B, L, R. The bounded operator row records the finite action, the operator-norm ledger records the displayed bound, and the $\mathsf{Real}^{\uparrow}$ row seals only the scalar coefficients and endpoints used by that ledger.

The structural rows H, C, P, N preserve this same finite route under transport and replay. Since the carrier has no coordinate for a spectral theorem, host infinite matrix, quotient operator equality, selected completion, or host Hilbert-space equality, the diagonal-constancy read stops at the displayed NameCert boundary. □

Falsifiable prediction: An accepted $\mathsf{ToeplitzOperator}^{\uparrow}$ read is refuted if a diagonal, boundedness, or scalar-bound consumer reaches a conclusion without first displaying the source window, target window, finite matrix row, diagonal-constancy row, bounded-operator row, operator-norm ledger, Real scalar seal, transport row, replay row, provenance row, and local naming row.

Independence witness: hankel-operator, matrix, boundedlinearoperator, operator-norm, regular-sequence-space, and real: $\mathsf{ToeplitzOperator}^{\uparrow}$ is not bijective to any listed sibling because only this packet jointly carries source and target sequence windows, diagonal-constant matrix data, bounded-operator and operator-norm rows, scalar seals, transport, replay, provenance, and local NameCert data.

Closure status for $\mathsf{NameCert}_{\mathsf{ToeplitzOperator}^{\uparrow}}$.

Constructive story: A $\mathsf{ToeplitzOperator}^{\uparrow}$ packet is generated from finite source and target sequence windows, a diagonal-constant MatrixUp row, a bounded-operator row, an OperatorNormUp ledger, a RealUp scalar seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{ToeplitzOperator}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8757.1, Definition 8757.2, and Definition 8757.3 seed the finite Toeplitz carrier consumed by matrix, bounded-operator, operator-norm, regular-sequence-space, Hankel-neighbor, and real scalar rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{ToeplitzOperator}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close Lean verification, standard bridge checking, the spectral theorem, host infinite matrices, quotient operator equality, selected completions, or host Hilbert-space equality.

Upgrade path: Obligation closure requires checked carrier admission, finite source and target window routing, diagonal-constancy exactness, boundedness exposure, operator-norm handoff, scalar sealing, transport, replay, provenance, and local naming for BEDC.Derived.ToeplitzOperatorUp.

Chapter 8758

A Concrete Naming Certificate for $\mathsf{RegularSequenceWindowCoherence}^{\uparrow}$

Following Bishop and Bridges on regular Cauchy real names, the $\mathsf{RegularSequenceWindowCoherence}^{\uparrow}$ packet records the finite observation-window route by which a stream name, a regular rational readback, a dyadic tolerance ledger, and a terminal Real seal are read as one coherent NameCert surface. It sits over the finite stream windows of chapter 126, the regular rational sequence route of chapter 301, the dyadic tolerance core of chapter 291, and the real-name boundary of chapter 38. The packet is a finite L10 handoff for Real and Completion consumers; it is not quotient stream equality, a selected representative, countable choice, trichotomy, host real equality, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 8758.1 (Regular sequence window coherence carrier)**.** *A* $\mathsf{RegularSequenceWindowCoherence}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (S, R, D, E, H, C, P, N)$$

with the following displayed rows:

1. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row recording exactly the inspected source indices, rational observations, and request tags.*
2. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row attached to the same inspected windows.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row against which every displayed regularity and comparison read is checked.*
4. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row available only after S, R, D have been read.*
5. *H records componentwise* hsame *transport for the stream window, regular readback, dyadic tolerance, Real seal, replay, provenance, and local naming rows.*
6. *C records displayed* Cont *replay of the route from a finite observation request through the stream window, regular readback, dyadic tolerance, and Real seal.*
7. *P is the* Pkg *provenance over* $\mathsf{RegularSequenceWindowCoherence}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
8. *N is the local* $\mathsf{NameCert}_{\mathsf{RegularSequenceWindowCoherence}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through S, R, D, E, H, C, P, N. It has no coordinate for quotient stream equality, a selected regular representative, countable choice, trichotomy, host real equality, an ambient limit object, or completeness of $\mathsf{Real}^{\uparrow}$.

Theorem 8758.2 (Regular sequence window coherence NameCert obligations)**.** *For every accepted* $\mathsf{RegularSequenceWindowCoherence}^{\uparrow}$ *carrier* $K = (S, R, D, E, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{RegularSequenceWindowCoher}}$ *surface consists exactly of carrier admission for the finite StreamName window row, the RegSeqRat readback row, the DyadicRatCore tolerance row, the terminal Real seal row, componentwise transport, displayed replay, provenance, and local naming.*

Every Real-facing consumer using the packet must read

$$S \longmapsto R \longmapsto D \longmapsto E$$

together with H, C, P, N, and receives no quotient stream equality, selected representative, countable-choice schedule, trichotomy, host real equality, ambient limit object, or ambient completeness theorem.

Proof. Project the carrier of Definition 8758.1. The only source observations are the finite window entries in S, and the only regular rational interpretation of those entries is the readback row R.

The tolerance row D is the sole dyadic budget against which the readback may be consumed. Hence any Real-facing request must pass from S to R and then through D before it can reach the terminal seal E.

The rows H, C, P, N transport, replay, source, and name the same finite route. Since the carrier has no slot for quotient equality, selected representatives, countable choice, trichotomy, host equality, an ambient limit object, or completeness, the listed rows exhaust the local NameCert obligations. □

Theorem 8758.3 (Regular sequence window coherence handoff)**.** *Every accepted* $\mathsf{RegularSequenceWindowCoherenc}$ *consumer of a Real-facing read factors through the finite handoff*

$$\mathsf{StreamName}^{\uparrow} \to \mathsf{RegSeqRat}^{\uparrow} \to \mathsf{DyadicRatCore}^{\uparrow} \to \mathsf{Real}^{\uparrow}.$$

Concretely, the consumer first exposes the window row S, then the regular rational readback row R, then the dyadic tolerance row D, and only then the terminal Real seal row E.

Proof. Start with the StreamName window row S. It is the only row that displays the inspected indices and source observations, so a consumer has no independent access to an infinite stream or a selected representative.

Read the regular rational row R over the same finite observations and then the dyadic tolerance row D. These two rows are the complete regular-sequence handoff: R supplies the readback discipline and D supplies the comparison budget.

The terminal Real seal E is downstream of that handoff. Transport, replay, provenance, and local naming preserve the route through H, C, P, N without adding quotient equality, countable choice, trichotomy, host real equality, selected limits, or ambient $\mathsf{Real}^{\uparrow}$ completeness. □

Falsifiable prediction: Every $\mathsf{RegularSequenceWindowCoherence}^{\uparrow}$ Real-facing read factors through a finite StreamName window row, a RegSeqRat readback row, a DyadicRatCore tolerance row, a terminal RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming.

Independence witness: streamname, regseqrat, dyadicratcore, real: $\mathsf{RegularSequenceWindowCoherence}^{\uparrow}$ is not bijective to any listed sibling because it jointly binds finite observation windows, regular rational readback, dyadic tolerance, terminal Real sealing, transport, replay, provenance, and local naming while refusing quotient streams, selected representatives, countable choice, and ambient completeness.

Closure status for $\mathsf{NameCert}_{\mathsf{RegularSequenceWindowCoherence}^{\uparrow}}$.

Constructive story: A $\mathsf{RegularSequenceWindowCoherence}^{\uparrow}$ packet is generated from a finite StreamName window row, RegSeqRat readback row, DyadicRatCore tolerance row, terminal RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RegularSequenceWindowCoherence}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8758.1, Definition 8758.2, and Definition 8758.3 seed the finite observation-window handoff consumed by Real and Completion routes.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RegularSequenceWindowCoherence}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient stream equality, selected representatives, trichotomy, countable choice, host real equality, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, finite-window exactness, RegSeqRat readback compatibility, dyadic tolerance compatibility, Real sealing, transport, replay, provenance, and local naming for BEDC.Derived.RegularSequenceWindowCoherenceUp.

Chapter 8759

A Concrete Naming Certificate for $\mathsf{LocatedMetricReflection}^{\uparrow}$

Following Bishop and Bridges on constructive metric completion, the $\mathsf{LocatedMetricReflection}^{\uparrow}$ packet records the finite route by which locatedness, metric distance, and separated reflection are displayed before a completion consumer reads a point or limit row. It sits over the located-space surface of chapter 2043, the metric carrier of chapter 57, the metric-completion route of chapter 1506, the separated-metric reflection of chapter 1790, the finite stream windows of chapter 126, and the terminal real-name seal of chapter 38. The packet names the L10 countable-completion interface as displayed NameCert data; it is not quotient completion, selected limits, host equality of points, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 8759.1 (Located metric reflection carrier)**.** *A* $\mathsf{LocatedMetricReflection}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (X, M, Q, S, W, E, H, C, P, N)$$

with the following displayed rows:

1. *X is the* $\mathsf{LocatedSpace}^{\uparrow}$ *row, carrying the finite locatedness request, positive-gap budget, and completion-facing refusal boundary.*
2. *M is the* $\mathsf{Met}^{\uparrow}$ *source row whose distance witnesses are exposed before any completion row can be read.*
3. *Q is the* $\mathsf{MetricCompletion}^{\uparrow}$ *route, or the equivalent* $\mathsf{Completion}^{\uparrow}$ *face, carrying the displayed Cauchy or filter completion handoff.*
4. *S is the* $\mathsf{SeparatedMetricReflection}^{\uparrow}$ *classifier row that turns displayed zero-distance evidence into a separated uniqueness read.*
5. *W is the* $\mathsf{StreamName}^{\uparrow}$ *inspection row through which source observations, distance requests, locatedness budgets, and completion windows are read.*
6. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal attached to distance and positive-gap readback before completion or separatedness is consumed.*
7. *H records componentwise* hsame *transport for locatedness, metric distance, completion route, separated reflection, stream window, real seal, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from a located metric request through X, M, W, E, then through Q or S according to whether the consumer asks for completion or separated reflection.*

9. *P is the* Pkg *provenance over* $\mathsf{LocatedMetricReflection}^{\uparrow}$, $\mathsf{LocatedSpace}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{MetricCompletion}^{\uparrow}$, $\mathsf{SeparatedMetricReflection}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{LocatedMetricReflection}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $X, M, Q, S, W, E, H, C, P, N$. It has no coordinate for quotient points, selected limits, host point equality, countable choice, an unrestricted completion operator, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 8759.2 (Located metric reflection NameCert obligations)**.** *For every accepted* $\mathsf{LocatedMetricReflection}^{\uparrow}$ *carrier*

$$L = (X, M, Q, S, W, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{LocatedMetricReflection}^{\uparrow}}$ *surface consists exactly of locatedness exposure through X; metric distance exposure through M; completion-route exposure through Q; separated-reflection exposure through S; finite StreamName inspection through W; Real sealing through E; componentwise* hsame *transport through H; displayed* Cont *replay through C; provenance through P; and local naming through N. Every completion or separated-reflection consumer must read locatedness and metric distance before it can consume the completion handoff or separated classifier.*

Proof. Project the carrier in Definition 8759.1. The displayed rows are exactly $X, M, Q, S, W, E, H, C, P, N$, so a consumer has no route to completion or separatedness before the locatedness and metric rows have been displayed.

The locatedness row X supplies the finite request and positive-gap budget, while the metric row M supplies the distance witnesses read through W and sealed at E. These rows are the only source of located metric information in the packet.

The completion and separated-reflection rows are downstream. Row Q may be consumed only after the located metric read has been exposed, and row S may turn zero-distance evidence into a uniqueness read only after the same located metric route has been displayed. Transport, replay, provenance, and local naming preserve that route without adding quotient points, selected limits, countable choice, host equality, or ambient completeness. □

Theorem 8759.3 (Located metric reflection completion handoff)**.** *Every completion-facing read from an accepted* $\mathsf{LocatedMetricReflection}^{\uparrow}$ *carrier factors through the ordered route*

$$\mathsf{LocatedSpace}^{\uparrow} \to \mathsf{Met}^{\uparrow} \to \mathsf{StreamName}^{\uparrow} \to \mathsf{Real}^{\uparrow} \to \mathsf{MetricCompletion}^{\uparrow}$$

before any separated uniqueness consumer may inspect $\mathsf{SeparatedMetricReflection}^{\uparrow}$. *Thus locatedness and metric reflection are read before completion or separatedness; the handoff exports no quotient point, selected limit, countable-choice schedule, host equality of completed points, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness principle.*

Proof. Read the carrier rows X, M, W, E, Q first. The locatedness row fixes the finite request and positive-gap boundary, the metric row fixes the displayed distance evidence, the StreamName row fixes the finite observations, and the Real seal records the numerical readback.

Only after that route is visible can a completion-facing consumer read Q. The completion handoff is therefore a row of the same finite packet rather than an ambient completion operator or a quotient class.

Finally, if a consumer asks for separated uniqueness, it must continue through S after the completion-facing route has exposed the located metric data. The support rows H, C, P, N replay and name the same sequence, so no selected limit, host equality, countable-choice schedule, or ambient completeness principle is exported. □

Closure status for $\mathsf{NameCert}_{\mathsf{LocatedMetricReflection}^{\uparrow}}$.

Constructive story: A $\mathsf{LocatedMetricReflection}^{\uparrow}$ packet is generated from a LocatedSpaceUp row, MetricUp distance row, MetricCompletionUp route, SeparatedMetricReflectionUp classifier row, StreamNameUp inspection row, RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{LocatedMetricReflection}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8759.1, Definition 8759.2, and Definition 8759.3 seed the finite located metric route consumed by completion and separated-reflection interfaces.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{LocatedMetricReflection}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient points, selected limits, host point equality, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, locatedness exposure, metric-distance exactness, completion handoff, separated-reflection handoff, transport stability, replay stability, and local naming for BEDC.Derived.LocatedMetricReflecti

Chapter 8760

A Concrete Naming Certificate for $\mathsf{BishopLocatedSupremum}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{BishopLocatedSupremum}^{\uparrow}$ packet records a finite located-supremum witness for a displayed Bishop-style family of real names. It consumes the real-name seal of chapter 38, the dyadic tolerance core of chapter 291, the stream-window surface of chapter 126, the regular-rational readback of chapter 301, and the located-supremum route of chapter 1427. The chapter names only the finite witness packet and its approximation handoffs; it does not claim classical least-upper-bound completeness, trichotomy, countable choice, or a completed quotient-real supremum.

Definition 8760.1 (BishopLocatedSupremum carrier)**.** *A* $\mathsf{BishopLocatedSupremum}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (F, W, D, Q, R, L, A, H, C, P, N)$$

with the following displayed rows:

1. *F is the finite Bishop family row whose members are read only as displayed* $\mathsf{Real}^{\uparrow}$ *names.*
2. *W is the* $\mathsf{StreamName}^{\uparrow}$ *window row used to inspect the family at the requested precision.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row recording the dyadic gap budget for upper and lower approximation tests.*
4. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row that repacks the displayed stream windows as regular rational names.*
5. *R is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row available only after F, W, D, Q have stayed visible.*
6. *L is the* $\mathsf{LocatedSupremum}^{\uparrow}$ *row recording the finite located upper-bound and lower-approximation tests visible in the same window.*
7. *A is the approximation ledger pairing each requested dyadic tolerance with a displayed family element and an upper-bound witness.*
8. *H records componentwise* hsame *transport for the family, window, tolerance, readback, real seal, located-supremum row, approximation ledger, continuation, provenance, and local naming rows.*
9. *C records displayed* Cont *replay from a supremum request through $F, W, D, Q, R, L, A, H, P, N$.*
10. *P is the* Pkg *provenance over* $\mathsf{BishopLocatedSupremum}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{LocatedSupremum}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$ *rows.*

11. *N is the local* $\mathsf{NameCert}_{\mathsf{BishopLocatedSupremum}^{\uparrow}}$ *row.*

The accepted carrier has no coordinate for a classical least upper bound, quotient-real equality, trichotomy, countable choice, selected maximizing sequence, or ambient completeness.

Theorem 8760.2 (BishopLocatedSupremum NameCert obligations)**.** *For every accepted* $\mathsf{BishopLocatedSupremum}^{\uparrow}$ *carrier* $S = (F, W, D, Q, R, L, A, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{BishopLocatedSupremum}^{\uparrow}}$ *surface consists exactly of carrier admission for the displayed family row, stream window, dyadic tolerance ledger, regular-rational readback, terminal real seal, located-supremum row, approximation ledger, componentwise transport, continuation replay, provenance, and local naming. Every accepted read factors through*

$$F, W, D, Q \longmapsto R, L, A, H, C, P, N$$

and refuses classical least-upper-bound completeness, quotient-real equality, trichotomy, countable choice, selected maximizing sequences, and ambient completeness data.

Proof. Project the carrier of Definition 8760.1. The visible rows are exactly $F, W, D, Q, R, L, A, H, C, P, N$, so the local NameCert can admit only those finite rows.

The approximation part begins with the family row F, the stream window W, and the dyadic tolerance row D. The regular-rational row Q repacks the displayed windows before the terminal $\mathsf{Real}^{\uparrow}$ seal R is available.

The located-supremum row L and approximation ledger A then record the upper-bound and lower-approximation witnesses in the same displayed window. The structural rows H, C, P, N transport, replay, source, and name this route without adding a classical least upper bound, quotient equality, trichotomy, countable choice, selected maximizing sequence, or ambient completeness coordinate. □

Theorem 8760.3 (BishopLocatedSupremum approximation nonescape)**.** *Every approximation read from an accepted* $\mathsf{BishopLocatedSupremum}^{\uparrow}$ *carrier factors through the displayed route*

$$\mathsf{StreamName}^{\uparrow},\ \mathsf{DyadicRatCore}^{\uparrow},\ \mathsf{RegSeqRat}^{\uparrow} \longrightarrow \mathsf{Real}^{\uparrow} \longrightarrow \mathsf{LocatedSupremum}^{\uparrow}.$$

The read receives only the finite witness rows $F, W, D, Q, R, L, A, H, C, P, N$ and cannot export a classical least upper bound, quotient-real equality, trichotomy, countable choice, selected maximizing sequence, or an ambient $\mathsf{Real}^{\uparrow}$ *completeness principle.*

Proof. Start with an approximation request and project the accepted carrier. The stream window W and dyadic tolerance row D are the only rows that determine which finite precision test is in scope.

The regular-rational readback Q and terminal real seal R are downstream of those displayed rows. Thus a consumer cannot inspect a real-facing approximation before the finite StreamName and DyadicRatCore route has been displayed.

Finally apply the located-supremum row L and approximation ledger A. They bind the upper-bound and lower-approximation witnesses to the same finite window, while H, C, P, N preserve the route. Since the carrier omits quotient reals, selected maximizing sequences, trichotomy, countable choice, and ambient completeness, the approximation route cannot escape the displayed packet. □

Closure status for $\mathsf{NameCert}_{\mathsf{BishopLocatedSupremum}^{\uparrow}}$.

Constructive story: A $\mathsf{BishopLocatedSupremum}^{\uparrow}$ packet is generated from a finite Bishop family row, StreamName window, DyadicRatCore tolerance ledger, RegSeqRat readback, RealUp seal, LocatedSupremum row, approximation ledger, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{BishopLocatedSupremum}^{\uparrow}}$, seed)

Scope closed: Definition 8760.1, Definition 8760.2, and Definition 8760.3 bind the finite located-supremum witness packet over the Real and Completion route.

Formal verification: FormalStatus(NameCert$_{\mathsf{BishopLocatedSupremum}\uparrow}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim classical least-upper-bound completeness, quotient-real equality, trichotomy, countable choice, selected maximizing sequences, checked Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, stream-window routing, dyadic tolerance exposure, regular-rational readback, Real seal handoff, located-supremum approximation, and structural nonescape for BEDC.Derived.BishopLocatedSupremumUp.

Chapter 8761

A Concrete Naming Certificate for $\mathsf{RationalFinitePlaceProduct}^{\uparrow}$

Following the classical product formula for the rationals, this chapter opens the $\mathsf{RationalFinitePlaceProduct}^{\uparrow}$ NameCert entry over the existing $\mathsf{Rational}^{\uparrow}$ rational valuation interface for a BEDC-native finite-place product surface. The target is to connect the finite prime-power counts exposed by `PrimeFactorizationProd` to the existing zero-axiom rational valuation interface, including `ratVal`, `ratValIndex`, `ratVal_mul`, and the archimedean absolute-value surface `ratAbsInfty`. The intended terminal equality is the rational global product formula, with the finite prime-indexed factor and the archimedean factor assembled inside BEDC rather than imported from mathlib. The complete acceptance law family, anti-degeneracy constraints, and bridge authority are the contract at `papers/bedc_mathlib_bridge/gap_contrac` this chapter records only the main-pipeline entrance for that contract.

The finite support is read from the prime-factorization rows of chapter 64, while the local factors are routed toward the restricted-product consumers of chapter 101 and the valued-field surface of chapter 173. Thus the chapter sits in the concrete-instance dependency lattice as a rational product bridge: prime-power rows determine the finite index support, the rational valuation rows determine each local factor, and the downstream Adele/local-field consumers receive only those displayed finite rows rather than a mathlib place object.

Definition 8761.1 (Rational finite-place support target)**.** *For a nonzero rational name q, the intended finite-place support is the finite list of prime places whose* `ratVal` *index for q is nonzero, derived from the* `PrimeFactorizationProduct` *data of the numerator and denominator. It is not an arbitrary natural-index surface and it carries no mathlib place object.*

Definition 8761.2 (Rational finite-place product target)**.** *The intended finite-place product is a BEDC-native finite product over the support of Definition 8761.1. Each local factor is read from the existing rational valuation surface, while the infinite factor is read from* `ratAbsInfty`*; the terminal target is the cancellation statement*

$$\texttt{ratAbsInfty}(q) \cdot \prod_{p \in \mathrm{supp}(q)} |q|_p = 1.$$

The displayed equation is a target signature for the seed entrance only, not a claimed theorem of this chapter.

Closure status for $\mathsf{NameCert}_{\mathsf{RationalFinitePlaceProduct}^{\uparrow}}$ **·**
Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RationalFinitePlaceProduct}^{\uparrow}}, \mathsf{seed})$

Formal verification: FormalStatus(NameCert$_{\mathsf{RationalFinitePlaceProduct}^{\uparrow}}$, unformalized)

Bridge status: none

Constructive story: The finite place product is to be assembled constructively from PrimeFactorizationProduct support data, existing ratVal indices, ratVal multiplicativity, and ratAbsInfty.

Scope closed: This chapter only declares the rational finite-place product formula gap target and its acceptance entry; it does not construct the support, product, or terminal equality.

Not claimed: The final product formula and the mathlib correspondence are not claimed here; the correspondence belongs to the bridge side.

Upgrade path: Upgrade requires implementing the contract required structure and laws, then passing the bridge exported_core authority for bedc-rational-product-formula.

Chapter 8762

A Concrete Naming Certificate for $\mathsf{CauchySequenceRing}^{\uparrow}$

Following Bishop and Bridges' constructive analysis, the $\mathsf{CauchySequenceRing}^{\uparrow}$ packet records the finite ring-level arithmetic surface for regular rational Cauchy sequence names before any quotient-free $\mathsf{Real}^{\uparrow}$ seal is read. It sits after the regular-rational readback of chapter 301, the finite observation windows of chapter 126, and the dyadic tolerance ledger of chapter 291; it supplies the ring-facing arithmetic row consumed later by chapter 3902; and it remains bounded by the terminal real-name boundary of chapter 38. The packet names rowwise addition, negation, multiplication, zero, one, and operation stability for regular Cauchy sequence arithmetic; it does not import quotient Cauchy classes, host real arithmetic, selected limits, trichotomy, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 8762.1 (CauchySequenceRing carrier)**.** *A* $\mathsf{CauchySequenceRing}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (X, Y, W, D, A, M, Z, E, H, C, P, N)$$

with the following visible rows:

1. *X and Y are accepted* $\mathsf{RegSeqRat}^{\uparrow}$ *source rows for the two regular rational Cauchy sequence names being combined.*
2. *W is the* $\mathsf{StreamName}^{\uparrow}$ *schedule that synchronizes the finite windows inspected from X and Y for the requested operation budget.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *ledger containing the tolerance cells and rational arithmetic rows used by the operation.*
4. *A is the additive row, displaying zero, addition, and negation over the synchronized regular-Cauchy source windows.*
5. *M is the multiplicative row, displaying one and multiplication over the same synchronized source windows and dyadic budget.*
6. *Z records the ring constants and the finite compatibility rows that keep zero, one, additive inverse, addition, and multiplication on the same regular-Cauchy name surface.*
7. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *boundary row, recording that downstream real-name consumers may read the operation result only after the regular-Cauchy arithmetic rows have been displayed.*
8. *H stores componentwise* hsame *transports for X, Y, W, D, A, M, Z, E and the local naming rows.*

9. *C stores displayed* Cont *replay for the regular source rows, synchronized windows, dyadic budget, additive row, multiplicative row, constant row, and real boundary in that order.*
10. *P is the* Pkg *provenance over* $\mathsf{CauchySequenceRing}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{CauchySequenceRing}^{\uparrow}}$ *row.*

The carrier asserts only that these rows form one displayed ring-arithmetic packet for regular Cauchy sequence names. It has no field for quotient classes, selected sequence representatives, countable choice over moduli, trichotomy, host real arithmetic, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 8762.2 (CauchySequenceRing NameCert obligations)**.** *For every accepted* $\mathsf{CauchySequenceRing}^{\uparrow}$ *carrier $K = (X, Y, W, D, A, M, Z, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{CauchySequenceRing}^{\uparrow}}$ *surface consists exactly of carrier admission, regular-rational source exposure through X and Y, synchronized-window exposure through W, dyadic operation-budget exposure through D, additive operation exposure through A, multiplicative operation exposure through M, constant and compatibility exposure through Z, terminal real-boundary exposure through E, componentwise* hsame *transport through H, displayed* Cont *replay through C,* Pkg *provenance through P, and local naming through N. No obligation may replace these rows by quotient Cauchy classes, selected representatives, host real arithmetic, trichotomy, countable choice, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the carrier of Definition 8762.1. The rows $X, Y, W, D, A, M, Z, E, H, C, P, N$ are the only coordinates available to the local certificate.

The source and window obligations read X and Y only through the synchronized schedule W. The dyadic ledger D supplies the finite tolerance and rational arithmetic cells needed by the displayed operation rows.

The additive row A exposes zero, addition, and negation, while the multiplicative row M exposes one and multiplication. The compatibility row Z keeps all five ring operations on the same regular-Cauchy source surface before the terminal $\mathsf{Real}^{\uparrow}$ boundary E is available to a downstream consumer.

Rows H, C, P, N transport, replay, source, and name exactly that displayed packet. Since the carrier contains no quotient row, selected representative row, countable-choice row, trichotomy row, host-real row, or ambient-completeness row, the NameCert obligations cannot export any of those stronger objects. □

Theorem 8762.3 (CauchySequenceRing operation stability)**.** *Every operation read exported by an accepted* $\mathsf{CauchySequenceRing}^{\uparrow}$ *packet factors through the displayed route*

$$\mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{DyadicRatCore}^{\uparrow} \longmapsto \mathsf{CauchySequenceRing}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}.$$

In particular, addition, negation, multiplication, zero, and one remain stable under componentwise hsame *transport of $X, Y, W, D, A, M, Z, E, H, C, P, N$, and any* $\mathsf{CauchySequenceField}^{\uparrow}$ *or* $\mathsf{Real}^{\uparrow}$ *consumer sees the ring row only after the regular-rational sources, finite windows, dyadic budget, operation rows, compatibility row, transport, replay, provenance, and local name have been exposed.*

Proof. Start from an accepted carrier $K = (X, Y, W, D, A, M, Z, E, H, C, P, N)$. Carrier projection exposes the regular-rational sources, synchronized windows, dyadic budget, additive row, multiplicative row, constants, compatibility row, real boundary, transport, replay, provenance, and local name.

For an additive read, use A together with the shared schedule W and budget D. For a multiplicative read, use M with the same W and D. The constant and compatibility row Z records

that zero, one, additive inverse, addition, and multiplication are read on the same regular-Cauchy sequence surface.

Componentwise hsame transport in H moves each displayed row to the corresponding transported packet, and C replays the same route after transport. The downstream consumer therefore receives the same route composition through $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{CauchySequenceRing}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$.

The final boundary is E, so the route never identifies quotient Cauchy classes, chooses representatives, invokes countable choice, decides trichotomy, imports host real arithmetic, or claims ambient $\mathsf{Real}^{\uparrow}$ completeness. □

Closure status for $\mathsf{NameCert}_{\mathsf{CauchySequenceRing}^{\uparrow}}$.

Constructive story: A $\mathsf{CauchySequenceRing}^{\uparrow}$ packet is generated from two RegSeqRat source rows, synchronized StreamName windows, a DyadicRatCore operation ledger, additive and multiplicative operation rows, ring constants and compatibility evidence, a Real boundary row, componentwise hsame transport, displayed Cont replay, package provenance, and local NameCert evidence.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{CauchySequenceRing}^{\uparrow}}$, seed)

Scope closed: Definition 8762.1, Definition 8762.2, and Definition 8762.3 seed the regular Cauchy sequence ring surface between RegSeqRat, StreamName, DyadicRatCore, CauchySequenceField, and Real rows.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{CauchySequenceRing}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim Lean verification, quotient Cauchy classes, selected sequence representatives, host real arithmetic, countable choice, trichotomy, field inverses, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Upgrade path: Obligation closure requires checked carrier admission, source-window synchronization, dyadic-budget exactness, additive and multiplicative operation exposure, constant compatibility, real-boundary handoff, transport, replay, and ledger refusal for BEDC.Derived.CauchySequenceRingUp.

Chapter 8763

A Concrete Naming Certificate for $\mathsf{FiniteMetrizableCompletion}^{\uparrow}$

Following Bishop and Bridges and Kelley, the $\mathsf{FiniteMetrizableCompletion}^{\uparrow}$ packet records the finite metrizable-completion handoff used by the L10 Real and Completion corridor. It sits after the metric-completion row of chapter 1506, the located completion row of chapter 2114, the Cauchy completion embedding of chapter 1934, the finite StreamName windows of chapter 126, the RegSeqRat readback of chapter 301, and the terminal Real seal of chapter 38. The packet names completion as displayed finite carrier data, not as quotient completion equality, selected representatives, countable choice, trichotomy, compactness, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 8763.1 (FiniteMetrizableCompletion carrier)**.** *A* $\mathsf{FiniteMetrizableCompletion}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$F = (M, J, L, W, R, E, H, C, P, N)$$

with the following displayed rows:

1. *M is the* $\mathsf{MetricCompletion}^{\uparrow}$ *source row exposing the metric source, finite tolerance ledger, and completion-facing route.*
2. *J is the* $\mathsf{CauchyCompletionEmbedding}^{\uparrow}$ *row by which source observations enter the completion surface.*
3. *L is the* $\mathsf{LocatedMetricCompletion}^{\uparrow}$ *row that keeps located completion evidence visible before a Real-facing read is public.*
4. *W is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row opened by the displayed tolerance and source data.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row extracted from the same finite windows.*
6. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal reached only after M, J, L, W, R have been displayed.*
7. *H records componentwise* hsame *transport for the metric source, embedding, located-completion, window, readback, Real seal, replay, provenance, and local naming rows.*
8. *C records the displayed* Cont *replay from the metric source through the Cauchy embedding, located completion row, finite windows, regular readback, and terminal Real seal.*
9. *P is the* Pkg *provenance over* $\mathsf{FiniteMetrizableCompletion}^{\uparrow}$, $\mathsf{MetricCompletion}^{\uparrow}$, $\mathsf{CauchyCompletionEmbedding}^{\uparrow}$, $\mathsf{LocatedMetricCompletion}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{FiniteMetrizableCompletion}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these rows. It has no coordinate for quotient completion equality, selected host limits, countable choice, trichotomy, compactness, host interval equality, or ambient completeness of $\mathsf{Real}^{\uparrow}$.

Theorem 8763.2 (FiniteMetrizableCompletion NameCert obligations)**.** *For an accepted* FiniteMetrizableCompletio *carrier* $F = (M, J, L, W, R, E, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{FiniteMetrizableCompletion}^{\uparrow}}$ *surface consists exactly of carrier admission, metric-completion source exposure through* M*, Cauchy-completion embedding through* J*, located-completion evidence through* L*, finite StreamName windows through* W*, RegSeqRat readback through* R*, terminal Real sealing through* E*, componentwise* hsame *transport through* H*, displayed* Cont *replay through* C*, provenance through* P*, and local naming through* N*.*

Proof. Project the accepted carrier of Definition 8763.1. Its only completion-facing rows are the metric source, Cauchy embedding, located completion, finite window, regular readback, Real seal, transport, replay, provenance, and local naming rows.

The metric source row M supplies the completion-facing tolerance and source route. The embedding row J records how source observations enter the Cauchy completion surface, and the located row L keeps located completion evidence visible before the packet is read as Real-facing.

The finite numerical read proceeds through W and R. The StreamName row opens only the displayed finite windows, and the RegSeqRat row supplies the corresponding regular rational readback before the terminal Real seal E is consumed.

Finally H, C, P, N transport, replay, package, and name the same displayed route. Since no further carrier coordinate is present, quotient completion equality, selected limits, countable choice, trichotomy, compactness, host equality, and ambient $\mathsf{Real}^{\uparrow}$ completeness are not exported. □

Theorem 8763.3 (FiniteMetrizableCompletion Real handoff)**.** *Every* $\mathsf{Real}^{\uparrow}$ *or completion-facing consumer of an accepted* $\mathsf{FiniteMetrizableCompletion}^{\uparrow}$ *packet must read the finite route*

$$\mathsf{MetricCompletion}^{\uparrow} \longmapsto \mathsf{CauchyCompletionEmbedding}^{\uparrow} \longmapsto \mathsf{LocatedMetricCompletion}^{\uparrow} \longmapsto \mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{RegSe}$$

with BHist, hsame, Cont, Pkg, *and* NameCert *support still visible. The handoff exports no quotient completion, selected endpoint or limit representative, countable-choice schedule, trichotomy, compactness theorem, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start with the obligation surface of Definition 8763.2. It places every accepted consumer read on the rows $M, J, L, W, R, E, H, C, P, N$.

The completion-facing prefix is M, J, L. The metric-completion source is read first, the Cauchy-completion embedding then admits the displayed source observations, and the located-completion row keeps located evidence attached to the same finite packet.

The Real-facing suffix is W, R, E. Finite StreamName windows are opened before RegSeqRat readback, and the terminal $\mathsf{Real}^{\uparrow}$ seal is available only after that regular readback has been displayed.

The structural rows H, C, P, N preserve the same route. Because the carrier has no coordinate for quotient completion equality, selected representatives, choice schedules, trichotomy, compactness, or ambient completeness, the Real and Completion corridor receives exactly the finite handoff stated above. □

Independence witness: metriccompletion, cauchycompletionembedding, locatedmetriccompletion, streamname, regseqrat, real: $\mathsf{FiniteMetrizableCompletion}^{\uparrow}$ is not bijective with any listed sibling because it joins metric source exposure, Cauchy embedding, located completion evidence,

finite windows, regular rational readback, Real sealing, componentwise hsame transport, Cont replay, Pkg provenance, and one local NameCert row.

Closure status for $\mathsf{NameCert}_{\mathsf{FiniteMetrizableCompletion}^{\uparrow}}$.

Constructive story: A $\mathsf{FiniteMetrizableCompletion}^{\uparrow}$ packet is generated from a metric-completion source row, Cauchy-completion embedding, located-completion evidence, StreamName finite windows, RegSeqRat readback, RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{FiniteMetrizableCompletion}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8763.1, Definition 8763.2, and Definition 8763.3 display the finite metrizable-completion handoff over MetricCompletion, CauchyCompletionEmbedding, LocatedMetricCompletion, StreamName, RegSeqRat, and Real rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{FiniteMetrizableCompletion}^{\uparrow}}, \mathsf{formalTarget})$

Bridge status: none

Not claimed: This chapter does not close quotient completion equality, selected host limits, countable choice, trichotomy, compactness, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Scoped closure requires kernel-scope routing for $\mathsf{MetricCompletion}^{\uparrow}$, $\mathsf{CauchyCompletionEmbedding}^{\uparrow}$, $\mathsf{LocatedMetricCompletion}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, hsame, Cont, Pkg, and NameCert over the same packet.

Chapter 8764

A Concrete Naming Certificate for $\mathsf{CauchySpaceCompletion}^{\uparrow}$

Following Bishop and Bridges on constructive completions, and Kelley on uniform and completion spaces, the $\mathsf{CauchySpaceCompletion}^{\uparrow}$ packet names a non-quotient completion carrier for a displayed Cauchy space. It reconstructs the traditional completion interface as finite BEDC rows: effective Cauchy data, filter-Cauchy data, located uniform control, metric-completion handoff, and Bishop-style metric completion readback. The chapter consumes chapter 4099, chapter 6129, chapter 3814, chapter 4023, and chapter 1506; it does not claim quotient completion, selected limit representatives, countable choice, or ambient real completeness.

Definition 8764.1 (CauchySpaceCompletion carrier)**.** *A* $\mathsf{CauchySpaceCompletion}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$C = (E, F, U, B, M, W, R, L, H, T, P, N)$$

with the following displayed rows.

1. *E is the source* $\mathsf{EffectiveCauchySpace}^{\uparrow}$ *row, exposing only the effective Cauchy approximation schedule accepted by the packet.*
2. *F is the* $\mathsf{CauchyFilterSpace}^{\uparrow}$ *row, recording the filter-Cauchy face read by completion consumers.*
3. *U is the* $\mathsf{LocatedUniformSpace}^{\uparrow}$ *row, recording the located uniform entourage tests used to compare Cauchy names.*
4. *B is the* $\mathsf{BishopMetricCompletion}^{\uparrow}$ *row, exposing the Bishop-style completion handoff without quotient representatives.*
5. *M is the* $\mathsf{MetricCompletion}^{\uparrow}$ *row, recording the metric-completion request as a displayed boundary row.*
6. *W is the finite window row aligning effective Cauchy approximations, filter tests, located uniform tests, and metric-completion requests.*
7. *R is the readback row for the completion name, available only after E, F, U, B, M, W remain visible.*
8. *L is the exactness ledger: two accepted completion names are compared only through displayed Cauchy agreement, located uniform tests, and metric-completion boundary rows.*
9. *H records componentwise* hsame *transport for $E, F, U, B, M, W, R, L, T, P, N$.*

10. *T records displayed* Cont *replay from a completion request through the effective, filter, uniform, Bishop-metric, metric-completion, readback, and exactness rows.*
11. *P is the* Pkg *provenance over* $\mathsf{CauchySpaceCompletion}^{\uparrow}$, $\mathsf{EffectiveCauchySpace}^{\uparrow}$, $\mathsf{CauchyFilterSpace}^{\uparrow}$, $\mathsf{LocatedUniformSpace}^{\uparrow}$, $\mathsf{BishopMetricCompletion}^{\uparrow}$, $\mathsf{MetricCompletion}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
12. *N is the local* $\mathsf{NameCert}_{\mathsf{CauchySpaceCompletion}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through $E, F, U, B, M, W, R, L, H, T, P, N$. It has no coordinate for quotient classes, selected representatives, countable-choice subsequences, ambient complete space data, or an external real-completeness principle.

Theorem 8764.2 (CauchySpaceCompletion NameCert obligations)**.** *For every accepted* $\mathsf{CauchySpaceCompletion}^{\uparrow}$ *carrier $C = (E, F, U, B, M, W, R, L, H, T, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{CauchySpaceCompletion}^{\uparrow}}$ *surface consists exactly of carrier admission for the effective Cauchy row, Cauchy-filter row, located-uniform row, Bishop metric-completion handoff, metric-completion boundary, finite window alignment, completion-name readback, exactness ledger, componentwise transport, continuation replay, provenance, and local naming. Every accepted completion read factors through*

$$E, F, U \longmapsto B, M, W \longmapsto R, L, H, T, P, N$$

and refuses quotient completion equality, selected limit representatives, countable choice, host completion objects, and ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the carrier of Definition 8764.1. The rows E, F, U are the only source Cauchy rows: E supplies the effective schedule, F supplies the filter-Cauchy face, and U supplies located uniform comparison tests.

The completion handoff is downstream of those rows. The Bishop-metric row B and metric-completion boundary row M are read only after the finite alignment window W displays the same Cauchy request on all three source faces.

The readback and exactness rows do not add quotient data. The row R exposes the completion name, and L compares completion names only through displayed Cauchy agreement, located uniform tests, and the metric-completion boundary. The structural rows H, T, P, N transport, replay, source, and name that same route.

Since the carrier has no coordinate for quotient classes, selected representatives, countable-choice subsequences, host completion objects, or ambient real completeness, the local NameCert surface is exactly the displayed non-quotient completion packet. □

Theorem 8764.3 (Cauchy completion standard-bridge boundary)**.** *Any later standard bridge from* $\mathsf{CauchySpaceCompletion}^{\uparrow}$ *to a classical completion schema must consume only the displayed rows $E, F, U, B, M, W, R, L, H, T, P, N$. In particular, the bridge may cite the effective Cauchy schedule, the filter-Cauchy face, the located uniform tests, the Bishop metric-completion handoff, and the metric-completion boundary, but it cannot introduce quotient representatives, a selected limit map, countable choice, or an ambient completed host space.*

Proof. The bridge source is the accepted carrier itself. By Definition 8764.2, every completion read first passes through E, F, U and then through B, M, W before the readback and exactness rows are exposed.

A standard bridge can therefore repackage only those displayed rows. The exactness ledger L is the sole comparison interface, while H, T, P, N preserve the packet route and provenance.

No row stores quotient representatives, selected limits, countable-choice schedules, host completion data, or ambient completeness. Thus any bridge using this packet has the stated boundary. □

Theorem 8764.4 (CauchySpaceCompletion exactness ledger)**.** *Two accepted* $\mathsf{CauchySpaceCompletion}^{\uparrow}$ *carriers classify together only through displayed effective Cauchy agreement, Cauchy-filter agreement, located-uniform tests,* $\mathsf{BishopMetricCompletion}^{\uparrow}$ *and* $\mathsf{MetricCompletion}^{\uparrow}$ *boundary rows, finite alignment window, completion readback, exactness ledger* L*, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming.*

Proof. Project the carrier of Definition 8764.1. The comparison interface is the displayed row family $E, F, U, B, M, W, R, L, H, T, P, N$, with L named as the exactness ledger.

The source comparison first reads effective Cauchy agreement through E, Cauchy-filter agreement through F, and located-uniform tests through U. The completion-facing comparison then passes through the Bishop metric-completion row B, the metric-completion boundary row M, the finite alignment window W, and the completion readback row R.

The ledger L has no coordinates for quotient representatives, selected limits, countable choice, host completion objects, or ambient $\mathsf{Real}^{\uparrow}$ completeness. The structural rows H, T, P, N only transport, replay, source, and name the displayed comparison route, so two accepted carriers classify together exactly through this ledger. □

Falsifiable prediction: A future $\mathsf{CauchySpaceCompletion}^{\uparrow}$ packet fails this NameCert surface if a completion read is accepted without the effective Cauchy row, Cauchy-filter row, located uniform row, Bishop metric-completion handoff, metric-completion boundary, finite alignment window, readback row, and exactness ledger all remaining displayed before the local NameCert row.

Independence witness: The packet is independent of quotient-completion principles: $\mathsf{CauchySpaceCompletion}^{\uparrow}$ binds effective Cauchy schedules, Cauchy filters, located uniform tests, Bishop metric-completion handoff, metric-completion boundary, readback, exactness, transport, replay, provenance, and local naming, but has no row for selected representatives, quotient equality, countable choice, host completion, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Closure status for $\mathsf{NameCert}_{\mathsf{CauchySpaceCompletion}^{\uparrow}}$**.**

Constructive story: A $\mathsf{CauchySpaceCompletion}^{\uparrow}$ packet is generated from an EffectiveCauchySpace row, CauchyFilterSpace row, LocatedUniformSpace row, BishopMetricCompletion row, MetricCompletion boundary row, finite alignment window, completion-name readback, exactness ledger, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CauchySpaceCompletion}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8764.1, Definition 8764.2, Definition 8764.3, and Definition 8764.4 seed the non-quotient Cauchy-space completion carrier and its standard-bridge boundary.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CauchySpaceCompletion}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient completion equality, selected limit representatives, countable choice, host completion objects, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, classifier exactness, effective-Cauchy routing, filter-Cauchy routing, located-uniform routing, completion readback, exactness nonescape, transport, replay, provenance, and local naming for BEDC.Derived.CauchySpaceCompletionUp.

Chapter 8765

A Concrete Naming Certificate for $\mathsf{FinitePrimeWindowGluing}^{\uparrow}$

The $\mathsf{FinitePrimeWindowGluing}^{\uparrow}$ packet realizes the finite-window side of chapter 9244 as concrete NameCert data. It reads the finite prime-window carrier of Definition 9244.1, the local defect rows of Definition 9244.6, the total-defect row of Definition 9244.7, and the completed gluing surface of Definition 9244.10. The packet consumes the prime-row source of chapter 64 and the zeta boundary surface of chapter 71 before its finite gluing ledger may be read. The packet is local to finite prime windows: it does not claim RH, global zeta recovery, nontrivial zero exclusion, Euler-product completeness, or analytic continuation beyond the displayed boundary.

Definition 8765.1 (FinitePrimeWindowGluing carrier)**.** *A* $\mathsf{FinitePrimeWindowGluing}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$G = (P, A, D, L, Z, T, R, V, H, C, Q, N)$$

with the following displayed rows.

1. *P is the finite prime-row ledger, listing the displayed window $S \subseteq \mathsf{Prime}^{\uparrow}$ and the prime-local amplitude rows available in that window.*
2. *A is the unit-window amplitude row, recording which displayed prime rows satisfy the local unit-amplitude test.*
3. *D is the local defect-row ledger, recording $D_p(s)$ for every displayed prime row in the finite window.*
4. *L is the gluing ledger, aligning the finite prime rows, defect rows, archimedean boundary request, functional-equation request, pole ledger, zero-ledger request, and branch-transport request.*
5. *Z is the zero-boundary row. It records only the local request for a later zero-ledger exclusion and does not decide any nontrivial zero.*
6. *T is the transport row from finite prime-window data into the completed carrier interface.*
7. *R is the replay row for the local proof route through finite rows, defect accumulation, completed-surface boundary, and zero-boundary request.*
8. *V is the provenance row tying the packet to the finite prime-window, local-defect, and carrier-gluing vision sites.*
9. *H records componentwise* hsame *transport for $P, A, D, L, Z, T, R, V, C, Q, N$.*

10. *C records displayed* Cont *replay for the local gluing request.*

11. *Q is the local replay provenance for the finite carrier data.*

12. *N is the local* $\mathsf{NameCert}_{\mathsf{FinitePrimeWindowGluing}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these finite rows. It requires later nontriviality and field-faithfulness input as separate TasteGate *instances before any global zeta or RH-facing consumer may treat the local carrier as an analytic proof object.*

Theorem 8765.2 (FinitePrimeWindowGluing NameCert obligations)**.** *For every accepted* FinitePrimeWindowGluin *carrier $G = (P, A, D, L, Z, T, R, V, H, C, Q, N)$, the local* $\mathsf{NameCert}_{\mathsf{FinitePrimeWindowGluing}^{\uparrow}}$ *surface consists exactly of finite prime-row admission, unit-window amplitude rows, local defect rows, gluing-ledger alignment, zero-boundary request, transport into the completed-carrier interface, replay, provenance, componentwise transport, continuation replay, local replay provenance, and local naming.*

Every accepted read factors through

$$P, A, D \longmapsto L, Z, T \longmapsto R, V, H, C, Q, N$$

and refuses global RH*, recovered zeta completeness, nontrivial zero exclusion, field faithfulness, Euler-product completion, analytic continuation, and archimedean normalization as closed conclusions.*

Proof. Project the accepted carrier. The finite prime-window side is exactly P, A, D: a displayed finite prime set, its unit-amplitude rows, and its local defect rows.

The gluing side starts only after those rows are visible. The row L aligns the finite rows with the archimedean, functional-equation, pole, zero-ledger, and branch-transport requests of the completed surface, while Z records the zero-boundary request without deciding it.

The transport and replay rows T, R, V, H, C, Q, N preserve the local route and provenance. None of these rows contains a nontrivial zero exclusion theorem, a recovered zeta carrier, an analytic continuation proof, a field-faithfulness witness, or a nontriviality gate.

Thus the NameCert surface is the finite gluing packet itself. Any RH-facing use must add the later nontrivial and field-faithful TasteGate instances outside this local carrier. □

Theorem 8765.3 (Finite prime-window gluing boundary)**.** *A* $\mathsf{FinitePrimeWindowGluing}^{\uparrow}$ *packet may be consumed by an RH route only as local carrier data: finite prime rows, defect rows, gluing ledger, zero-boundary request, transport, replay, provenance, and local NameCert naming. It does not supply the later* Nontrivial *and* FieldFaithful TasteGate *instances required for global zeta recovery, and it does not close* RH *or any nontrivial zero-exclusion theorem.*

Proof. The consumer first reads the finite rows P, A, D and the gluing ledger L. These rows are local to a displayed finite prime window and cannot by themselves expose the completed zeta carrier.

The zero-boundary row Z is only a request boundary. The transport and replay rows carry the request toward the completed surface, but they do not add the missing nontriviality and field-faithfulness gates.

Since the carrier has no row for global zeta recovery, nontrivial zero exclusion, Euler-product completeness, analytic continuation, or closed RH evidence, every accepted read remains a finite NameCert packet. □

Falsifiable prediction: A future finite prime-window packet fails this NameCert surface if it accepts a gluing read without a displayed finite prime-row ledger, unit-window amplitude rows, local defect rows, gluing ledger, zero-boundary request, transport, replay, provenance, and local NameCert row, or if it treats those rows as a closed proof of RH.

Independence witness: RH, prime-window, zeta-recovery: $\mathsf{FinitePrimeWindowGluing}^{\uparrow}$ is not bijective to any listed sibling because it binds finite prime rows, defect rows, local gluing, zero-boundary request, transport, replay, provenance, and local naming while explicitly leaving nontriviality, field faithfulness, recovered zeta completeness, analytic continuation, and global zero exclusion outside the packet.

Closure status for $\mathsf{NameCert}_{\mathsf{FinitePrimeWindowGluing}^{\uparrow}}$.

Constructive story: A $\mathsf{FinitePrimeWindowGluing}^{\uparrow}$ packet is generated from finite prime rows, unit-window amplitude rows, local defect rows, a gluing ledger, zero-boundary request, transport into the completed-carrier interface, replay, provenance, componentwise hsame transport, displayed Cont replay, local replay provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{FinitePrimeWindowGluing}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8765.1, Definition 8765.2, and Definition 8765.3 seed the finite local gluing packet for prime-window RH routes.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{FinitePrimeWindowGluing}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close RH, recovered zeta completeness, nontrivial zero exclusion, Euler-product completion, analytic continuation, archimedean normalization, nontrivial TasteGate evidence, field-faithful TasteGate evidence, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, finite prime-row exactness, defect-row exactness, gluing-ledger alignment, zero-boundary nonescape, transport, replay, provenance, and local naming for BEDC.Derived.FinitePrimeWindowGluin global routes require later Nontrivial and FieldFaithful TasteGate instances.

Chapter 8766

A Concrete Naming Certificate for $\mathsf{FiniteMeshRefinementTree}^{\uparrow}$

Following Bishop–Bridges finite-net practice on compact intervals, the $\mathsf{FiniteMeshRefinementTree}^{\uparrow}$ packet names the finite refinement tree through which an interval mesh is repeatedly subdivided before a completion-facing consumer reads a finite window. It sits between the dyadic interval cells of chapter 5966, the finite mesh surface of chapter 7835, the finite observation discipline of chapter 126, the regular rational readback of chapter 301, and the terminal real-name seal of chapter 38. The packet records finite refinement data only; it is not an open-cover compactness theorem, a selected infinite branch, a quotient real equality principle, a countable-choice operation, or an ambient completeness coordinate for $\mathsf{Real}^{\uparrow}$.

Definition 8766.1 (Finite mesh refinement tree carrier)**.** *A* $\mathsf{FiniteMeshRefinementTree}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$T = (N, M, R, W, Q, E, H, C, P, L)$$

with the following displayed rows:

1. *N is the* $\mathsf{DyadicIntervalNet}^{\uparrow}$ *source row, listing the dyadic interval cells inspected by the refinement request.*
2. *M is the* $\mathsf{FiniteDyadicMesh}^{\uparrow}$ *mesh row, recording the finite dyadic mesh at the root scale.*
3. *R is the refinement-tree row, a finite parent-child ledger whose children are dyadic subintervals of the displayed parent cell.*
4. *W is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row opened by the displayed mesh and refinement requests.*
5. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row obtained from the finite windows and dyadic mesh ledger.*
6. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row, available only after N, M, R, W, Q have already been displayed.*
7. *H records componentwise* hsame *transport for the net, mesh, refinement tree, window, readback, seal, replay, provenance, and local name rows.*
8. *C records displayed* Cont *replay from a finite refinement request through N, M, R, W, Q, E.*
9. *P is the* Pkg *provenance over* $\mathsf{FiniteMeshRefinementTree}^{\uparrow}$, $\mathsf{DyadicIntervalNet}^{\uparrow}$, $\mathsf{FiniteDyadicMesh}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *L is the local* $\mathsf{NameCert}_{\mathsf{FiniteMeshRefinementTree}^{\uparrow}}$ *row.*

The carrier has no coordinate for open-cover compactness, a selected infinite branch, quotient real equality, countable choice, ambient $\mathsf{Real}^{\uparrow}$ *completeness, Lean verification, or bridge checking.*

Theorem 8766.2 (Finite refinement tree Real-window boundary)**.** *Every accepted* $\mathsf{FiniteMeshRefinementTree}^{\uparrow}$ *packet exports completion-facing data only through the finite route*

$$\mathsf{DyadicIntervalNet}^{\uparrow} \longrightarrow \mathsf{FiniteDyadicMesh}^{\uparrow} \longrightarrow \mathsf{StreamName}^{\uparrow} \longrightarrow \mathsf{RegSeqRat}^{\uparrow} \longrightarrow \mathsf{Real}^{\uparrow}.$$

In particular, the refinement tree supplies a finite parent-child mesh ledger before any regular-Cauchy or real-name consumer can inspect a terminal seal.

Proof. Project the carrier of Definition 8766.1. The only interval cells available to a consumer are the displayed $\mathsf{DyadicIntervalNet}^{\uparrow}$ cells and the finite mesh row M.

The refinement row R is finite, so every child request is replayed through the same displayed parent-child ledger. The consumer then opens only the $\mathsf{StreamName}^{\uparrow}$ windows and $\mathsf{RegSeqRat}^{\uparrow}$ readback rows attached to that ledger.

The terminal seal E is downstream of these finite rows. Since the carrier contains no coordinate for the excluded principles, the $\mathsf{Real}^{\uparrow}$ read is a finite-window handoff rather than an appeal to open-cover compactness, selected branches, quotient equality, countable choice, or ambient real completeness. □

Theorem 8766.3 (Finite mesh refinement tree NameCert obligations)**.** *For every accepted* FiniteMeshRefinementTr *packet, the local* $\mathsf{NameCert}_{\mathsf{FiniteMeshRefinementTree}^{\uparrow}}$ *surface consists exactly of carrier admission,* $\mathsf{DyadicIntervalNet}^{\uparrow}$ *exposure,* $\mathsf{FiniteDyadicMesh}^{\uparrow}$ *root mesh exposure, finite parent-child refinement ledger,* $\mathsf{StreamName}^{\uparrow}$ *window readback,* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff,* $\mathsf{Real}^{\uparrow}$ *seal nonescape, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming.*

Proof. Project the carrier of Definition 8766.1. The rows N, M, R display the interval-net source, root mesh, and finite parent-child refinement ledger before any window request is available.

The window and readback rows W, Q are downstream of that finite tree. The structural rows H, C, P, L transport, replay, source, and name the same packet, so no additional NameCert obligation can enter from outside the displayed carrier.

Finally apply Definition 8766.2. It keeps the downstream seal route on the finite $\mathsf{DyadicIntervalNet}^{\uparrow}$, $\mathsf{FiniteDyadicMesh}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ path, excluding open-cover compactness, selected branches, quotient equality, countable choice, and ambient real completeness. □

Closure status for $\mathsf{NameCert}_{\mathsf{FiniteMeshRefinementTree}^{\uparrow}}$**.**

Constructive story: A $\mathsf{FiniteMeshRefinementTree}^{\uparrow}$ packet is generated from a DyadicIntervalNet source row, a FiniteDyadicMesh root mesh, a finite refinement-tree ledger, StreamName finite windows, RegSeqRat readback, a RealUp terminal seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{FiniteMeshRefinementTree}^{\uparrow}}$, seed)

Scope closed: Definition 8766.1, Definition 8766.2, and Definition 8766.3 seed the finite mesh-refinement route from dyadic interval nets to regular-Cauchy and RealUp finite-window consumers.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{FiniteMeshRefinementTree}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close open-cover compactness, selected infinite branches, quotient real equality, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, refinement-tree boundary, finite-window handoff, transport, replay, provenance, and local naming for BEDC.Derived.FiniteMeshRefinementTreeUp.

Chapter 8767

A Concrete Naming Certificate for $\mathsf{RegularCauchyWindowPullback}^{\uparrow}$

Following Bishop–Bridges regular Cauchy completion, the $\mathsf{RegularCauchyWindowPullback}^{\uparrow}$ packet names the finite pullback of a requested real precision to the stream windows and regular-rational rows that witness it. It refines the diagonal-limit route of section 9238.1 by sitting beside the finite observation discipline of chapter 126, the regular rational readback packet of chapter 301, the dyadic tolerance ledger of chapter 291, and the terminal real-name seal of chapter 38. The packet records a finite pullback surface for regular-Cauchy windows; it is not a selected limit, quotient stream equality, countable choice, host real equality, or ambient completeness of $\mathsf{Real}^{\uparrow}$.

Definition 8767.1 (Regular Cauchy window pullback carrier)**.** *A* $\mathsf{RegularCauchyWindowPullback}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$W = (P, S, R, D, E, H, C, Q, L)$$

with the following displayed rows:

1. *P is the precision request row, naming the requested real-window budget and its finite regular-Cauchy tail index.*
2. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row opened at exactly the indices demanded by P.*
3. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row obtained from the displayed stream windows.*
4. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, recording the finite dyadic comparisons used to transport the requested precision through S and R.*
5. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row, available only after P, S, R, D have been displayed.*
6. *H records componentwise* hsame *transport for the precision, window, readback, tolerance, seal, replay, provenance, and local name rows.*
7. *C records displayed* Cont *replay from a precision request through P, S, R, D, E.*
8. *Q is the* Pkg *provenance over* $\mathsf{RegularCauchyWindowPullback}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
9. *L is the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyWindowPullback}^{\uparrow}}$ *row.*

The carrier has no coordinate for selected limits, quotient stream equality, countable choice, host real equality, ambient $\mathsf{Real}^{\uparrow}$ *completeness, Lean verification, or bridge checking.*

Theorem 8767.2 (Regular Cauchy window pullback handoff)**.** *Every accepted* $\mathsf{RegularCauchyWindowPullback}^{\uparrow}$ *packet factors a Real-completion precision request through the displayed finite route*

$$\mathsf{StreamName}^{\uparrow} \longrightarrow \mathsf{RegSeqRat}^{\uparrow} \longrightarrow \mathsf{DyadicRatCore}^{\uparrow} \longrightarrow \mathsf{Real}^{\uparrow}.$$

The route exposes the finite stream windows and dyadic tolerance ledger before a terminal $\mathsf{Real}^{\uparrow}$ *seal can be read.*

Proof. Project the carrier of Definition 8767.1. The precision row P fixes the finite tail window to inspect, and the only observations opened by the packet are the coordinates listed in S.

The readback row R interprets those observations as regular rational data, while the dyadic ledger D records the tolerance comparisons needed by the same finite request. These rows are displayed before the seal row is available.

The terminal row E therefore records only the RealUp boundary attached to the finite pullback. Since the carrier contains no coordinate for selected limits, quotient stream equality, countable choice, host real equality, or ambient completeness, every completion-facing read stays on the displayed route. □

Theorem 8767.3 (Regular Cauchy window pullback NameCert obligations)**.** *For every accepted* $\mathsf{RegularCauchyWindowPullback}^{\uparrow}$ *packet, the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyWindowPullback}^{\uparrow}}$ *surface consists exactly of the precision request row,* $\mathsf{StreamName}^{\uparrow}$ *finite-window row,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger,* $\mathsf{Real}^{\uparrow}$ *terminal seal, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming.*

Proof. Project the carrier of Definition 8767.1. The row P fixes the requested precision and the row S lists the only stream windows opened by that request.

The rows R, D, E keep the readback, dyadic tolerance ledger, and terminal seal on the same displayed finite route. The structural rows H, C, Q, L then transport, replay, source, and name that route without adding selected limits or quotient stream equality.

Apply Definition 8767.2. It identifies the finite completion-facing route through $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$, so the NameCert surface is exactly the packet displayed by the carrier. □

Closure status for $\mathsf{NameCert}_{\mathsf{RegularCauchyWindowPullback}^{\uparrow}}$.

Constructive story: A $\mathsf{RegularCauchyWindowPullback}^{\uparrow}$ packet is generated from a precision request row, StreamName finite windows, RegSeqRat readback, a DyadicRatCore tolerance ledger, a RealUp terminal seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RegularCauchyWindowPullback}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8767.1, Definition 8767.2, and Definition 8767.3 seed the finite-window pullback route for regular-Cauchy and RealUp completion consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RegularCauchyWindowPullback}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close selected limits, quotient stream equality, countable choice, host real equality, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, finite-window pullback handoff, tolerance transport, replay, provenance, and local naming for BEDC.Derived.RegularCauchyWindowPullbackUp.

Chapter 8768

A Concrete Naming Certificate for CompactlyGeneratedWeakHausdorff$^{\uparrow}$

Following Kelley and Steenrod, the CompactlyGeneratedWeakHausdorff$^{\uparrow}$ packet records the compactly generated weak Hausdorff interface as finite BEDC NameCert data. It sits after the topology carrier of chapter 88, the core-compact neighbourhood route of chapter 6350, the compact-open topology ledger of chapter 4138, and the Kelleyfication boundary of chapter 6830. The packet names compact-window tests, weak-Hausdorff diagonal separation, transport, replay, provenance, and local naming rows only; it does not import a host category of compactly generated spaces, quotient-open equality, choice-selected compact tests, or ambient separation theorems.

Definition 8768.1 (Compactly generated weak Hausdorff carrier)**.** *A* CompactlyGeneratedWeakHausdorff$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$G = (T, K, O, D, W, H, C, P, N)$$

with the following displayed rows:

1. *T is the* Topology$^{\uparrow}$ *source row whose indexed opens and incidence data are already admitted as finite BEDC carrier rows.*
2. *K is the compact-generation test row, recording the displayed compact probes through which openness may be inspected.*
3. *O is the* CompactOpenTopology$^{\uparrow}$ *compact-open window ledger, listing the compact-domain windows and open-target tests available to function-space consumers.*
4. *D is the weak-Hausdorff diagonal-separation row. It records the displayed compact-source tests by which a diagonal read is separated, without exporting a host equality theorem for points.*
5. *W is the finite inspection window row for compact probes, diagonal tests, and compact-open subbasic reads.*
6. *H records componentwise* hsame *transport for the topology source, compact-generation tests, compact-open windows, diagonal-separation data, inspection windows, replay, provenance, and local naming rows.*
7. *C records displayed* Cont *replay of the same compact-window and diagonal-separation route.*
8. *P is the* Pkg *provenance over* CompactlyGeneratedWeakHausdorff$^{\uparrow}$*,* Topology$^{\uparrow}$*,* CoreCompact$^{\uparrow}$*,* CompactOpenTopology$^{\uparrow}$*,* Kelleyfication$^{\uparrow}$*,* BHist*,* hsame*,* Cont*, and* NameCert*.*

9. N is the local $\mathsf{NameCert}_{\mathsf{CompactlyGeneratedWeakHausdorff}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through these nine rows. It has no coordinate for a host category of spaces, quotient-open equality, a selected family of compact probes, classical point separation, countable choice, or an ambient compactly generated topology theorem.

Theorem 8768.2 (Compactly generated weak Hausdorff NameCert obligations)**.** *For every accepted* $\mathsf{CompactlyGeneratedWeakHausdorff}^{\uparrow}$ *carrier* $G = (T, K, O, D, W, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{CompactlyGener}}$ *surface consists exactly of topology-source exposure through* T*, compact-generation tests through* K*, compact-open window exposure through* O*, weak-Hausdorff diagonal-separation exposure through* D*, finite inspection through* W*, componentwise transport through* H*, displayed replay through* C*, provenance through* P*, and local naming through* N*.*

Proof. Project the carrier of Definition 8768.1. The analytic rows are exactly T, K, O, D, W, and the structural rows are exactly H, C, P, N.

The compact-generation side is therefore read from K and O. The first row records compact probes over the source topology, while the second records the compact-open window ledger used by function-space consumers.

The separation side is read from D. It is a diagonal-separation row attached to the same compact-source tests, so it cannot provide host equality of points or an ambient Hausdorff theorem outside the carrier.

Finally, transport, replay, provenance, and naming are supplied by H, C, P, N for those same rows. Since the packet has no further coordinate, the listed rows exhaust the local NameCert obligations. □

Theorem 8768.3 (Compactly generated weak Hausdorff diagonal separation)**.** *Let* $G = (T, K, O, D, W, H, C, P, N)$ *be an accepted* $\mathsf{CompactlyGeneratedWeakHausdorff}^{\uparrow}$ *carrier. Every weak-Hausdorff read of* G *must expose the topology source* T*, the compact-generation tests* K*, the diagonal-separation row* D*, and the finite inspection row* W *before any topology or function-space consumer may consume the separation result. The read exports no host diagonal closedness theorem, quotient point equality, selected compact family, countable choice, or ambient separation principle.*

Proof. Start with the carrier projection. The only topology-facing source is T, and the only compact-test source is K.

The diagonal-separation datum is then forced through D. Because D is a row of the same packet, it is read with the finite inspection window W rather than by consulting an external diagonal predicate.

The remaining rows bind the read to the accepted packet. Componentwise transport and displayed replay preserve the route through H and C, while provenance and local naming record the same dependency through P and N.

Thus the consumer receives a compact-window diagonal-separation surface and not a host closed-diagonal theorem, quotient equality, choice-selected compact family, or ambient separation principle. □

Theorem 8768.4 (Compactly generated weak Hausdorff compact-window scope)**.** *For every accepted* $\mathsf{CompactlyGeneratedWeakHausdorff}^{\uparrow}$ *carrier* $G = (T, K, O, D, W, H, C, P, N)$*, every compact-open or Kelleyfication-facing consumer is scoped by the ordered route*

$$T \longmapsto K \longmapsto O \longmapsto D \longmapsto W \longmapsto H \longmapsto C \longmapsto P \longmapsto N.$$

The route supplies compact-generation tests, compact-open windows, and weak-Hausdorff diagonal separation as displayed rows of one finite carrier, and it supplies no host compactly generated space, detached mapping-space topology, quotient-open equality, selected compact tests, or ambient separation theorem.

Proof. Read T, K, O first. These rows place the source topology, compact-generation tests, and compact-open ledger before any downstream function-space or Kelleyfication consumer can inspect the packet.

Read D and W next. The diagonal-separation surface and the finite inspection window are attached to the same compact-window route, so the weak-Hausdorff condition is not detached from the compact-generation data.

Finally read H, C, P, N. Transport, replay, provenance, and local naming preserve the displayed row order and add no independent topology or separation coordinate.

Therefore the compact-window scope is exactly the finite route displayed in the statement. Any read outside that route would require a carrier field that G does not contain. □

Closure status for $\mathsf{NameCert}_{\mathsf{CompactlyGeneratedWeakHausdorff}^{\uparrow}}$.

Constructive story: A $\mathsf{CompactlyGeneratedWeakHausdorff}^{\uparrow}$ packet is generated from a Topology source row, compact-generation tests, CompactOpenTopology windows, weak-Hausdorff diagonal-separation data, finite inspection windows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CompactlyGeneratedWeakHausdorff}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8768.1, Definition 8768.2, Definition 8768.3, and Definition 8768.4 seed the finite compactly generated weak Hausdorff route over topology, compact-generation, compact-open, diagonal-separation, transport, replay, provenance, and local naming rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CompactlyGeneratedWeakHausdorff}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close a host category of compactly generated weak Hausdorff spaces, quotient-open equality, selected compact-test families, countable choice, classical point separation, Lean theorem checking, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, compact-generation test exactness, compact-open window scope, diagonal-separation routing, transport and replay stability, provenance, local naming, and nonescape for BEDC.Derived.CompactlyGeneratedWeakHausdorffUp.

Chapter 8769

A Concrete Naming Certificate for $\mathsf{StaticGreenBoundaryFlux}^{\uparrow}$

The $\mathsf{StaticGreenBoundaryFlux}^{\uparrow}$ packet realizes the static boundary-flux branch of Definition 9346.50 as finite graph-Laplacian NameCert data. It sits beside the finite-volume boundary ledger of chapter 6277, the Gauss flux-boundary route of chapter 8156, the displayed matrix surface of chapter 49, and the rational finite-place product carrier of chapter 8761. The packet names static reduced-Laplacian exactness only; it does not identify the dynamic Green response, a running susceptibility, a host PDE solution, or a selected boundary trace.

Definition 8769.1 (Static Green boundary-flux carrier)**.** *A* $\mathsf{StaticGreenBoundaryFlux}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (G, I, B, L, A, E, Z, T, R, P, N)$$

with the following displayed rows:

1. *G is the finite weighted graph row, listing retained vertices, boundary vertices, edge weights, and incidence windows.*
2. *I is the retained-block row for the internal vertex set on which the reduced Dirichlet problem is read.*
3. *B is the boundary-cut row, naming the deleted boundary block and the cut weights from retained vertices into that block.*
4. *L is the reduced Laplacian row over I, with diagonal entries read from full weighted degree and off-diagonal entries read from retained-retained edge weights.*
5. *A is the cut-source row, recording the vector whose retained coordinate is the total edge weight from that vertex into B.*
6. *E is the exactness row, displaying the identity $L\mathbf{1}_I = A$ before any Green-class read is consumed.*
7. *Z is the localized-denominator row. It records the finite determinant and the designated unit factors without turning the cokernel read into a dynamic Green response.*
8. *T records componentwise* hsame *transport for graph, retained-block, boundary-cut, reduced-Laplacian, source, exactness, denominator, replay, provenance, and local naming rows.*
9. *R records displayed* Cont *replay of the static cut-source route.*

10. *P is the* Pkg *provenance over* $\mathsf{StaticGreenBoundaryFlux}^{\uparrow}$, $\mathsf{FiniteVolume}^{\uparrow}$, $\mathsf{GaussDivergenceTheorem}^{\uparrow}$, $\mathsf{Mat}^{\uparrow}$, $\mathsf{RationalFinitePlaceProduct}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{StaticGreenBoundaryFlux}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through these rows. It has no coordinate for a dynamic Green operator, a Green–Kubo susceptibility, a host finite-volume theorem, quotient equality of sources, selected traces, or a physical running parameter.

Theorem 8769.2 (Static Green boundary-flux NameCert obligations)**.** *For every accepted* StaticGreenBoundaryFlu *carrier $S = (G, I, B, L, A, E, Z, T, R, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{StaticGreenBoundaryFlux}^{\uparrow}}$ *surface consists exactly of finite graph exposure through G, retained-block exposure through I, boundary-cut exposure through B, reduced-Laplacian exposure through L, cut-source exposure through A, exactness exposure through E, localized-denominator exposure through Z, componentwise transport through T, displayed replay through R, provenance through P, and local naming through N.*

Proof. Project the carrier of Definition 8769.1. The finite graph and cut data are exactly G, I, B, while the algebraic readback rows are L, A, E, Z.

The reduced Laplacian and cut-source are not external objects. The row L is computed from the retained graph incidence in G, I, and the row A is computed from the boundary-cut row B.

The exactness claim is carried only by E. It displays $L\mathbf{1}_I = A$ before the localized-denominator row Z is inspected, so the packet cannot claim Green-exactness while hiding the reduced Laplacian or the cut source.

Finally, T, R, P, N transport, replay, source, and name the same finite route. Since no dynamic Green operator, susceptibility, host finite-volume theorem, quotient source equality, selected trace, or physical running parameter occurs in the carrier, the listed rows exhaust the local obligations. □

Theorem 8769.3 (Static Green boundary-flux exactness)**.** *Let $S = (G, I, B, L, A, E, Z, T, R, P, N)$ be an accepted* $\mathsf{StaticGreenBoundaryFlux}^{\uparrow}$ *carrier. Any static boundary-flux read that claims Green-exactness must expose the reduced Laplacian row L and the cut-source row A before reading the exactness row E. The visible exactness is the finite identity $L\mathbf{1}_I = A$, and it exports no dynamic Green response, no Green–Kubo susceptibility, no selected boundary trace, and no host finite-volume theorem.*

Proof. Read the graph, retained-block, and boundary-cut rows first. They determine which vertices remain internal and which edge weights contribute to the boundary source.

Project the reduced Laplacian row L. Its diagonal entries use the full weighted degree of each retained vertex, while its off-diagonal entries use only retained-retained edge weights.

Project the cut-source row A. Each coordinate records exactly the omitted boundary weights from the same retained vertex into B.

The row E then displays the coordinatewise identity $L\mathbf{1}_I = A$: multiplying L by the constant retained vector cancels retained-retained edge contributions and leaves precisely the boundary-cut coordinate. The transport, replay, provenance, and local naming rows preserve that static identity, and no row supplies the excluded dynamic or host-theorem data. □

Theorem 8769.4 (Static Green boundary-flux vision realization)**.** *The* $\mathsf{StaticGreenBoundaryFlux}^{\uparrow}$ *carrier realizes the static part of Definition 9346.50: a Window-six or finite graph boundary read is accepted only when the rows $G, I, B, L, A, E, Z, T, R, P, N$ expose the reduced Laplacian, cut source, exactness identity, localized denominator, transport, replay, provenance, and local naming. The*

realization is static and exact; the dynamic Green response of Definition 9346.51 remains a separate readout surface.

Proof. Start with Definition 8769.1. Its rows bind the finite graph, retained block, deleted boundary block, reduced Laplacian, and cut-source vector before any exactness read is public.

Apply Definition 8769.3. The exactness row is the displayed identity $L\mathbf{1}_I = A$, so the static boundary source is a reduced-Laplacian image inside the same finite packet.

The localized-denominator row Z records which determinant factors remain visible after the designated finite-place localization. It does not create a running Green operator and does not turn the zero static cokernel class into a dynamic susceptibility.

Thus the vision is realized only as static finite NameCert data. The dynamic centered relaxation and Green-excess quantities cited by the vision require their own packet and cannot be recovered from S. □

Falsifiable prediction: Any accepted $\mathsf{StaticGreenBoundaryFlux}^{\uparrow}$ read that claims static Green-exactness must expose the reduced Laplacian row and the cut-source row before the exactness row is consumed; a read that hides either row refutes the carrier of Definition 8769.1.

Independence witness: finite-volume, gauss-divergence-theorem, matrix, rational-finite-place-product: $\mathsf{StaticGreenBoundaryFlux}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries finite graph incidence, retained-block data, boundary-cut rows, reduced-Laplacian rows, cut-source rows, exactness, localized-denominator data, transport, replay, provenance, and local naming, while the siblings isolate conservation ledgers, flux-boundary calculus, matrix display, or finite-place arithmetic.

The Lean-side taste surface for $\mathsf{StaticGreenBoundaryFlux}^{\uparrow}$ must eventually provide ‘Nontrivial StaticGreenBoundaryFluxUp‘ and ‘FieldFaithful StaticGreenBoundaryFluxUp‘ instances in ‘TasteGate.lean‘, so that nontrivial boundary-flux content and finite-field faithful readback are checked before stronger closure is claimed.

Closure status for $\mathsf{NameCert}_{\mathsf{StaticGreenBoundaryFlux}^{\uparrow}}$.

Constructive story: A $\mathsf{StaticGreenBoundaryFlux}^{\uparrow}$ packet is generated from a finite weighted graph row, retained-block row, boundary-cut row, reduced-Laplacian row, cut-source row, exactness row, localized-denominator row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{StaticGreenBoundaryFlux}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8769.1, Definition 8769.2, Definition 8769.3, and Definition 8769.4 seed the finite static boundary-flux route over reduced Laplacians, cut sources, exactness, localized denominators, transport, replay, provenance, and local naming rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{StaticGreenBoundaryFlux}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close dynamic Green response, Green–Kubo susceptibility, host finite-volume theorems, selected traces, physical running parameters, Lean theorem checking, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, reduced-Laplacian construction, cut-source construction, exactness, localized-denominator faithful readback, transport and replay stability, provenance, local naming, Nontrivial instance, and FieldFaithful instance for BEDC.Derived.StaticGreenBoundaryFluxUp.

Chapter 8770

A Concrete Naming Certificate for $\mathsf{WeylCauchyCriterion}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{WeylCauchyCriterion}^{\uparrow}$ packet records the finite BEDC route by which a stream of rational approximants is certified Cauchy before it is sealed as a real. It consumes the $\mathsf{StreamName}^{\uparrow}$ windows of chapter 126, the $\mathsf{RegSeqRat}^{\uparrow}$ readback of chapter 301, the dyadic rational core of chapter 291, the $\mathsf{CauchyModulus}^{\uparrow}$ request surface of chapter 292, and the terminal $\mathsf{Real}^{\uparrow}$ boundary of chapter 38. The packet is a finite Cauchy-criterion certificate; it does not quotient streams, choose limits, or import ambient completeness.

Definition 8770.1 (Weyl Cauchy Criterion carrier)**.** *A* $\mathsf{WeylCauchyCriterion}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (S, M, W, D, Q, E, H, C, P, N)$$

with the following displayed rows:

1. *S is the* $\mathsf{StreamName}^{\uparrow}$ *source row naming the rational stream whose tails are inspected.*
2. *M is the* $\mathsf{CauchyModulus}^{\uparrow}$ *row storing the finite request-to-tail assignment used by the criterion.*
3. *W is the finite tail-window ledger: for each displayed precision request it names the window beyond which the stream comparison is read.*
4. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *comparison row carrying the dyadic tolerance and dyadic distance witnesses used inside each tail window.*
5. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row attached to the stream observations and dyadic comparisons.*
6. *E is the* $\mathsf{Real}^{\uparrow}$ *seal boundary reached only after the stream, modulus, window, dyadic, and readback rows have been displayed.*
7. *H records componentwise* hsame *transport for S, M, W, D, Q, E and for replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay of every consumer route through*

$$S, M, W, D, Q \longmapsto E.$$

9. *P is the* Pkg *provenance over* $\mathsf{WeylCauchyCriterion}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{CauchyModulus}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.

10. *N is the local* $\mathsf{NameCert}_{\mathsf{WeylCauchyCriterion}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $S, M, W, D, Q, E, H, C, P, N$. It has no coordinate for quotient stream equality, selected limits, countable choice, trichotomy, ambient completeness, Lean verification, or a standard bridge.

Theorem 8770.2 (Weyl Cauchy Criterion NameCert obligations)**.** *For every accepted* $\mathsf{WeylCauchyCriterion}^{\uparrow}$ *carrier*

$$K = (S, M, W, D, Q, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{WeylCauchyCriterion}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier exposure for the displayed stream name, Cauchy modulus, tail-window ledger, dyadic comparison row, regular rational readback, real seal, transport, replay, provenance, and local naming rows;*
2. *tail-window stability, requiring every transported or replayed precision request to keep the same stream S, modulus M, window W, dyadic comparison D, and readback Q before exposing the real seal E;*
3. *modulus extraction, requiring the tail index used by each criterion request to be read from M and not from a chosen subsequence, selected limit, or ambient completeness theorem;*
4. *Real-seal nonescape, requiring every* $\mathsf{Real}^{\uparrow}$*-facing consumer to pass through S, M, W, D, Q, E and to receive no quotient representative or host real equality from the packet;*
5. *refusal of quotient streams, selected limits, countable choice, trichotomy, and ambient completeness, requiring H, C, P, N to transport, replay, source, and name only the displayed rows.*

No Weyl Cauchy Criterion NameCert obligation is stored outside these rows.

Proof. Carrier exposure is projection from Definition 8770.1. The packet displays the stream, modulus, tail windows, dyadic comparisons, regular readback, real seal, and the four structural rows.

Tail-window stability is componentwise. A transported or replayed request keeps the same S, M, W, D, Q route, so a consumer cannot replace the displayed tail comparison by a quotient over streams.

Modulus extraction is forced by the M row. Each precision request reads its tail index from the displayed Cauchy modulus, and the dyadic comparison row D checks only the window named by W.

The real seal E appears after S, M, W, D, Q have been exposed. Thus a $\mathsf{Real}^{\uparrow}$ consumer receives a finite criterion route rather than a selected limit, a quotient representative, or an ambient completeness theorem.

Finally, H, C, P, N only transport, replay, source, and name the carrier rows. Since the packet contains no countable choice, trichotomy, quotient stream equality, selected limit, Lean verification, or bridge credential, the listed rows exhaust the local NameCert surface. □

Closure status for $\mathsf{NameCert}_{\mathsf{WeylCauchyCriterion}^{\uparrow}}$**.**

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{WeylCauchyCriterion}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8770.1 and Definition 8770.2 seed the finite Weyl Cauchy Criterion surface over stream names, regular rational readback, dyadic comparisons, Cauchy modulus extraction, and the Real seal boundary.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{WeylCauchyCriterion}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient stream equality, selected limits, countable choice, trichotomy, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier exposure, tail-window stability, modulus extraction, Real-seal nonescape, and ledger refusal for BEDC.Derived.WeylCauchyCriterionUp.

Constructive story: A WeylCauchyCriterion$^{\uparrow}$ packet is generated from a StreamName row, a CauchyModulus row, finite tail windows, DyadicRatCore comparisons, RegSeqRat readback, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 8771

A Concrete Naming Certificate for $\mathsf{DyadicIntervalContinuityModulus}^{\uparrow}$

Following Bishop–Bridges constructive practice, the $\mathsf{DyadicIntervalContinuityModulus}^{\uparrow}$ packet names a finite dyadic interval modulus for a continuous map on a located closed interval. It sits beside the dyadic interval cells of chapter 5966, the located finite-net interval surface of chapter 1808, the finite observation discipline of chapter 126, the regular rational readback of chapter 301, and the terminal real-name seal of chapter 38. The packet records finite modulus data only; it is not an open-cover compactness theorem, a choice-selected modulus, quotient-real equality, or ambient completeness coordinate for $\mathsf{Real}^{\uparrow}$.

Definition 8771.1 (Dyadic interval continuity modulus carrier)**.** *A* $\mathsf{DyadicIntervalContinuityModulus}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M = (I, N, L, S, R, E, B, H, C, P, Q)$$

with the following displayed rows:

1. *I is the located closed interval row carrying the two dyadic endpoint certificates and the located membership test used by the packet.*
2. *N is the* $\mathsf{DyadicIntervalNet}^{\uparrow}$ *row listing the dyadic subinterval cells inspected at the chosen mesh scale.*
3. *L is the* $\mathsf{LocatedClosedIntervalFiniteNet}^{\uparrow}$ *row certifying that the listed cells are the finite located interval net consumed by the packet.*
4. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row opened for the function reads at the cell endpoints and selected interior probes.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row obtained from those finite stream windows.*
6. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row for the displayed readbacks.*
7. *B is the modulus-budget row: for each requested output dyadic tolerance it displays a finite input mesh scale and the cell-window ledger that witnesses the corresponding oscillation bound.*
8. *H records componentwise* hsame *transport for the interval, net, located-net, stream-window, rational-readback, real-seal, budget, replay, provenance, and local-name rows.*
9. *C records displayed* Cont *replay from a requested tolerance through I, N, L, S, R, E, B.*

10. *P is the* Pkg *provenance over* DyadicIntervalContinuityModulus$^{\uparrow}$, DyadicIntervalNet$^{\uparrow}$, LocatedClosedIntervalFiniteN StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, Real$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

11. *Q is the local* NameCert$_{\text{DyadicIntervalContinuityModulus}^{\uparrow}}$ *row.*

The carrier has no coordinate for open-cover compactness, choice-selected subcovers, quotient-real equality, host real equality, ambient Real$^{\uparrow}$ *completeness, Lean verification, or bridge checking.*

Theorem 8771.2 (Dyadic interval modulus window stability)**.** *Every accepted* DyadicIntervalContinuityModulus$^{\uparrow}$ *packet preserves its modulus decision under componentwise* hsame *transport of the displayed interval, net, finite-window, readback, real-seal, budget, replay, provenance, and local-name rows.*

Proof. Project the carrier of Definition 8771.1. The modulus budget row B is not a standalone host function; it is read only together with the interval row I, the dyadic net N, the located finite-net certificate L, the StreamName windows S, the RegSeqRat readback R, and the RealUp seal E.

Now transport the packet componentwise along the displayed hsame row H. Because H compares exactly the rows listed in the carrier, it preserves the cell ledger, the opened stream windows, the rational readback, and the requested output tolerance attached to B.

The replay row C then replays the same finite route after transport. Hence a consumer that reads the transported packet sees the same finite modulus decision, and no new open cover, selected subcover, quotient-real equality, or completeness principle is introduced. □

Theorem 8771.3 (Dyadic interval modulus regular-Cauchy handoff)**.** *Every accepted* DyadicIntervalContinuityMod *packet exports completion-facing data only through the finite route*

$$\text{DyadicIntervalNet}^{\uparrow} \longrightarrow \text{LocatedClosedIntervalFiniteNet}^{\uparrow} \longrightarrow \text{StreamName}^{\uparrow} \longrightarrow \text{RegSeqRat}^{\uparrow} \longrightarrow \text{Real}^{\uparrow}.$$

The modulus budget is therefore a finite regular-Cauchy window handoff, not an appeal to open-cover compactness or ambient Real$^{\uparrow}$ *completeness.*

Proof. The source of a completion-facing read is the dyadic interval net N together with the located finite-net row L. These rows determine the finite cells and probes available to the packet.

The only observation route then passes through the StreamName windows S and the RegSeqRat readback row R. The terminal seal E records that the displayed rational windows have been presented as a RealUp-facing name, but it does not add a selected limit or a completeness theorem.

Finally the budget row B is tied to those same finite windows by the replay row C and the local NameCert row Q. Since no excluded principle is a coordinate of the carrier, every completion consumer receives exactly the finite regular-Cauchy handoff displayed in the statement. □

Closure status for NameCert$_{\text{DyadicIntervalContinuityModulus}^{\uparrow}}$.

Constructive story: A DyadicIntervalContinuityModulus$^{\uparrow}$ packet is generated from a located closed interval row, a DyadicIntervalNet row, a LocatedClosedIntervalFiniteNet row, StreamName finite windows, RegSeqRat readback, a RealUp terminal seal, a finite modulus-budget ledger, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\text{DyadicIntervalContinuityModulus}^{\uparrow}}$, seed)

Scope closed: Definition 8771.1, Definition 8771.2, and Definition 8771.3 seed the finite dyadic interval modulus route from located interval nets to regular-Cauchy and RealUp consumers.

Formal verification: FormalStatus(NameCert$_{\text{DyadicIntervalContinuityModulus}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close open-cover compactness, choice-selected modulus extraction, quotient-real equality, host real equality, ambient Real$^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, window stability, regular-Cauchy handoff, transport, replay, provenance, and local naming for BEDC.Derived.DyadicIntervalContinuityModulusUp.

Chapter 8772

A Concrete Naming Certificate for $\mathsf{ZetaZeroTypeFactorization}^{\uparrow}$

The $\mathsf{ZetaZeroTypeFactorization}^{\uparrow}$ packet realizes the zero-fiber route of chapter 9253 as finite NameCert data. It binds a zeta-domain source row, a displayed zero-value fiber, legal generator factorization, fixed-half ledger rows, componentwise transport, replay, provenance, and local naming before any consumer may read the fixed-half sufficiency interface. The packet is narrower than the analytic zeta carrier and wider than a bare zero row: it is a concrete bridge from the vision's zero-type carrier to BEDC packet data, with sibling context from chapter 8761 and chapter 4238.

Falsifiable prediction: If the zero-fiber row is absent, no accepted packet can prove the fixed-half sufficiency theorem for this carrier.

Independence witness: zeta, prime, rational-finite-place-product, metacic-parallel-diamond-frontier: the packet has a zero-fiber/generator/fixed-half ledger not bijective to Euler-product, primality, finite-place-product, or residual-diamond carriers.

Definition 8772.1 (Zeta zero type factorization carrier)**.** *A* $\mathsf{ZetaZeroTypeFactorization}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Z = (D, V, F, G, T, J, K, H, C, P, N)$$

with the following displayed rows:

1. *D is the zeta-domain source row, carrying the continuation-domain provenance and the pole-exclusion ledger used by the zero-type vision.*
2. *V is the zeta-value relation row, displaying a finite witness that the source row has a value readout.*
3. *F is the zero-fiber row, displaying the value witness together with the zero-complex classifier row of Definition 9253.4.*
4. *G is the legal-generator factorization row, recording that every admitted generator read factors through the same displayed zero fiber.*
5. *T is the non-trivial strip row, recording the critical-strip witness required before the fixed-half interface is meaningful.*
6. *J is the fixed-half ledger row, recording the critical-line witness supplied to the sufficiency consumer.*

7. *K is the TasteGate-facing row requiring later Lean files to provide* Nontrivial ZetaZeroTypeFactorization$^{\uparrow}$ *and* FieldFaithful ZetaZeroTypeFactorization$^{\uparrow}$ *instances for the displayed carrier fields.*
8. *H records componentwise* hsame *transport for the domain, value, zero-fiber, generator, strip, fixed-half, TasteGate, replay, provenance, and local-name rows.*
9. *C records displayed* Cont *replay from a legal generator through D, V, F, G, T, J, K.*
10. *P is the* Pkg *provenance over* ZetaZeroTypeFactorization$^{\uparrow}$, BHist, hsame, Cont, Pkg, NameCert, *the zero-type vision,* RationalFinitePlaceProduct$^{\uparrow}$, *and* MetaCICParallelDiamondFrontier$^{\uparrow}$.
11. *N is the local* NameCert$_{\text{ZetaZeroTypeFactorization}^{\uparrow}}$ *row.*

The classifier accepts only packets in which F, G, T, J occur in the same finite carrier. It has no coordinate for Euler-product reconstruction, primality, finite-place product equality, residual-diamond confluence, analytic continuation proof, host complex equality, or a proof of RH.

Theorem 8772.2 (Zeta zero type factorization zero-fiber boundary)**.** *Every accepted* ZetaZeroTypeFactorization$^{\uparrow}$ *packet exposes the zero-type route through the displayed row F before any generator or fixed-half consumer can read the packet.*

Proof. Project the carrier of Definition 8772.1. The source row D and value row V are not yet a zero-type packet; the zero-fiber row F is the displayed witness that the value readout is classified with the zero complex history.

The generator row G is downstream of F. A legal generator is accepted only after its output is routed through the same zero-fiber row, so it cannot bypass the zero-type carrier described in chapter 9253.

The fixed-half rows T, J are also downstream of F. They refine a non-trivial zero packet by strip and critical-line ledgers, but they do not create the zero witness. Thus the zero-fiber row is the boundary through which every accepted packet must pass. □

Theorem 8772.3 (Zeta zero type factorization ledger)**.** *For the carrier of Definition 8772.1, the local* NameCert$_{\text{ZetaZeroTypeFactorization}^{\uparrow}}$ *surface consists exactly of the finite zero-fiber row, generator-factorization row, fixed-half ledger rows, TasteGate-facing row, componentwise transport, displayed replay, provenance, and local naming.*

Proof. Read the rows D, V, F first. They display the source, the value relation, and the zero-fiber witness. Without F, the packet is merely a zeta-value readout and cannot feed the fixed-half sufficiency interface.

Next read G, T, J. The generator row records factorization through the displayed zero fiber, while the non-trivial strip row and fixed-half row record the two ledgers required by the RH-facing subtype route. These are finite ledger rows, not an analytic proof of the Riemann hypothesis.

Finally read K, H, C, P, N. The TasteGate row names the future Nontrivial and FieldFaithful obligations for the same carrier fields, and the transport, replay, provenance, and local-name rows exhaust the BEDC certificate surface. No Euler-product, primality, finite-place-product, residual-diamond, host-equality, or analytic-continuation coordinate is available to a consumer. □

Closure status for NameCert$_{\text{ZetaZeroTypeFactorization}^{\uparrow}}$.

Constructive story: A ZetaZeroTypeFactorization$^{\uparrow}$ packet is generated from a zeta-domain source row, a value-relation row, a zero-fiber row, a legal-generator factorization row, non-trivial strip and fixed-half ledger rows, a TasteGate-facing row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\text{ZetaZeroTypeFactorization}^{\uparrow}}$, seed)

Scope closed: Definition 8772.1, Definition 8772.2, and Definition 8772.3 seed the zero-fiber, generator-factorization, and fixed-half ledger surface for the RH zero-type route.

Formal verification: FormalStatus(NameCert$_{\mathsf{ZetaZeroTypeFactorization}\uparrow}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close Euler-product reconstruction, primality, finite-place product equality, residual-diamond confluence, analytic continuation, host complex equality, a proof of RH, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, zero-fiber boundary, generator-factorization ledger, fixed-half ledger, TasteGate Nontrivial and FieldFaithful instances, transport, replay, provenance, and local naming for BEDC.Derived.ZetaZeroTypeFactorizationUp.

Chapter 8773

A Concrete Naming Certificate for $\mathsf{BishopCauchyModulusEnvelope}^{\uparrow}$

Following Bishop–Bridges constructive analysis, the $\mathsf{BishopCauchyModulusEnvelope}^{\uparrow}$ packet names the finite envelope through which a Cauchy-modulus request is routed before the L10 Real and Completion spine reads a terminal seal. It sits beside the finite observation discipline of chapter 126, the regular rational readback of chapter 301, the dyadic tolerance core of chapter 291, the directed modulus comparison surface of chapter 2386, and the terminal real-name seal of chapter 38. The packet binds those sibling routes into one displayed finite envelope; it is not a selected limit, quotient stream equality principle, countable-choice operation, host modulus function, or ambient completeness claim for $\mathsf{Real}^{\uparrow}$.

Definition 8773.1 (Bishop Cauchy modulus envelope carrier)**.** *A* $\mathsf{BishopCauchyModulusEnvelope}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$E = (M, S, R, D, J, A, H, C, P, N)$$

with the following displayed rows:

1. *M is the modulus request row, naming the requested dyadic precision and the finite tail window demanded by a Bishop-style Cauchy argument.*
2. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row opened exactly at the indices exposed by M.*
3. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row obtained from those stream windows.*
4. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger recording the finite dyadic comparisons used by the request.*
5. *J is the* $\mathsf{DyadicCauchyModulusLattice}^{\uparrow}$ *comparison row, placing the displayed request inside the directed modulus lattice before a stronger request is consumed.*
6. *A is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row, available only after M, S, R, D, J have all been displayed.*
7. *H records componentwise* hsame *transport for the modulus request, stream window, regular readback, dyadic ledger, lattice comparison, seal, replay, provenance, and local name rows.*
8. *C records displayed* Cont *replay from a modulus request through M, S, R, D, J, A.*
9. *P is the* Pkg *provenance over* $\mathsf{BishopCauchyModulusEnvelope}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{DyadicCauchyModulusLattice}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

10. N is the local $\mathsf{NameCert}_{\mathsf{BishopCauchyModulusEnvelope}^{\uparrow}}$ *row.*
The carrier has no coordinate for quotient representatives, selected limits, countable choice, a host modulus oracle, ambient $\mathsf{Real}^{\uparrow}$ *completeness, Lean verification, or bridge checking.*

Theorem 8773.2 (Bishop Cauchy modulus envelope NameCert obligations)**.** *For every accepted* $\mathsf{BishopCauchyModulusEnvelope}^{\uparrow}$ *carrier* $E = (M, S, R, D, J, A, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{BishopCauchyModulusEnvel}}$ *surface consists exactly of carrier admission for the modulus request row,* $\mathsf{StreamName}^{\uparrow}$ *finite-window exposure,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger,* $\mathsf{DyadicCauchyModulusLattice}^{\uparrow}$ *comparison,* $\mathsf{Real}^{\uparrow}$ *seal nonescape, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming.*

Proof. Project the carrier of Definition 8773.1. The row M is the only source of requested precision, and the row S opens only the finite windows demanded by that request.

The readback row R and dyadic ledger D interpret the same displayed window. The lattice row J then compares the request with finite directed-modulus data before any stronger completion-facing request is consumed.

The terminal row A is downstream of M, S, R, D, J. The structural rows H, C, P, N transport, replay, source, and name that same finite route, so the NameCert obligations are exactly the displayed rows and no hidden completion principle is available. □

Theorem 8773.3 (Bishop Cauchy modulus envelope Real-seal boundary)**.** *Every accepted* BishopCauchyModulusEr *packet exposes its* $\mathsf{Real}^{\uparrow}$ *seal only through the finite route*

$$\mathsf{StreamName}^{\uparrow} \longrightarrow \mathsf{RegSeqRat}^{\uparrow} \longrightarrow \mathsf{DyadicRatCore}^{\uparrow} \longrightarrow \mathsf{DyadicCauchyModulusLattice}^{\uparrow} \longrightarrow \mathsf{Real}^{\uparrow}.$$

Thus the envelope ties a Bishop Cauchy modulus request to Real and Completion consumers without importing quotient equality, selected limits, countable choice, a host modulus oracle, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Use Definition 8773.2. The accepted carrier displays the modulus request before any finite stream window is opened, and the regular rational readback and dyadic comparisons remain attached to that request.

The comparison row J is the only component that relates the request to a dyadic Cauchy modulus lattice. Any stronger tolerance request must therefore pass through the displayed directed lattice row rather than through an external modulus function.

The seal row A is exposed only after this finite route has been replayed. Since the carrier has no coordinate for quotient equality, selected limits, countable choice, host modulus data, or ambient completeness, the Real-facing read cannot leave the displayed envelope. □

Falsifiable prediction: A $\mathsf{BishopCauchyModulusEnvelope}^{\uparrow}$ packet fails this NameCert surface if a Real or Completion consumer can read the terminal seal without first displaying the modulus request, StreamName finite windows, RegSeqRat readback, DyadicRatCore tolerance ledger, DyadicCauchyModulusLattice comparison row, transport, replay, provenance, and local naming.

Independence witness: streamname, regseqrat, dyadicratcore, dyadic-cauchy-modulus-lattice, real: no listed sibling carries the whole envelope $E = (M, S, R, D, J, A, H, C, P, N)$, because each sibling supplies only finite windows, readback, tolerance arithmetic, directed modulus comparison, or terminal Real sealing while this packet binds the request-to-seal route into one local NameCert.

Closure status for $\mathsf{NameCert}_{\mathsf{BishopCauchyModulusEnvelope}^{\uparrow}}$.

Constructive story: A BishopCauchyModulusEnvelope$^{\uparrow}$ packet is generated from a modulus request row, StreamName finite windows, RegSeqRat readback, a DyadicRatCore tolerance ledger, a DyadicCauchyModulusLattice comparison row, a RealUp terminal seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\text{BishopCauchyModulusEnvelope}^{\uparrow}}$, seed)

Scope closed: Definition 8773.1, Definition 8773.2, and Definition 8773.3 seed the finite Bishop Cauchy modulus envelope over StreamName, RegSeqRat, DyadicRatCore, DyadicCauchyModulusLattice, and Real rows.

Formal verification: FormalStatus(NameCert$_{\text{BishopCauchyModulusEnvelope}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close quotient real equality, selected limits, countable choice, host modulus functions, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, modulus request exposure, finite-window readback, dyadic tolerance routing, lattice comparison, Real seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.BishopCauchyModulusEnvelopeUp.

Chapter 8774

A Concrete Naming Certificate for $\mathsf{CauchyCompletionMonadMultiplication}^{\uparrow}$

Following Bishop and Bridges, completion is a constructive metric operation on displayed Cauchy data rather than a passage to a hidden quotient object. The $\mathsf{CauchyCompletionMonadMultiplication}^{\uparrow}$ packet records the finite NameCert seed for flattening a Cauchy completion of a Cauchy completion. It sits after the Cauchy completion monad law surface of chapter 3834, the bind route of chapter 3777, the multiplication sibling of chapter 1829, the StreamName windows of chapter 126, the regular rational readback of chapter 301, the dyadic tolerance core of chapter 291, and the terminal Real seal of chapter 38. The packet names the displayed flattening service only; it is not a quotient completion, a selected limit, host equality of completed points, countable choice, or ambient completeness of $\mathsf{Real}^{\uparrow}$.

Definition 8774.1 (Cauchy completion monad multiplication carrier)**.** *A* $\mathsf{CauchyCompletionMonadMultiplication}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$J = (O, I, B, L, S, R, D, E, H, C, P, N)$$

with the following displayed rows:

1. *O is the outer completion row, naming the completion-of-completion request before any flattening read is public.*
2. *I is the inner completion row, naming the regular Cauchy family whose completion has already been admitted.*
3. *B is the bind row inherited from* $\mathsf{CauchyCompletionBind}^{\uparrow}$*, displaying the source family and the completion-facing bind schedule.*
4. *L is the* $\mathsf{CauchyCompletionMonadLaw}^{\uparrow}$ *ledger row, carrying the finite associativity and unit comparisons used by the flattening route.*
5. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row shared by the outer request, inner request, and flattened read.*
6. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *tail-stability row attached to the displayed stream windows.*
7. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row recording the precision budget and triangle slack for the flattening comparison.*
8. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal reached only after O, I, B, L, S, R, D have been displayed.*

9. *H records componentwise* hsame *transport for the outer, inner, bind, law, window, readback, dyadic, seal, replay, provenance, and local naming rows.*

10. *C records displayed* Cont *replay of the route from nested completion data to the flattened classifier.*

11. *P is the* Pkg *provenance over* $\mathsf{CauchyCompletionMonadMultiplication}^{\uparrow}$, $\mathsf{CauchyCompletionMonad}^{\uparrow}$, $\mathsf{CauchyCompletionBind}^{\uparrow}$, $\mathsf{CauchyCompletionMonadLaw}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

12. *N is the local* $\mathsf{NameCert}_{\mathsf{CauchyCompletionMonadMultiplication}^{\uparrow}}$ *row.*

The flattened classifier compares accepted packets only through $O, I, B, L, S, R, D, E, H, C, P, N$. It has no coordinate for quotient completion equality, selected representatives, host equality of completed points, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 (statement) `BEDC.Derived.CauchyCompletionMonadMultiplicationUp`

Theorem 8774.2 (Flattening scope)**.** *For every accepted* $\mathsf{CauchyCompletionMonadMultiplication}^{\uparrow}$ *carrier*

$$J = (O, I, B, L, S, R, D, E, H, C, P, N),$$

the flattening map from a nested completion request to its flattened classifier depends only on the nested Cauchy completion rows O, I, the bind and law rows B, L, the regular-Cauchy tail stability recorded by S, R, D, and classifier transport through H, C, P, N. Any consumer of the flattened classifier must read those rows before the terminal Real seal E is available. The map exports no quotient completion class, selected limit, host equality of completed points, countable-choice schedule, or ambient $\mathsf{Real}^{\uparrow}$ *completeness row.*

Proof. Project the carrier of Definition 8774.1. The nested completion request is visible only through the outer and inner rows O, I, while the completion-facing computation is visible only through the bind row B and the monad-law ledger L.

The regular-Cauchy tail data are read next. The stream windows S, regular readback R, and dyadic tolerance ledger D determine the finite tail-stability comparison used by the flattened classifier before the seal row E can be consumed.

Finally H, C, P, N transport, replay, source, and name the same displayed packet. Since none of the excluded principles has a carrier coordinate, the flattening map cannot depend on them. □

Theorem 8774.3 (Cauchy completion monad multiplication NameCert obligations)**.** *For every accepted* $\mathsf{CauchyCompletionMonadMultiplication}^{\uparrow}$ *carrier $J = (O, I, B, L, S, R, D, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{CauchyCompletionMonadMultiplication}^{\uparrow}}$ *surface consists of exactly five finite obligation rows:*

1. *carrier admission: the accepted object is the displayed* BHist *packet over nested completion, bind, law, StreamName, RegSeqRat, DyadicRatCore, Real seal, transport, replay, provenance, and local naming rows;*

2. *nested-source visibility: O and I must be displayed before the flattening route is read;*

3. *bind-and-law exactness: B and L supply the completion bind schedule and the finite associativity ledger used by the flattened classifier;*

4. *tail-stability transport: S, R, D, E, H, C preserve the regular-Cauchy windows, readback, dyadic tolerances, Real seal, componentwise transport, and displayed replay;*

5. *provenance and local naming: P and N bind the packet to* Pkg *and* NameCert *without adding quotient completion, selected representatives, host equality, countable choice, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Read the carrier admission row first. It exposes the twelve displayed coordinates of J and no other data.

For nested-source visibility, inspect O and I. These rows are the only source of completion-of-completion information, so the flattened route cannot be read before they are present.

For bind-and-law exactness, inspect B and L. The bind row supplies the completion-facing schedule, and the law row supplies the finite associativity ledger used to compare the two possible replays of a nested request.

For tail-stability transport, inspect S, R, D, E, H, C. These rows preserve the StreamName windows, regular readback, dyadic tolerances, terminal Real seal, componentwise transport, and displayed continuation replay across the flattening step.

Finally P and N provide package provenance and local naming for the same displayed packet. Since the carrier has no row for the excluded principles, the five listed rows exhaust the local NameCert surface. □

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyCompletionMonadMultiplication}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CauchyCompletionMonadMultiplication}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8774.1, Definition 8774.2, and Definition 8774.3 seed the finite completion-of-completion flattening surface over $\mathsf{CauchyCompletionMonad}^{\uparrow}$, $\mathsf{CauchyCompletionBind}^{\uparrow}$, $\mathsf{CauchyCompletionMonadLaw}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, Pkg, and NameCert rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CauchyCompletionMonadMultiplication}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient completion equality, selected representatives, host equality of completed points, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, nested-source visibility, bind-and-law exactness, tail-stability transport, Real-seal nonescape, provenance, and local naming for BEDC.Derived.CauchyCompletionMonadMultiplicationUp.

Constructive story: A $\mathsf{CauchyCompletionMonadMultiplication}^{\uparrow}$ packet is generated from outer and inner completion rows, bind and monad-law rows, StreamName windows, RegSeqRat readback, DyadicRatCore tolerances, a Real seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 8775

A Concrete Naming Certificate for $\mathsf{GelfandTriple}^{\uparrow}$

Following Gelfand and Vilenkin's rigged Hilbert space tradition, the $\mathsf{GelfandTriple}^{\uparrow}$ packet records the finite NameCert surface for a test carrier sitting densely inside a Hilbert carrier and read against a displayed dual carrier. It sits beside the Sobolev carrier of chapter 5911, the Schwartz carrier of chapter 5877, the tempered-distribution handoff of chapter 2310, and the dual-space interface of chapter 8458. The chapter names the $\Phi \to H \to \Phi'$ sandwich as finite BEDC rows; it is not a host locally convex completion, a selected distribution representative, spectral decomposition, reflexivity theorem, countable choice, or ambient Hilbert-space duality.

Definition 8775.1 (Gelfand triple carrier)**.** *A* $\mathsf{GelfandTriple}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$G = (\Phi, H, D, I, J, P, N)$$

with the following displayed rows:

1. *Φ is the test carrier row. It records the finite test-function or finite-energy windows read from sibling packets such as* $\mathsf{SchwartzSpace}^{\uparrow}$ *and* $\mathsf{SobolevSpace}^{\uparrow}$*.*
2. *H is the Hilbert carrier row. It records the inner-product and norm-facing readback surface through which Φ is interpreted as a dense Hilbert-facing test domain.*
3. *D is the dual carrier row. It records the displayed* $\mathsf{DualSpace}^{\uparrow}$ *or* $\mathsf{TemperedDistribution}^{\uparrow}$ *action rows that consume test windows from Φ.*
4. *I is the dense inclusion row $\Phi \to H$. It records that every Hilbert-facing read of the test carrier must pass through the displayed inclusion and its finite density ledger.*
5. *J is the dual inclusion and pairing row $H \to D$. It records the pairing of a Hilbert row against a dual row only after the test row, Hilbert row, and dense inclusion row have been displayed.*
6. *P is the* Pkg *provenance over* $\mathsf{GelfandTriple}^{\uparrow}$*,* $\mathsf{SobolevSpace}^{\uparrow}$*,* $\mathsf{SchwartzSpace}^{\uparrow}$*,* $\mathsf{TemperedDistribution}^{\uparrow}$*,* $\mathsf{DualSpace}^{\uparrow}$*,* $\mathsf{Hilbert}^{\uparrow}$*,* BHist*,* hsame*,* Cont*, and* $\mathsf{NameCert}$*.*
7. *N is the local* $\mathsf{NameCert}_{\mathsf{GelfandTriple}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through Φ, H, D, I, J, P, N. It has no coordinate for a host locally convex topology, unrestricted continuous dual, selected representative, spectral basis, countable-choice schedule, or ambient Hilbert-space completeness theorem.

Theorem 8775.2 (Gelfand triple NameCert obligations)**.** *For the carrier of Definition 8775.1, the local* $\mathsf{NameCert}_{\mathsf{GelfandTriple}^{\uparrow}}$ *surface consists exactly of test-carrier admission, Hilbert-carrier admission, dual-carrier admission, dense inclusion exposure for* $\Phi \to H$*, dual-pairing exposure for* $H \to \Phi'$*,* Pkg *provenance, and local naming. Every accepted read is confined to the displayed route*

$$\Phi, I, H, J, D \longmapsto P, N.$$

The surface exports no host locally convex completion, unrestricted dual equality, selected distribution representative, spectral decomposition, countable choice, or ambient Hilbert-space duality theorem.

Proof. Carrier admission is projection from Definition 8775.1. The rows Φ, H, D, I, J, P, N are the only rows available to a consumer.

The inclusion obligations are ordered. The row I is the only dense route from the test carrier into the Hilbert carrier, while J is the only pairing route from the Hilbert carrier toward the displayed dual carrier.

The provenance and naming rows preserve that same finite packet. Since no excluded topology, unrestricted dual, selected representative, spectral basis, choice schedule, or ambient duality theorem appears as a coordinate, the listed obligations exhaust the local NameCert surface. □

Theorem 8775.3 (Gelfand triple density sandwich)**.** *Every Hilbert-facing consumer of an accepted* $\mathsf{GelfandTriple}^{\uparrow}$ *carrier must read the test row* Φ*, the dense inclusion row* I*, and the Hilbert row* H *before consuming any dual-facing row. Thus the packet exposes a finite density sandwich*

$$\Phi \longmapsto H \longmapsto D$$

without replacing Φ*,* H*, or* D *by host completions or quotient representatives.*

Proof. Project the accepted carrier. The only test row is Φ, the only Hilbert row is H, and the only row connecting them is I.

Apply the NameCert obligations of Definition 8775.2. They place dense inclusion exposure before any dual-pairing exposure, so a Hilbert-facing read cannot skip directly to D.

The structural rows P, N source and name the same ordered route. Therefore the public analytic shape available from the packet is the displayed density sandwich, not a host completion or quotient construction. □

Theorem 8775.4 (Gelfand triple dual-pairing ledger)**.** *Every dual-pairing read of an accepted* $\mathsf{GelfandTriple}^{\uparrow}$ *carrier factors through the ledger*

$$\Phi, H, D, I, J, P, N.$$

The pairing row J *may be consumed only after the test carrier, Hilbert carrier, dual carrier, and dense inclusion rows have been displayed. The ledger does not export unrestricted distribution equality, a selected dual representative, reflexive identification of* H *with* D*, spectral decomposition, countable choice, or ambient completeness.*

Proof. Read the carrier rows from Definition 8775.1. The dual carrier D is visible, but it is paired with Hilbert-facing data only through J.

Use the density sandwich theorem. It forces the route through Φ, I, H before a dual-facing read may use the Hilbert row.

Finally apply the local obligations. The row J is the only dual-pairing ledger, and P, N only source and name that ledger. Since the excluded dual, spectral, choice, and completeness objects are absent from the packet, every dual-pairing read remains inside the displayed finite rows. □

Closure status for $\mathsf{NameCert}_{\mathsf{GelfandTriple}^{\uparrow}}$.

Constructive story: A $\mathsf{GelfandTriple}^{\uparrow}$ packet is generated from a test carrier row, Hilbert carrier row, dual carrier row, dense inclusion row, dual-pairing ledger, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{GelfandTriple}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8775.1, Definition 8775.2, Definition 8775.3, and Definition 8775.4 seed the finite rigged-Hilbert sandwich and its dual-pairing boundary.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{GelfandTriple}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host locally convex completion, unrestricted dual equality, selected distribution representatives, spectral decomposition, reflexivity, countable choice, ambient Hilbert-space duality, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, dense inclusion exposure, dual-pairing exactness, provenance, and local naming for BEDC.Derived.GelfandTripleUp.

Chapter 8776

A Concrete Naming Certificate for $\mathsf{Prohorov}^{\uparrow}$

Following Prohorov on tight probability families and weak compactness, the $\mathsf{Prohorov}^{\uparrow}$ packet records the finite BEDC surface where a probability family may be read through displayed tightness ledgers, metric compactness witnesses, and weak-convergence test windows. It sits over the probability source of chapter 184, the distribution readback of chapter 186, the metric distance vocabulary of chapter 57, and the compact metric witness route of chapter 129. The packet names only the finite dependency route for tight probability data; it does not import ambient weak compactness, select subsequences, quotient measures, countable choice, or an external topology of measures.

Definition 8776.1 (Prohorov carrier)**.** *A* $\mathsf{Prohorov}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$P = (S, D, T, K, W, M, R, V, H, C, Q, N)$$

with the following displayed rows:

1. *S is the* $\mathsf{ProbSpace}^{\uparrow}$ *probability source row, naming the total-mass and measurable-event surface from which the family is read.*
2. *D is the* $\mathsf{Distribution}^{\uparrow}$ *readback row, recording the pushed-forward probability endpoints inspected by the packet.*
3. *T is the tightness ledger, displaying the finite list of compact windows and tolerance requests that must be met before any weak-convergence read is public.*
4. *K is the* $\mathsf{CompactMetric}^{\uparrow}$ *witness row for the compact windows named by T.*
5. *W is the weak-convergence test-window row, containing the finite family of bounded continuous tests and tolerance comparisons currently admitted.*
6. *M is the* $\mathsf{Met}^{\uparrow}$ *distance row used to compare test-window endpoints and compact-window neighborhoods.*
7. *R is the* $\mathsf{Real}^{\uparrow}$ *readback row for the displayed probabilities, tolerances, and test-window endpoint comparisons.*
8. *V records transport of probability mass through the displayed distribution rows and compact windows.*

9. *H records componentwise* hsame *transport for $S, D, T, K, W, M, R, V, C, Q, N$.*
10. *C records displayed* Cont *replay from a Prohorov request through probability source, distribution readback, tightness ledger, compact metric witness, weak-convergence tests, metric comparison, Real readback, and transport.*
11. *Q is the* Pkg *provenance over* $\mathsf{Prohorov}^{\uparrow}$, $\mathsf{ProbSpace}^{\uparrow}$, $\mathsf{Distribution}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
12. *N is the local* $\mathsf{NameCert}_{\mathsf{Prohorov}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $S, D, T, K, W, M, R, V, H, C, Q, N$. It has no coordinate for selected subsequences, quotient probability measures, ambient weak compactness, countable choice, or a host topology on all measures.

Theorem 8776.2 (Prohorov NameCert obligations)**.** *For every accepted* $\mathsf{Prohorov}^{\uparrow}$ *carrier*

$$P = (S, D, T, K, W, M, R, V, H, C, Q, N),$$

the local $\mathsf{NameCert}_{\mathsf{Prohorov}^{\uparrow}}$ *surface consists exactly of probability-source admission through S, distribution readback through D, tightness-ledger exposure through T, compact metric witness exposure through K, weak-convergence test-window admission through W, metric comparison through M, Real readback through R, transport through V and H, displayed replay through C, provenance through Q, and local naming through N.*

No Prohorov obligation is stored outside these rows.

Proof. Project the accepted carrier. The probability source row S and the distribution row D are the only measure-facing data available to the packet, so every probability endpoint is read through the displayed source and pushforward surfaces.

The tightness ledger T must be displayed before a compact-window witness can be consumed. The compact metric row K supplies only the finite compact windows named by the ledger, not an ambient compactness theorem or a selected subsequence.

The weak-convergence test row W, metric row M, and Real readback row R then record the finite comparisons that are public. The transport, replay, provenance, and local naming rows V, H, C, Q, N preserve the same route, so the listed rows exhaust the local NameCert obligations. □

Theorem 8776.3 (Prohorov tightness metric handoff)**.** *Every consumer that reads a weak-convergence or compactness-facing conclusion from an accepted* $\mathsf{Prohorov}^{\uparrow}$ *carrier must first pass through the probability source row S, distribution readback row D, tightness ledger T, compact metric witness K, weak-convergence test window W, metric comparison row M, and Real readback row R. The handoff is the finite route*

$$S, D, T, K, W, M, R, V, H, C, Q, N$$

and exports no selected subsequence, quotient measure equality, countable-choice schedule, ambient weak compactness principle, or host topology of probability measures.

Proof. Start with the NameCert obligations of Definition 8776.2. They place source admission, distribution readback, tightness exposure, compact metric witnessing, weak test windows, metric comparison, and Real readback inside one accepted packet.

Read the tightness row before the compact metric row. This forces every compactness-facing consumer to inspect the displayed compact windows and tolerance requests before using any compact metric witness.

Next read the weak-convergence test window and metric comparison rows. These rows expose only finite tests and metric endpoint comparisons; they do not choose a subsequence or introduce an external topology of measures.

Finally replay V, H, C, Q, N. Transport, componentwise equality, continuation replay, provenance, and local naming preserve the same finite handoff, so the consumer cannot replace the route by quotient measure equality, countable choice, or ambient weak compactness. □

Closure status for $\mathsf{NameCert}_{\mathsf{Prohorov}\uparrow}$**.**

Constructive story: A $\mathsf{Prohorov}^{\uparrow}$ packet is generated from probability source rows, distribution readback rows, tightness ledgers, compact metric witnesses, weak-convergence test windows, metric comparison rows, Real readback rows, transport, componentwise hsame, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{Prohorov}\uparrow}, \mathsf{seed})$

Scope closed: Definition 8776.1, Definition 8776.2, and Definition 8776.3 seed the finite Prohorov packet over probability sources, distributions, tightness ledgers, compact metric witnesses, weak test windows, metric comparisons, Real readback, transport, replay, provenance, and local naming.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{Prohorov}\uparrow}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim selected subsequences, quotient measures, countable choice, ambient weak compactness, a host topology of measures, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked probability-source admission, distribution readback, tightness-ledger exposure, compact metric witnessing, weak-test routing, metric comparison, Real readback, transport, replay, provenance, and local naming for BEDC.Derived.ProhorovUp.

Chapter 8777

A Concrete Naming Certificate for $\mathsf{ContractiveCauchyRealizer}^{\uparrow}$

Following Bishop and Bridges on constructive metric fixed-point methods, the $\mathsf{ContractiveCauchyRealizer}^{\uparrow}$ packet records the finite route by which displayed contraction data generates a Cauchy endpoint realizer before any ambient completed fixed point is named. It sits after the contraction modulus surface of chapter 7948, the finite density-net route of chapter 6003, the stream-window surface of chapter 126, the regular rational readback of chapter 301, and the terminal real-name seal of chapter 38. The packet names only the displayed finite endpoint-realizer route; it is not a global Banach fixed-point theorem, a selected limit, quotient representative data, countable choice, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 8777.1 (Contractive Cauchy realizer carrier)**.** *A* $\mathsf{ContractiveCauchyRealizer}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$R = (K, O, D, W, Q, E, F, H, C, P, N)$$

with the following displayed rows:

1. *K is the* $\mathsf{DyadicContractionModulus}^{\uparrow}$ *row, recording the contraction budget and the dyadic shrinkage rule consumed by every endpoint request.*
2. *O is the Picard-orbit row, naming the finite iterate window generated from the displayed start row and the contraction self-map.*
3. *D is the* $\mathsf{FiniteCauchyDensityNet}^{\uparrow}$ *row, recording the finite density and tolerance cells through which the orbit is compared.*
4. *W is the* $\mathsf{StreamName}^{\uparrow}$ *window row, exposing exactly the orbit observations inspected at the requested precision.*
5. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row attached to the same window and contraction budget.*
6. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal, available only after K, O, D, W, Q have been displayed.*
7. *F is the endpoint certificate row, recording that the finite Picard window, density-net comparison, and regular-rational readback jointly supply the displayed endpoint realizer.*
8. *H records componentwise* hsame *transport for $K, O, D, W, Q, E, F, C, P, N$.*
9. *C records displayed* Cont *replay from a precision request through the contraction budget, orbit window, density net, stream window, readback, Real seal, endpoint row, transport, provenance, and local naming.*

10. *P is the* Pkg *provenance over* $\mathsf{ContractiveCauchyRealizer}^{\uparrow}$, $\mathsf{DyadicContractionModulus}^{\uparrow}$, $\mathsf{FiniteCauchyDensityNet}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{ContractiveCauchyRealizer}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $K, O, D, W, Q, E, F, H, C, P, N$. It has no coordinate for selected limits, quotient representatives, countable-choice schedules, trichotomy branches, host fixed-point equality, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 8777.2 (Contractive Cauchy realizer NameCert obligations)**.** *For every accepted* ContractiveCauchyRealiz *carrier $R = (K, O, D, W, Q, E, F, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{ContractiveCauchyRealizer}^{\uparrow}}$ *surface consists exactly of carrier admission for the contraction modulus, Picard orbit, finite Cauchy density net, finite stream window, regular rational readback, terminal Real seal, endpoint certificate, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming rows. Every endpoint-facing consumer must expose the same finite route*

$$K \to O \to D \to W \to Q \to E \to F \to H \to C \to P \to N$$

before it treats the packet as contraction-driven Cauchy endpoint data.

Proof. Project the carrier of Definition 8777.1. Its displayed coordinates are exactly $K, O, D, W, Q, E, F, H, C, P, N$, so the local naming surface has no hidden row outside the packet.

The contraction modulus K determines the finite shrinkage budget used by the Picard orbit row O. The density-net row D and stream window W then identify the finite observations through which the requested tolerance is inspected.

The regular rational readback Q is attached to those observations, and the terminal Real seal E is downstream of that readback. The endpoint certificate F records the fact that this finite route is the endpoint-facing data, while H, C, P, N transport, replay, source, and name the same route.

Since none of the rows stores selected limits, quotient representatives, countable-choice schedules, trichotomy branches, host fixed-point equality, or ambient $\mathsf{Real}^{\uparrow}$ completeness, the listed rows exhaust the NameCert obligations. □

Theorem 8777.3 (Contractive Cauchy route)**.** *Every Cauchy read exported by an accepted* ContractiveCauchyRealiz *carrier factors through the contraction modulus, Picard orbit, finite Cauchy density net, stream window, and regular rational readback rows before the terminal* $\mathsf{Real}^{\uparrow}$ *seal is available. In the notation of Definition 8777.1, the route is*

$$\mathsf{DyadicContractionModulus}^{\uparrow},\ O,\ \mathsf{FiniteCauchyDensityNet}^{\uparrow},\ \mathsf{StreamName}^{\uparrow},\ \mathsf{RegSeqRat}^{\uparrow} \longrightarrow \mathsf{Real}^{\uparrow}.$$

Thus the packet supplies a finite Cauchy endpoint-realizer route rather than a selected completed fixed point.

Proof. Open the finite route named in Definition 8777.2. The first row K fixes the dyadic contraction budget, and O records only the Picard iterates visible in the finite orbit window.

The density-net row D compares those iterates through finite cells. The stream window W exposes the inspected observations, and the regular rational row Q reads those observations at the requested precision.

Only after those rows have been displayed can the Real seal E be read. Therefore each Cauchy read factors through the finite contraction, orbit, density, window, and readback route, with no selected limit or ambient completeness principle added to the packet. □

Theorem 8777.4 (Contractive Cauchy fixed-endpoint seal)**.** *Let $R = (K, O, D, W, Q, E, F, H, C, P, N)$ be an accepted* $\mathsf{ContractiveCauchyRealizer}^{\uparrow}$ *carrier. Any consumer that reaches the endpoint certificate F must first read the terminal* $\mathsf{Real}^{\uparrow}$ *seal E through the displayed Cauchy route of Definition 8777.3, and must then read H, C, P, N as the transport, replay, provenance, and naming rows for that same endpoint certificate. The seal does not assert global Banach fixed-point existence, selected limits, quotient representatives, countable choice, trichotomy, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. The endpoint certificate F is a row of the carrier, not a detached fixed-point selector. By Definition 8777.1, it appears only after the contraction modulus, Picard orbit, density net, stream window, regular rational readback, and Real seal rows have been displayed.

Apply Definition 8777.3 to the seal row E. The consumer therefore reaches E only through the finite Cauchy readback route and then reaches F as the named endpoint certificate for that route.

Finally H, C, P, N record transport, replay, provenance, and local naming for the same packet. Because the classifier contains no coordinate for global Banach fixed-point existence, selected limits, quotient representatives, countable choice, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ completeness, the fixed-endpoint seal is exactly the displayed finite endpoint-realizer seal. □

Falsifiable prediction: Every accepted $\mathsf{ContractiveCauchyRealizer}^{\uparrow}$ endpoint consumer exposes a DyadicContractionModulus row, Picard-orbit row, FiniteCauchyDensityNet row, StreamName window, RegSeqRat readback, RealUp seal, endpoint certificate, hsame transport, Cont replay, Pkg provenance, and local NameCert row before it receives endpoint data.

Independence witness: dyadic-contraction-modulus, finite-cauchy-density-net, streamname, regseqrat, real: no listed sibling supplies the joint packet containing contraction budget, Picard orbit, density-net comparison, finite stream window, regular rational readback, terminal Real seal, endpoint certificate, transport, replay, provenance, and local NameCert rows while refusing selected limits and ambient completeness.

Closure status for $\mathsf{NameCert}_{\mathsf{ContractiveCauchyRealizer}^{\uparrow}}$**.**

Constructive story: A $\mathsf{ContractiveCauchyRealizer}^{\uparrow}$ packet is generated from a DyadicContractionModulus row, Picard orbit row, FiniteCauchyDensityNet row, StreamName window, RegSeqRat readback, a RealUp seal, endpoint certificate, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{ContractiveCauchyRealizer}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8777.1, Definition 8777.2, Definition 8777.3, and Definition 8777.4 seed the finite contraction-driven Cauchy endpoint-realizer route.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{ContractiveCauchyRealizer}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close global Banach fixed-point existence, selected limits, quotient representatives, countable choice, trichotomy, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, contraction-modulus exactness, Picard-window routing, finite density-net comparison, StreamName readback, RegSeqRat handoff, Real-seal non-escape, endpoint-certificate sealing, transport, replay, provenance, and local naming for BEDC.Derived.ContractiveCauchyRealizerUp.

Chapter 8778

A Concrete Naming Certificate for $\mathsf{CauchyCompletionSeparatedUniversal}^{\uparrow}$

Following Bishop and Bridges and the categorical reflection reading of completion, the CauchyCompletionSeparatedU packet records the separated universal-property boundary for Cauchy completion as finite BEDC NameCert data. It sits after the functorial completion surface of chapter 423, the adjunction row of chapter 1456, the dense embedding of chapter 3351, the separated-reflection boundary of chapter 1790, the finite observation surface of chapter 126, the regular rational readback of chapter 301, and the terminal real-name seal of chapter 38. The packet names exactly the rows through which a separated target may consume a completion universal arrow; it is not a quotient completion, a selected limit, a host equality principle, or an assertion of ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 8778.1 (Cauchy completion separated universal carrier)**.** *A* $\mathsf{CauchyCompletionSeparatedUniversal}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$U = (F, A, D, S, W, R, E, H, C, P, N)$$

with the following displayed rows:

1. *F is the* $\mathsf{CauchyCompletionFunctor}^{\uparrow}$ *row exposing the source completion surface before any universal-property consumer reads the packet.*
2. *A is the* $\mathsf{CauchyCompletionAdjunction}^{\uparrow}$ *row carrying the unit and extension handoff over the same source data.*
3. *D is the* $\mathsf{MetricCompletionDenseEmbedding}^{\uparrow}$ *dense-source row, visible before a separated target is allowed to inspect the completion value.*
4. *S is the* $\mathsf{SeparatedMetricReflection}^{\uparrow}$ *row witnessing that the target-side comparison is separated at the NameCert boundary.*
5. *W is the finite* $\mathsf{StreamName}^{\uparrow}$ *window surface through which source and image observations are requested.*
6. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row attached to those windows.*
7. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached only after W and R have been displayed.*
8. *H records componentwise* hsame *transport for the functor, adjunction, dense embedding, separated reflection, window, readback, seal, and local naming rows.*

9. *C records displayed* Cont *replay from a universal-property request through F, A, D, S, W, R, E.*

10. *P is the* Pkg *provenance over* $\mathsf{CauchyCompletionSeparatedUniversal}^{\uparrow}$, $\mathsf{CauchyCompletionFunctor}^{\uparrow}$, $\mathsf{CauchyCompletionAdjunction}^{\uparrow}$, $\mathsf{MetricCompletionDenseEmbedding}^{\uparrow}$, $\mathsf{SeparatedMetricReflection}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

11. *N is the local* $\mathsf{NameCert}_{\mathsf{CauchyCompletionSeparatedUniversal}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these rows. It has no coordinate for quotient equality of completion points, selected representatives, choice-selected limits, host equality of maps, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 8778.2 (Cauchy completion separated universal obligations)**.** *For every accepted* CauchyCompletionSepar *carrier*

$$U = (F, A, D, S, W, R, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{CauchyCompletionSeparatedUniversal}^{\uparrow}}$ *surface consists exactly of carrier admission, functor-row exposure, adjunction handoff, dense-embedding exposure, separated-reflection exposure, finite window readback, terminal Real sealing, componentwise transport, continuation replay, provenance, and local naming. No obligation may replace these rows by quotient equality, selected limits, host map equality, countable choice, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the carrier of Definition 8778.1. Its public rows are exactly $F, A, D, S, W, R, E, H, C, P, N$.

The universal-property part is read through F, A, D, S. The functor and adjunction rows expose the completion-facing source and extension route, the dense embedding row supplies the source image inside the completion surface, and the separated-reflection row is the only target-side separatedness datum.

The numerical readback is read through W, R, E. Stream windows and regular rational readback are displayed before the terminal Real seal is available.

Finally H, C, P, N transport, replay, source, and name the same rows. Since the carrier has no quotient, selected-limit, host-map-equality, choice, or ambient-completeness coordinate, the listed rows exhaust the local NameCert obligations. □

Theorem 8778.3 (Cauchy completion separated universal factorization)**.** *Every separated-target consumer of an accepted* $\mathsf{CauchyCompletionSeparatedUniversal}^{\uparrow}$ *packet factors through*

$\mathsf{CauchyCompletionFunctor}^{\uparrow}$, $\mathsf{CauchyCompletionAdjunction}^{\uparrow}$, $\mathsf{MetricCompletionDenseEmbedding}^{\uparrow}$, SeparatedMetricRe

before any public universal-property read is exposed. The factorization supplies a displayed completion functor row, adjunction handoff, dense-source row, separated-reflection row, finite windows, regular readback, Real seal, transport, replay, provenance, and local naming; it exports no quotient completion, selected representative, choice-selected limit, host map equality, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start with the functor and adjunction rows F, A. They identify the completion-facing source and extension route by finite NameCert data.

Next read the dense embedding and separated-reflection rows D, S. The dense image must be visible before the target consumes the completion value, and separatedness is recorded only as the row S.

Then replay the observation route through W, R, E. The consumer receives finite stream windows, regular rational readback, and the terminal Real seal in that order.

The structural rows H, C, P, N preserve and name the same route. Thus a separated-target consumer can only factor through the displayed rows and cannot obtain quotient equality, selected limits, host map equality, choice, or ambient completeness from the packet. □

Theorem 8778.4 (Cauchy completion separated universal nonescape)**.** *Every public read from an accepted* $\mathsf{CauchyCompletionSeparatedUniversal}^{\uparrow}$ *packet exposes separatedness only as the* $\mathsf{SeparatedMetricReflection}^{\uparrow}$ *row S attached to the displayed completion route. The read cannot escape to quotient equality of completion points, chosen representatives, choice-selected limits, host equality of maps, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Use Definition 8778.2. It fixes the packet inventory to the finite rows $F, A, D, S, W, R, E, H, C, P, N$.

Apply Definition 8778.3. Any separated-target consumer reaches the universal-property boundary only after the functor, adjunction, dense embedding, separated-reflection, finite-window, readback, and Real-seal rows are displayed.

The separatedness datum is therefore the visible row S, not an equality principle outside the carrier. Because no excluded object is a coordinate of the packet, no public read can export it. □

Falsifiable prediction: Every accepted $\mathsf{CauchyCompletionSeparatedUniversal}^{\uparrow}$ read must expose $F, A, D, S, W, R, E, H, C, P, N$ before a separated universal-property consumer may inspect the completion boundary.

Independence witness: cauchycompletionfunctor, cauchycompletionadjunction, metric-completion-dense-embedding, separatedmetricreflection, streamname, regseqrat, real: no listed sibling jointly carries the separated universal-property packet with functor, adjunction, dense embedding, separated reflection, finite observation, regular readback, Real seal, transport, replay, provenance, and local NameCert rows.

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyCompletionSeparatedUniversal}^{\uparrow}}$.

Constructive story: A $\mathsf{CauchyCompletionSeparatedUniversal}^{\uparrow}$ packet is generated from CauchyCompletionFunctor, CauchyCompletionAdjunction, MetricCompletionDenseEmbedding, SeparatedMetricReflection, StreamName, RegSeqRat, Real seal, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CauchyCompletionSeparatedUniversal}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8778.1, Definition 8778.2, and Definition 8778.3 seed the separated universal-property boundary for Cauchy completion consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CauchyCompletionSeparatedUniversal}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close ambient $\mathsf{Real}^{\uparrow}$ completeness, quotient equality, choice-selected limits, host map equality, selected representatives, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, functor-row exposure, adjunction handoff, dense embedding, separated-reflection visibility, finite readback, Real sealing, and ledger nonescape for BEDC.Derived.CauchyCompletionSeparatedUn

Chapter 8779

A Concrete Naming Certificate for $\mathsf{MarkHistContSpine}^{\uparrow}$

The $\mathsf{MarkHistContSpine}^{\uparrow}$ packet realizes the finite mark-history-continuation spine of chapter 9351 as concrete NameCert data. It binds the raw BMark emissions, generated BHist rows, Ext one-step extension rows, Cont continuation rows, hsame transport, replay, provenance, and local naming into one inspectable packet before any higher BEDC layer reads a continuation trace. The carrier is not a package object, not a signature relation, not a quotient of histories, and not an external normalization theorem.

Definition 8779.1 (MarkHistContSpine carrier)**.** *A* $\mathsf{MarkHistContSpine}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (M, H, E, T, Q, R, P, N)$$

with the following displayed rows:

1. *M is the finite* BMark *emission row, exposing only generated raw marks.*
2. *H is the generated* BHist *history row recording the finite mark sequence read by the packet.*
3. *E is the* Ext *one-step extension ledger from a source history and displayed mark to the resulting history.*
4. *T is the* Cont *continuation trace row, recording the finite concatenation route consumed by downstream replay.*
5. *Q is the continuation-trace normal form row, asserting that the same generated history route is read by the displayed continuation trace rather than by an external quotient.*
6. *R records componentwise* hsame *transport for M, H, E, T, Q and the local classifier row.*
7. *P is the* Pkg *provenance over* $\mathsf{MarkHistContSpine}^{\uparrow}$, BMark, BHist, Ext, Cont, hsame, *and* $\mathsf{NameCert}$ *rows.*
8. *N is the local* $\mathsf{NameCert}_{\mathsf{MarkHistContSpine}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through M, H, E, T, Q, R, P, N. It has no coordinate for package formation, signature equality, hidden history quotienting, external normalization, or an unrecorded continuation route.

Theorem 8779.2 (MarkHistContSpine NameCert obligations)**.** *For every accepted* $\mathsf{MarkHistContSpine}^{\uparrow}$ *carrier*

$$K = (M, H, E, T, Q, R, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{MarkHistContSpine}^{\uparrow}}$ *surface consists exactly of carrier admission for raw mark emissions, generated history rows, one-step extension rows, continuation trace rows, continuation-trace normal form, componentwise* hsame *transport, provenance, and local naming. No obligation may replace those rows by package structure, signature equality, quotient histories, external normalization, or an unrecorded continuation route.*

Proof. Project the carrier of Definition 8779.1. The visible kernel rows are M, H, E, T, Q, and the structural rows are R, P, N.

The raw mark and history obligations are read from M, H. The one-step extension obligation is read from E, and the continuation obligation is read from T.

The normal-form row Q records only that the displayed continuation trace has the stated generated history shape. It does not identify histories by a quotient or by an external conversion principle.

Finally R, P, N transport, source, and name the same finite packet. Since no excluded object is stored in the carrier, the listed rows exhaust the local NameCert surface. □

Theorem 8779.3 (MarkHistContSpine continuation trace)**.** *Every continuation read from an accepted* $\mathsf{MarkHistContSpine}^{\uparrow}$ *packet factors through the displayed route*

$$\mathsf{BMark},\ \mathsf{BHist},\ \mathsf{Ext},\ \mathsf{Cont},\ \mathsf{hsame},\ \mathsf{NameCert}.$$

The read exposes raw marks, generated histories, one-step extensions, the continuation trace, trace normal form, componentwise transport, provenance, and local naming before any downstream kernel consumer may inspect the trace.

Proof. Start with the raw mark row M and generated history row H. They expose the finite source material of the trace.

Use the extension row E to read each displayed one-step move. The continuation row T then concatenates those moves inside the generated BHist surface.

Read the normal-form row Q and transport row R last. They keep the trace attached to the same generated history shape without replacing it by quotient history equality or external normalization. □

Theorem 8779.4 (Additive continuation dependency)**.** *Any arithmetic consumer that reads a* $\mathsf{MarkHistContSpine}^{\uparrow}$ *continuation row as an additive continuation must pass through chapter 29 and its unary continuation route. The spine itself supplies only the displayed* BMark, BHist, Ext, *and* Cont *rows, with transport, provenance, and local naming; it does not create* $\mathsf{Add}^{\uparrow}$ *arithmetic or the unary-source discipline required by additive continuation.*

Proof. Project the continuation trace of Definition 8779.3. The rows M, H, E, T, Q, R, P, N expose generated marks, generated histories, one-step extension, displayed continuation, trace normal form, transport, provenance, and naming.

An additive reading needs more than those rows. By Definition 29.1, an accepted $\mathsf{Add}^{\uparrow}$ row first reads its two sources through the unary $\mathsf{Nat}^{\uparrow}$ spine and only then consumes the displayed Cont witness as additive output.

Thus the present spine can hand a continuation trace to a downstream consumer, but the arithmetic interpretation is supplied by the $\mathsf{Add}^{\uparrow}$ sibling route. Without that route, the trace remains a mark-history continuation packet rather than an additive continuation certificate. □

Theorem 8779.5 (MarkHistContSpine nonescape)**.** *Every public consumer of an accepted* $\mathsf{MarkHistContSpine}^{\uparrow}$ *packet receives only the finite rows* M, H, E, T, Q, R, P, N*. The packet cannot export package formation, signature equality, quotient-history identification, external normalization, a hidden continuation route, or any object above the mark-history-continuation spine.*

Proof. Apply the obligations theorem, Definition 8779.2. It fixes the admitted packet surface to raw marks, histories, extension, continuation, normal form, transport, provenance, and local naming.

Apply the continuation-trace theorem, Definition 8779.3. Any trace consumer must read those rows before the continuation trace is public.

The omitted structures are not fields of the carrier. A consumer can therefore use the packet only as a finite kernel-spine NameCert surface. □

Falsifiable prediction: An accepted $\mathsf{MarkHistContSpine}^{\uparrow}$ read that exposes a continuation trace without first displaying M, H, E, T, Q, R, P, N refutes the carrier surface.

Independence witness: continuationtrace, continuationtracenormalform, namecert, core: no listed sibling jointly carries raw BMark emissions, generated BHist rows, Ext one-step rows, Cont trace rows, trace normal form, hsame transport, provenance, and local NameCert data as one finite kernel-spine packet.

Future Lean work for this packet must exhibit nontriviality and field faithfulness as TasteGate instances: a Nontrivial witness separates at least two accepted spine carriers, and FieldFaithful confirms that the displayed M, H, E, T, Q, R, P, N fields are the classifier surface consumed by the local NameCert row.

Closure status for $\mathsf{NameCert}_{\mathsf{MarkHistContSpine}^{\uparrow}}$.

Constructive story: A $\mathsf{MarkHistContSpine}^{\uparrow}$ packet is generated from BMark emissions, BHist generated histories, Ext one-step rows, Cont continuation trace rows, continuation-trace normal form, componentwise hsame transport, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{MarkHistContSpine}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8779.1, Definition 8779.2, and Definition 8779.3 seed the finite mark-history-continuation spine packet.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{MarkHistContSpine}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close package formation, signature equality, quotient histories, external normalization, Lean verification, TasteGate instance checking, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, raw mark exposure, generated history exposure, extension rows, continuation trace rows, trace normal form, nonescape, and TasteGate field faithfulness for BEDC.Derived.MarkHistContSpineUp.

Chapter 8780

A Concrete Naming Certificate for $\mathsf{BishopRegularCauchyTailBound}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{BishopRegularCauchyTailBound}^{\uparrow}$ packet records the finite tail-bound row by which a Bishop regular Cauchy name exposes its eventual dyadic control before any Real or completion-facing consumer reads it. It sits beside the finite stream windows of chapter 126, the regular rational readback of chapter 301, the dyadic tolerance ledger of chapter 291, the shift-stability route of chapter 1578, and the terminal Real seal of chapter 38. The packet names only a displayed tail-bound certificate; it does not assert quotient stream equality, selected limits, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 8780.1 (Bishop regular Cauchy tail-bound carrier)**.** *A* $\mathsf{BishopRegularCauchyTailBound}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$T = (S, R, D, Q, N, W, H, C, P, L)$$

with the following displayed rows:

1. *S is the* $\mathsf{StreamName}^{\uparrow}$ *observation row, listing the finite windows from which the Cauchy name is read.*
2. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row, repacking the windows as regular rational data.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row, recording the dyadic radius used for the tail request.*
4. *Q is the* $\mathsf{RegularCauchyShift}^{\uparrow}$ *row, recording that the same tail request is stable under a displayed finite shift of the observation window.*
5. *N is the unary tail-index row, naming the finite stage after which the dyadic radius is enforced.*
6. *W is the later-window comparison row, displaying only those later observations that the packet certifies inside the radius from D after N.*
7. *H records componentwise* hsame *transport for $S, R, D, Q, N, W, C, P, L$.*
8. *C records displayed* Cont *replay from the stream and regular readback rows through*

$$S, R, D, Q, N, W \longmapsto H, C, P, L.$$

9. *P is the* Pkg *provenance over* $\mathsf{BishopRegularCauchyTailBound}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegularCauchyShift}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

10. L is the local $\mathsf{NameCert}_{\mathsf{BishopRegularCauchyTailBound}^{\uparrow}}$ *row.*
The classifier compares accepted carriers only through $S, R, D, Q, N, W, H, C, P, L$. It has no coordinate for a quotient completion object, selected representative, countable-choice schedule, trichotomy decision, host real equality, or ambient completeness theorem.

Theorem 8780.2 (Bishop regular Cauchy tail-bound NameCert obligations)**.** *For every accepted* $\mathsf{BishopRegularCauchyTailBound}^{\uparrow}$ *carrier*

$$T = (S, R, D, Q, N, W, H, C, P, L),$$

the local $\mathsf{NameCert}_{\mathsf{BishopRegularCauchyTailBound}^{\uparrow}}$ *surface consists exactly of StreamName observation exposure through S, RegSeqRat readback through R, dyadic-radius accounting through D, shift-stable tail routing through Q, tail-index exposure through N, later-window comparison through W, componentwise transport through H, displayed replay through C, package provenance through P, and local naming through L.*

Proof. Project the carrier of Definition 8780.1. The accepted packet displays exactly the stream, readback, dyadic tolerance, shift, tail-index, later-window, transport, replay, provenance, and local naming rows.

Read the tail request in order. A consumer first opens S and R, then consumes the dyadic radius D, then checks that the same request survives the shift row Q before reading N and W.

The structural rows preserve only that finite route. The hsame and Cont rows transport and replay the displayed comparisons, while P and L source and name the packet. Since the carrier has no coordinate for quotient streams, selected limits, countable choice, trichotomy, host real equality, or ambient $\mathsf{Real}^{\uparrow}$ completeness, none of those principles is part of the local NameCert surface. □

Theorem 8780.3 (Bishop regular Cauchy tail-bound Real handoff)**.** *Every* $\mathsf{Real}^{\uparrow}$ *or completion-facing consumer of an accepted* $\mathsf{BishopRegularCauchyTailBound}^{\uparrow}$ *packet must read the finite route*

$$\mathsf{StreamName}^{\uparrow},\ \mathsf{RegSeqRat}^{\uparrow},\ \mathsf{DyadicRatCore}^{\uparrow},\ \mathsf{RegularCauchyShift}^{\uparrow},\ \mathsf{BHist},\ \mathsf{hsame},\ \mathsf{Cont},\ \mathsf{Pkg},\ \mathsf{NameCert}.$$

The handoff supplies only the displayed tail-bound packet for downstream Real sealing. It does not supply quotient stream equality, selected limits, countable choice, trichotomy, host real equality, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Apply Definition 8780.2. It forces every Real-facing read through S, R, D, Q, N, W before the structural rows may be consumed.

The completion-facing part is finite. Stream windows are repacked as regular rational readback, the dyadic row supplies the radius, the shift row keeps the request stable under displayed finite shifts, and the tail-index plus later-window rows provide the bound.

Inspect the missing coordinates of the carrier. The packet contains no quotient stream, selected representative, countable-choice schedule, trichotomy decision, host equality row, or ambient completeness theorem. Thus a downstream Real or completion consumer receives only the finite tail-bound handoff. □

Falsifiable prediction: A candidate $\mathsf{BishopRegularCauchyTailBound}^{\uparrow}$ packet fails this NameCert surface if it accepts a Real-facing tail-bound read without displayed StreamName observations, RegSeqRat readback, dyadic tolerance, shift-stable routing, tail index, later-window comparison, transport, replay, provenance, and local naming rows.

Independence witness: streamname, regseqrat, dyadicratcore, regular-cauchy-shift, real: BishopRegularCauchyT is not bijective to any listed sibling because it stores the Bishop tail-index and later-window comparison together with shift-stable routing and a Real-facing handoff, while excluding quotient streams, selected limits, countable choice, trichotomy, host real equality, and ambient completeness.

Closure status for $\mathsf{NameCert}_{\mathsf{BishopRegularCauchyTailBound}\uparrow}$.

Constructive story: A $\mathsf{BishopRegularCauchyTailBound}^{\uparrow}$ packet is generated from StreamName observations, RegSeqRat readback, a DyadicRatCore tolerance row, a RegularCauchyShift stability row, a unary tail-index row, later-window comparisons, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BishopRegularCauchyTailBound}\uparrow}, \mathsf{seed})$

Scope closed: Definition 8780.1, Definition 8780.2, and Definition 8780.3 seed the finite Bishop tail-bound packet over stream observations, regular rational readback, dyadic radii, shift-stable routing, tail indices, later-window comparisons, transport, replay, provenance, and local naming.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BishopRegularCauchyTailBound}\uparrow}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim Real completeness, countable choice, quotient stream equality, selected limits, trichotomy, host real equality, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, tail-index exposure, later-window comparison, dyadic-radius accounting, shift-stable routing, replay stability, and ledger nonescape for BEDC.Derived.BishopRegularCauchyTailBoundUp.

Chapter 8781

A Concrete Naming Certificate for $\mathsf{CauchyEntourageCompletion}^{\uparrow}$

Following Bishop and Bridges and Kelley, the $\mathsf{CauchyEntourageCompletion}^{\uparrow}$ packet names the finite L10 completion route in which Cauchy-entourage filter data, regular basis rows, uniform completion data, finite stream windows, regular rational readback, dyadic tolerances, and the terminal Real seal are displayed before any completion-facing consumer reads the packet. It sits after the Cauchy-entourage filter surface of chapter 1791, the entourage-base discipline of chapter 1819, the regular Cauchy entourage-basis packet of chapter 3805, and the uniform entourage completion boundary of chapter 8620. The packet is a displayed NameCert route for completion data; it is not a quotient filter, selected representative, selected limit, countable-choice schedule, host equality of completion points, or ambient completeness theorem for $\mathsf{Real}^{\uparrow}$.

Definition 8781.1 (Cauchy entourage completion carrier)**.** *A* $\mathsf{CauchyEntourageCompletion}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (F, B, A, U, S, R, D, E, H, C, P, N)$$

with the following displayed rows:

1. *F is the* $\mathsf{CauchyEntourageFilter}^{\uparrow}$ *source row, exposing Cauchy requests as finite entourage-filter observations before any completion read is public.*
2. *B is the* $\mathsf{EntourageBase}^{\uparrow}$ *row, naming the base entourages and refinement ledger consumed by the Cauchy request.*
3. *A is the* $\mathsf{RegularCauchyEntourageBasis}^{\uparrow}$ *row, aligning regular Cauchy windows with the displayed entourage-base generators.*
4. *U is the* $\mathsf{UniformEntourageCompletion}^{\uparrow}$ *row, recording the uniform completion handoff read downstream of F, B, A.*
5. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row shared by the source, regular basis, and uniform completion reads.*
6. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row attached to those finite windows.*
7. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger used by the entourage, regularity, and completion comparisons.*
8. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal reached only after F, B, A, U, S, R, D have been displayed.*

9. *H records componentwise* hsame *transport for the Cauchy-entourage filter, entourage base, regular basis, uniform completion, stream, readback, dyadic, Real-seal, replay, provenance, and local naming rows.*

10. *C records displayed* Cont *replay from a completion request through the route*

$$F, B, A \longmapsto U, S, R, D \longmapsto E, H, P, N.$$

11. *P is the* Pkg *provenance over* $\mathsf{CauchyEntourageCompletion}^{\uparrow}$, $\mathsf{CauchyEntourageFilter}^{\uparrow}$, $\mathsf{EntourageBase}^{\uparrow}$, $\mathsf{RegularCauchyEntourageBasis}^{\uparrow}$, $\mathsf{UniformEntourageCompletion}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* NameCert.

12. *N is the local* $\mathsf{NameCert}_{\mathsf{CauchyEntourageCompletion}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through $F, B, A, U, S, R, D, E, H, C, P, N$. It has no coordinate for quotient filters, selected representatives, selected limits, countable-choice schedules, host equality, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 8781.2 (Cauchy entourage completion NameCert obligations)**.** *For every accepted* $\mathsf{CauchyEntourageCompletion}^{\uparrow}$ *carrier $K = (F, B, A, U, S, R, D, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{CauchyEntourageCompl}}$ *surface consists exactly of carrier admission for the displayed rows, CauchyEntourageFilter source exposure through F, EntourageBase refinement exposure through B, RegularCauchyEntourageBasis alignment through A, UniformEntourageCompletion handoff through U, StreamName window preservation through S, RegSeqRat readback preservation through R, DyadicRatCore tolerance preservation through D, Real-seal preservation through E, componentwise transport through H, displayed replay through C, provenance through P, and local naming through N. No local NameCert clause is stored outside those rows.*

Proof. Project the carrier of Definition 8781.1. The projection exposes exactly the source, base, regular-basis, uniform-completion, finite-window, readback, dyadic, Real-seal, transport, replay, provenance, and local naming rows.

The source route is read first. A Cauchy-entourage request must display F, then open the base-entourage row B, and then align that base with the regular Cauchy entourage-basis row A before the uniform completion row U is available.

The L10 readback route is downstream of that source route. StreamName windows, RegSeqRat readback, and DyadicRatCore tolerances are read as the shared rows S, R, D before the terminal seal E can be consumed.

Finally attach H, C, P, N. These rows transport, replay, source, and name only the displayed packet. Since the carrier has no quotient, selected representative, selected limit, choice schedule, host-equality, or ambient completeness coordinate, the listed rows exhaust the local NameCert surface. □

Theorem 8781.3 (Cauchy entourage completion Real handoff)**.** *Every* $\mathsf{Real}^{\uparrow}$*-facing consumer of an accepted* $\mathsf{CauchyEntourageCompletion}^{\uparrow}$ *carrier factors through the finite route*

$$\mathsf{CauchyEntourageFilter}^{\uparrow},\ \mathsf{EntourageBase}^{\uparrow},\ \mathsf{RegularCauchyEntourageBasis}^{\uparrow} \longmapsto \mathsf{UniformEntourageCompletion}^{\uparrow},\ \mathsf{Strean}$$

In carrier notation, every such read passes through

$$F, B, A \longmapsto U, S, R, D \longmapsto E, H, C, P, N.$$

The handoff exports no quotient filter, selected representative, selected limit, countable-choice schedule, host equality of completed points, host Real equality, or ambient $\mathsf{Real}^{\uparrow}$ *completeness premise.*

Proof. Apply the NameCert obligation surface of Definition 8781.2. It confines every accepted Real-facing read to the displayed carrier rows.

Read the source side in row order. The Cauchy-entourage filter row F, the entourage-base row B, and the regular Cauchy entourage-basis row A must be visible before the uniform completion handoff row U can be opened.

Read the finite completion side next. The StreamName row S, RegSeqRat row R, and DyadicRatCore row D provide the common observation and tolerance route that reaches the seal row E.

The structural rows preserve this route. Componentwise hsame, displayed Cont replay, Pkg provenance, and the local NameCert row record the same finite handoff, so no omitted quotient, selector, choice, host-equality, or ambient-completeness coordinate can be introduced downstream. □

Falsifiable prediction: Every accepted $\mathsf{CauchyEntourageCompletion}^{\uparrow}$ read exposes $\mathsf{CauchyEntourageFilter}^{\uparrow}$, $\mathsf{EntourageBase}^{\uparrow}$, $\mathsf{RegularCauchyEntourageBasis}^{\uparrow}$, $\mathsf{UniformEntourageCompletion}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, Pkg, and NameCert rows before a Real-facing completion consumer can inspect the terminal seal.

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyEntourageCompletion}^{\uparrow}}$.

Constructive story: A $\mathsf{CauchyEntourageCompletion}^{\uparrow}$ packet is generated from CauchyEntourageFilterUp source data, EntourageBaseUp refinement data, RegularCauchyEntourageBasisUp alignment data, UniformEntourageCompletionUp handoff data, finite StreamNameUp windows, RegSeqRatUp readback, DyadicRatCoreUp tolerances, a RealUp seal, and structural NameCert rows.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CauchyEntourageCompletion}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8781.1, Definition 8781.2, and Definition 8781.3 seed the L10 Cauchy-entourage completion route over CauchyEntourageFilterUp, EntourageBaseUp, RegularCauchyEntourageBasisUp, UniformEntourageCompletionUp, StreamNameUp, RegSeqRatUp, DyadicRatCoreUp, RealUp, BHist, hsame, Cont, Pkg, and NameCert rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CauchyEntourageCompletion}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close Lean verification, bridge checking, quotient filters, selected representatives, selected limits, countable choice, host equality, host Real equality, or ambient RealUp completeness.

Upgrade path: Obligation closure requires checked carrier admission, Cauchy-entourage source exposure, entourage-base refinement, regular-basis alignment, uniform completion handoff, finite readback preservation, Real-seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.CauchyEntourageCompletionUp.

Chapter 8782

A Concrete Naming Certificate for $\mathsf{LocatedRealFastCauchy}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{LocatedRealFastCauchy}^{\uparrow}$ packet records the finite bridge by which located-real interval data is read as a fast Cauchy and regular-rational real name before any completion-facing consumer receives it. It sits after the Bishop located-real surface of chapter 6180, the fast sequence surface of chapter 2185, the fast real-name carrier of chapter 1589, and the two-way comparison route of chapter 1656. The packet is a finite L10 bridge from located intervals to fast and regular Cauchy readback; it is not quotient real equality, a selected representative, countable choice, trichotomy, host real equality, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 8782.1 (LocatedRealFastCauchy carrier)**.** *A* $\mathsf{LocatedRealFastCauchy}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (L, I, M, R, D, E, H, C, P, N)$$

with the following displayed rows:

1. *L is the located-real interval data row, carrying the finite interval enclosures, strict-side evidence, and located-cut requests inherited from the* $\mathsf{BishopLocatedReal}^{\uparrow}$ *surface.*
2. *I is the interval-refinement witness row, recording the finite refinement steps by which later intervals remain compatible with the earlier located enclosure.*
3. *M is the fast-Cauchy modulus row, displaying the threshold schedule that sends each requested tolerance to a finite sequence window.*
4. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row obtained from the same interval refinements and fast-Cauchy windows.*
5. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row, recording dyadic radii, comparison slack, midpoint arithmetic, and endpoint budgets used by L, I, M, R.*
6. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal handoff reached only after L, I, M, R, D have been displayed.*
7. *H records componentwise* hsame *transport for located intervals, refinements, modulus rows, readback rows, dyadic tolerances, Real seal handoff, replay, provenance, and local naming.*
8. *C records displayed* Cont *replay for every located-interval request, fast threshold request, regular readback request, and Real seal request through the same finite route.*

9. *P is the* Pkg *provenance over* $\mathsf{LocatedRealFastCauchy}^{\uparrow}$, $\mathsf{BishopLocatedReal}^{\uparrow}$, $\mathsf{FastCauchySequence}^{\uparrow}$, $\mathsf{FastCauchyReal}^{\uparrow}$, $\mathsf{FastRegularCauchyEquivalence}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

10. *N is the local* $\mathsf{NameCert}_{\mathsf{LocatedRealFastCauchy}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $L, I, M, R, D, E, H, C, P, N$. It has no coordinate for quotient stream equality, selected limits, countable-choice schedules, trichotomy, host real equality, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 8782.2 (LocatedRealFastCauchy NameCert obligations)**.** *For every accepted* $\mathsf{LocatedRealFastCauchy}^{\uparrow}$ *carrier $K = (L, I, M, R, D, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{LocatedRealFastCauchy}^{\uparrow}}$ *surface consists exactly of carrier admission, located-interval exposure, interval-refinement exposure, fast-Cauchy modulus exposure,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance accounting,* $\mathsf{Real}^{\uparrow}$ *seal handoff, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming for the displayed rows $L, I, M, R, D, E, H, C, P, N$.*

Proof. Project the accepted packet. The analytic rows are precisely L, I, M, R, D, E: located intervals first, refinement evidence next, the fast modulus route next, regular rational readback next, dyadic tolerance accounting alongside those reads, and the terminal Real seal last.

Read the sibling obligations through provenance. The row L is the located-real interface of chapter 6180; the row M is the fast sequence and fast real-name schedule visible through chapter 2185 and chapter 1589; and the row R is the regular readback disciplined by chapter 1656.

Transport, replay, provenance, and local naming do not add analytic content. The rows H, C, P, N preserve and name the same finite route, so quotient streams, selected limits, countable-choice schedules, trichotomy, host equality, and ambient completeness remain outside the local certificate. □

Theorem 8782.3 (LocatedRealFastCauchy regular readback)**.** *Every accepted* $\mathsf{LocatedRealFastCauchy}^{\uparrow}$ *carrier $K = (L, I, M, R, D, E, H, C, P, N)$ supplies a regular readback route*

$$\mathsf{BishopLocatedReal}^{\uparrow},\ \mathsf{DyadicRatCore}^{\uparrow} \longmapsto \mathsf{FastCauchySequence}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}.$$

The route reads the located interval row L, interval refinements I, fast threshold row M, dyadic tolerance row D, regular readback row R, and terminal seal E before any Real-facing or completion-facing consumer may inspect the packet. It supplies no detached uniform limit, quotient stream, selected representative, countable-choice schedule, trichotomy decision, host equality, or ambient $\mathsf{Real}^{\uparrow}$ *completeness theorem.*

Proof. Begin with the located row L and refinement row I. These rows display the finite interval enclosures and the refinement witnesses that keep later precision requests attached to the same located-real surface.

Use the fast row M and the tolerance row D. A requested precision is routed to a finite sequence window and dyadic comparison budget before any regular rational readback can be consumed.

Read R and then E. The $\mathsf{RegSeqRat}^{\uparrow}$ row is downstream of the same located, refinement, fast, and dyadic rows, and the $\mathsf{Real}^{\uparrow}$ seal is terminal with respect to that route. Componentwise transport and replay preserve these rows, while provenance and local naming bind the packet without adding any detached limit, quotient stream, selected representative, choice schedule, trichotomy decision, host equality, or ambient completeness coordinate. □

Closure status for $\mathsf{NameCert}_{\mathsf{LocatedRealFastCauchy}^{\uparrow}}$.

Constructive story: A $\mathsf{LocatedRealFastCauchy}^{\uparrow}$ packet is generated from located-real interval data, interval-refinement witnesses, fast-Cauchy modulus rows, RegSeqRat readback, DyadicRatCore tolerance rows, a RealUp seal handoff, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{LocatedRealFastCauchy}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8782.1, Definition 8782.2, and Definition 8782.3 seed the located-real to fast-Cauchy and regular-readback bridge over finite L10 rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{LocatedRealFastCauchy}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient real equality, selected representatives, countable choice, trichotomy, host real equality, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, located-interval exposure, interval-refinement exactness, fast-modulus exposure, RegSeqRat readback, DyadicRatCore tolerance accounting, Real seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.LocatedRealFastCauchyUp.

Chapter 8783

A Concrete Naming Certificate for $\mathsf{SequentialPrecompact}^{\uparrow}$

Following Bishop and Bridges, sequential precompactness is witnessed by finite nets and regular readback windows rather than by selected convergent subsequences or completed quotient streams. The $\mathsf{SequentialPrecompact}^{\uparrow}$ packet sits after the finite density-net route of chapter 6003, the dyadic interval net surface of chapter 5966, the stream-window interface of chapter 126, the regular rational readback of chapter 301, and the terminal real-name seal of chapter 38. It gives L10 compactness and completion consumers a finite inspection route for a displayed sequence source; it is not open-cover compactness, countable choice, selected subsequence extraction, quotient stream equality, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 8783.1 (Sequential precompact carrier)**.** *A* $\mathsf{SequentialPrecompact}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Q = (X, N, S, R, E, H, C, P, L)$$

with the following displayed rows:

1. *X is the displayed sequence source row, naming the finite observation interface through which a consumer asks for sequence data.*
2. *N is the finite-net extractor row, read through* $\mathsf{FiniteCauchyDensityNet}^{\uparrow}$ *and* $\mathsf{DyadicIntervalNet}^{\uparrow}$ *before any completion-facing density claim is exposed.*
3. *S is the* $\mathsf{StreamName}^{\uparrow}$ *window row, recording the inspected finite prefixes of the displayed sequence source and net cells.*
4. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row obtained only after the finite window and dyadic tolerance data have been displayed.*
5. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row for real-facing consumers of the finite-net readback.*
6. *H records componentwise* hsame *transport for sequence source, finite net, windows, readback, seal, replay, provenance, and local name.*
7. *C records displayed* Cont *replay from a sequential-precompactness request through X, N, S, R, E, H, P, L.*
8. *P is the* Pkg *provenance over* $\mathsf{SequentialPrecompact}^{\uparrow}$, $\mathsf{FiniteCauchyDensityNet}^{\uparrow}$, $\mathsf{DyadicIntervalNet}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$ *rows.*
9. *L is the local* $\mathsf{NameCert}_{\mathsf{SequentialPrecompact}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $X, N, S, R, E, H, C, P, L$. It has no coordinate for quotient streams, selected subsequences, countable choice, open-cover compactness, host sequence equality, or a general completeness theorem for $\mathsf{Real}^{\uparrow}$.

Theorem 8783.2 (Sequential precompact NameCert obligations)**.** *For every accepted* $\mathsf{SequentialPrecompact}^{\uparrow}$ *carrier $Q = (X, N, S, R, E, H, C, P, L)$, the local* $\mathsf{NameCert}_{\mathsf{SequentialPrecompact}^{\uparrow}}$ *surface consists exactly of sequence-source admission, finite-net extraction, StreamName window display, RegSeqRat readback, terminal Real seal, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. No obligation is stored outside those finite rows.*

Proof. Project the carrier of Definition 8783.1. The displayed packet has exactly the rows $X, N, S, R, E, H, C, P, L$, so carrier admission and local naming must be read from those rows.

The sequence source row X supplies only inspected sequence data. The finite-net row N supplies the finite density and dyadic-cell route, while S and R record the finite window and regular rational readback through which the sequence is compared to those cells.

The terminal seal E is downstream of the net, window, and readback rows. The rows H, C, P, L preserve, replay, source, and name the same finite route. Since the carrier has no further coordinate, selected subsequences, quotient stream equality, countable choice, open-cover compactness, and ambient completeness cannot become local certificate obligations. □

Theorem 8783.3 (Sequential precompact finite-net handoff)**.** *Every completion-facing consumer of an accepted* $\mathsf{SequentialPrecompact}^{\uparrow}$ *packet reads the finite-net row N through chapter 6003 and the dyadic interval cell surface of chapter 5966 before it consumes the* $\mathsf{StreamName}^{\uparrow}$ *window row,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row, or terminal* $\mathsf{Real}^{\uparrow}$ *seal. The handoff is the displayed route*

$$X, N \longmapsto S \longmapsto R \longmapsto E \longmapsto H, C, P, L.$$

It exports finite dyadic density rows for L10 completion consumers, not quotient streams, selected subsequences, countable choice, open-cover compactness, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start with the NameCert obligations of Definition 8783.2. They force the consumer to expose the sequence source, finite net, stream window, readback, and seal rows in the same accepted packet.

Next read N through the finite density-net and dyadic interval-net sibling chapters. The density route supplies the finite Cauchy density witness, and the dyadic interval-net route supplies the finite cell and endpoint-incidence surface used by the requested tolerance.

Finally use the carrier exhaustion in Definition 8783.1. The packet has no row for selected subsequence extraction, quotient stream representatives, countable-choice schedules, open-cover compactness, or ambient completeness. Thus the completion-facing handoff is exactly the displayed finite-net route into S, R, E, H, C, P, L. □

Closure status for $\mathsf{NameCert}_{\mathsf{SequentialPrecompact}^{\uparrow}}$**.**

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{SequentialPrecompact}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8783.1, Definition 8783.2, and Definition 8783.3 seed the displayed finite-net route from a sequence source to StreamName windows, RegSeqRat readback, and the terminal RealUp seal.

Constructive story: A $\mathsf{SequentialPrecompact}^{\uparrow}$ packet is generated from a displayed sequence source row, finite density-net and dyadic-cell rows, StreamName finite windows, RegSeqRat readback, a terminal RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{SequentialPrecompact}^{\uparrow}}, \mathsf{unformalized})$

Lean target: `BEDC.Derived.SequentialPrecompactUp`

Bridge status: none

Not claimed: This chapter does not close quotient streams, selected subsequences, countable choice, open-cover compactness, ambient $\mathrm{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked sequence-source admission, finite-net extraction, dyadic-cell handoff, StreamName window coverage, RegSeqRat readback, Real seal ordering, transport, replay, provenance, and local naming for BEDC.Derived.SequentialPrecompactUp.

Chapter 8784

A Concrete Naming Certificate for $\mathsf{BaireCategoryCompactMetric}^{\uparrow}$

Following Baire, Oxtoby, and Kelley, the $\mathsf{BaireCategoryCompactMetric}^{\uparrow}$ packet records the finite compact-metric route by which a dense-open schedule is read as an input surface for the complete-metric Baire theorem. It sits between the Baire category theorem of chapter 1542, the complete-metric Baire surface of chapter 3535, the compact-metric carrier of chapter 129, the stream-window surface of chapter 126, the regular rational readback of chapter 301, and the terminal real-name seal of chapter 38. The packet names only the displayed finite bridge from compact-metric data to the complete-metric Baire route; it does not claim countable choice, a host intersection point, open-cover compactness, quotient equality, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 8784.1 (Baire category compact metric carrier)**.** *A* $\mathsf{BaireCategoryCompactMetric}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (D, F, B, S, Q, E, H, C, P, N)$$

with the following displayed rows:

1. *D is the dense-open schedule row, listing the finite prefix of dense-open tests consumed by the Baire read.*
2. *F is the compact-metric finite-net source row, read through the* $\mathsf{CompactMetric}^{\uparrow}$ *carrier of chapter 129.*
3. *B is the* $\mathsf{CompleteMetricBaireSurface}^{\uparrow}$ *inspection row, exposing the complete-metric Baire route of chapter 3535 only after D and F are displayed.*
4. *S is the* $\mathsf{StreamName}^{\uparrow}$ *window row controlling the finite schedule prefix inspected by the consumer.*
5. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the rational tolerances and window bounds attached to S.*
6. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached from the regular rational readback.*
7. *H records componentwise* hsame *transport for the schedule, compact-metric source, Baire inspection, stream window, regular readback, Real seal, replay, provenance, and local naming.*
8. *C records displayed* Cont *replay from the dense-open schedule and compact finite-net source through the complete-metric Baire inspection row.*
9. *P is the* Pkg *provenance over* $\mathsf{BaireCategoryCompactMetric}^{\uparrow}$, $\mathsf{BaireCategoryTheorem}^{\uparrow}$, $\mathsf{CompleteMetricBaireSurfac}$ $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$ *rows.*

10. N is the local $\mathsf{NameCert}_{\mathsf{BaireCategoryCompactMetric}^{\uparrow}}$ *row.*
The classifier compares accepted packets only through $D, F, B, S, Q, E, H, C, P, N$. It has no coordinate for countable choice, a host intersection witness, open-cover compactness, quotient equality, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 8784.2 (BaireCategoryCompactMetric NameCert obligations)**.** *For every accepted* BaireCategoryCompac *carrier*

$$K = (D, F, B, S, Q, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{BaireCategoryCompactMetric}^{\uparrow}}$ *surface consists exactly of dense-open schedule admission for D, compact-metric finite-net source admission for F,* $\mathsf{CompleteMetricBaireSurface}^{\uparrow}$ *inspection for B,* $\mathsf{StreamName}^{\uparrow}$ *finite-window exposure for S,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback for Q,* $\mathsf{Real}^{\uparrow}$ *sealing for E, componentwise* hsame *transport through H, displayed* Cont *replay through C, sibling provenance through P, and local naming through N.*

No Baire category compact-metric obligation is stored outside these rows.

Proof. Project the accepted carrier. The dense-open schedule D and compact-metric finite-net source F are the only inputs available to the packet, and the complete-metric Baire inspection row B is read only after both rows are displayed.

The finite-window and rational readback rows S and Q then expose the inspected prefix and its tolerance data before the terminal Real seal E is consumed. This is a finite compact-metric route, not a selected point of the full intersection.

Finally H, C, P, N transport, replay, source, and name the same route. Since the carrier contains no row for countable choice, host intersection, open-cover compactness, quotient equality, or ambient completeness, the listed rows exhaust the local NameCert obligations. □

Theorem 8784.3 (BaireCategoryCompactMetric route)**.** *Every consumer that reads a compact-metric Baire handoff from an accepted* $\mathsf{BaireCategoryCompactMetric}^{\uparrow}$ *carrier must factor the read through*

$$D, F, B, S, Q, E, H, C, P, N.$$

The handoff reaches the $\mathsf{BaireCategoryTheorem}^{\uparrow}$ *surface of chapter 1542 only through the* CompleteMetricBaireSurfac *inspection row, after the compact-metric finite-net source, stream window, regular rational readback, and Real seal have all been displayed. It exports no countable-choice schedule, host intersection point, open-cover compactness theorem, quotient equality, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness principle.*

Proof. Start with the carrier of Definition 8784.1. It fixes the public compact-metric Baire packet as the rows $D, F, B, S, Q, E, H, C, P, N$ and gives no consumer a separate complete-metric or Real-facing coordinate.

Apply the NameCert obligations of Definition 8784.2. They require the dense-open schedule, compact finite-net source, complete-metric Baire inspection, stream window, rational readback, and Real seal to be displayed in that order before the local name row is consumed.

The structural rows then preserve the same route under hsame transport, Cont replay, and Pkg provenance. Thus the compact-metric Baire handoff is a finite bridge into the complete-metric Baire route, not an assertion of countable choice, host intersection, open-cover compactness, quotient equality, or ambient completeness. □

Closure status for $\mathsf{NameCert}_{\mathsf{BaireCategoryCompactMetric}^{\uparrow}}$.

Constructive story: A $\mathsf{BaireCategoryCompactMetric}^{\uparrow}$ packet is generated from a dense-open schedule row, a compact-metric finite-net source row, a CompleteMetricBaireSurface inspection row, a StreamName window row, a RegSeqRat

readback row, a Real seal row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\text{BaireCategoryCompactMetric}\uparrow}$, seed)

Scope closed: Definition 8784.1, Definition 8784.2, and Definition 8784.3 seed the finite compact-metric Baire handoff through dense-open schedules, finite nets, complete-metric Baire inspection, stream windows, rational readback, Real sealing, transport, replay, provenance, and local naming.

Formal verification: FormalStatus(NameCert$_{\text{BaireCategoryCompactMetric}\uparrow}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim countable choice, a host intersection point, open-cover compactness, quotient equality, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked dense-open schedule admission, compact-metric finite-net admission, complete-metric Baire inspection, stream-window exposure, regular rational readback, Real sealing, transport stability, replay stability, provenance, and non-escape for BEDC.Derived.BaireCategoryCompactMetricUp.

Chapter 8785

A Concrete Naming Certificate for $\mathsf{IwasawaDecomposition}^{\uparrow}$

Following Iwasawa and standard Lie group theory, the $\mathsf{IwasawaDecomposition}^{\uparrow}$ packet records the KAN factorization surface as finite NameCert data rather than as an ambient global analytic theorem. It sits beside the Cartan decomposition of chapter 7926, the Lie-group carrier of chapter 140, the Lie-algebra carrier of chapter 141, the matrix readback of chapter 49, and the underlying group route of chapter 41. The chapter names only the displayed compact, abelian, nilpotent, multiplication, factorization, transport, replay, provenance, and local naming rows.

Definition 8785.1 (Iwasawa decomposition carrier)**.** *An* $\mathsf{IwasawaDecomposition}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$I = (G, K, A, N, M, F, H, C, P, L)$$

with the following displayed rows:

1. *G is the* $\mathsf{LieGroup}^{\uparrow}$ *source row, read through the underlying* $\mathsf{Group}^{\uparrow}$ *multiplication route and, when a matrix presentation is displayed, through the* $\mathsf{Mat}^{\uparrow}$ *readback row.*
2. *K is the compact factor row, recording the subgroup surface consumed from the Cartan-side compact data.*
3. *A is the abelian factor row, recording the displayed split abelian direction read from the Lie-algebra and Cartan rows.*
4. *N is the nilpotent factor row, recording the displayed nilpotent direction read from the same Lie-algebra source.*
5. *M is the multiplication route row, recording the ordered product read $K \times A \times N \to G$ using only the visible* $\mathsf{Group}^{\uparrow}$ *multiplication coordinates.*
6. *F is the factorization witness row, recording that the currently accepted source element of G is reached by the displayed K, A, N entries through M.*
7. *H stores componentwise* hsame *transport for the group source, compact factor, abelian factor, nilpotent factor, multiplication route, factorization witness, replay, provenance, and local naming rows.*
8. *C stores displayed* Cont *replay from an Iwasawa-decomposition request through G, K, A, N, M, F, H.*
9. *P is the* Pkg *provenance over* $\mathsf{IwasawaDecomposition}^{\uparrow}$, $\mathsf{CartanDecomposition}^{\uparrow}$, $\mathsf{LieGroup}^{\uparrow}$, $\mathsf{LieAlgebra}^{\uparrow}$, $\mathsf{Mat}^{\uparrow}$, $\mathsf{Group}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.

10. L is the local $\mathsf{NameCert}_{\mathsf{IwasawaDecomposition}^{\uparrow}}$ *row.*
The classifier compares accepted packets only through $G, K, A, N, M, F, H, C, P, L$. It has no coordinate for global Lie theory, Haar measure, selected analytic coordinates, quotient equality, or ambient smooth manifold completeness.

Theorem 8785.2 (Iwasawa decomposition NameCert obligations)**.** *For an accepted* $\mathsf{IwasawaDecomposition}^{\uparrow}$ *packet*

$$I = (G, K, A, N, M, F, H, C, P, L),$$

the local $\mathsf{NameCert}_{\mathsf{IwasawaDecomposition}^{\uparrow}}$ *surface is exhausted by the source group row, compact factor row, abelian factor row, nilpotent factor row, multiplication route, factorization witness, componentwise transport, replay, provenance, and local naming. Every accepted read is confined to the displayed route*

$$G, K, A, N, M, F, H, C, P, L.$$

Proof. Project the carrier of Definition 8785.1. The only group-facing source is G, and the only factor rows available to a consumer are K, A, N.

The multiplication and factorization obligations are carried by M and F. They record the ordered product route and the witness that the displayed source element is read through that route.

The structural rows H, C, P, L preserve the same finite packet under transport, replay, provenance, and local naming. Since no global analytic or quotient coordinate is present, the listed rows exhaust the local NameCert obligations. □

Theorem 8785.3 (Iwasawa decomposition KAN route)**.** *Every KAN read from an accepted* $\mathsf{IwasawaDecomposition}^{\uparrow}$ *packet must pass through the Cartan-side compact data, the Lie-algebra abelian and nilpotent directions, the underlying* $\mathsf{Group}^{\uparrow}$ *multiplication route, and any displayed* $\mathsf{Mat}^{\uparrow}$ *readback before the local* $\mathsf{IwasawaDecomposition}^{\uparrow}$ *name is consumed. The public route is the finite packet*

$$K, A, N \xrightarrow{M} G \longmapsto L$$

together with F, H, C, P.

Proof. Start with the factor rows K, A, N. The compact row is sourced through the Cartan decomposition, while the abelian and nilpotent rows are read from the displayed Lie-algebra source.

Next use the multiplication row M. It is the only route in the carrier from the ordered factor rows into the source group G, and it reads the underlying group operation rather than an external analytic product theorem.

Finally apply F, H, C, P, L. The factorization witness, transport, replay, provenance, and local name rows keep the same KAN route visible, so a consumer cannot skip directly from the source group to a local Iwasawa name. □

Theorem 8785.4 (Iwasawa decomposition nonescape)**.** *No accepted* $\mathsf{IwasawaDecomposition}^{\uparrow}$ *read can escape the finite rows of Definition 8785.1. In particular, the packet does not export global Lie theory, Haar measure, selected analytic coordinates, quotient equality, or ambient smooth manifold completeness from the existence of a displayed KAN factorization route.*

Proof. Inspect the carrier coordinates. They name the source group, three factor rows, multiplication, factorization, transport, replay, provenance, and local NameCert row.

Each excluded object would require an additional coordinate: global Lie theory would need a separate theorem surface, Haar measure a measure row, analytic coordinates a chart-selection row, quotient equality a quotient carrier, and ambient smooth manifold completeness a completion row.

Because none of those coordinates is part of the accepted packet, every consumer remains inside the finite KAN route displayed by $G, K, A, N, M, F, H, C, P, L$. □

Falsifiable prediction: An accepted $\mathsf{IwasawaDecomposition}^{\uparrow}$ consumer is refuted if it reaches a local KAN name without first displaying the LieGroupUp source row, compact factor, abelian factor, nilpotent factor, multiplication route, factorization witness, transport, replay, provenance, and local NameCert rows.

Independence witness: cartandecomposition, liegroup, liealgebra, matrix, group: none is bijective to IwasawaDecompositionUp because only the Iwasawa decomposition packet jointly carries the compact factor, abelian factor, nilpotent factor, ordered multiplication route, factorization witness, transport, replay, provenance, and local NameCert rows.

Closure status for $\mathsf{NameCert}_{\mathsf{IwasawaDecomposition}^{\uparrow}}$.

Constructive story: An $\mathsf{IwasawaDecomposition}^{\uparrow}$ packet is generated from a LieGroup source row, compact factor row, abelian factor row, nilpotent factor row, displayed multiplication route, factorization witness, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{IwasawaDecomposition}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8785.1, Definition 8785.2, Definition 8785.3, and Definition 8785.4 seed the finite KAN packet over CartanDecompositionUp, LieGroupUp, LieAlgebraUp, MatrixUp, GroupUp, BHist, hsame, Cont, Pkg, and NameCert rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{IwasawaDecomposition}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close global Lie theory, Haar measure, selected analytic coordinates, quotient equality, ambient smooth manifold completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, KAN route exactness, factorization witness preservation, transport, replay, provenance, and local naming for BEDC.Derived.IwasawaDecompositionUp.

Chapter 8786

A Concrete Naming Certificate for $\mathsf{LocatedLimitOperator}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{LocatedLimitOperator}^{\uparrow}$ packet records the finite operator surface that turns located nested-interval or regular Cauchy evidence into a $\mathsf{Real}^{\uparrow}$-facing limit handoff. It sits after the located nested-interval route of chapter 1713, the retained interval source of chapter 320, the dyadic tolerance core of chapter 291, the finite window surface of chapter 126, the regular rational readback of chapter 301, and the terminal real-name seal of chapter 38. The packet names the finite handoff route only: it does not assert ambient completeness, quotient equality, trichotomy, countable choice, or a selected host limit.

Definition 8786.1 (Located limit-operator carrier)**.** *A* $\mathsf{LocatedLimitOperator}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (I, J, D, W, Q, R, A, H, C, P, N)$$

with the following displayed rows:

1. *I is the source* $\mathsf{NestedInterval}^{\uparrow}$ *row, exposing the retained nested interval evidence.*
2. *J is the* $\mathsf{LocatedRealNestedIntervals}^{\uparrow}$ *handoff row, recording the located containment and diameter route used by the source.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger for endpoint widths, requested precisions, and rational enclosure checks.*
4. *W is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row selected by each precision request.*
5. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row extracted from the displayed finite windows and dyadic tolerances.*
6. *R is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row that may be consumed only after I, J, D, W, Q have been displayed.*
7. *A is the operator-admission row, recording that the input route I, J, D, W, Q has been assembled before the Real-facing handoff R.*
8. *H records componentwise* hsame *transport for $I, J, D, W, Q, R, A, C, P, N$.*
9. *C records displayed* Cont *replay from a precision request through the nested interval, window, readback, and seal rows.*

10. *P is the* Pkg *provenance over* $\mathsf{LocatedLimitOperator}^{\uparrow}$, $\mathsf{NestedInterval}^{\uparrow}$, $\mathsf{LocatedRealNestedIntervals}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{LocatedLimitOperator}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $I, J, D, W, Q, R, A, H, C, P, N$. It has no coordinate for host completeness, quotient representatives, exact trichotomy, countable choice, or a selected limit outside the displayed rows.

Theorem 8786.2 (Located limit-operator NameCert obligations)**.** *For every accepted* $\mathsf{LocatedLimitOperator}^{\uparrow}$ *carrier $L = (I, J, D, W, Q, R, A, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{LocatedLimitOperator}^{\uparrow}}$ *surface consists exactly of carrier admission for the nested interval row I, located nested-interval handoff J, dyadic tolerance ledger D, finite window row W, regular rational readback Q, terminal Real seal R, operator-admission row A, componentwise* hsame *transport H, displayed* Cont *replay C,* Pkg *provenance P, and local naming N.*

Proof. Project the carrier of Definition 8786.1. The rows I, J, D, W, Q expose the input evidence from retained nested intervals to regular rational readback, and R is the only Real-facing row.

The operator-admission row A records that the displayed input route has already been assembled before R is consumed. Transport and replay through H and C preserve the same rows and cannot add a hidden selected point or quotient representative.

Finally, provenance and naming through P, N bind the packet to the sibling surfaces cited above. Since no excluded coordinate is present in the carrier, the listed rows exhaust the local NameCert obligations. □

Theorem 8786.3 (Located limit-operator L10 handoff)**.** *Every L10 Real or Completion consumer of an accepted* $\mathsf{LocatedLimitOperator}^{\uparrow}$ *carrier receives its limit handoff only through the finite route*

$$\mathsf{NestedInterval}^{\uparrow},\ \mathsf{LocatedRealNestedIntervals}^{\uparrow},\ \mathsf{DyadicRatCore}^{\uparrow},\ \mathsf{StreamName}^{\uparrow},\ \mathsf{RegSeqRat}^{\uparrow},\ \mathsf{Real}^{\uparrow}.$$

The handoff exports a displayed Real-facing seal after finite windows and dyadic tolerances have been read; it exports no completeness principle, quotient equality, trichotomy, countable-choice schedule, or selected host limit.

Proof. Read the route from the input side. The $\mathsf{NestedInterval}^{\uparrow}$ row supplies retained interval evidence, and chapter 1713 supplies the located nested-interval handoff that turns that evidence into finite window requests.

The dyadic, stream, and regular rational rows then provide the inspected tolerance ledger, finite windows, and readback data. These rows are the same Real-facing corridor used by chapter 301 before the terminal $\mathsf{Real}^{\uparrow}$ seal may be consumed.

Thus the operator is a finite handoff surface, not a selector. Any consumer that skips one of these rows leaves the accepted $\mathsf{LocatedLimitOperator}^{\uparrow}$ packet. □

Falsifiable prediction: Every accepted $\mathsf{LocatedLimitOperator}^{\uparrow}$ read exposes NestedInterval, LocatedRealNestedIntervals, DyadicRatCore, StreamName, RegSeqRat, Real, operator-admission, transport, replay, provenance, and local NameCert rows before a Real or Completion consumer receives the handoff.

Independence witness: nestedinterval, locatedrealnestedintervals, dyadicratcore, streamname, regseqrat, real: $\mathsf{LocatedLimitOperator}^{\uparrow}$ is not bijective to any listed sibling because it binds all six rows into one operator-admission packet while refusing host completeness, quotient equality, trichotomy, choice, and selected limits.

Closure status for $\mathsf{NameCert}_{\mathsf{LocatedLimitOperator}\uparrow}$.

Constructive story: A $\mathsf{LocatedLimitOperator}^{\uparrow}$ packet is generated from a NestedInterval row, a LocatedRealNestedIntervals handoff row, a DyadicRatCore tolerance ledger, StreamName finite windows, RegSeqRat readback, a Real seal, operator admission, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{LocatedLimitOperator}\uparrow}, \mathsf{seed})$

Scope closed: Definition 8786.1, Definition 8786.2, and Definition 8786.3 seed the finite operator surface from located nested-interval evidence to a Real-facing handoff.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{LocatedLimitOperator}\uparrow}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim ambient completeness, quotient equality, trichotomy, countable choice, selected host limits, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, nested-interval exposure, located nested-interval handoff, dyadic tolerance coverage, finite window readback, Real seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.LocatedLimitOperatorUp.

Chapter 8787

A Concrete Naming Certificate for $\mathsf{BishopRealInterval}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{BishopRealInterval}^{\uparrow}$ packet records a constructive closed real interval as finite endpoint and regularity data rather than as a classical subset of a completed line. It sits after the dyadic rational arithmetic of chapter 291, the finite stream-window interface of chapter 126, the regular rational readback of chapter 301, and the terminal real-name seal of chapter 38. The packet gives L10 Real and Completion consumers an endpoint-bounded enclosure route without claiming Heine–Borel compactness, quotient real equality, selected representatives, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 8787.1 (BishopRealInterval carrier)**.** *A* $\mathsf{BishopRealInterval}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$I = (L, U, T, Q, D, E, H, C, P, N)$$

with the following rows:

1. *L is the lower endpoint row, displayed as a regular rational name and sealed only through the terminal real-name route.*
2. *U is the upper endpoint row, displayed as a regular rational name with the same endpoint discipline.*
3. *T is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row used to inspect both endpoint names at requested precisions.*
4. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the endpoint regular sequences.*
5. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance and comparison row recording the finite dyadic scale at which L is below U.*
6. *E is the* $\mathsf{Real}^{\uparrow}$ *enclosure seal available only after the endpoint windows, regular readbacks, and dyadic comparison row have been displayed.*
7. *H records componentwise* hsame *transport for the endpoint, stream, readback, dyadic, seal, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from an interval-enclosure request through the same endpoint and tolerance rows.*
9. *P is the* Pkg *provenance over* $\mathsf{BishopRealInterval}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*

10. N is the local $\mathsf{NameCert}_{\mathsf{BishopRealInterval}^{\uparrow}}$ *row.*
The carrier has no coordinate for classical interval subsets, quotient real equality, selected endpoint representatives, Heine–Borel compactness, countable choice, or ambient completeness of $\mathsf{Real}^{\uparrow}$.

Theorem 8787.2 (BishopRealInterval NameCert obligations)**.** *For every accepted* $\mathsf{BishopRealInterval}^{\uparrow}$ *carrier* $I = (L, U, T, Q, D, E, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{BishopRealInterval}^{\uparrow}}$ *surface consists exactly of lower endpoint admission through* L*, upper endpoint admission through* U*, finite endpoint-window exposure through* T*, regular rational readback through* Q*, dyadic tolerance and order comparison through* D*, real-enclosure sealing through* E*, componentwise* hsame *stability through* H*, displayed* Cont *replay through* C*,* Pkg *provenance through* P*, and local naming through* N*. A consumer therefore reads the interval only through the finite route*

$$L, U, T, Q, D \longmapsto E, H, C, P, N.$$

Proof. Project the carrier of Definition 8787.1. The endpoint rows L and U are not host real numbers; they are displayed regular names whose finite prefixes are exposed by the shared $\mathsf{StreamName}^{\uparrow}$ row T.

Use the $\mathsf{RegSeqRat}^{\uparrow}$ readback row Q and the $\mathsf{DyadicRatCore}^{\uparrow}$ comparison row D. These rows supply the regular-sequence and dyadic-order evidence before the interval can be treated as a Real-facing enclosure.

Finally replay the structural rows. The seal E, transport H, continuation replay C, provenance P, and local name N preserve the same finite endpoint packet, so the NameCert surface cannot import quotient equality of reals, selected representatives, Heine–Borel compactness, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness. □

Theorem 8787.3 (BishopRealInterval regular seal route)**.** *Every* $\mathsf{Real}^{\uparrow}$*-readable enclosure request accepted by a* $\mathsf{BishopRealInterval}^{\uparrow}$ *carrier factors through the displayed route*

$$\mathsf{StreamName}^{\uparrow},\ \mathsf{RegSeqRat}^{\uparrow},\ \mathsf{DyadicRatCore}^{\uparrow} \longrightarrow \mathsf{Real}^{\uparrow}.$$

Equivalently, the endpoint classifier reads finite stream windows, regular rational endpoint readback, and dyadic tolerance comparison before the terminal Real seal is public. The route is an L10 completion interface over chapter 301 and chapter 38, not a classical interval subset or an ambient completeness principle.

Proof. Start with the NameCert obligations of Definition 8787.2. They require endpoint admission, stream-window exposure, regular rational readback, and dyadic comparison before any Real-facing interval seal can be consumed.

Read the endpoint rows through the sibling $\mathsf{StreamName}^{\uparrow}$ and $\mathsf{RegSeqRat}^{\uparrow}$ routes. The stream row exposes only finite endpoint prefixes, while the regular rational row supplies the endpoint readback used by completion consumers.

Now apply the dyadic comparison row D. Its finite tolerance ledger is the boundary at which the lower and upper endpoint names become an interval enclosure rather than two unrelated real-name seals.

Finally consume E, H, C, P, N. The terminal $\mathsf{Real}^{\uparrow}$ seal is reached only after those displayed rows remain visible, so the route supplies a constructive interval enclosure without selected endpoint representatives, quotient real equality, countable choice, Heine–Borel compactness, or ambient completeness. □

Closure status for $\mathsf{NameCert}_{\mathsf{BishopRealInterval}^{\uparrow}}$.

Constructive story: A $\mathsf{BishopRealInterval}^{\uparrow}$ packet is generated from lower and upper endpoint rows, finite StreamName endpoint windows, RegSeqRat endpoint readback, DyadicRatCore tolerance comparison, a Real enclosure seal, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BishopRealInterval}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8787.1, Definition 8787.2, and Definition 8787.3 seed the endpoint-bounded interval route over StreamName, RegSeqRat, DyadicRatCore, Real, transport, replay, provenance, and local naming rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BishopRealInterval}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close classical interval subsets, quotient real equality, selected endpoint representatives, Heine–Borel compactness, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked endpoint carrier admission, finite endpoint-window routing, regular rational readback, dyadic endpoint comparison, Real enclosure sealing, and structural nonescape for BEDC.Derived.BishopRealIntervalUp.

Chapter 8788

A Concrete Naming Certificate for TubeLemmaFiniteProduct$^{\uparrow}$

Following Munkres and Kelley on product topology, compact fibres, and the tube lemma, the TubeLemmaFiniteProduct$^{\uparrow}$ packet records the finite product form of the tube-neighbourhood argument. It refines the one-slice tube packet of chapter 3861 through the finite-product topology certificate of chapter 2000, the compact-row surface of chapter 60, the generated-open topology rows of chapter 88, and the finite-cover refinement route of chapter 3430. The chapter names only the finite product tube carrier and its local obligations; it does not assert arbitrary product compactness, countable products, quotient equality of product points, selected neighbourhood bases, or an ambient open-cover theorem outside the displayed finite rows.

Definition 8788.1 (Finite product tube lemma carrier)**.** *A* TubeLemmaFiniteProduct$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$T_{\mathrm{fin}} = (I, X, K, O, U, V, F, R, H, C, P, N)$$

with the following displayed rows:

1. *I is the finite index row naming the product coordinates used by the argument.*
2. *X is the finite family of* Topology$^{\uparrow}$ *rows indexed by I.*
3. *K is the finite family of* Compact$^{\uparrow}$ *slice rows for the compact coordinates.*
4. *O is the* ProductTopology$^{\uparrow}$ *open-neighbourhood row containing the displayed compact product slice.*
5. *U is the finite family of coordinate product-neighbourhood rows read from O.*
6. *V is the resulting finite tube-neighbourhood row in the remaining product coordinates.*
7. *F is the finite-cover-refinement row that extracts one displayed tube from the coordinate neighbourhood family.*
8. *R records the route back to the ordinary* TubeLemma$^{\uparrow}$ *slice packet for each exposed coordinate fibre.*
9. *H records componentwise* hsame *transport for the finite index, topology rows, compact rows, product-open row, coordinate neighbourhood family, tube row, finite-cover row, slice route, replay, provenance, and local name.*
10. *C records displayed* Cont *replay from a finite product-neighbourhood request through $I, X, K, O, U, V, F, R, H, P, N$*

11. *P is the* Pkg *provenance over* TubeLemmaFiniteProduct$^{\uparrow}$, TubeLemma$^{\uparrow}$, ProductTopology$^{\uparrow}$, Topology$^{\uparrow}$, Compact$^{\uparrow}$, FiniteCoverRefinement$^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* NameCert.
12. *N is the local* NameCert$_{\text{TubeLemmaFiniteProduct}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $I, X, K, O, U, V, F, R, H, C, P, N$. It has no coordinate for countable products, arbitrary product compactness, quotient equality of product points, selected bases, or a detached ambient open-cover selector.

Lean4 (definition) `BEDC.Derived.TubeLemmaFiniteProductUp`

Theorem 8788.2 (Finite product tube lemma NameCert obligations)**.** *For every accepted* TubeLemmaFiniteProduc *carrier $T_{\text{fin}} = (I, X, K, O, U, V, F, R, H, C, P, N)$, the local* NameCert$_{\text{TubeLemmaFiniteProduct}^{\uparrow}}$ *surface is exhausted by finite-index admission, topology-row exposure for the indexed factors, compact-slice exposure through K, product-open exposure through O, coordinate product-neighbourhood exposure through U, tube-neighbourhood exposure through V, finite-cover refinement through F, coordinatewise routing through R to* TubeLemma$^{\uparrow}$*, componentwise* hsame *transport through H, displayed* Cont *replay through C,* Pkg *provenance through P, and local naming through N.*

Proof. Project the carrier of Definition 8788.1. The finite index row I bounds the product coordinates, while X and K expose only the displayed topology rows and compact slice rows attached to those coordinates.

The product-neighbourhood data then pass through O, U, V, F. The row O supplies the finite product-open neighbourhood, U records the coordinate neighbourhood family read from it, F records the finite-cover refinement, and V is the resulting tube-neighbourhood row.

Finally the route R reuses the ordinary tube packet coordinatewise, and H, C, P, N preserve the same finite data under transport, replay, provenance, and naming. Since no carrier coordinate names countable products, arbitrary product compactness, quotient product equality, selected bases, or a detached open-cover selector, the listed rows exhaust the local NameCert obligations. □

Theorem 8788.3 (Finite product compact route)**.** *Every accepted* TubeLemmaFiniteProduct$^{\uparrow}$ *carrier routes a compact finite product slice through the displayed chain*

$$I, X, K \longmapsto O \longmapsto U \longmapsto F \longmapsto V \longmapsto R.$$

Thus a downstream compact-product or uniform-continuity consumer must first inspect the finite index row, the factor topology rows, the compact slice rows, the product-open row, the coordinate neighbourhood family, the finite-cover refinement row, and the coordinatewise TubeLemma$^{\uparrow}$ *route before it can read the finite tube neighbourhood.*

Proof. The carrier projection supplies the finite source rows I, X, K. These rows determine which coordinates participate in the compact product slice and prevent any appeal to countable or arbitrary products.

The neighbourhood construction is forced through O, U, F, V. Product openness is exposed first, the coordinate neighbourhood family is then read from that product row, and the finite-cover refinement row chooses the finite tube data used by V.

The final row R records that each coordinate fibre is routed through the ordinary TubeLemma$^{\uparrow}$ packet. Transport, replay, provenance, and naming do not introduce further compactness principles, so the displayed chain is the complete compact route available to downstream consumers. □

Closure status for $\mathsf{NameCert}_{\mathsf{TubeLemmaFiniteProduct}^{\uparrow}}$.

Constructive story: A $\mathsf{TubeLemmaFiniteProduct}^{\uparrow}$ packet is generated from a finite index row, indexed Topology rows, Compact slice rows, a ProductTopology open-neighbourhood row, coordinate neighbourhood rows, a tube neighbourhood row, a FiniteCoverRefinement row, a coordinatewise TubeLemma route, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{TubeLemmaFiniteProduct}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8788.1, Definition 8788.2, and Definition 8788.3 seed the finite product tube-neighbourhood packet over product topology, compact slice, topology, tube lemma, and finite-cover refinement rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{TubeLemmaFiniteProduct}^{\uparrow}}, \mathsf{encodedDef})$

Lean target: `BEDC.Derived.TubeLemmaFiniteProductUp`

Bridge status: none

Not claimed: This chapter does not close arbitrary product compactness, countable products, quotient equality of product points, selected neighbourhood bases, theorem-level Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked finite-index exposure, topology-row exposure, compact-slice exposure, product-open exposure, coordinate neighbourhood exactness, finite-cover refinement, coordinatewise TubeLemma routing, transport replay, provenance exhaustion, and local naming for BEDC.Derived.TubeLemmaFiniteProductUp.

Chapter 8789

A Concrete Naming Certificate for $\mathsf{BishopCompactIntervalFanModulus}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{BishopCompactIntervalFanModulus}^{\uparrow}$ packet records the finite fan-modulus surface used when a compact interval argument is read through constructive interval data. It sits after the compact fan bridge of chapter 6946, the modulus selector of chapter 8199, the dyadic interval-net surface of chapter 5966, the finite stream-name route of chapter 126, the regular rational readback of chapter 301, and the terminal real seal of chapter 38. The packet names a finite modulus row for compact interval consumers without asserting open-cover compactness, selected subcovers, quotient real equality, countable choice, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 8789.1 (BishopCompactIntervalFanModulus carrier)**.** *A* $\mathsf{BishopCompactIntervalFanModulus}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M = (B, S, D, W, R, E, H, C, P, N)$$

with the following displayed rows:

1. *B is the* $\mathsf{CompactIntervalFanBridge}^{\uparrow}$ *row, carrying the finite bridge from interval subdivision data to fan-indexed compact interval reads.*
2. *S is the* $\mathsf{CompactIntervalFanModulusSelector}^{\uparrow}$ *row, recording the selected finite modulus depth for the displayed interval and precision request.*
3. *D is the* $\mathsf{DyadicIntervalNet}^{\uparrow}$ *row, exposing the dyadic interval-net cells inspected at the chosen depth.*
4. *W is the* $\mathsf{StreamName}^{\uparrow}$ *window row for the interval endpoints, sampled cells, and modulus witnesses.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row turning those windows into regular rational observations.*
6. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row available only after the finite fan, dyadic-net, stream, and regular-rational rows have been displayed.*
7. *H records componentwise* hsame *transport for the bridge, selector, dyadic-net, stream, readback, seal, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay for compact interval modulus requests through $B, S, D, W, R, E, H, P, N$.*

9. *P is the* Pkg *provenance over* $\mathsf{BishopCompactIntervalFanModulus}^{\uparrow}$, $\mathsf{CompactIntervalFanBridge}^{\uparrow}$, $\mathsf{CompactIntervalFanModulusSelector}^{\uparrow}$, $\mathsf{DyadicIntervalNet}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

10. *N is the local* $\mathsf{NameCert}_{\mathsf{BishopCompactIntervalFanModulus}^{\uparrow}}$ *row.*

The carrier predicate asserts that these rows form one finite fan-modulus history for a displayed compact interval request. It has no coordinate for open-cover compactness, a selected arbitrary subcover, quotient real equality, countable choice, trichotomy, or ambient completeness of $\mathsf{Real}^{\uparrow}$.

Theorem 8789.2 (BishopCompactIntervalFanModulus NameCert obligations)**.** *For every accepted* $\mathsf{BishopCompactIntervalFanModulus}^{\uparrow}$ *carrier* $M = (B, S, D, W, R, E, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{BishopCompactIntervalFanModulus}^{\uparrow}}$ *surface consists exactly of compact fan bridge admission, finite modulus-depth selection, dyadic interval-net exposure, stream-window exposure, regular rational readback, Real seal nonescape, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. No compact interval modulus obligation is stored outside those rows.*

Proof. Project the carrier of Definition 8789.1. The fan bridge row B, selector row S, and dyadic interval-net row D are the only compact interval modulus data in the packet.

Read the analytic-facing rows next. The stream row W exposes finite endpoint and cell observations, the regular rational row R supplies the readback used by completion-facing consumers, and the terminal row E seals only those displayed observations as Real-facing data.

Finally use H, C, P, N. Componentwise transport, continuation replay, provenance, and local naming preserve the same finite packet, so the excluded open-cover, arbitrary subcover, quotient-equality, choice, trichotomy, and ambient-completeness principles cannot enter the local NameCert surface. □

Theorem 8789.3 (BishopCompactIntervalFanModulus finite-cover route)**.** *Every downstream consumer of an accepted* $\mathsf{BishopCompactIntervalFanModulus}^{\uparrow}$ *packet receives the finite route*

$$\mathsf{CompactIntervalFanBridge}^{\uparrow},\ \mathsf{CompactIntervalFanModulusSelector}^{\uparrow},\ \mathsf{DyadicIntervalNet}^{\uparrow} \longmapsto \mathsf{StreamName}^{\uparrow},\ \mathsf{RegSeqRa}$$

Consequently the consumer may read a displayed finite fan depth and its dyadic interval-net witnesses, but it receives no theorem of open-cover compactness, no selected arbitrary subcover, no quotient real equality, no countable-choice schedule, no order trichotomy, and no ambient completeness principle for $\mathsf{Real}^{\uparrow}$.

Proof. Start with the bridge and selector rows. The row B supplies the compact interval fan bridge, and S records the finite modulus depth attached to the displayed request.

Use the dyadic interval-net row D. It exposes the concrete interval cells available at that depth, so a consumer sees finite coverage data rather than an arbitrary family of opens or a selected subcover.

Route every Real-facing read through W, R, E and preserve the packet through H, C, P, N. Since the carrier contains only those finite rows, the public route is exactly the displayed finite means route and not an ambient compactness principle. □

Closure status for $\mathsf{NameCert}_{\mathsf{BishopCompactIntervalFanModulus}^{\uparrow}}$.

Constructive story: A $\mathsf{BishopCompactIntervalFanModulus}^{\uparrow}$ packet is generated from compact fan bridge rows, a finite modulus selector, dyadic interval-net cells, StreamName windows, RegSeqRat readback, a Real seal, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{BishopCompactIntervalFanModulus}^{\uparrow}}$, seed)

Scope closed: Definition 8789.1, Definition 8789.2, and Definition 8789.3 seed the finite fan-modulus route over compact fan bridge, modulus selector, dyadic interval net, StreamName, RegSeqRat, Real, transport, replay, provenance, and local naming rows.

Formal verification: FormalStatus(NameCert$_{\mathsf{BishopCompactIntervalFanModulus}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close open-cover compactness, selected arbitrary subcovers, quotient real equality, countable choice, trichotomy, ambient Real$^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, fan bridge admission, finite modulus-depth selection, dyadic interval-net exposure, Real seal nonescape, and structural nonescape for BEDC.Derived.BishopCompactIntervalFanModulusUp.

Chapter 8790

A Concrete Naming Certificate for $\mathsf{BishopCompletionComparisonSquare}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{BishopCompletionComparisonSquare}^{\uparrow}$ packet records the finite comparison square between the dense-source induction route of chapter 1776 and the completion-interface route of chapter 1844. It shares the finite windows of chapter 126, the regular rational readback of chapter 301, the dyadic tolerance ledger of chapter 291, and the terminal Real seal of chapter 38. The packet names a square witness for the L10 completion route; it does not assert ambient $\mathsf{Real}^{\uparrow}$ completeness, quotient stream equality, selected limits, countable choice, host function equality, Lean verification, or bridge checking.

Definition 8790.1 (Bishop completion comparison square carrier)**.** *A* $\mathsf{BishopCompletionComparisonSquare}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$X = (Q_0, Q_1, I_0, I_1, D, S, R, E, L, H, C, P, N)$$

with the following displayed rows:

1. *Q_0 and Q_1 are the two dense-source faces, exposing the source data read by the induction-extension route and by the completion-interface route.*
2. *I_0 and I_1 are the two completion-interface faces, naming the* $\mathsf{BishopCompletionInduction}^{\uparrow}$ *extension read and the* $\mathsf{CauchyRealCompletionInterface}^{\uparrow}$ *boundary read over the same source faces.*
3. *D is the shared* $\mathsf{DyadicRatCore}^{\uparrow}$ *endpoint and tolerance ledger used by both faces before any Real seal is visible.*
4. *S is the shared* $\mathsf{StreamName}^{\uparrow}$ *finite-window row opened by the dyadic tolerance ledger.*
5. *R is the shared* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row attached to D and S.*
6. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal reached only after the common route D, S, R has been displayed.*
7. *L is the square-commutation ledger, recording that both paths from Q_0, Q_1 through I_0, I_1 reach the same shared rows D, S, R, E before any structural export.*
8. *H records componentwise* hsame *transport for the dense-source faces, completion-interface faces, shared route rows, commutation ledger, replay, provenance, and local naming rows.*
9. *C records displayed* Cont *replay of the square from each dense-source face through the shared route rows and the commutation ledger.*

10. *P is the* Pkg *provenance over* $\mathsf{BishopCompletionComparisonSquare}^{\uparrow}$, $\mathsf{BishopCompletionInduction}^{\uparrow}$, $\mathsf{CauchyRealCompletionInterface}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

11. *N is the local* $\mathsf{NameCert}_{\mathsf{BishopCompletionComparisonSquare}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $Q_0, Q_1, I_0, I_1, D, S, R, E, L, H, C, P, N$. It has no coordinate for ambient $\mathsf{Real}^{\uparrow}$ *completeness, quotient streams, selected host limits, countable choice, host function equality, Lean verification, or bridge checking.*

Lean4 ✓ `BEDC.Derived.BishopCompletionComparisonSquareUp.BishopCompletionComparisonSquareTasteGate`
`single carrier alignment`

Theorem 8790.2 (Bishop completion comparison square NameCert obligations)**.** *For every accepted* $\mathsf{BishopCompletionComparisonSquare}^{\uparrow}$ *carrier*

$$X = (Q_0, Q_1, I_0, I_1, D, S, R, E, L, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{BishopCompletionComparisonSquare}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the two dense-source faces, two completion-interface faces, shared dyadic ledger, finite windows, regular readback, Real seal, commutation ledger, transport, replay, provenance, and local naming rows;*
2. *dense-source visibility, requiring Q_0 and Q_1 to be displayed before either completion-facing face is read;*
3. *interface-face exactness, requiring I_0 to read the* $\mathsf{BishopCompletionInduction}^{\uparrow}$ *extension face and I_1 to read the* $\mathsf{CauchyRealCompletionInterface}^{\uparrow}$ *boundary face over the same displayed source data;*
4. *shared-route discipline, requiring both faces to consume the same D, S, R, E route through* $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$*;*
5. *square-commutation, requiring L to compare only the two displayed paths and their shared route rows;*
6. *structural non-escape, requiring H, C, P, N to transport, replay, source, and name no row outside the displayed packet.*

No local obligation is stored outside these rows.

Proof. Carrier admission is projection from Definition 8790.1. The accepted packet displays exactly the two dense-source faces, two completion-interface faces, the shared route rows, and the structural rows.

Dense-source visibility is forced by the row order. Both completion-facing faces can be read only after Q_0 and Q_1 are visible, so neither path can introduce a hidden source representative.

The interface-face exactness clauses are the rows I_0 and I_1. The first reads the Bishop completion-induction extension face, and the second reads the Cauchy real completion-interface boundary face, both over the same displayed source data.

The shared-route and commutation clauses are the rows D, S, R, E, L. The dyadic ledger opens the finite windows, the regular readback consumes those windows, the Real seal is terminal, and the ledger L compares only the two paths through those rows.

Finally H, C, P, N add only transport, replay, provenance, and local naming. Since the carrier contains none of the excluded coordinates, the displayed rows exhaust the local NameCert surface. □

Theorem 8790.3 (Bishop completion comparison square commutes)**.** *Let $X = (Q_0, Q_1, I_0, I_1, D, S, R, E, L, H, C, P$ be an accepted* $\mathsf{BishopCompletionComparisonSquare}^{\uparrow}$ *carrier. Every completion-facing comparison exported by X factors through the finite square*

$$Q_0, Q_1 \longmapsto I_0 \longmapsto D, S, R, E \longmapsto L, H, C, P, N,$$
$$Q_0, Q_1 \longmapsto I_1 \longmapsto D, S, R, E \longmapsto L, H, C, P, N.$$

Thus the two displayed paths commute at the local NameCert surface: each reaches the same dyadic tolerance ledger, finite StreamName windows, RegSeqRat readback, terminal Real seal, commutation ledger, transport, replay, provenance, and local name.

Proof. Project the accepted carrier. Both paths begin with the same dense-source faces Q_0, Q_1 and can inspect no completion-facing datum before those faces are displayed.

The upper path opens I_0, the Bishop completion-induction extension face. The lower path opens I_1, the Cauchy real completion-interface boundary face. By carrier admission, both faces are attached to the same source data and to the same shared route rows.

The shared route then forces the comparison. Both paths pass through D, S, R, E before the commutation ledger can be read, so they reach the same dyadic tolerance, StreamName window, regular readback, and terminal Real-seal coordinates.

The ledger L records exactly this comparison, while H, C, P, N preserve, replay, source, and name it. No additional coordinate is present from which a second completion route could diverge. □

Theorem 8790.4 (Bishop completion comparison square Real handoff)**.** *For an accepted* BishopCompletionCompari *carrier $X = (Q_0, Q_1, I_0, I_1, D, S, R, E, L, H, C, P, N)$, any Real-facing consumer must receive the terminal* $\mathsf{Real}^{\uparrow}$ *seal E only through the shared finite route*

$$D \longmapsto S \longmapsto R \longmapsto E.$$

The handoff is therefore a common dyadic-tolerance, finite-window, regular-readback, Real-seal route for both the induction-extension face and the completion-interface face, not an appeal to ambient $\mathsf{Real}^{\uparrow}$ *completeness or to a selected host limit.*

Proof. Start with a Real-facing consumer of the square. Projection of the carrier gives the shared route rows D, S, R, E and no other Real-facing coordinate.

The dyadic ledger D is opened first. It supplies the tolerance budget that controls the finite StreamName windows S and the regular rational readback R.

Only after D, S, R have been displayed can the terminal seal E be read. Both completion-facing faces I_0 and I_1 use the same route, so the consumer receives one Real handoff rather than two independent seals.

Since the excluded coordinates are absent from X, the consumer cannot replace this handoff by ambient completeness, quotient equality, selected limits, countable choice, host function equality, Lean verification, or bridge checking. □

Theorem 8790.5 (Bishop completion comparison square nonescape)**.** *No consumer of an accepted* $\mathsf{BishopCompletionComparisonSquare}^{\uparrow}$ *carrier may export ambient* $\mathsf{Real}^{\uparrow}$ *completeness, quotient stream equality, a selected host limit, countable choice, host function equality, Lean verification, or bridge checking. The consumer may export only the displayed comparison square on* $Q_0, Q_1, I_0, I_1, D, S, R, E, L, H, C, P, N$ *and the local* $\mathsf{NameCert}_{\mathsf{BishopCompletionComparisonSquare}^{\uparrow}}$ *evidence attached to those rows.*

Proof. Inspect the carrier inventory in Definition 8790.1. The tuple contains only dense-source faces, completion-interface faces, shared route rows, a commutation ledger, and structural naming rows.

Definition 8790.2 exhausts the local obligation surface. Each allowed export is tied to one of the displayed rows, and no excluded row is introduced by the obligation theorem.

Definition 8790.3 and Definition 8790.4 then fix the consumer route. Every comparison and every Real-facing handoff passes through the shared finite square before it can be named.

Thus any exported consumer result remains inside the displayed packet. The listed ambient completeness, quotient, choice, host-equality, Lean, and bridge objects are absent from the carrier and cannot escape through the local NameCert row. □

Closure status for $\mathsf{NameCert}_{\mathsf{BishopCompletionComparisonSquare}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BishopCompletionComparisonSquare}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8790.1, Definition 8790.2, Definition 8790.3, Definition 8790.4, and Definition 8790.5 seed the finite L10 comparison square between the Bishop completion-induction extension route and the Cauchy real completion-interface boundary route.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BishopCompletionComparisonSquare}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close ambient $\mathsf{Real}^{\uparrow}$ completeness, quotient stream equality, selected host limits, countable choice, host function equality, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, dense-source visibility, interface-face exactness, shared-route discipline, square commutation, Real handoff, and consumer nonescape for BEDC.Derived.BishopCompletionComparisonSquareUp

Constructive story: A $\mathsf{BishopCompletionComparisonSquare}^{\uparrow}$ packet is generated from two dense-source faces, two completion-interface faces, a DyadicRatCore tolerance ledger, StreamName finite windows, RegSeqRat readback, a terminal RealUp seal, a square-commutation ledger, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 8791

A Concrete Naming Certificate for $\mathsf{PrimeShadowInterface}^{\uparrow}$

The $\mathsf{PrimeShadowInterface}^{\uparrow}$ packet realizes the bulk–boundary prime-shadow vision of chapter 9332 as finite NameCert data. It sits after the arithmetic prime certificate of chapter 64, the finite prime-window gluing route of chapter 8765, the zeta source of chapter 71, the zeta-zero surface of chapter 73, the zeta zero type factorization of chapter 8772, and the critical-line witness route of chapter 548. The packet names only a finite interface row: it does not prove RH, does not discharge the analytic incompatibility row, and does not assert zero-free strips, Euler product convergence on the critical strip, quotient complex equality, or ambient analytic completeness.

Definition 8791.1 (PrimeShadowInterface carrier)**.** *A* $\mathsf{PrimeShadowInterface}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (P, W, Z, A, D, H, C, G, N)$$

with the following displayed rows:

1. *P is the* $\mathsf{Prime}^{\uparrow}$ *row naming the prime classifier and the local prime-invariant read used by the boundary shadow.*
2. *W is the* $\mathsf{FinitePrimeWindowGluing}^{\uparrow}$ *row recording the finite prime window through which boundary-visible prime data is inspected.*
3. *Z is the* $\mathsf{Zeta}^{\uparrow}$ *and* $\mathsf{ZetaZeros}^{\uparrow}$ *source row, retaining only the displayed zeta and zero-locus surfaces.*
4. *A is the* $\mathsf{ZetaZeroTypeFactorization}^{\uparrow}$ *row that connects a legal zero-facing type read to the finite zeta-zero surface.*
5. *D is the prime-shadow defect row: it records the layer index, finite readout, nonzero defect witness, and refusal of a hidden bulk invariant.*
6. *H records componentwise* hsame *transport for prime, window, zeta, zero-factor, defect, replay, provenance, and local naming rows.*
7. *C records displayed* Cont *replay for the finite prime-shadow boundary read through P, W, Z, A, D, H, G, N.*
8. *G is the* Pkg *provenance over* $\mathsf{PrimeShadowInterface}^{\uparrow}$, $\mathsf{Prime}^{\uparrow}$, $\mathsf{FinitePrimeWindowGluing}^{\uparrow}$, $\mathsf{Zeta}^{\uparrow}$, $\mathsf{ZetaZeros}^{\uparrow}$, $\mathsf{ZetaZeroTypeFactorization}^{\uparrow}$, $\mathsf{CriticalLineWitness}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
9. *N is the local* $\mathsf{NameCert}_{\mathsf{PrimeShadowInterface}^{\uparrow}}$ *row.*

The carrier has no coordinate for an RH proof, a global zero classifier, a completed Euler product, analytic continuation outside the displayed sibling rows, quotient equality of complex data, or an ambient completeness principle.

Theorem 8791.2 (PrimeShadowInterface NameCert obligations)**.** *For every accepted* $\mathsf{PrimeShadowInterface}^{\uparrow}$ *carrier* $S = (P, W, Z, A, D, H, C, G, N)$*, the local* $\mathsf{NameCert}_{\mathsf{PrimeShadowInterface}^{\uparrow}}$ *surface consists exactly of prime-row admission, finite prime-window admission, zeta-source admission, zeta-zero factorization admission, prime-shadow defect exposure, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. The obligation surface may cite chapter 9332, but it exports only these finite boundary rows.*

Proof. Project the carrier of Definition 8791.1. The rows P, W, Z, A, D are the complete mathematical surface of the packet: prime classifier data, a finite prime window, zeta and zero-facing rows, zero-type factorization, and a displayed defect read.

Use the structural rows H, C, G, N. They transport, replay, package, and name the same finite boundary interface, so the local certificate cannot introduce an analytic theorem beyond the displayed siblings.

The RH vision is therefore consumed only as a target diagram. The packet supplies a concrete boundary interface for that diagram, not an incompatibility proof or an RH conclusion. □

Theorem 8791.3 (PrimeShadowInterface finite boundary route)**.** *Every RH-facing consumer of an accepted* $\mathsf{PrimeShadowInterface}^{\uparrow}$ *packet must read the finite prime-shadow boundary through*

$$\mathsf{Prime}^{\uparrow},\ \mathsf{FinitePrimeWindowGluing}^{\uparrow},\ \mathsf{Zeta}^{\uparrow},\ \mathsf{ZetaZeros}^{\uparrow},\ \mathsf{ZetaZeroTypeFactorization}^{\uparrow} \longmapsto \mathsf{CriticalLineWitness}^{\uparrow},\ \mathsf{BHist}$$

The route keeps bulk–boundary prime-shadow detection finite and local. It does not claim RH, analytic defect-zero incompatibility, a zero-free strip theorem, completed Euler products on the critical strip, quotient complex equality, or host analytic completeness.

Proof. Start from P and W. The prime-facing side is a displayed prime classifier read plus a finite prime window, so the consumer receives only finite boundary-visible prime data.

Read Z and A next. These rows expose the zeta source and zeta-zero type factorization before any critical-line consumer can treat a zero-facing row as boundary data.

Finally preserve the route through D, H, C, G, N. The defect row is local to the same packet, while transport, replay, provenance, and naming keep all reads inside the finite interface. The refused analytic claims are absent from the carrier and therefore remain outside the exported boundary route. □

Falsifiable prediction: If the finite prime-window row W or the defect row D is removed, an RH-facing consumer can no longer distinguish a visible prime-shadow defect from an untracked zeta-zero read.

Independence witness: Nearest siblings: prime, finite-prime-window-gluing, zeta-basic, zeta-zeros, criticallinewitness. None carries the combined boundary interface because each sibling supplies only the prime classifier, finite window, zeta source, zero surface, or critical-line witness, while $\mathsf{PrimeShadowInterface}^{\uparrow}$ binds them to one defect-read packet.

The Lean follow-up for namespace BEDC.Derived.PrimeShadowInterfaceUp.TasteGate must provide explicit Nontrivial $\mathsf{PrimeShadowInterface}^{\uparrow}$ and FieldFaithful $\mathsf{PrimeShadowInterface}^{\uparrow}$ instances before a checked carrier-alignment theorem can serve as the TasteGate witness. Those instances must preserve $P, W, Z, A, D, H, C, G, N$ as distinct fields.

Closure status for $\mathsf{NameCert}_{\mathsf{PrimeShadowInterface}^{\uparrow}}$.

Constructive story: A $\mathsf{PrimeShadowInterface}^{\uparrow}$ packet is generated from a Prime row, finite prime-window gluing, zeta source rows, zeta-zero factorization rows, a prime-shadow defect read, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{PrimeShadowInterface}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8791.1, Definition 8791.2, and Definition 8791.3 seed the finite prime-shadow boundary interface over Prime, finite prime-window, Zeta, ZetaZeros, zero-factorization, critical-line, transport, replay, provenance, and local naming rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{PrimeShadowInterface}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close RH, analytic defect-zero incompatibility, zero-free strips, completed Euler products on the critical strip, quotient complex equality, ambient analytic completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, prime-window exactness, zeta-zero factorization readback, local defect exposure, TasteGate nontriviality, field faithfulness, transport, replay, provenance, and local naming for BEDC.Derived.PrimeShadowInterfaceUp.

Chapter 8792

A Concrete Naming Certificate for $\mathsf{DnaWindowTriggerFrontier}^{\uparrow}$

The $\mathsf{DnaWindowTriggerFrontier}^{\uparrow}$ packet realizes the boundary-tile hinge and ablation rows of Definition 9462.1468 as finite BEDC NameCert data. It consumes the boundary-tile source of chapter 3393, the six-boundary coverage rows of chapter 3470, the trigger algebra of chapter 3478, the closure/refusal discipline of chapter 3508, and the reliability surfaces of chapter 3583 and chapter 3657. The packet names a finite trigger-frontier row for DNA-window ablation reads; it is not a biological mechanism, stochastic evolution model, quotient codon semantics, hidden probability oracle, or infinite trigger search.

Definition 8792.1 (DNA-window trigger frontier carrier)**.** *A* $\mathsf{DnaWindowTriggerFrontier}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$F = (W, B, C, A, L, R, T, U, V, H, Q, P, N)$$

with the following displayed rows:

1. *W is the* $\mathsf{DnaWindowSixBoundaryTile}^{\uparrow}$ *boundary-window source row.*
2. *B is the boundary-tile hinge row, naming the displayed codon-window faces inspected by ablation.*
3. *C is the* $\mathsf{SixBoundaryTileCoverage}^{\uparrow}$ *coverage row, recording support coverage for the same boundary faces.*
4. *A is the* $\mathsf{WindowCoverageTriggerAlgebra}^{\uparrow}$ *row, carrying finite trigger-support operations.*
5. *L is the* $\mathsf{DnaBoundaryTriggerClosure}^{\uparrow}$ *closure/refusal row, retaining blocked infinite-branch and quotient-codon reads.*
6. *R is the reliability row, read through* $\mathsf{EnergyBiasedTriggerReliability}^{\uparrow}$ *and* $\mathsf{TriggerHypergraphReliability}^{\uparrow}$.
7. *T is the finite trigger-frontier row, listing the trigger, support, and ablation boundary entries visible to consumers.*
8. *U is the transport row for boundary-tile, support, reliability, and refusal data across the displayed frontier.*
9. *V is the replay row for the source vision's hinge and ablation calculations.*
10. *H records componentwise* hsame *transport for $W, B, C, A, L, R, T, U, V, Q, P, N$.*
11. *Q records displayed* Cont *replay through the same finite rows.*

12. *P is the* Pkg *provenance over* DnaWindowTriggerFrontier$^{\uparrow}$, DnaWindowSixBoundaryTile$^{\uparrow}$, SixBoundaryTileCoverag WindowCoverageTriggerAlgebra$^{\uparrow}$, DnaBoundaryTriggerClosure$^{\uparrow}$, EnergyBiasedTriggerReliability$^{\uparrow}$, TriggerHypergrap *the source vision of Definition 9462.1468,* BHist, hsame, Cont, *and* NameCert.

13. *N is the local* NameCert$_{\text{DnaWindowTriggerFrontier}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $W, B, C, A, L, R, T, U, V, H, Q, P, N$. It has no coordinate for biological mechanism, stochastic fitness, quotient codon equality, hidden probability, infinite trigger enumeration, or host spectral oracle.

Theorem 8792.2 (DNA-window trigger frontier obligations)**.** *For every accepted* DnaWindowTriggerFrontier$^{\uparrow}$ *carrier $F = (W, B, C, A, L, R, T, U, V, H, Q, P, N)$, the local* NameCert$_{\text{DnaWindowTriggerFrontier}^{\uparrow}}$ *surface consists exactly of boundary-window admission, hinge-row exposure, coverage-row exposure, trigger-algebra exposure, closure/refusal exposure, reliability-row exposure, finite trigger-frontier exposure, transport, replay, provenance, and local naming. A consumer may read a boundary-tile hinge or ablation frontier only after all these rows are displayed.*

Proof. Project the carrier of Definition 8792.1. The source and support rows are W, B, C, A, L, the reliability and frontier rows are R, T, and the structural rows are U, V, H, Q, P, N.

The boundary rows are supplied by chapter 3393 and chapter 3470. They expose the finite window faces and support coverage before any trigger-frontier read is public.

The trigger rows are supplied by chapter 3478 and chapter 3508. These keep support closure and refusal rows visible, so an accepted frontier cannot become an infinite trigger search or quotient codon semantics.

The reliability row R is read only through chapter 3583 and chapter 3657. Finally T, U, V, H, Q, P, N expose, transport, replay, source, and name the same finite frontier. Since no excluded coordinate occurs in the carrier, the listed rows exhaust the obligation surface. □

Falsifiable prediction: Every accepted DnaWindowTriggerFrontier$^{\uparrow}$ consumer must exhibit DnaWindowSixBoundaryTile, SixBoundaryTileCoverage, WindowCoverageTriggerAlgebra, DnaBoundaryTriggerClosure, EnergyBiasedTriggerReliability, TriggerHypergraphReliability, trigger-frontier, support, refusal, transport, replay, provenance, and local NameCert rows before reading a hinge or ablation frontier.

Independence witness: dna-window-six-boundary-tile, six-boundary-tile-coverage, window-coverage-trigger-algebra, dna-boundary-trigger-closure, energy-biased-trigger-reliability: DnaWindowTriggerFrontier$^{\uparrow}$ is not bijective to any listed sibling because it jointly carries boundary windows, hinge rows, coverage rows, trigger algebra, closure/refusal rows, reliability rows, finite trigger-frontier entries, transport, replay, provenance, and local naming.

Closure status for NameCert$_{\text{DnaWindowTriggerFrontier}^{\uparrow}}$.

Constructive story: A DnaWindowTriggerFrontier$^{\uparrow}$ packet is generated from boundary-window rows, boundary-tile hinge rows, six-boundary coverage rows, finite trigger-algebra rows, closure/refusal rows, reliability rows, finite trigger-frontier entries, transport, replay, provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\text{DnaWindowTriggerFrontier}^{\uparrow}}$, seed)

Scope closed: Definition 8792.1 and Definition 8792.2 seed the finite DNA-window trigger-frontier interface over boundary-tile, coverage, trigger-algebra, closure/refusal, reliability, transport, replay, provenance, and local naming rows.

Formal verification: FormalStatus(NameCert$_{\text{DnaWindowTriggerFrontier}^{\uparrow}}$, formalTarget)

Bridge status: none

Not claimed: This chapter does not close biological mechanism, stochastic evolution, quotient codon semantics, hidden probability models, infinite trigger search, theorem checking, or bridge checking.

Upgrade path: Obligation closure requires checked boundary-window admission, hinge-row exposure, coverage exposure, trigger-algebra exposure, refusal exposure, reliability exposure, frontier exposure, transport, replay, provenance, and local naming for BEDC.Derived.DnaWindowTriggerFrontierUp.

Chapter 8793

A Concrete Naming Certificate for $\mathsf{HenstockGaugeIntegral}^{\uparrow}$

Following Henstock and Kurzweil, the $\mathsf{HenstockGaugeIntegral}^{\uparrow}$ packet names the finite gauge-integral interface obtained from Cousin-style tagged partitions and regulated-function control. It consumes the Cousin partition route of chapter 7385, the Henstock gauge-partition packet of chapter 8286, the regulated-function surface of chapter 1906, and the positive-radius discipline supplied by chapter 2301. The packet records tagged sums, gauge fineness, oscillation control, tolerance readback, Real sealing, transport, replay, provenance, and local naming; it is not open-cover compactness, selected subcovers, measure completion, host integration, quotient function equality, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 8793.1 (Henstock gauge integral carrier)**.** *A* $\mathsf{HenstockGaugeIntegral}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$I = (F, G, P, S, O, T, E, H, C, Q, N)$$

with the following displayed rows:

1. *F is the* $\mathsf{RegulatedFunction}^{\uparrow}$ *source row, carrying the regulated-window data visible to the integral consumer.*
2. *G is the positive gauge row, read through the same finite radius discipline used by* $\mathsf{LebesgueNumberLemma}^{\uparrow}$*.*
3. *P is the* $\mathsf{HenstockGaugePartition}^{\uparrow}$ *partition row, with tags, endpoint readback, coverage, disjointness, and gauge-fineness already displayed.*
4. *S is the tagged-sum row over the finite partition P and the regulated source F.*
5. *O is the oscillation-control row, recording the finite local error bound available on the cells of P.*
6. *T is the tolerance readback row, binding the requested precision to the displayed gauge, partition, sum, and oscillation rows.*
7. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal for the accepted integral read.*
8. *H records componentwise* hsame *transport for the regulated source, gauge, partition, tagged sum, oscillation control, tolerance, Real seal, replay, provenance, and local naming rows.*
9. *C records displayed* Cont *replay through $F, G, P, S, O, T, E, H, Q, N$.*

10. *Q is the* Pkg *provenance over* $\mathsf{HenstockGaugeIntegral}^{\uparrow}$, $\mathsf{CousinPartition}^{\uparrow}$, $\mathsf{HenstockGaugePartition}^{\uparrow}$, $\mathsf{RegulatedFunction}^{\uparrow}$, $\mathsf{LebesgueNumberLemma}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

11. *N is the local* $\mathsf{NameCert}_{\mathsf{HenstockGaugeIntegral}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $F, G, P, S, O, T, E, H, C, Q, N$. It has no coordinate for open-cover compactness, a selected subcover, a host integration primitive, measure completion, quotient function equality, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 8793.2 (Henstock gauge integral NameCert obligations)**.** *For every accepted* $\mathsf{HenstockGaugeIntegral}^{\uparrow}$ *carrier $I = (F, G, P, S, O, T, E, H, C, Q, N)$, the local* $\mathsf{NameCert}_{\mathsf{HenstockGaugeIntegral}^{\uparrow}}$ *surface consists exactly of regulated-source admission, positive-gauge admission, Henstock gauge-partition admission, tagged-sum exposure, oscillation-control exposure, tolerance readback, terminal Real sealing, componentwise transport, displayed replay, provenance, and local naming. Every integral consumer must read the* $\mathsf{CousinPartition}^{\uparrow}$, $\mathsf{HenstockGaugePartition}^{\uparrow}$, $\mathsf{RegulatedFunction}^{\uparrow}$, *and* $\mathsf{LebesgueNumberLemma}^{\uparrow}$ *rows before reading the terminal integral value.*

Proof. Project the carrier of Definition 8793.1. The analytic rows are F, G, P, S, O, T, E, and the structural rows are H, C, Q, N.

The partition row P is already finite because chapter 7385 and chapter 8286 display tags, endpoint readback, fineness, coverage, and disjointness before any sum is consumed. The gauge row G is read through the positive-radius discipline of chapter 2301.

The regulated source row F supplies only the finite regulated windows named by chapter 1906. The tagged-sum row S, oscillation row O, tolerance row T, and Real seal E therefore remain downstream of displayed finite data.

Finally H, C, Q, N transport, replay, source, and name the same packet. Since no carrier coordinate stores a selected subcover, host integral, measure completion, quotient function equality, countable-choice schedule, or ambient Real completeness theorem, the listed rows exhaust the local NameCert surface. □

Theorem 8793.3 (Henstock gauge integral regulated handoff)**.** *Every* $\mathsf{RegulatedFunction}^{\uparrow}$ *consumer that reads an accepted* $\mathsf{HenstockGaugeIntegral}^{\uparrow}$ *packet factors through*

$$F, G, P, S, O, T, E \longmapsto H, C, Q, N.$$

The handoff first displays the regulated source row, then the positive gauge and finite Henstock gauge partition, then the tagged sum and oscillation-control ledger, and only then the tolerance readback and terminal $\mathsf{Real}^{\uparrow}$ *seal. It exports no open-cover compactness, selected subcover, host integration primitive, measure completion, quotient function equality, countable choice, or ambient Real completeness.*

Proof. Start from the regulated source row F. By chapter 1906, the source is visible only through finite step-window and tolerance data, so the integral packet cannot read an ambient host function.

Next read G and P. The positive gauge is displayed before the partition row is consumed, and the Henstock gauge-partition route supplies a finite tagged partition with endpoint readback, gauge fineness, coverage, and disjointness.

Now consume S, O, T, E. The tagged-sum row is computed on the displayed partition, the oscillation-control row records the local error budget on those cells, the tolerance row binds the requested precision to that finite ledger, and the terminal Real seal exposes the accepted integral read.

The remaining rows H, C, Q, N only transport, replay, source, and name this finite route. Thus the regulated handoff remains a constructive gauge-integral packet rather than a hidden compactness, choice, measure, quotient, host-integration, or Real-completeness principle. □

Falsifiable prediction: Every accepted $\mathsf{HenstockGaugeIntegral}^{\uparrow}$ consumer must expose RegulatedFunction, positive gauge, CousinPartition, HenstockGaugePartition, tagged-sum, oscillation-control, tolerance-readback, Real-seal, transport, replay, provenance, and local NameCert rows before reading the integral value.

Independence witness: cousin-partition, henstock-gauge-partition, regulated-function, lebesgue-number-lemma: $\mathsf{HenstockGaugeIntegral}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries a regulated source, positive gauge, finite Henstock gauge partition, tagged sum, oscillation control, tolerance readback, terminal Real seal, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{HenstockGaugeIntegral}^{\uparrow}}$.

Constructive story: A $\mathsf{HenstockGaugeIntegral}^{\uparrow}$ packet is generated from a regulated-function source row, positive gauge row, finite Henstock gauge partition, tagged-sum row, oscillation-control ledger, tolerance readback, terminal Real seal, hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{HenstockGaugeIntegral}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8793.1, Definition 8793.2, and Definition 8793.3 seed the finite Henstock gauge-integral interface over CousinPartition, HenstockGaugePartition, RegulatedFunction, LebesgueNumberLemma, and Real rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{HenstockGaugeIntegral}^{\uparrow}}, \mathsf{formalTarget})$

Bridge status: none

Not claimed: This chapter does not close open-cover compactness, selected subcovers, measure completion, host integration, quotient function equality, countable choice, ambient Real completeness, theorem checking, or bridge checking.

Upgrade path: Obligation closure requires checked regulated-source admission, positive-gauge admission, finite partition admission, tagged-sum exposure, oscillation control, tolerance readback, Real sealing, transport, replay, provenance, and local naming for BEDC.Derived.HenstockGaugeIntegralUp.

Chapter 8794

A Concrete Naming Certificate for $\mathsf{NewtonInverseRadiusLedger}^{\uparrow}$

Following Kantorovich and the finite-dimensional inverse-function theorem, the $\mathsf{NewtonInverseRadiusLedger}^{\uparrow}$ packet records the finite radius budget that lets a Newton consumer open an inverse window without invoking a global inverse theorem. It sits beside the Newton-Kantorovich route of chapter 1785, the inverse-function carrier of chapter 2055, the complete-metric handoff of chapter 128, the terminal Real surface of chapter 38, the metric source of chapter 57, and the continuous-map route of chapter 130. The chapter names a local ledger for contraction, inverse-window, and Real-facing handoff rows; it does not assert selected limits, host differentiability, quotient representatives, global inverse functions, or Lean verification.

Definition 8794.1 (Newton inverse-radius ledger carrier)**.** *A* $\mathsf{NewtonInverseRadiusLedger}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (M, R, F, D, I, A, W, Q, K, E, H, C, P, N)$$

with the following displayed rows:

1. *M is the* $\mathsf{Met}^{\uparrow}$ *source row, naming the domain and codomain distance windows used by the local inverse read.*
2. *R is the* $\mathsf{Real}^{\uparrow}$ *radius row, carrying the positive radius, tolerance budget, and endpoint comparisons used by the inverse window.*
3. *F is the* $\mathsf{ContinuousMap}^{\uparrow}$ *source map row, displayed before any derivative or Newton read is consumed.*
4. *D is the local derivative or finite-difference control row read by the inverse-window calculation.*
5. *I is the inverse-witness row for the derivative control displayed by D at the centre of the window.*
6. *A is the approximation ledger, storing the finite residual and Lipschitz or majorant comparisons that bound the Newton correction inside the radius row R.*
7. *W is the inverse-window row, recording the accepted ball, target ball, and nonescape side condition.*
8. *Q is the contraction-obligation row, recording that the Newton transform determined by F, D, I, A, W is contractive on the displayed radius window.*

9. *K is the* NewtonKantorovich$^{\uparrow}$ *handoff row, opened only after M, R, F, D, I, A, W, Q have been displayed.*
10. *E is the* CompleteMetric$^{\uparrow}$ *handoff row that accepts the contraction ledger as a local completion route for the window.*
11. *H records componentwise* hsame *transport for the metric source, radius budget, map row, derivative control, inverse witness, approximation ledger, inverse window, contraction row, Newton-Kantorovich handoff, complete-metric handoff, replay, provenance, and local naming rows.*
12. *C records displayed* Cont *replay from the map row through the radius ledger, inverse witness, contraction obligation, and local handoff rows.*
13. *P is the* Pkg *provenance over* NewtonInverseRadiusLedger$^{\uparrow}$, NewtonKantorovich$^{\uparrow}$, InverseFunction$^{\uparrow}$, CompleteMetric$^{\uparrow}$, Real$^{\uparrow}$, Met$^{\uparrow}$, ContinuousMap$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
14. *N is the local* NameCert$_{\text{NewtonInverseRadiusLedger}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $M, R, F, D, I, A, W, Q, K, E, H, C, P, N$. It has no coordinate for selected limits, host differentiability, quotient representatives, global inverse functions, Lean verification, or bridge checking.

Theorem 8794.2 (Newton inverse-radius ledger contraction obligation)**.** *For every accepted* NewtonInverseRadiusL *carrier*

$$L = (M, R, F, D, I, A, W, Q, K, E, H, C, P, N),$$

the contraction row Q is readable only after the metric source M, radius budget R, continuous-map row F, derivative-control row D, inverse-witness row I, approximation ledger A, and inverse-window row W are displayed. Thus every contraction claim exported by the packet is a local radius-budget claim about the displayed Newton transform, not a global inverse-function claim.

Proof. Project the carrier of Definition 8794.1. The only rows upstream of Q are M, R, F, D, I, A, W, so the contraction obligation has no separate source from which it can read a global inverse theorem.

The metric and radius rows determine the window. The map row and derivative-control row determine the local Newton transform, while the inverse witness and approximation ledger record the finite bounds used by that transform.

Only after those rows are visible can W expose the nonescape window and Q record contraction inside it. Since the carrier lacks global inverse-function and selected-limit coordinates, the exported contraction claim remains confined to the displayed radius ledger. □

Theorem 8794.3 (Newton inverse-radius ledger inverse-window obligation)**.** *Every accepted* NewtonInverseRadiusL *read of an inverse window factors through*

$$M, R, F, D, I, A \longmapsto W \longmapsto Q \longmapsto K, E, H, C, P, N.$$

The row W names only the local ball, target ball, and nonescape side condition carried by the radius ledger; it does not select a host limit, choose a quotient representative, assert host differentiability, or export a global inverse function.

Proof. The inverse-window row is W. By carrier admission, it is downstream of the metric source, radius row, map row, derivative-control row, inverse witness, and approximation ledger.

The contraction row Q can consume W only as a finite local window. It then hands the data to the Newton-Kantorovich row K and the complete-metric row E for local completion-facing use.

The structural rows H, C, P, N preserve, replay, source, and name the same displayed route. None of them adds selected limits, quotient representatives, host differentiability, or a global inverse function, so the inverse-window read remains local to W. □

Theorem 8794.4 (Newton inverse-radius ledger NameCert ledger)**.** *For every accepted* NewtonInverseRadiusLedger *carrier, the local* $\mathsf{NameCert}_{\mathsf{NewtonInverseRadiusLedger}^{\uparrow}}$ *surface is exhausted by carrier admission, metric-source visibility, radius-budget exactness, continuous-map source visibility, derivative-control compatibility, inverse-witness stability, approximation-ledger exactness, inverse-window nonescape, contraction-row exactness, Newton-Kantorovich handoff, complete-metric handoff, componentwise transport, displayed replay, provenance, and local naming.*

Proof. Carrier admission gives exactly the tuple $M, R, F, D, I, A, W, Q, K, E, H, C, P, N$. The source rows M, R, F, D, I, A describe the local metric, radius, map, derivative-control, inverse-witness, and approximation data.

The window and contraction obligations are the rows W and Q. They bind the source data to one local inverse window and one contraction claim inside that window.

The handoff rows K and E route the same data through the Newton-Kantorovich and complete-metric surfaces. The structural rows H, C, P, N add only transport, replay, provenance, and local naming, so no additional obligation lies outside the displayed ledger. □

Theorem 8794.5 (Newton inverse-radius ledger local handoff)**.** *Any consumer of an accepted* $\mathsf{NewtonInverseRadiusLedger}^{\uparrow}$ *packet may export only the local handoff through* $\mathsf{NewtonKantorovich}^{\uparrow}$ *and* $\mathsf{CompleteMetric}^{\uparrow}$ *named by K and E. The consumer may cite the finite radius budget, inverse-window row, and contraction row, but it may not export selected limits, host differentiability, quotient representatives, global inverse functions, Lean verification, or bridge checking.*

Proof. The downstream analytic rows are K and E. They are downstream of the radius ledger, inverse-window row, and contraction row, so they cannot be read before the local finite budget is displayed.

The packet contains no selected-limit row, host differentiability row, quotient-representative row, global inverse-function row, Lean marker, or bridge row. A consumer therefore has no coordinate from which to export those claims.

The only public handoff left is the finite local route through $M, R, F, D, I, A, W, Q, K, E, H, C, P, N$, with K and E naming the Newton-Kantorovich and complete-metric consumers of that route. □

Falsifiable prediction: Every accepted $\mathsf{NewtonInverseRadiusLedger}^{\uparrow}$ packet displays MetricUp source data, a RealUp radius row, ContinuousMapUp source data, derivative control, inverse-witness data, an approximation ledger, an inverse-window row, a contraction row, NewtonKantorovichUp handoff, CompleteMetricUp handoff, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert data before any inverse-window consumer is accepted.

Independence witness: newtonkantorovich, inversefunction, completemetric, real, metric, continuousmap: $\mathsf{NewtonInverseRadiusLedger}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries the radius budget, inverse-window nonescape row, contraction obligation, Newton-Kantorovich handoff, complete-metric handoff, transport, replay, provenance, and local naming in one finite ledger.

Closure status for $\mathsf{NameCert}_{\mathsf{NewtonInverseRadiusLedger}^{\uparrow}}$**.**

Constructive story: A $\mathsf{NewtonInverseRadiusLedger}^{\uparrow}$ packet is generated from MetricUp source data, a RealUp radius row, ContinuousMapUp source data, derivative control, inverse-witness data, an approximation ledger, an inverse-window

row, a contraction row, NewtonKantorovichUp handoff, CompleteMetricUp handoff, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\mathsf{NewtonInverseRadiusLedger}\uparrow}$, seed)

Scope closed: Definition 8794.1, Definition 8794.2, Definition 8794.3, Definition 8794.4, and Definition 8794.5 seed the finite inverse-radius ledger for local Newton inverse-window consumers.

Formal verification: FormalStatus(NameCert$_{\mathsf{NewtonInverseRadiusLedger}\uparrow}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close selected limits, host differentiability, quotient representatives, global inverse functions, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, metric-source visibility, radius-budget exactness, continuous-map source visibility, derivative-control compatibility, inverse-witness stability, approximation-ledger exactness, inverse-window nonescape, contraction-row exactness, Newton-Kantorovich handoff, complete-metric handoff, transport, replay, provenance, and local naming for BEDC.Derived.NewtonInverseRadiusLedgerUp.

Chapter 8795

A Concrete Naming Certificate for MetaCICNormalizationConfluenceFrontier$^{\uparrow}$

The MetaCICNormalizationConfluenceFrontier$^{\uparrow}$ packet realizes the candidate-mediated normalization boundary of chapter 9383 as finite NameCert data. It sits beside the candidate normalization/confluence handoff of chapter 5547, the normalization audit packet of chapter 3779, the typed-normalization audit of chapter 3539, the normalization frontier of chapter 892, and the finite-window confluence route of chapter 6027. The packet names the exact frontier where candidate evidence, residual-join visibility, and confluence-boundary rows are retained before any public normalization consumer may proceed.

Definition 8795.1 (MetaCIC normalization-confluence frontier carrier)**.** *A* MetaCICNormalizationConfluenceFronti *carrier is a finite* BHist *packet*

$$F = (T, K, S, R, J, B, A, O, H, C, P, N)$$

with the following displayed rows:

1. *T is the closed typed MetaCIC term row being inspected.*
2. *K is the candidate-evidence row, carrying reducibility-candidate, closed-candidate, or candidate-set evidence before any strong-normalization projection is read.*
3. *S is the candidate-mediated strong-normalization row for T.*
4. *R is the residual-frontier row, recording the redex or residual window that remains visible when normalization and confluence routes meet.*
5. *J is the residual-join boundary row, recording the finite local join or blocked-join status for the displayed residual window.*
6. *B is the confluence-boundary row, recording exactly which confluence claim is available and which subject-reduction or closed-consistency obligations remain outside the packet.*
7. *A is the normalization-audit row, routing the same T, K, S, R, J, B data through the audit map of chapter 9383.*
8. *O is the obstruction row retained whenever a consumer asks to erase candidate evidence, residual-join boundary rows, subject-reduction obligations, or the confluence boundary.*

9. *H records componentwise* hsame *transport for the closed typed term, candidate evidence, SN row, residual frontier, residual join boundary, confluence boundary, audit row, obstruction row, replay, provenance, and local naming rows.*
10. *C records displayed* Cont *replay from a normalization-confluence request through candidate evidence, residual visibility, join boundary, confluence boundary, obstruction, and local naming.*
11. *P is the* Pkg *provenance over* $\mathsf{MetaCICNormalizationConfluenceFrontier}^{\uparrow}$, $\mathsf{MetaCICCandidateNormalizationConfluen}$ $\mathsf{MetaCICNormalizationAuditPacket}^{\uparrow}$, $\mathsf{MetaCICTypedNormalizationAudit}^{\uparrow}$, $\mathsf{MetaCICNormalizationFrontier}^{\uparrow}$, $\mathsf{FiniteWindowConfluence}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
12. *N is the local* $\mathsf{NameCert}_{\mathsf{MetaCICNormalizationConfluenceFrontier}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $T, K, S, R, J, B, A, O, H, C, P, N$. It has no coordinate for evidence-free strong normalization, unconditional confluence, unrestricted subject reduction, quotient syntax equality, host evaluator soundness, completed closed consistency, Lean verification, or bridge checking.

Theorem 8795.2 (MetaCIC normalization-confluence frontier NameCert obligations)**.** *For every accepted* $\mathsf{MetaCICNormalizationConfluenceFrontier}^{\uparrow}$ *carrier*

$$F = (T, K, S, R, J, B, A, O, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{MetaCICNormalizationConfluenceFrontier}^{\uparrow}}$ *surface consists exactly of carrier admission, closed-typed-term visibility, candidate-evidence retention, candidate-mediated strong-normalization projection, residual-frontier visibility, residual-join boundary retention, confluence-boundary retention, normalization-audit routing, obstruction exposure, componentwise transport, displayed replay, provenance, and local naming.*

Proof. Carrier admission projects the tuple $T, K, S, R, J, B, A, O, H, C, P, N$. The closed typed term row and candidate-evidence row are the source rows for any normalization read.

The candidate-mediated projection is S. It can be read only after K is visible, so the carrier cannot produce evidence-free strong normalization.

The confluence-facing rows are R, J, B. They retain the residual frontier, the residual-join boundary, and the confluence boundary before the audit row A can route the packet through the normalization audit map.

The obstruction and structural rows O, H, C, P, N preserve the same finite route. Since the carrier contains none of the excluded global coordinates, the listed rows exhaust the local NameCert surface. □

Theorem 8795.3 (MetaCIC normalization-confluence candidate gate)**.** *Every normalization read from an accepted* $\mathsf{MetaCICNormalizationConfluenceFrontier}^{\uparrow}$ *packet factors through*

$$T \longmapsto K \longmapsto S$$

before it may inspect residual-frontier, residual-join, confluence-boundary, audit, obstruction, transport, replay, provenance, or local naming rows. A consumer that erases K is outside the carrier.

Proof. The source term is T, and the only normalization evidence row upstream of S is K. Thus any strong-normalization read must first retain the displayed candidate evidence.

After S is visible, the consumer may inspect $R, J, B, A, O, H, C, P, N$. These rows refine the same candidate-mediated route by recording residual and confluence boundaries.

If K is erased, the route no longer matches the carrier inventory. The consumer has then left the finite NameCert surface and cannot be accepted by the local classifier. □

Theorem 8795.4 (MetaCIC normalization-confluence residual boundary)**.** *Every confluence-facing read from an accepted* MetaCICNormalizationConfluenceFrontier$^{\uparrow}$ *packet factors through the finite boundary*

$$R \longmapsto J \longmapsto B \longmapsto A, O, H, C, P, N.$$

The residual-frontier row, residual-join row, and confluence-boundary row remain visible together; none may be replaced by an unconditional confluence theorem or by an erased subject-reduction assumption.

Proof. Project the carrier. The residual-frontier row is R, the join boundary is J, and the confluence-boundary row is B.

The audit row A can route the packet only after those rows are displayed. It therefore records a bounded normalization-confluence interface, not an unconditional confluence theorem.

The obstruction row O remains visible when a requested consumer would erase residual joins or subject-reduction obligations. The structural rows preserve that same boundary, so the packet cannot silently replace it by a stronger global claim. □

Theorem 8795.5 (MetaCIC normalization-confluence frontier nonescape)**.** *No accepted* MetaCICNormalizationCon *consumer may export evidence-free strong normalization, unconditional confluence, unrestricted subject reduction, quotient syntax equality, host evaluator soundness, completed closed consistency, Lean verification, or bridge checking. The consumer may export only the candidate-mediated normalization route and the residual-join/confluence-boundary rows displayed by* $T, K, S, R, J, B, A, O, H, C, P, N$.

Proof. Inspect the carrier inventory in Definition 8795.1. Every accepted row is listed explicitly, and the global claims named in the statement are not coordinates of the packet.

Definition 8795.3 fixes the normalization side to the candidate-mediated route through T, K, S. Definition 8795.4 fixes the confluence side to the displayed residual and boundary rows.

The obstruction, transport, replay, provenance, and local naming rows preserve those two routes. Since no excluded coordinate is introduced downstream, every public consumer remains inside the displayed frontier. □

Falsifiable prediction: Any accepted MetaCICNormalizationConfluenceFrontier$^{\uparrow}$ consumer that erases candidate evidence or residual-join boundary rows refutes the carrier, as does any consumer that reads confluence without the displayed confluence-boundary row.

Independence witness: metacic-candidate-normalization-confluence-handoff, metacic-residual-join-envelope, metacic-normalization-audit-packet, metacic-confluence-substitution-boundary: MetaCICNormalizati is not bijective to any listed sibling because it jointly retains candidate evidence, candidate-mediated SN, residual-frontier visibility, residual-join boundary, confluence boundary, audit routing, obstruction, transport, replay, provenance, and local naming.

The Lean follow-up for BEDC.Derived.MetaCICNormalizationConfluenceFrontierUp must provide ‘Nontrivial‘ and ‘FieldFaithful‘ instances in ‘lean4/BEDC/Derived/MetaCICNormalizationConfluenceFrontier before any downstream taste gate treats the carrier as a non-smoke frontier.

Closure status for NameCert$_{\text{MetaCICNormalizationConfluenceFrontier}^{\uparrow}}$.

Constructive story: A MetaCICNormalizationConfluenceFrontier$^{\uparrow}$ packet is generated from a closed typed MetaCIC term row, candidate evidence, candidate-mediated strong-normalization projection, residual-frontier row, residual-join boundary, confluence-boundary row, normalization-audit route, obstruction row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\text{MetaCICNormalizationConfluenceFrontier}^{\uparrow}}$, seed)

Scope closed: Definition 8795.1, Definition 8795.2, Definition 8795.3, Definition 8795.4, and Definition 8795.5 seed the candidate-mediated normalization/confluence frontier over residual joins and confluence-boundary rows.

Formal verification: FormalStatus(NameCert$_{\text{MetaCICNormalizationConfluenceFrontier}\uparrow}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close evidence-free strong normalization, unconditional confluence, unrestricted subject reduction, quotient syntax equality, host evaluator soundness, completed closed consistency, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, candidate-evidence retention, candidate-mediated SN projection, residual-frontier visibility, residual-join boundary retention, confluence-boundary retention, audit routing, obstruction exposure, transport, replay, provenance, local naming, and the taste-gate instances for BEDC.Derived.MetaCICNormalizati

Chapter 8796

A Concrete Naming Certificate for $\mathsf{OgdenLemma}^{\uparrow}$

Following Hopcroft–Ullman and Sipser, the $\mathsf{OgdenLemma}^{\uparrow}$ packet records the marked-position strengthening of the context-free pumping lemma as finite NameCert data. It sits beside the grammar carrier of chapter 356 and the unmarked pumping route of chapter 2298; its role is to expose which marked terminal positions force the repeated nonterminal route, not to import host language equality, infinite parse trees, grammar quotients, or an ambient semantic pumping theorem.

Definition 8796.1 (Ogden lemma carrier)**.** *An* $\mathsf{OgdenLemma}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$O = (G, W, M, D, A, E, I, Y, H, C, R, Q, N)$$

with the following displayed rows:

1. *G is the finite* $\mathsf{ContextFreeGrammar}^{\uparrow}$ *grammar packet, including the terminal alphabet, nonterminal carrier, start row, production ledger, and terminal-yield window.*
2. *W is the terminal word row, read as a* $\mathsf{List}^{\uparrow}$ *spine with a displayed length bound supplied by* $\mathsf{Nat}^{\uparrow}$*.*
3. *M is the finite marked-position ledger over W, recording only the displayed positions chosen for the Ogden read.*
4. *D is the finite derivation ledger whose prefix rows are read through the grammar packet and whose marked leaves are aligned with M.*
5. *A is the repeated-nonterminal exposure row forced by the marked derivation route.*
6. *E is the decomposition row naming the five displayed word pieces and the marked-position split attached to them.*
7. *I is the pump-index row.*
8. *Y is the yielded-word row obtained by replaying the marked pumping route at the displayed index.*
9. *H records componentwise* hsame *transport for the grammar, word, marked-position ledger, derivation ledger, repeated-nonterminal row, decomposition, pump index, yielded word, replay, provenance, and local naming rows.*

10. *C records displayed* Cont *replay through $G, W, M, D, A, E, I, Y, H, R, Q, N$.*
11. *R is the sibling route to the* $\mathsf{ContextFreePumpingLemma}^{\uparrow}$ *packet, forgetting only the marked-position ledger while preserving the displayed derivation-prefix route.*
12. *Q is the* Pkg *provenance over* $\mathsf{OgdenLemma}^{\uparrow}$, $\mathsf{ContextFreeGrammar}^{\uparrow}$, $\mathsf{ContextFreePumpingLemma}^{\uparrow}$, $\mathsf{List}^{\uparrow}$, $\mathsf{Nat}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*
13. *N is the local* $\mathsf{NameCert}_{\mathsf{OgdenLemma}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $G, W, M, D, A, E, I, Y, H, C, R, Q, N$. The carrier contains no host language set, grammar quotient, infinite derivation tree, selected parse tree, or ambient semantic pumping principle.

Lean4 ✓ `BEDC.Derived.OgdenLemmaUp.OgdenLemmaTasteGate single carrier alignment`

Theorem 8796.2 (Ogden lemma NameCert obligations)**.** *For every accepted* $\mathsf{OgdenLemma}^{\uparrow}$ *carrier*

$$O = (G, W, M, D, A, E, I, Y, H, C, R, Q, N),$$

the local $\mathsf{NameCert}_{\mathsf{OgdenLemma}^{\uparrow}}$ *surface consists exactly of carrier admission for the grammar packet, terminal word row, marked-position ledger, finite derivation ledger, repeated-nonterminal exposure row, decomposition, pump index, yielded word, transport, replay, sibling pumping route, provenance, and local naming. The marked-position ledger M must be displayed before A and E are read, and the sibling route R may forget only that ledger after the finite derivation-prefix path has been exposed.*

Proof. Project the accepted carrier of Definition 8796.1. The rows G, W, M, D, A, E, I, Y are the whole formal-language surface, while H, C, R, Q, N transport, replay, compare with the unmarked pumping sibling, source, and name the same packet.

First read the grammar and terminal word rows. The finite production ledger and terminal-yield window of G supply the derivation-prefix route, and W supplies the bounded terminal spine on which marked positions can be displayed.

Next expose M before the pumping witness. The repeated-nonterminal row A and decomposition row E are accepted only as reads of the marked derivation ledger D, so no unmarked host pumping argument can replace them.

Finally replay the chosen pump index through I and Y, then package the route through H, C, R, Q, N. The sibling row R erases only the marked-position annotation after the finite derivation-prefix data has been read, and no carrier coordinate stores a host language set, grammar quotient, infinite derivation tree, selected parse tree, or ambient semantic pumping principle. □

Theorem 8796.3 (Ogden lemma marked-position pumping route)**.** *Let*

$$O = (G, W, M, D, A, E, I, Y, H, C, R, Q, N)$$

be an accepted $\mathsf{OgdenLemma}^{\uparrow}$ *carrier. Every marked pumping read of O factors through the finite route*

$$G \longmapsto W \longmapsto M \longmapsto D \longmapsto A \longmapsto E \longmapsto I \longmapsto Y$$

before it reaches transport, replay, provenance, local naming, or the $\mathsf{ContextFreePumpingLemma}^{\uparrow}$ *sibling route. A consumer may therefore recover a standard pumping-lemma surface only through the displayed forgetful row R, not by replacing the marked route with host language equality, quotient grammar semantics, an infinite parse tree, or an ambient membership theorem.*

Proof. Begin with Definition 8796.2. It orders the formal-language rows so that the grammar packet and terminal word are read before the marked-position ledger and derivation ledger.

The marked ledger then controls the pumping witness. The repeated-nonterminal row A and decomposition row E are downstream of M and D, and the pump index I can be replayed to the yielded row Y only along that displayed finite path.

The structural rows do not add a second pumping argument. Componentwise transport H and continuation replay C preserve the same path, while Q and N source and name it. The sibling row R gives the only route to the unmarked $\mathsf{ContextFreePumpingLemma}^{\uparrow}$ surface, and that route forgets the mark ledger only after the derivation-prefix witness has been displayed. □

Closure status for $\mathsf{NameCert}_{\mathsf{OgdenLemma}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{OgdenLemma}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8796.1, Definition 8796.2, and Definition 8796.3 seed the marked-position pumping surface over ContextFreeGrammarUp, ContextFreePumpingLemmaUp, ListUp, NatUp, BHist, hsame, Cont, Pkg, and NameCert rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{OgdenLemma}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host language equality, grammar quotient semantics, infinite parse trees, selected parse trees, ambient semantic pumping, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, marked-position exposure, repeated-nonterminal extraction, decomposition exactness, pump replay, sibling forgetful routing, transport, replay, provenance, and local naming for BEDC.Derived.OgdenLemmaUp.

Constructive story: An $\mathsf{OgdenLemma}^{\uparrow}$ packet is generated from a finite ContextFreeGrammarUp grammar packet, a terminal ListUp word row, a NatUp-bounded marked-position ledger, a finite derivation ledger, repeated-nonterminal exposure, decomposition, pump index, yielded word, componentwise hsame transport, Cont replay, sibling ContextFreePumpingLemmaUp routing, package provenance, and a local NameCert row.

Chapter 8797

A Concrete Naming Certificate for BolzanoWeierstrassFiniteSubsequence$^{\uparrow}$

Following Bolzano, Weierstrass, Bishop, and Bridges, the BolzanoWeierstrassFiniteSubsequence$^{\uparrow}$ packet records the finite-window face of the bounded-sequence compactness argument as BEDC NameCert data. It sits after the bounded real sequence carrier of chapter 1415, the finite-window compactness route of chapter 5145, the compact regular Cauchy subsequence surface of chapter 3913, the dyadic tolerance core of chapter 291, the finite stream-name route of chapter 126, the regular rational readback of chapter 301, and the terminal real-name seal of chapter 38. The packet gives Real and Completion consumers a named finite subsequence-window object; it is not general sequential compactness, an infinite selected subsequence, countable choice, trichotomy, or ambient Real$^{\uparrow}$ completeness.

Definition 8797.1 (Bolzano–Weierstrass finite-subsequence carrier)**.** *A* BolzanoWeierstrassFiniteSubsequence$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (X, K, W, I, D, S, R, E, H, C, P, N)$$

with the following displayed rows:

1. *X is the bounded* Real$^{\uparrow}$ *sequence source row, read through* BoundedRealSequence$^{\uparrow}$ *before any compactness-facing request is accepted.*
2. *K is the finite-window compactness row, recording the displayed finite interval, mesh, and pigeonhole ledger consumed from* FiniteWindowCompactness$^{\uparrow}$*.*
3. *W is the* StreamName$^{\uparrow}$ *observation row for the inspected sequence values and mesh witnesses.*
4. *I is the finite increasing index row, stored as a displayed finite list of positions rather than as an infinite subsequence function.*
5. *D is the* DyadicRatCore$^{\uparrow}$ *tolerance ledger comparing the sampled values with the selected finite mesh cell.*
6. *S is the compact regular Cauchy subsequence sibling row, available only as a finite-window handoff to chapter 3913.*
7. *R is the* RegSeqRat$^{\uparrow}$ *readback row obtained from the displayed windows and dyadic tolerances.*
8. *E is the terminal* Real$^{\uparrow}$ *seal row for the finite-window readback.*

9. *H records componentwise* hsame *transport for the source, compactness window, stream observations, finite index list, dyadic tolerance ledger, sibling handoff, readback, seal, replay, provenance, and local naming rows.*

10. *C records displayed* Cont *replay through $X, K, W, I, D, S, R, E, H, P, N$.*

11. *P is the* Pkg *provenance over* $\mathsf{BolzanoWeierstrassFiniteSubsequence}^{\uparrow}$, $\mathsf{BoundedRealSequence}^{\uparrow}$, $\mathsf{FiniteWindowCompactness}^{\uparrow}$, $\mathsf{CompactRegularCauchySubsequence}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*

12. *N is the local* $\mathsf{NameCert}_{\mathsf{BolzanoWeierstrassFiniteSubsequence}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $X, K, W, I, D, S, R, E, H, C, P, N$. It has no coordinate for a host sequential compactness theorem, a selected infinite subsequence, countable choice, order trichotomy, quotient stream equality, or ambient completeness of $\mathsf{Real}^{\uparrow}$.

Theorem 8797.2 (Bolzano–Weierstrass finite-subsequence NameCert obligations)**.** *For every accepted* $\mathsf{BolzanoWeierstrassFiniteSubsequence}^{\uparrow}$ *carrier*

$$B = (X, K, W, I, D, S, R, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{BolzanoWeierstrassFiniteSubsequence}^{\uparrow}}$ *surface consists exactly of the following finite rows:*

1. *carrier admission for the bounded* $\mathsf{Real}^{\uparrow}$ *sequence source X and the finite-window compactness row K;*

2. *classifier stability under componentwise* hsame *transport of $X, K, W, I, D, S, R, E, H, C, P, N$;*

3. *finite-window extraction of the displayed increasing index list I from the inspected stream observations W and dyadic tolerance ledger D;*

4. *the no-choice boundary asserting that I is a finite row and does not name an infinite selected subsequence, countable-choice schedule, trichotomy decision, quotient stream representative, or ambient completeness proof for* $\mathsf{Real}^{\uparrow}$*;*

5. *local* NameCert *packaging through S, R, E, H, C, P, N, with the compact regular Cauchy subsequence sibling read only after the finite window has been exposed.*

No Bolzano–Weierstrass obligation is stored outside those rows.

Proof. Project the carrier of Definition 8797.1. The bounded sequence source X and finite-window compactness row K are the only rows that can introduce the inspected window.

Read W, I, D next. The stream row W exposes the finite sequence observations, the finite index list I records the positions selected inside that displayed window, and the dyadic ledger D checks the tolerance comparison against the chosen mesh cell.

The sibling row S is therefore downstream of a finite extraction. It can hand the displayed data toward the compact regular Cauchy subsequence surface, but it cannot replace the finite index list with a selected infinite subsequence.

Finally route the readback and seal through R, E, H, C, P, N. Since the carrier has no coordinate for countable choice, trichotomy, quotient stream equality, host sequential compactness, or ambient $\mathsf{Real}^{\uparrow}$ completeness, the local NameCert surface is exactly the finite-window package listed in the theorem. □

Theorem 8797.3 (Bolzano–Weierstrass finite-window handoff)**.** *Every Real or Completion consumer of an accepted* $\mathsf{BolzanoWeierstrassFiniteSubsequence}^{\uparrow}$ *packet must read the route*

$$X, K \longmapsto W, I, D \longmapsto S \longmapsto R, E \longmapsto H, C, P, N$$

before it treats the packet as compactness-facing data. The handoff exposes a bounded real sequence source, an explicit finite compactness window, a finite increasing index list, dyadic tolerance comparisons, regular rational readback, and a terminal real seal. It exports no theorem of general sequential compactness, no infinite selected subsequence, no countable-choice schedule, no trichotomy decision, no quotient stream equality, and no ambient completeness principle for $\mathsf{Real}^{\uparrow}$*.*

Proof. Apply Definition 8797.2. It orders the carrier so that boundedness and the compactness window are exposed before the stream observations and finite index list are consumed.

The dyadic ledger then fixes the tolerance comparison for the displayed finite window. The compact regular Cauchy subsequence sibling row can be read only after those finite rows have been presented.

The remaining rows preserve and name the same route. Regular rational readback, the terminal Real seal, componentwise transport, replay, provenance, and local naming do not add a second selection principle, so the consumer receives precisely the displayed finite-window handoff. □

Closure status for $\mathsf{NameCert}_{\mathsf{BolzanoWeierstrassFiniteSubsequence}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BolzanoWeierstrassFiniteSubsequence}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8797.1, Definition 8797.2, and Definition 8797.3 seed the finite-window Bolzano–Weierstrass surface over bounded Real sequence, finite compactness window, StreamName, DyadicRatCore, RegSeqRat, Real, transport, replay, provenance, and local naming rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BolzanoWeierstrassFiniteSubsequence}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close general sequential compactness, infinite selected subsequences, countable choice, trichotomy, quotient stream equality, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, classifier stability, finite-window extraction, no-choice boundary, sibling compact-subsequence handoff, readback, seal, transport, replay, provenance, and local naming for BEDC.Derived.BolzanoWeierstrassFiniteSubsequenceUp.

Constructive story: A $\mathsf{BolzanoWeierstrassFiniteSubsequence}^{\uparrow}$ packet is generated from a bounded Real sequence source, an explicit finite compactness window, StreamName observations, a finite increasing index list, DyadicRatCore tolerance comparisons, a compact regular Cauchy subsequence sibling row, RegSeqRat readback, a Real seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 8798

A Concrete Naming Certificate for CompactIntervalFiniteSubcoverBudget$^{\uparrow}$

Following Bishop and Bridges on compact intervals and finite-cover arguments, the CompactIntervalFiniteSubcoverBu packet records the finite budget by which a displayed located interval cover is read through dyadic mesh cells and refinement depth before any finite subcover conclusion is available. It sits after the dyadic interval-net surface of chapter 5966, the located interval cover packet of chapter 1885, and the finite subcover modulus budget of chapter 8630. The packet supplies a compact-interval consumer route; it does not claim general open-cover compactness, selected representatives of real names, countable choice, quotient stream equality, or ambient Real$^{\uparrow}$ completeness.

Definition 8798.1 (Compact interval located cover selector)**.** *A* CompactIntervalFiniteSubcoverBudget$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (I, L, D, M, R, S, Q, H, C, P, N)$$

with the following displayed rows:

1. *I is the compact interval source row, exposed only as located endpoint and containment data.*
2. *L is the* LocatedIntervalCover$^{\uparrow}$ *row listing the finite located interval cover requests and their endpoint-membership witnesses.*
3. *D is the* DyadicIntervalNet$^{\uparrow}$ *cell row, listing the dyadic mesh cells inspected by the cover selector.*
4. *M is the finite mesh-refinement row, recording the displayed refinement depth and parent-child cell ledger.*
5. *R is the finite selector budget, listing the retained cover entries and the mesh cells certified by each retained entry.*
6. *S is the* StreamName$^{\uparrow}$ *window row opened by the displayed cover, mesh, and refinement data.*
7. *Q is the* RegSeqRat$^{\uparrow}$ *readback and terminal* Real$^{\uparrow}$ *seal row reached only after I, L, D, M, R, S have been displayed.*
8. *H records componentwise* hsame *transport for interval source, located cover, dyadic cells, refinement depth, selector budget, readback, and seal rows.*
9. *C records displayed* Cont *replay from the located cover request through the finite mesh cells, refinement depth, selector budget, and terminal readback.*

10. *P is the* Pkg *provenance over* $\mathsf{CompactIntervalFiniteSubcoverBudget}^{\uparrow}$, $\mathsf{LocatedIntervalCover}^{\uparrow}$, $\mathsf{DyadicIntervalNet}^{\uparrow}$, $\mathsf{FiniteMeshRefinementTree}^{\uparrow}$, $\mathsf{FiniteSubcoverModulusBudget}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

11. *N is the local* $\mathsf{NameCert}_{\mathsf{CompactIntervalFiniteSubcoverBudget}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $I, L, D, M, R, S, Q, H, C, P, N$. It has no coordinate for an arbitrary open cover, a host-side subcover selector, quotient equality of real names, countable choice, or ambient completeness.

Theorem 8798.2 (Compact interval finite-subcover budget)**.** *For every accepted* CompactIntervalFiniteSubcoverBud *carrier*

$$B = (I, L, D, M, R, S, Q, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{CompactIntervalFiniteSubcoverBudget}^{\uparrow}}$ *surface consists exactly of carrier admission, compact interval source exposure, located cover exposure through L, dyadic interval-net exposure through D, finite mesh-refinement depth through M, finite selector budget through R, finite window and regular readback through S, Q, componentwise transport through H, displayed replay through C, package provenance through P, and local naming through N. Every compact-interval finite-subcover consumer must read the sibling routes of chapter 5966, chapter 1885, and chapter 8630 before the retained finite selector budget is public.*

Proof. Project the carrier of Definition 8798.1. The only interval and cover inputs are the displayed compact interval source row I and the located cover row L.

The finite route then passes through D and M. The dyadic interval-net row lists the cells being inspected, and the finite mesh-refinement row records the depth and parent-child ledger used to compare those cells against the located cover requests.

The selector budget R is downstream of those finite rows. It may retain only displayed cover entries and displayed mesh cells, while S and Q keep the finite observation windows, regular rational readback, and Real seal on the same route.

Finally H, C, P, N transport, replay, source, and name the same finite packet. Since no other carrier coordinate is present, the certificate cannot export arbitrary open-cover compactness, countable choice, quotient stream equality, host real equality, or ambient completeness. □

Falsifiable prediction: Every accepted $\mathsf{CompactIntervalFiniteSubcoverBudget}^{\uparrow}$ consumer exposes compact interval source rows, $\mathsf{LocatedIntervalCover}^{\uparrow}$ cover data, $\mathsf{DyadicIntervalNet}^{\uparrow}$ cells, finite mesh-refinement depth, finite selector budget, $\mathsf{StreamName}^{\uparrow}$ windows, $\mathsf{RegSeqRat}^{\uparrow}$ readback, a terminal $\mathsf{Real}^{\uparrow}$ seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert before any finite-subcover budget is public.

Independence witness: dyadic interval net, located interval cover, finite subcover modulus budget: $\mathsf{CompactIntervalFiniteSubcoverBudget}^{\uparrow}$ is not bijective to any listed sibling because it jointly binds located cover requests, dyadic mesh cells, refinement depth, retained cover entries, readback windows, Real sealing, transport, replay, provenance, and local naming into one compact-interval finite-cover budget packet.

Closure status for $\mathsf{NameCert}_{\mathsf{CompactIntervalFiniteSubcoverBudget}^{\uparrow}}$.

Constructive story: A $\mathsf{CompactIntervalFiniteSubcoverBudget}^{\uparrow}$ packet is generated from compact interval source rows, LocatedIntervalCoverUp cover rows, DyadicIntervalNetUp cell rows, finite mesh-refinement depth, a finite selector budget, StreamName windows, RegSeqRat readback, a terminal RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CompactIntervalFiniteSubcoverBudget}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8798.1 and Definition 8798.2 seed the finite compact-interval subcover budget route over located covers, dyadic interval nets, and finite refinement depth.

Formal verification: FormalStatus(NameCert$_{\mathsf{CompactIntervalFiniteSubcoverBudget}\uparrow}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close general open-cover compactness, arbitrary subcover selection, quotient stream equality, countable choice, host real equality, ambient Real$^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, located-cover exposure, dyadic-cell exposure, finite refinement-depth exactness, selector-budget exactness, readback ordering, transport, replay, provenance, and local naming for BEDC.Derived.CompactIntervalFiniteSubcoverBudgetUp.

Chapter 8799

A Concrete Naming Certificate for $\mathsf{RhFreeZeroInitiality}^{\uparrow}$

The $\mathsf{RhFreeZeroInitiality}^{\uparrow}$ packet realizes the RH-free zero-generation initiality route of chapter 9255 as finite NameCert data. It consumes the zero-fiber and legal-generator factorization rows of chapter 8772 before forming its RH-free generated-zero signature and no-circularity audit. It records a generated zero signature, a no-circularity audit, initial-algebra rows, exactness obligations, and fixed-half refusal boundaries without asserting the Riemann Hypothesis, analytic continuation, zero completeness, or a fixed-half section. The packet is a BEDC-native audit surface for the route; it is not a zero generator and not a proof of the analytic claim.

The no-circularity row also consumes the halting-boundary refusal route of chapter 5564 and the fixed-statement separation route of chapter 8824 before its generated-carrier initiality row is public. Thus an accepted initiality read has already separated constructor generation from RH-route halting refusal and fixed-statement closure boundaries.

Definition 8799.1 (RH-free zero initiality NameCert)**.** *A* $\mathsf{RhFreeZeroInitiality}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Z = (F, A, G, I, E, K, X, H, C, P, N)$$

with the following displayed rows:

1. *F is the RH-free zero signature row, listing constructor kinds for the zero-generation endofunctor.*
2. *A is the* $\mathsf{NoRHCirc}$ *audit row, refusing any constructor input that consumes an* $\mathsf{OnCritLine}$ *witness, a fixed-half section witness, the proposition* RH*, or an unfactored zero-source oracle.*
3. *G is the generated zero carrier row, naming the displayed initial algebra over F.*
4. *I is the initiality row, recording the fold and uniqueness surface available for generated zero rows.*
5. *E is the zero-presentation exactness obligation row: soundness, faithfulness, and essential coverage are stored as separate finite obligations.*
6. *K is the fixed-half closure obligation row, recording constructor-by-constructor preservation requirements without supplying a fixed-half witness as input.*
7. *X is the no-circularity refusal ledger, retaining failed rows whose constructor reads* $\mathsf{OnCritLine}$ *or a fixed-half section before generation.*

8. *H records componentwise* hsame *transport for signature, audit, generated carrier, initiality, exactness, fixed-half closure, refusal, replay, provenance, and local naming rows.*
9. *C records displayed* Cont *replay from a zero-generation constructor request through F, A, G, I, E, K, X, H.*
10. *P is the* Pkg *provenance over* $\mathsf{RhFreeZeroInitiality}^{\uparrow}$*, the RH-free zero-generation vision route,* BHist*,* hsame*,* Cont*, and* NameCert*.*
11. *N is the local* $\mathsf{NameCert}_{\mathsf{RhFreeZeroInitiality}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $F, A, G, I, E, K, X, H, C, P, N$. It has no coordinate for an analytic zero source, a proof that all zeta zeros are generated, an OnCritLine *witness, a fixed-half section, or an RH theorem.*

Theorem 8799.2 (RH-free zero initiality no fixed-half circularity)**.** *For every accepted* $\mathsf{RhFreeZeroInitiality}^{\uparrow}$ *carrier*

$$Z = (F, A, G, I, E, K, X, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{RhFreeZeroInitiality}^{\uparrow}}$ *obligation surface has exactly five mathematical rows:*

1. *RH-free signature admission through F;*
2. *no-circularity audit through A and refusal ledger X;*
3. *generated zero carrier and initiality exposure through G, I;*
4. *zero-presentation exactness obligations through E;*
5. *fixed-half closure obligations through K.*

The structural rows H, C, P, N transport, replay, source, and name those five rows. No accepted constructor row may consume an OnCritLine *witness or fixed-half section witness before the generated carrier, exactness obligations, and fixed-half closure obligations have been displayed.*

Proof. Project the carrier of Definition 8799.1. The visible mathematical rows are F, A, G, I, E, K, X, followed by the structural rows H, C, P, N.

The no-circularity rows are read before initiality is used. If a constructor consumes OnCritLine, a fixed-half section, RH, or an unfactored zero-source oracle, the row is stored in X as a refusal rather than in the accepted constructor surface.

Initiality then applies only to the generated carrier G over the admitted signature F. The exactness row E and fixed-half closure row K remain obligations displayed beside the initiality row; neither is supplied by initiality alone.

Transport and replay preserve the same route. Since P and N contain no analytic zero source, fixed-half witness, section witness, or RH theorem coordinate, the packet records the no-circularity audit without proving the analytic conclusion. □

Falsifiable prediction: Any accepted $\mathsf{RhFreeZeroInitiality}^{\uparrow}$ zero-generation constructor row fails if it consumes an OnCritLine witness, a fixed-half section witness, the proposition RH, or an unfactored zero-source oracle before the no-circularity audit, generated carrier, exactness obligations, fixed-half closure obligations, transport, replay, provenance, and local NameCert rows are displayed.

Independence witness: `rh_layered_translation`, `zeta_self_similar_recovered_carrier`, `prime_fingerprint_separation`, `zero_skew_eventflow_target`: $\mathsf{RhFreeZeroInitiality}^{\uparrow}$ is not bijective to any listed sibling because the NoRHCirc row and the separated initiality, exactness, and fixed-half closure obligations jointly form a no-circularity audit surface rather than a zero carrier, a prime fingerprint classifier, an event-flow target, or a fixed-half section.

Closure status for $\mathsf{NameCert}_{\mathsf{RhFreeZeroInitiality}^{\uparrow}}$.

Constructive story: A $\mathsf{RhFreeZeroInitiality}^{\uparrow}$ packet is generated from an RH-free zero signature, a NoRHCirc audit row, generated zero carrier rows, initiality rows, exactness obligations, fixed-half closure obligations, refusal ledger rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RhFreeZeroInitiality}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8799.1 and Definition 8799.2 seed the finite no-circularity audit surface for RH-free zero-generation initiality.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RhFreeZeroInitiality}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close analytic continuation, zero completeness, an RH proof, fixed-half section existence, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked signature admission, NoRHCirc refusal, generated-carrier initiality, zero-presentation exactness, fixed-half closure, transport, replay, provenance, and local naming for BEDC.Derived.RhFreeZeroInitialityUp.

Chapter 8800

A Concrete Naming Certificate for $\mathsf{BishopMonotoneConvergenceBoundary}^{\uparrow}$

Following Bishop and Bridges on bounded monotone convergence, the $\mathsf{BishopMonotoneConvergenceBoundary}^{\uparrow}$ packet records the finite boundary at which bounded monotone sequence data may hand off to the Bishop Cauchy convergence criterion and then to the L10 Real route. It sits beside the criterion packet of chapter 6459, the bounded real sequence surface of chapter 1415, the dyadic tolerance core of chapter 291, the finite stream windows of chapter 126, the regular rational readback of chapter 301, and the terminal real-name seal of chapter 38. The packet names only the constructive finite handoff from monotone bounded data to Cauchy-readiness; it does not assert an ambient completeness theorem for all $\mathsf{Real}^{\uparrow}$ streams.

Definition 8800.1 (Bishop monotone convergence boundary carrier)**.** *A* $\mathsf{BishopMonotoneConvergenceBoundary}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (S, B, M, Q, D, R, E, H, C, P, N)$$

with the following displayed rows:

1. *S is the sequence schedule row, recording the finite* $\mathsf{StreamName}^{\uparrow}$ *windows through which the monotone source is inspected.*
2. *B is the boundedness row, exposing the* $\mathsf{BoundedRealSequence}^{\uparrow}$ *bound ledger attached to the same windows.*
3. *M is the monotone ledger, recording the displayed order comparisons that make later tails compatible with earlier bounds.*
4. *Q is the Bishop Cauchy convergence criterion row, reached only after the boundedness and monotone ledgers have stayed visible.*
5. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row, displaying the requested radii, split budgets, comparison scales, and endpoint tolerances used by Q.*
6. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row, repacking the inspected windows as regular rational data for Real-facing consumers.*
7. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row, available only after S, B, M, Q, D, R have been displayed.*
8. *H records componentwise* hsame *transport for the schedule, boundedness, monotone ledger, criterion, tolerance, readback, real seal, replay, provenance, and local naming rows.*

9. *C records displayed* Cont *replay from a monotone-convergence request through $S, B, M, Q, D, R, E, H, P, N$.*
10. *P is the* Pkg *provenance over* $\mathsf{BishopMonotoneConvergenceBoundary}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{BoundedRealSequence}^{\uparrow}$, $\mathsf{BishopCauchyConvergenceCriterion}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{BishopMonotoneConvergenceBoundary}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $S, B, M, Q, D, R, E, H, C, P, N$. It has no coordinate for a selected limit, quotient equality of streams, countable choice, detached monotone convergence, host real completeness, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 8800.2 (Bishop monotone convergence boundary NameCert obligations)**.** *For every accepted* $\mathsf{BishopMonotoneConvergenceBoundary}^{\uparrow}$ *carrier*

$$K = (S, B, M, Q, D, R, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{BishopMonotoneConvergenceBoundary}^{\uparrow}}$ *surface consists exactly of the following finite obligation families:*

1. *carrier admission for the sequence schedule, boundedness row, monotone ledger, Bishop Cauchy convergence criterion row, dyadic tolerance row, RegSeqRat readback, Real seal, transport, replay, provenance, and local naming;*
2. *bounded-monotone exposure, requiring B and M to be read from the finite windows scheduled by S before any convergence criterion is consumed;*
3. *criterion handoff, requiring Q to consume the displayed boundedness and monotone rows rather than an external monotone convergence theorem;*
4. *finite L10 seal nonescape, requiring D, R, E to expose dyadic tolerances, regular rational readback, and the terminal Real seal in order;*
5. *transport, replay, provenance, and local naming, requiring H, C, P, N to preserve and name the same finite route without adding selected limits, quotient stream equality, countable choice, host real completeness, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

No local obligation is stored outside these rows.

Proof. Carrier admission is projection from Definition 8800.1. The accepted packet displays exactly the schedule, boundedness, monotone, criterion, tolerance, readback, seal, and structural rows.

Bounded-monotone exposure is read from S, B, M. The boundedness row and monotone ledger are attached to the same finite windows, so no consumer can replace them by a detached convergence theorem.

The criterion handoff is the role of Q. It receives only the displayed boundedness and monotone data, then passes through the dyadic tolerance row D and the regular readback row R before any Real-facing seal is available.

Finally E, H, C, P, N add only the terminal seal, transport, replay, provenance, and local naming. Since the carrier has no selected-limit, quotient-stream, countable-choice, host-completeness, or ambient-completeness coordinate, the listed families exhaust the local NameCert surface. □

Theorem 8800.3 (Bishop monotone convergence boundary L10 nonescape)**.** *Every* $\mathsf{Real}^{\uparrow}$*-facing consumer of an accepted* $\mathsf{BishopMonotoneConvergenceBoundary}^{\uparrow}$ *packet factors through the displayed route*

$$\mathsf{StreamName}^{\uparrow},\ \mathsf{BoundedRealSequence}^{\uparrow},\ \mathsf{BishopCauchyConvergenceCriterion}^{\uparrow},\ \mathsf{DyadicRatCore}^{\uparrow},\ \mathsf{RegSeqRat}^{\uparrow},\ \mathsf{Real}^{\uparrow}.$$

In carrier coordinates, the consumer reads S for StreamName windows, B and M for bounded monotone exposure, Q for the Bishop Cauchy convergence criterion, D for DyadicRatCore tolerances, R for RegSeqRat readback, and E for the Real seal before H, C, P, N may transport, replay, source, and name the route.

Proof. Start with a Real-facing read of an accepted packet. Projection exposes the ordered carrier rows $S, B, M, Q, D, R, E, H, C, P, N$.

The window row S is the only schedule coordinate. The boundedness row B and monotone ledger M are attached to that schedule, so the consumer receives bounded monotone sequence data only through finite StreamName windows.

Apply Definition 8800.2. The criterion handoff requires Q to consume the displayed S, B, M rows, and the finite L10 seal obligation then routes the read through D, R, E.

The structural rows H, C, P, N preserve and name the same route. Therefore every Real-facing consumer passes through StreamName, BoundedRealSequence, BishopCauchyConvergenceCriterion, DyadicRatCore, RegSeqRat, and Real rows, and none can extract a selected limit, quotient stream equality, countable choice, detached monotone convergence theorem, host real completeness, or ambient $\mathsf{Real}^{\uparrow}$ completeness. □

Falsifiable prediction: Every accepted $\mathsf{BishopMonotoneConvergenceBoundary}^{\uparrow}$ Real-facing read factors through $\mathsf{StreamName}^{\uparrow}$ windows, $\mathsf{BoundedRealSequence}^{\uparrow}$ boundedness, a monotone ledger, $\mathsf{BishopCauchyConvergenceCriterion}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$ tolerances, $\mathsf{RegSeqRat}^{\uparrow}$ readback, a terminal $\mathsf{Real}^{\uparrow}$ seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming.

Independence witness: bishop-cauchy-convergence-criterion, boundedrealsequence, streamname, regseqrat, dyadicratcore, real: $\mathsf{BishopMonotoneConvergenceBoundary}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries bounded monotone source exposure, criterion handoff, dyadic tolerance accounting, regular rational readback, Real sealing, transport, replay, provenance, and local NameCert rows.

Closure status for $\mathsf{NameCert}_{\mathsf{BishopMonotoneConvergenceBoundary}^{\uparrow}}$.

Constructive story: A $\mathsf{BishopMonotoneConvergenceBoundary}^{\uparrow}$ packet is generated from StreamName windows, BoundedRealSequence boundedness, a monotone ledger, a BishopCauchyConvergenceCriterion handoff, DyadicRatCore tolerances, RegSeqRat readback, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BishopMonotoneConvergenceBoundary}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8800.1, Definition 8800.2, and Definition 8800.3 seed the finite monotone-bounded convergence boundary over StreamName, BoundedRealSequence, BishopCauchyConvergenceCriterion, DyadicRatCore, RegSeqRat, Real, transport, replay, provenance, and local naming rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BishopMonotoneConvergenceBoundary}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close selected limits, quotient stream equality, countable choice, detached monotone convergence, host real completeness, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, bounded-monotone exposure, criterion handoff, finite L10 seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.BishopMonotoneConvergenceBoundaryUp.

Chapter 8801

Located Interval Enclosure NameCert Construction

Following Bishop and Bridges on constructive real intervals, the $\mathsf{LocatedIntervalEnclosure}^{\uparrow}$ packet records a finite enclosure of a displayed real-name read by dyadic endpoints before any nested-interval or completion consumer may use it. It consumes the dyadic endpoint arithmetic of chapter 291, finite observation windows from chapter 126, regular rational readback from chapter 301, the terminal real-name seal of chapter 38, and the dyadic interval-cell route of chapter 5966. The packet names a displayed enclosure row; it does not assert interval compactness, choose a completed point, identify host real equality, invoke countable choice, or claim ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 8801.1 (Located interval enclosure carrier)**.** *A* $\mathsf{LocatedIntervalEnclosure}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$E = (L, U, O, W, R, S, H, C, P, N)$$

with the following displayed rows:

1. *L and U are* $\mathsf{DyadicRatCore}^{\uparrow}$ *endpoint rows for the lower and upper dyadic bounds.*
2. *O is the endpoint order row, displaying that the lower endpoint precedes the upper endpoint inside the same dyadic tolerance ledger.*
3. *W is the* $\mathsf{StreamName}^{\uparrow}$ *finite observation window inspected before the enclosure is admitted.*
4. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *regular rational readback row attached to the same window and dyadic tolerance budget.*
5. *S is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row for the named real read enclosed by L, U, W, R.*
6. *H records componentwise* hsame *transport for the endpoints, order row, containment witness, stream window, readback row, Real seal, replay row, provenance row, and local name.*
7. *C records displayed* Cont *replay from the window request through the endpoint, containment, readback, seal, transport, provenance, and naming rows.*
8. *P is the* Pkg *provenance over* $\mathsf{LocatedIntervalEnclosure}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{DyadicIntervalNet}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
9. *N is the local* $\mathsf{NameCert}_{\mathsf{LocatedIntervalEnclosure}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through $L, U, O, W, R, S, H, C, P, N$. It has no coordinate for host real equality, quotient representatives, selected limits, countable choice, open-cover compactness, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 8801.2 (Located interval enclosure carrier extraction)**.** *Every accepted* $\mathsf{LocatedIntervalEnclosure}^{\uparrow}$ *read exposes the dyadic endpoint rows* L, U*, the endpoint order row* O*, the* $\mathsf{StreamName}^{\uparrow}$ *finite window* W*, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback* R*, the terminal* $\mathsf{Real}^{\uparrow}$ *seal* S*, and the structural rows* H, C, P, N *before an enclosure judgment is public.*

Proof. Project the carrier of Definition 8801.1. The tuple lists exactly the endpoint, order, window, readback, seal, transport, replay, provenance, and local naming rows.

The sibling routes named in the introduction supply those rows only as displayed finite data. Dyadic endpoints and the interval-net cell are read before the stream window and regular readback, and the Real seal is reached only after those finite rows have been displayed.

Since the classifier has no coordinate beyond $L, U, O, W, R, S, H, C, P, N$, no public enclosure read can bypass this extraction route. □

Theorem 8801.3 (Located interval enclosure endpoint-refinement transport)**.** *Let* $E = (L, U, O, W, R, S, H, C, P, N$ *be an accepted* $\mathsf{LocatedIntervalEnclosure}^{\uparrow}$ *carrier. If refined dyadic endpoints* L', U' *preserve the endpoint order row and the containment witness through the same* $\mathsf{DyadicIntervalNet}^{\uparrow}$ *cell, then the enclosure transports to*

$$E' = (L', U', O, W, R, S, H, C, P, N)$$

without changing the stream window, regular readback, Real seal, replay, provenance, or local name.

Proof. Read the endpoint refinement through the dyadic endpoint rows and the interval-net cell. The hypotheses keep the order and containment witness attached to the same displayed dyadic route.

Apply the componentwise hsame transport row H. It carries endpoint replacement while leaving the finite observation window, regular readback, Real seal, replay, provenance, and local name on their original rows.

The transported carrier therefore remains an accepted enclosure packet. Because no host real equality or quotient coordinate is present, the transport is only the displayed endpoint-refinement route. □

Theorem 8801.4 (Located interval enclosure Real-seal nonescape)**.** *Every* $\mathsf{Real}^{\uparrow}$*-facing consumer of an accepted* $\mathsf{LocatedIntervalEnclosure}^{\uparrow}$ *packet factors through the displayed route*

$$L, U, O, W, R, S, H, C, P, N.$$

The consumer receives a sealed real-name read inside dyadic enclosure rows, but it receives no host real equality, quotient representative, selected limit, countable-choice schedule, interval compactness theorem, or ambient $\mathsf{Real}^{\uparrow}$ *completeness principle.*

Proof. Start with carrier extraction, Definition 8801.2. It forces the dyadic endpoints, order row, finite window, regular readback, and terminal seal to be visible before any enclosure judgment is public.

Use endpoint-refinement transport, Definition 8801.3, for the only permitted endpoint variation. Refinement preserves the displayed rows and cannot introduce a new host-side coordinate.

Finally read the refusal inventory in the classifier of Definition 8801.1. Since the accepted packet has no coordinate for the excluded objects, the Real-facing route cannot escape the finite enclosure surface. □

Falsifiable prediction: An accepted $\mathsf{LocatedIntervalEnclosure}^{\uparrow}$ consumer that reaches a $\mathsf{Real}^{\uparrow}$ seal without first displaying dyadic endpoints, endpoint order, a finite StreamName window, a RegSeqRat readback row, transport, replay, provenance, and local naming refutes the carrier surface.

Independence witness: dyadicratcore, streamname, regseqrat, real, dyadic-interval-net: no listed sibling supplies the whole packet $E = (L, U, O, W, R, S, H, C, P, N)$, because each sibling contributes only endpoint arithmetic, finite observation, regular readback, terminal sealing, or interval-cell routing while this chapter binds them into one enclosure certificate.

Closure status for $\mathsf{NameCert}_{\mathsf{LocatedIntervalEnclosure}^{\uparrow}}$.

Constructive story: A $\mathsf{LocatedIntervalEnclosure}^{\uparrow}$ packet is generated from DyadicRatCore endpoint rows, an endpoint order row, a containment witness routed through DyadicIntervalNet, a StreamName finite observation window, RegSeqRat readback, a terminal RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert data.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{LocatedIntervalEnclosure}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8801.1, Definition 8801.2, Definition 8801.3, and Definition 8801.4 seed the finite enclosure packet over dyadic endpoints, finite windows, regular readback, terminal sealing, transport, replay, provenance, and local naming.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{LocatedIntervalEnclosure}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close interval compactness, point extraction, host real equality, quotient representatives, selected limits, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier extraction, endpoint-refinement transport, and Real-seal nonescape for BEDC.Derived.LocatedIntervalEnclosureUp.

Chapter 8802

Golden-Mean Shift Window-Six NameCert Construction

Following Lind and Marcus, the golden-mean subshift is the finite-type no-adjacent-one shift. The $\mathsf{GoldenMeanShiftWindowSix}^{\uparrow}$ packet realizes the window-six kernel of Definition 9347.15 as finite BHist data: a six-cell binary window, a two-state transition classifier, a shift-stability row, a finite-window growth row, Zeckendorf carry-facing provenance through chapter 278 and chapter 544, and local NameCert evidence. The packet names the finite symbolic-dynamics carrier used by the Axis-Zeckendorf vision; it is not an invariant measure, a two-sided completion, a host entropy theorem, or a claim that all Zeckendorf carries have been bridged.

Definition 8802.1 (Golden-mean window-six carrier)**.** *A* $\mathsf{GoldenMeanShiftWindowSix}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$G = (W, K, T, S, F, H, C, P, N)$$

with the following displayed rows:

1. *W is a six-symbol binary window row.*
2. *K is the no-adjacent-one transition-kernel classifier of Definition 9347.15, restricted to adjacent pairs inside W.*
3. *T is the transition ledger recording which adjacent pairs are admitted by K.*
4. *S is the one-step shift-stability row: deleting the first cell and reading the remaining five-cell suffix preserves the admitted adjacent-pair rows.*
5. *F is the finite-window growth row, recording the Fibonacci recurrence of Definition 9347.16 at the inspected window length.*
6. *H records componentwise* hsame *transport for the window, transition classifier, transition ledger, shift row, growth row, replay row, provenance row, and local name.*
7. *C records displayed* Cont *replay from the window read through K, T, S, F, H, P, N.*
8. *P is the* Pkg *provenance over* $\mathsf{GoldenMeanShiftWindowSix}^{\uparrow}$*, the Axis-Zeckendorf kernel of Definition 9347.15,* $\mathsf{ZeckendorfNormal}^{\uparrow}$*,* $\mathsf{ZCarry}^{\uparrow}$*,* BHist*,* hsame*,* Cont*, and* $\mathsf{NameCert}$*.*
9. *N is the local* $\mathsf{NameCert}_{\mathsf{GoldenMeanShiftWindowSix}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $W, K, T, S, F, H, C, P, N$. It has no coordinate for a host subshift object, invariant measure, entropy limit, two-sided completion, unrestricted carry propagation, or bridge credential.

Theorem 8802.2 (Golden-mean transition-kernel obligations)**.** *For every accepted* $\mathsf{GoldenMeanShiftWindowSix}^{\uparrow}$ *carrier* $G = (W, K, T, S, F, H, C, P, N)$*, the local transition-kernel obligations are exactly pair admission by the no-adjacent-one classifier, transport of those pair rows under* hsame*, and replay of the admitted finite window through* C, P, N*.*

Proof. Project the carrier of Definition 8802.1. The only transition coordinates are K and T, so every adjacent-pair decision is read through the displayed no-adjacent-one classifier.

The transport row H carries the same pair decisions under accepted renaming of the finite window. Replay and provenance through C, P, N can name the route but cannot add another transition classifier.

Since no host subshift, measure, entropy, or unrestricted carry coordinate belongs to the carrier, the listed rows exhaust the local transition obligations. □

Theorem 8802.3 (Golden-mean window-six shift stability)**.** *Every accepted* $\mathsf{GoldenMeanShiftWindowSix}^{\uparrow}$ *carrier exports shift stability only by reading* S *after* W, K, T *have displayed the no-adjacent-one pair rows. The shifted five-cell suffix remains inside the same transition-kernel classifier and the same* BHist*,* hsame*,* Cont*,* Pkg*, and* $\mathsf{NameCert}$ *surface.*

Proof. Read the finite window W and transition rows K, T. They display every adjacent pair whose preservation matters after the first cell is dropped.

The shift row S is then a suffix read of the same finite window. It preserves all adjacent-pair rows that remain in the suffix and does not introduce a second classifier.

Finally H, C, P, N transport, replay, source, and name that suffix route. Thus shift stability is a finite NameCert row, not a host dynamical-system completion. □

Theorem 8802.4 (Golden-mean window-six finite growth route)**.** *Any finite-window growth read from an accepted* $\mathsf{GoldenMeanShiftWindowSix}^{\uparrow}$ *packet factors through* F *after the transition classifier* K *and ledger* T *have been displayed. The read may cite the recurrence of Definition 9347.16, but it exports only the inspected finite growth row and not a host entropy limit or a completed inverse-limit carrier.*

Proof. Start with the kernel obligations of Definition 8802.2. They ensure that the no-adjacent-one grammar has been displayed as finite adjacent-pair data.

The growth row F reads the same grammar at the inspected window length. It records the Fibonacci recurrence locally, using the vision proposition only as the named source of the finite recurrence.

The refusal inventory in Definition 8802.1 excludes host entropy and completed inverse-limit coordinates. Therefore the growth route remains a finite NameCert row. □

Falsifiable prediction: An accepted $\mathsf{GoldenMeanShiftWindowSix}^{\uparrow}$ read that exports shift stability or finite growth without first displaying the six-cell window, no-adjacent-one classifier, transition ledger, transport, replay, provenance, and local naming refutes the carrier surface.

Independence witness: axiszeckendorf-kernel, zeckendorf-normal, zcarry: no listed source supplies the whole packet $G = (W, K, T, S, F, H, C, P, N)$, because the vision source supplies the grammar while the Zeckendorf and carry-facing siblings supply normal-word provenance rather than the local window-six transition, shift, growth, transport, replay, provenance, and NameCert rows.

Closure status for $\mathsf{NameCert}_{\mathsf{GoldenMeanShiftWindowSix}^{\uparrow}}$**.**

Constructive story: A GoldenMeanShiftWindowSix$^{\uparrow}$ packet is generated from a six-cell binary BHist window, the no-adjacent-one transition kernel, a transition ledger, a shift-stability row, a finite-window growth row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert data.

Theory closure: TheoryGate(NameCert$_{\text{GoldenMeanShiftWindowSix}\uparrow}$, seed)

Scope closed: Definition 8802.1, Definition 8802.2, Definition 8802.3, and Definition 8802.4 seed the finite no-adjacent-one window packet over transition, shift, growth, transport, replay, provenance, and local naming rows.

Formal verification: FormalStatus(NameCert$_{\text{GoldenMeanShiftWindowSix}\uparrow}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close invariant measures, entropy limits, two-sided completions, unrestricted Zeckendorf carry propagation, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked transition-kernel obligations, shift stability, finite growth, and provenance ledger rows for BEDC.Derived.GoldenMeanShiftWindowSixUp.

Chapter 8803

A Concrete Naming Certificate for $\mathsf{ContinuousLattice}^{\uparrow}$

Following Gierz–Hofmann–Keimel–Lawson–Mislove–Scott, the $\mathsf{ContinuousLattice}^{\uparrow}$ packet records the domain-theoretic carrier in which every displayed element has a finite approximation row and every directed read remains tied to a complete-lattice substrate. It sits between the directed-supremum surface of chapter 5905, the complete meet–join surface of chapter 5155, the Scott-open consumer of chapter 5950, and the point-free open comparison route of chapter 5153. The packet names finite way-below, directed-join, and Scott-handoff rows for L10 approximation consumers; it is not a host powerset lattice, not an unrestricted frame theorem, not a selected basis theorem, and not an ambient spatiality claim.

Definition 8803.1 (Continuous lattice carrier)**.** *A* $\mathsf{ContinuousLattice}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Q = (D, C, W, A, S, L, H, R, P, N)$$

with the following displayed rows:

1. *D is the* $\mathsf{DCPO}^{\uparrow}$ *source row, exposing finite order, directed-family, supremum, and lower-bound exactness data.*
2. *C is the* $\mathsf{CompleteLattice}^{\uparrow}$ *source row, exposing displayed certified-family joins and meets.*
3. *W is the way-below ledger: every approximant named by the packet is tied to a finite directed-window witness.*
4. *A is the approximation row, recording that each listed element is read through directed joins of its visible way-below approximants.*
5. *S is the* $\mathsf{ScottTopology}^{\uparrow}$ *handoff row for upper-set and directed-inaccessibility reads.*
6. *L is the* $\mathsf{LocaleSpace}^{\uparrow}$ *comparison row for point-free finite-open and cover-refinement observations.*
7. *H records componentwise* hsame *transport for all visible continuous-lattice rows.*
8. *R records displayed* Cont *replay from directed reads to approximation rows and Scott-facing handoff rows.*
9. *P is the* Pkg *provenance over* $\mathsf{ContinuousLattice}^{\uparrow}$, $\mathsf{DCPO}^{\uparrow}$, $\mathsf{CompleteLattice}^{\uparrow}$, $\mathsf{ScottTopology}^{\uparrow}$, $\mathsf{LocaleSpace}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$ *rows.*

10. N is the local $\mathsf{NameCert}_{\mathsf{ContinuousLattice}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $D, C, W, A, S, L, H, R, P, N$. It has no coordinate for host powersets, arbitrary joins outside the displayed complete-lattice row, selected bases, quotient opens, global spatiality, Lean verification, or bridge checking.

Theorem 8803.2 (Continuous lattice NameCert obligations)**.** *For every accepted* $\mathsf{ContinuousLattice}^{\uparrow}$ *carrier $Q = (D, C, W, A, S, L, H, R, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{ContinuousLattice}^{\uparrow}}$ *surface consists exactly of DCPO source admission, complete-lattice source admission, way-below ledger exposure, approximation-row exposure, Scott-topology handoff, locale comparison, componentwise transport, continuation replay, provenance, and local naming. Every approximation consumer must read D, C, W, A before using S or L as a topology-facing observation.*

Proof. Project the carrier of Definition 8803.1. The order-theoretic substrate is split into the directed-complete row D and the complete-lattice row C, so no consumer can read approximation data before both source rows are visible.

The finite approximation evidence is stored in W and A. The way-below ledger W names the displayed approximants, while A records the directed-join read by which each listed element is approximated.

The topology-facing rows are downstream. The Scott handoff S may be read only after the directed-supremum and approximation rows have been inspected, and the locale comparison L may be read only as point-free finite-open data tied to the same packet.

Finally H, R, P, N preserve the displayed rows as certificate data. Thus the local surface is finite NameCert evidence over the listed rows, not a host complete lattice or unrestricted frame construction. □

Theorem 8803.3 (Continuous lattice Scott handoff)**.** *Every* $\mathsf{ScottTopology}^{\uparrow}$ *or* $\mathsf{LocaleSpace}^{\uparrow}$ *consumer of an accepted* $\mathsf{ContinuousLattice}^{\uparrow}$ *packet must factor its read through*

$$\mathsf{DCPO}^{\uparrow}, \quad \mathsf{CompleteLattice}^{\uparrow}, \quad W, \quad A$$

before it treats S or L as public open data. The handoff exports the finite approximation route needed by Scott-open and locale-facing consumers, but it does not claim spatiality, a selected basis, a host frame of all opens, or equality with an unrestricted continuous-domain construction.

Proof. Use Definition 8803.2. It requires every accepted packet to expose the DCPO row, complete-lattice row, way-below ledger, and approximation row before topology-facing observations are public.

The $\mathsf{ScottTopology}^{\uparrow}$ consumer reads S only as an upper-set and directed-inaccessibility handoff tied to D, W, A. The $\mathsf{LocaleSpace}^{\uparrow}$ consumer reads L only as a point-free comparison row tied to the same finite approximation packet.

Since neither S nor L contains a coordinate for selected bases, host powersets, quotient opens, or spatiality, the handoff remains the displayed finite route from order and approximation rows to topology-facing observations. □

Falsifiable prediction: An accepted $\mathsf{ContinuousLattice}^{\uparrow}$ consumer that exports Scott-open or locale-facing data while omitting the $\mathsf{DCPO}^{\uparrow}$ row D, $\mathsf{CompleteLattice}^{\uparrow}$ row C, way-below ledger W, or approximation row A refutes the packet.

Independence witness: dcpo, complete-lattice, scott-topology, locale-space: none is bijective to $\mathsf{ContinuousLattice}^{\uparrow}$ because this packet jointly carries directed completeness, complete-lattice family

joins and meets, finite way-below approximation, Scott handoff, locale comparison, transport, replay, provenance, and local naming as one certificate surface.

Closure status for $\mathsf{NameCert}_{\mathsf{ContinuousLattice}^{\uparrow}}$.

Constructive story: A $\mathsf{ContinuousLattice}^{\uparrow}$ packet is generated from a DCPO source row, CompleteLattice source row, finite way-below ledger, approximation row, ScottTopology handoff, LocaleSpace comparison, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{ContinuousLattice}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8803.1, Definition 8803.2, and Definition 8803.3 seed the finite continuous-lattice approximation route over DCPO, CompleteLattice, ScottTopology, LocaleSpace, BHist, hsame, Cont, Pkg, and NameCert rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{ContinuousLattice}^{\uparrow}}, \mathsf{formalTarget})$

Bridge status: none

Not claimed: This chapter does not close selected bases, host powerset lattices, arbitrary frame completeness, spatiality, quotient-open equality, Lean theorem checking, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, way-below ledger exactness, approximation-row exactness, ScottTopology handoff, LocaleSpace comparison, transport, replay, provenance, and local naming for BEDC.Derived.ContinuousLatticeUp.

Lean4 (statement) `BEDC.Derived.ContinuousLatticeUp`

Chapter 8804

A Concrete Naming Certificate for $\mathsf{WeierstrassFunction}^{\uparrow}$

Following Weierstrass and Bishop–Bridges constructive analysis, the $\mathsf{WeierstrassFunction}^{\uparrow}$ packet records a finite approximation route for the classical nowhere-smooth trigonometric series by using only displayed windows, dyadic ledgers, and regular real-name handoffs. It sits after the majorant route of chapter 399, the uniform Cauchy series surface of chapter 1736, the finite stream-window interface of chapter 126, the regular rational readback of chapter 301, the dyadic tolerance core of chapter 291, and the terminal real-name seal of chapter 38. The packet names the constructive finite-window approximation route; it does not assert a host function space, differentiability failure, quotient equality of functions, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 8804.1 (Weierstrass function finite-approximation carrier)**.** *A* $\mathsf{WeierstrassFunction}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$W = (T, A, M, U, S, Q, R, H, C, P, N)$$

with the following displayed rows:

1. *T is the finite trigonometric-polynomial window, listing only the inspected frequencies, phase samples, and partial sums of the approximation.*
2. *A is the dyadic amplitude and frequency ledger for the same window, including the finite amplitude weights and frequency growth entries read by T.*
3. *M is the M-test majorant row that bounds the displayed tail requests through positive dyadic comparison data.*
4. *U is the uniform Cauchy threshold row, stated as a finite request-to-tail ledger rather than as an ambient infinite sum.*
5. *S is the* $\mathsf{StreamName}^{\uparrow}$ *window surface through which sample points, partial sums, and tail requests are observed.*
6. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row attached to the visible rational approximants.*
7. *R is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached after the uniform Cauchy threshold and regular readback have been displayed.*
8. *H records componentwise* hsame *transport for trigonometric windows, dyadic ledgers, majorant rows, uniform thresholds, stream windows, readbacks, real seals, replay, provenance, and local naming.*

9. *C records displayed* Cont *replay of the same finite route.*
10. *P is the* Pkg *provenance over* $\mathsf{WeierstrassFunction}^{\uparrow}$, $\mathsf{WeierstrassMTest}^{\uparrow}$, $\mathsf{UniformCauchySeries}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{WeierstrassFunction}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through $T, A, M, U, S, Q, R, H, C, P, N$. It has no coordinate for a completed function space, a global infinite series object, differentiability failure, quotient equality of functions, countable choice, selected limits, or ambient completeness of $\mathsf{Real}^{\uparrow}$.

Theorem 8804.2 (Weierstrass function finite-window NameCert obligations)**.** *For every accepted* $\mathsf{WeierstrassFunction}^{\uparrow}$ *carrier*

$$W = (T, A, M, U, S, Q, R, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{WeierstrassFunction}^{\uparrow}}$ *surface consists exactly of finite trigonometric-polynomial window exposure through T, dyadic amplitude and frequency ledger exposure through A, M-test majorant exposure through M, uniform Cauchy threshold exposure through U, StreamName observation through S, RegSeqRat readback through Q, RealUp sealing through R, componentwise transport through H, displayed replay through C, provenance through P, and local naming through N.*

Proof. Project the carrier of Definition 8804.1. The visible analytic rows are exactly T, A, M, U, S, Q, R, so every local certificate read must expose the finite partial polynomial window, its dyadic amplitude and frequency ledger, the majorant row, the uniform threshold, the observed stream windows, the regular rational readback, and the final real-name seal.

Read the dependencies in route order. The M-test row is the majorant interface of chapter 399; the uniform Cauchy threshold is the series route of chapter 1736; the visible samples are $\mathsf{StreamName}^{\uparrow}$ windows; and the rational approximants pass through $\mathsf{RegSeqRat}^{\uparrow}$ before reaching the $\mathsf{Real}^{\uparrow}$ seal.

Finally H, C, P, N transport, replay, source, and name the same finite packet. Since the carrier has no coordinate for a completed function space, host infinite series, differentiability failure, quotient function equality, choice schedule, selected limit, or ambient completeness, the listed rows exhaust the local NameCert obligations. □

Theorem 8804.3 (Weierstrass function uniform Cauchy route)**.** *Every approximation or Real-facing consumer of an accepted* $\mathsf{WeierstrassFunction}^{\uparrow}$ *packet factors through the finite route*

$$\mathsf{WeierstrassMTest}^{\uparrow},\ \mathsf{UniformCauchySeries}^{\uparrow},\ \mathsf{StreamName}^{\uparrow},\ \mathsf{RegSeqRat}^{\uparrow},\ \mathsf{DyadicRatCore}^{\uparrow},\ \mathsf{Real}^{\uparrow}.$$

The consumer receives a finite trigonometric-polynomial window, dyadic amplitude and frequency data, a majorant row, and a uniform Cauchy threshold before any terminal Real seal can be inspected. The route exports no global infinite series object, quotient equality of functions, selected limit, countable-choice schedule, differentiability claim, or ambient $\mathsf{Real}^{\uparrow}$ *completeness principle.*

Proof. Start with the NameCert obligations of Definition 8804.2. They force each consumer read through the finite rows T, A, M, U, S, Q, R before the packet can be used as a named approximation object.

The M-test row supplies the majorant-tail control, and the uniform Cauchy threshold turns that control into a finite request-to-tail ledger. The stream and regular-rational rows then determine which approximants are visible before the terminal real-name row is consumed.

The structural rows H, C, P, N preserve this route under transport, replay, provenance, and local naming. Because no excluded host-level coordinate is present in the carrier, every consumer factors through the displayed finite route. □

Theorem 8804.4 (Weierstrass function Real-seal nonescape)**.** *Let*

$$W = (T, A, M, U, S, Q, R, H, C, P, N)$$

be an accepted $\mathsf{WeierstrassFunction}^{\uparrow}$ *carrier. Any read of the terminal* $\mathsf{Real}^{\uparrow}$ *seal* R *from* W *is preceded by the displayed rows* T, A, M, U, S, Q *and is replayed only through* H, C, P, N*. Thus the real-name handoff cannot be used to infer a host function object, a completed ambient series, differentiability failure, quotient function equality, countable choice, a selected limit, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Use Definition 8804.3. A Real-facing read must first expose the trigonometric-polynomial window, dyadic amplitude and frequency ledger, majorant row, uniform Cauchy threshold, stream windows, and regular rational readback.

The seal R is therefore terminal for this displayed route, not a source of additional host-level structure. The only remaining rows are transport, replay, provenance, and local naming rows, and each preserves the already displayed packet.

Since the carrier lacks coordinates for the excluded objects, reading R cannot introduce them. The Real seal is a handoff boundary for the finite approximation route and not an ambient completeness principle. □

Falsifiable prediction: Every accepted $\mathsf{WeierstrassFunction}^{\uparrow}$ approximation read exposes finite trigonometric-polynomial windows, dyadic amplitude and frequency ledgers, M-test majorant rows, uniform Cauchy thresholds, StreamName windows, RegSeqRat readback, RealUp seals, componentwise hsame transport, Cont replay, Pkg provenance, and local NameCert rows before any Real-facing consumer is served.

Independence witness: weierstrassmtest, uniformcauchyseries, streamname, regseqrat, dyadicratcore, real: none alone is bijective with $\mathsf{WeierstrassFunction}^{\uparrow}$ because this packet alone binds the finite trigonometric window, dyadic amplitude and frequency ledger, majorant row, uniform threshold, observation route, readback, seal, transport, replay, provenance, and local naming as one certificate.

Closure status for $\mathsf{NameCert}_{\mathsf{WeierstrassFunction}^{\uparrow}}$**.**

Constructive story: A $\mathsf{WeierstrassFunction}^{\uparrow}$ packet is generated from finite trigonometric-polynomial windows, dyadic amplitude and frequency ledgers, M-test majorant rows, uniform Cauchy thresholds, StreamName windows, RegSeqRat readback, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{WeierstrassFunction}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8804.1, Definition 8804.2, Definition 8804.3, and Definition 8804.4 seed the finite approximation route for the constructive Weierstrass function packet.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{WeierstrassFunction}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close a completed function space, a global infinite series object, differentiability failure, quotient equality of functions, countable choice, selected limits, ambient $\mathsf{Real}^{\uparrow}$ completeness, theorem-level Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, trigonometric-window exposure, dyadic ledger exactness, M-test majorant exposure, uniform Cauchy thresholding, StreamName observation, RegSeqRat readback, RealUp seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.WeierstrassFunctionUp.

Chapter 8805

A Concrete Naming Certificate for $\mathsf{PhillipsLemma}^{\uparrow}$

Following Phillips on lifting/local-reflexivity phenomena in Banach-space theory, the $\mathsf{PhillipsLemma}^{\uparrow}$ packet records the finite BEDC surface by which a bounded lifting request is read through Banach endpoints, dual-pair windows, finite approximation data, and an explicit obstruction row. It sits after the functional-analysis surface of chapter 94, the Banach carrier of chapter 90, the bounded-operator route of chapter 1644, and the operator-ideal consumer boundary of chapter 213. The certificate names the local lifting packet only; it does not assert a quotient dual space, a globally selected local inverse, reflexivity of the source, exactness of every short sequence, or ambient choice over finite-dimensional subspaces.

Definition 8805.1 (PhillipsLemma carrier)**.** *A* $\mathsf{PhillipsLemma}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$P = (S, T, B, D, A, O, H, C, Q, N)$$

with the following displayed rows:

1. *S is the source* $\mathsf{Banach}^{\uparrow}$ *row, including the norm, metric, completion, and real-seal reads available to the lifting request.*
2. *T is the target* $\mathsf{Banach}^{\uparrow}$ *row, displayed with the same Banach-facing endpoint discipline.*
3. *B is the bounded lifting row. It records the bounded-operator surface through which a local lift is inspected, including its action window, norm-bound row, and compatibility with the Banach endpoints.*
4. *D is the dual-pair readback row. It displays the finite dual tests used by the lifting request before any operator-ideal or functional-analysis consumer reads the packet.*
5. *A is the finite approximation witness row, listing the inspected finite-dimensional source window, tolerance ledger, and bounded image data.*
6. *O is the obstruction/refusal row. It records which global lifting, quotient-dual, or selector claims are not exported by the packet.*
7. *H records componentwise* hsame *transport for the Banach endpoint rows, bounded lifting row, dual-pair readback, approximation witness, obstruction row, replay, provenance, and local naming.*
8. *C records displayed* Cont *replay from a lifting request through S, T, B, D, A, O, H.*

9. *Q is the* Pkg *provenance over* $\mathsf{PhillipsLemma}^{\uparrow}$, $\mathsf{FunctionalAnalysis}^{\uparrow}$, $\mathsf{Banach}^{\uparrow}$, $\mathsf{BoundedLinearOperator}^{\uparrow}$, $\mathsf{OperatorIdeal}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*

10. *N is the local* $\mathsf{NameCert}_{\mathsf{PhillipsLemma}^{\uparrow}}$ *row.*

The carrier has no coordinate for a quotient-dual equality, a selected complement, a global right inverse, countable choice over subspaces, host operator equality, or reflexivity beyond the displayed Banach endpoint rows.

Lean4 ✓ `BEDC.Derived.PhillipsLemmaUp.PhillipsLemmaTasteGate single carrier alignment`

Theorem 8805.2 (PhillipsLemma NameCert obligations)**.** *For every accepted* $\mathsf{PhillipsLemma}^{\uparrow}$ *carrier*

$$P = (S, T, B, D, A, O, H, C, Q, N),$$

the local $\mathsf{NameCert}_{\mathsf{PhillipsLemma}^{\uparrow}}$ *surface is exhausted by five grouped rows: Banach source and target admission through S, T; bounded lifting exposure through B; dual-pair readback and finite approximation exposure through D, A; obstruction and refusal visibility through O; and structural closure through componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming through H, C, Q, N. Every functional-analysis, Banach, bounded-operator, or operator-ideal consumer must read those grouped rows before treating a local Phillips lifting witness as public certificate data.*

Proof. Project the carrier of Definition 8805.1. The Banach endpoint rows S, T are the only source and target data available to the packet, and the bounded lifting row B is the only row carrying an operator action and norm-bound ledger.

Read the dual and approximation data next. The row D supplies the displayed dual-pair tests, while A supplies the finite-dimensional window and tolerance ledger used by the local lifting witness.

The obstruction row O blocks the packet from exporting a global right inverse, selected complement, quotient-dual equality, or choice schedule. Thus the lifting read remains local to the displayed finite window.

Finally replay H, C, Q, N. Componentwise transport, continuation replay, provenance, and local naming preserve the same rows, so the five grouped obligations exhaust the NameCert surface before any consumer in chapter 94, chapter 90, chapter 1644, or chapter 213 can cite the packet. □

Falsifiable prediction: Every accepted $\mathsf{PhillipsLemma}^{\uparrow}$ read exposes Banach source and target rows, a bounded lifting row, a dual-pair readback row, a finite approximation witness row, an obstruction/refusal row, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row before any functional-analysis or operator-ideal consumer is served.

Independence witness: functionalanalysis, banach, boundedlinearoperator, operatorideal: none alone is bijective with $\mathsf{PhillipsLemma}^{\uparrow}$ because this packet alone binds the Banach endpoint rows, bounded lifting window, dual-pair readback, finite approximation witness, obstruction/refusal row, transport, replay, provenance, and local naming as one certificate.

Closure status for $\mathsf{NameCert}_{\mathsf{PhillipsLemma}^{\uparrow}}$**.**

Constructive story: A $\mathsf{PhillipsLemma}^{\uparrow}$ packet is generated from Banach source and target rows, a bounded lifting row, a dual-pair readback row, a finite approximation witness row, an obstruction/refusal row, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{PhillipsLemma}^{\uparrow}}$, seed)

Scope closed: Definition 8805.1 and Definition 8805.2 seed the local Banach lifting certificate route over functional-analysis, bounded-operator, operator-ideal, transport, replay, provenance, and local naming rows.

Formal verification: FormalStatus(NameCert$_{\mathsf{PhillipsLemma}\uparrow}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close quotient-dual equality, selected complements, global right inverses, exactness of arbitrary short sequences, countable choice over subspaces, host operator equality, reflexivity beyond displayed endpoint rows, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked Banach endpoint admission, bounded lifting exposure, dual-pair readback, finite approximation witness exactness, obstruction/refusal visibility, transport, replay, provenance, and local naming for BEDC.Derived.PhillipsLemmaUp.

Chapter 8806

A Concrete Naming Certificate for $\mathsf{HellySelectionFiniteVariation}^{\uparrow}$

Following Helly's selection theorem for uniformly bounded finite-variation functions, the HellySelectionFiniteVariatio packet records the finite partition, shared-window, and regular-readback data that a constructive Real or Completion consumer may inspect before any subsequence language is used. It sits over the compact interval source of chapter 3986, the finite partition ledger of chapter 398, the regular rational readback of chapter 301, the terminal real-name seal of chapter 38, and the finite cell discipline of chapter 5966. The packet names only displayed partition budgets, selected finite windows, shared-window agreement, transport, replay, provenance, and local naming; it does not claim open-cover compactness, countable choice, a host-selected subsequence, quotient equality of functions, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 8806.1 (Helly selection finite-variation carrier)**.** *A* $\mathsf{HellySelectionFiniteVariation}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$H = (I, P, V, W, A, R, E, T, C, Q, N)$$

with the following displayed rows:

1. *I is the* $\mathsf{CompactInterval}^{\uparrow}$ *source row, recording the named compact interval only through displayed endpoint, cell, and finite-cover data.*
2. *P is the finite partition row. It lists the inspected partition points, adjacent interval cells, and refinement witnesses used by the variation request.*
3. *V is the finite variation-budget row, read through* $\mathsf{BoundedVariation}^{\uparrow}$ *and recording only the displayed partition sums and common-refinement budgets.*
4. *W is the selected-window row, recording the finite set of indices, interval cells, and rational scales retained for the Helly-facing request.*
5. *A is the shared selected-window agreement row, comparing two retained windows only through displayed endpoint reads, variation budgets, and cell incidences.*
6. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row attached to the selected finite windows and their rational tail budgets.*
7. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row, available only after I, P, V, W, A, R have been displayed.*
8. *T records componentwise* hsame *transport for interval data, partitions, variation budgets, selected windows, agreement rows, readback, and Real seals.*

9. *C records displayed* Cont *replay from compact interval cells through partition variation budgets, selected-window agreement, regular readback, and the Real seal.*
10. *Q is the* Pkg *provenance over* $\mathsf{HellySelectionFiniteVariation}^{\uparrow}$, $\mathsf{CompactInterval}^{\uparrow}$, $\mathsf{BoundedVariation}^{\uparrow}$, $\mathsf{DyadicIntervalNet}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{HellySelectionFiniteVariation}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $I, P, V, W, A, R, E, T, C, Q, N$. It has no coordinate for a host subsequence theorem, arbitrary open-cover compactness, choice-selected branches, quotient equality of functions, variation measures, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 8806.2 (Helly selection finite-variation NameCert obligations)**.** *For every accepted* $\mathsf{HellySelectionFiniteVariation}^{\uparrow}$ *carrier*

$$H = (I, P, V, W, A, R, E, T, C, Q, N),$$

the local $\mathsf{NameCert}_{\mathsf{HellySelectionFiniteVariation}^{\uparrow}}$ *surface consists exactly of carrier admission for the eleven displayed rows; compact interval exposure through I; finite partition exposure through P; variation-budget exposure through V; selected-window exposure through W; shared selected-window agreement through A;* $\mathsf{RegSeqRat}^{\uparrow}$ *readback through R; terminal* $\mathsf{Real}^{\uparrow}$ *sealing through E; componentwise* hsame *transport through T; displayed* Cont *replay through C;* Pkg *provenance through Q; and local naming through N.*

Proof. Project the carrier of Definition 8806.1. The compact interval and finite partition rows I, P are the only domain-facing data available to the packet.

The variation and window rows are then read in order. Row V supplies the displayed finite partition sums and common-refinement budgets, while W lists the retained windows and A records their shared agreement through the same endpoint and cell data.

The readback and seal remain downstream. Row R gives regular rational access only for those selected windows, and row E seals the corresponding real names only after I, P, V, W, A, R have been displayed.

Finally T, C, Q, N transport, replay, source, and name the same finite surface. Since the carrier has no coordinate for host subsequence selection, open-cover compactness, quotient equality of functions, variation measures, or ambient Real completeness, none of those principles is a local NameCert obligation. □

Theorem 8806.3 (Helly selection shared-window route)**.** *Every accepted* $\mathsf{HellySelectionFiniteVariation}^{\uparrow}$ *packet exposes the route*

$$\mathsf{CompactInterval}^{\uparrow},\ \mathsf{DyadicIntervalNet}^{\uparrow},\ \mathsf{BoundedVariation}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}$$

through its displayed rows $I, P, V, W, A, R, E, T, C, Q, N$ before any downstream consumer reads a Helly-style selected-window conclusion. The agreement row A is a finite comparison of retained windows over the same compact interval cells and variation budgets, not a selected infinite subsequence and not a function-space compactness theorem.

Proof. Start with the compact interval and dyadic-cell side. The interval source row I and partition row P force every retained window to be attached to displayed finite cells and their endpoint data.

Use the variation row V next. It records finite partition sums and common-refinement budgets, so the selected-window row W receives bounded-variation data only as a visible finite ledger.

The agreement row A compares retained windows over those same rows. It can test shared endpoint reads, shared variation budgets, and shared cell incidence, but it cannot introduce a host subsequence or a completed function-space object.

Finally the readback row R and Real seal E are reached after the finite agreement route, and T, C, Q, N preserve that route. Thus every downstream Helly-facing read is a displayed finite-variation window handoff. □

Falsifiable prediction: An accepted $\mathsf{HellySelectionFiniteVariation}^{\uparrow}$ consumer that reaches a Real-facing selected-window conclusion without reading compact interval cells, finite partition variation budgets, shared selected-window agreement, and RegSeqRat readback refutes the carrier surface.

Independence witness: compactinterval, boundedvariation, regseqrat, real, dyadicintervalnet: none is bijective to $\mathsf{HellySelectionFiniteVariation}^{\uparrow}$ because this packet jointly carries compact interval cells, finite partition variation budgets, selected windows, shared-window agreement, regular readback, Real sealing, transport, replay, provenance, and local NameCert rows.

Closure status for $\mathsf{NameCert}_{\mathsf{HellySelectionFiniteVariation}^{\uparrow}}$.

Constructive story: A $\mathsf{HellySelectionFiniteVariation}^{\uparrow}$ packet is generated from compact interval rows, finite partition rows, bounded-variation budgets, selected finite windows, shared-window agreement rows, RegSeqRat readback, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{HellySelectionFiniteVariation}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8806.1, Definition 8806.2, and Definition 8806.3 seed the finite Helly selection packet over compact interval cells, partition variation budgets, shared selected-window agreement, regular rational readback, and Real seals.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{HellySelectionFiniteVariation}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close open-cover compactness, countable choice, host-selected subsequences, quotient equality of functions, variation measures, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, compact interval exposure, finite partition exposure, variation-budget exposure, selected-window agreement, regular readback, Real sealing, transport, replay, provenance, and local naming for BEDC.Derived.HellySelectionFiniteVariationUp.

Chapter 8807

A Concrete Naming Certificate for $\mathsf{VCDimension}^{\uparrow}$

Following Vapnik–Chervonenkis and Sauer–Shelah, the $\mathsf{VCDimension}^{\uparrow}$ packet records finite classifier complexity by displaying the sample rows, Boolean label rows, concept-class rows, shattering-pattern ledger, and growth-boundary row that a downstream statistical-learning consumer may inspect. It sits beside the Boolean and list carriers of chapter 32 and chapter 36, the unary size rows of chapter 28, the displayed membership discipline of chapter 3668, the finite-set surface of chapter 7157, and the finite concentration neighbour chapter 5726. The packet names only finite shattering data and a finite growth-boundary obligation; it does not assert PAC bounds, probability measures, empirical risk convergence, a complete Sauer–Shelah proof, host finite-set quotients, or ambient powerset semantics.

Definition 8807.1 (VC dimension finite classifier carrier)**.** *A* $\mathsf{VCDimension}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$V = (X, K, S, L, F, T, G, H, C, P, N)$$

with the following displayed rows:

1. *X is the finite sample-domain row, read through the displayed membership discipline and the finite-set surface rather than through a host powerset.*
2. *K is the inspected cardinality row, a* $\mathsf{Nat}^{\uparrow}$ *ledger recording the sample size and the growth-boundary size request.*
3. *S is the finite sample row, a* $\mathsf{List}^{\uparrow}$ *spine of displayed sample points with an explicit support boundary in X.*
4. *L is the Boolean label-row ledger, listing only the inspected* $\mathsf{Bool}^{\uparrow}$ *label patterns on the sample row S.*
5. *F is the concept-class row, recording the finite family of displayed classifier rows that are tested against S and L.*
6. *T is the shattering-pattern ledger: for each displayed label pattern in L, it names a concept row in F whose readback agrees with that pattern on S.*
7. *G is the growth-boundary row, recording the first displayed size at which the packet refuses a full shattering ledger and exposes only the counted pattern boundary.*

8. *H records componentwise* hsame *transport for sample-domain, cardinality, sample, label, concept-class, shattering, growth-boundary, replay, provenance, and local naming rows.*
9. *C records displayed* Cont *replay through $X, K, S, L, F, T, G, H, P, N$.*
10. *P is the* Pkg *provenance over* $\mathsf{VCDimension}^{\uparrow}$, $\mathsf{Bool}^{\uparrow}$, $\mathsf{List}^{\uparrow}$, $\mathsf{Nat}^{\uparrow}$, $\mathsf{SetLike}^{\uparrow}$, $\mathsf{KuratowskiFiniteSet}^{\uparrow}$, $\mathsf{HoeffdingFiniteSum}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*
11. *N is the local* $\mathsf{NameCert}_{\mathsf{VCDimension}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $X, K, S, L, F, T, G, H, C, P, N$. It has no coordinate for a host concept class, quotient finite set, powerset of labels, probability measure, risk functional, ambient growth theorem, or selected infinite sample family.

Theorem 8807.2 (VC dimension shattering obligation)**.** *For every accepted* $\mathsf{VCDimension}^{\uparrow}$ *carrier*

$$V = (X, K, S, L, F, T, G, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{VCDimension}^{\uparrow}}$ *shattering surface consists exactly of carrier admission for the sample-domain row, inspected cardinality row, finite sample row, Boolean label-row ledger, concept-class row, shattering-pattern ledger, transport, replay, provenance, and local naming. The shattering ledger T must be read after S, L, F are displayed, and each entry of T may cite only a displayed concept row whose Boolean readback on S matches the corresponding label row in L.*

Proof. Project the accepted carrier of Definition 8807.1. The rows X, K, S, L, F, T are the full finite classifier surface before any growth boundary is inspected.

First read the sample route. The row X supplies the displayed membership boundary, K records the relevant size request, and S supplies the finite list of sample points whose labels can be tested.

Next read the classifier route. The row L lists the Boolean patterns being requested, while F lists the displayed concept rows available for the test. The ledger T is accepted only after both rows are visible, so a shattering read cannot be replaced by a host powerset, quotient finite set, or ambient concept-class equality.

Finally H, C, P, N transport, replay, source, and name the same finite packet. Since no carrier coordinate stores a probability measure, risk functional, infinite sample family, or host classifier semantics, the listed rows exhaust the local shattering obligation. □

Theorem 8807.3 (VC dimension growth-boundary obligation)**.** *Let*

$$V = (X, K, S, L, F, T, G, H, C, P, N)$$

be an accepted $\mathsf{VCDimension}^{\uparrow}$ *carrier. Any read of the growth-boundary row G is downstream of the displayed sample-domain, cardinality, sample, Boolean label, concept-class, and shattering-pattern rows. Thus a statistical-learning or finite-combinatorics consumer may use G only as the finite refusal boundary attached to the displayed shattering ledger, not as a PAC guarantee, probability space, empirical-risk convergence theorem, complete Sauer–Shelah proof, host finite-set quotient, or ambient growth function oracle.*

Proof. Use Definition 8807.2. It orders the finite classifier rows so that the sample, label, concept, and shattering ledgers are read before a consumer can inspect any boundary row.

The growth-boundary row G records only the displayed size at which the packet refuses a full shattering ledger and exposes a counted pattern boundary. It is therefore tied to the same

X, K, S, L, F, T route rather than to an external Sauer–Shelah theorem or host powerset calculation.

The structural rows H, C, P, N preserve that finite route under transport, replay, provenance, and local naming. Because the carrier has no coordinate for PAC probability, empirical risk, quotient finite sets, or ambient growth semantics, no consumer can read such data from G. □

Falsifiable prediction: Every accepted $\mathsf{VCDimension}^{\uparrow}$ classifier-complexity read exposes finite sample-domain rows, NatUp cardinality ledgers, ListUp sample spines, BoolUp label rows, concept-class rows, shattering-pattern ledgers, growth-boundary rows, componentwise hsame transport, Cont replay, Pkg provenance, and local NameCert rows before any learning-facing consumer is served.

Independence witness: bool, list, nat, setlike, kuratowski finite set, hoeffding finite sum: none alone is bijective with $\mathsf{VCDimension}^{\uparrow}$ because this packet alone binds finite sample rows, Boolean label ledgers, displayed concept rows, shattering-pattern witnesses, growth-boundary refusal, transport, replay, provenance, and local naming as one classifier-complexity certificate.

Closure status for $\mathsf{NameCert}_{\mathsf{VCDimension}^{\uparrow}}$.

Constructive story: A $\mathsf{VCDimension}^{\uparrow}$ packet is generated from finite sample-domain rows, NatUp cardinality ledgers, ListUp sample rows, BoolUp label ledgers, displayed concept-class rows, shattering-pattern ledgers, growth-boundary rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{VCDimension}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8807.1, Definition 8807.2, and Definition 8807.3 seed the finite VC-dimension classifier-complexity route over Boolean labels, finite samples, displayed concept rows, and finite growth boundaries.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{VCDimension}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close PAC bounds, probability measures, empirical risk convergence, Sauer–Shelah proof completeness, host finite-set quotients, ambient powerset semantics, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, sample-row exposure, Boolean label-row exactness, concept-class row exposure, shattering-pattern ledger exactness, growth-boundary refusal, transport, replay, provenance, and local naming for BEDC.Derived.VCDimensionUp.

Chapter 8808

A Concrete Naming Certificate for $\mathsf{JordanCanonicalForm}^{\uparrow}$

Following the classical Jordan canonical form over algebraically closed fields, the $\mathsf{JordanCanonicalForm}^{\uparrow}$ packet records the finite certificate by which a displayed endomorphism is read as a block diagonal matrix with eigenvalue labels and nilpotent successor rows. It sits after the matrix carrier of chapter 49, the vector-space source of chapter 47, the polynomial ledger of chapter 50, and the scalar field carrier of chapter 45. It also records the finite spectral comparison surface shared with chapter 6037 and chapter 6602. The packet names only displayed finite rows; it is not an algebraic-closure theorem, a selected host eigenbasis, quotient eigenspace equality, or an ambient spectral theorem.

Definition 8808.1 (Jordan canonical form carrier)**.** *A* $\mathsf{JordanCanonicalForm}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$J = (M, V, F, Q, E, B, K, S, D, H, C, P, N)$$

with the following displayed rows:

1. *M is the* $\mathsf{Mat}^{\uparrow}$ *row, recording the finite matrix entries, multiplication windows, and row-column indices of the source endomorphism.*
2. *V is the* $\mathsf{VecSpace}^{\uparrow}$ *row, recording the finite-dimensional vector-space presentation and the displayed basis windows used by the matrix read.*
3. *F is the* $\mathsf{Field}^{\uparrow}$ *row, recording the scalar carrier over which the eigenvalue names and polynomial coefficients are interpreted.*
4. *Q is the* $\mathsf{Poly}^{\uparrow}$ *row, recording the characteristic-polynomial, minimal-polynomial, and annihilator ledgers visible to the block scheduler.*
5. *E is the eigenvalue-name row, listing the displayed roots that label the Jordan blocks inside the accepted packet.*
6. *B is the block-layout row, a finite ledger of block sizes, block order, diagonal eigenvalue labels, and superdiagonal successor positions.*
7. *K is the chain-stability row, recording the finite nilpotent-chain checks attached to each block size and eigenvalue label.*
8. *S is the similarity-transport row, recording the displayed source presentation, block presentation, and change-of-presentation rows.*

9. *D is the comparison row to* $\mathsf{SingularValueDecomposition}^{\uparrow}$ *and* $\mathsf{PolarDecomposition}^{\uparrow}$*, recording that those sibling packets may read the matrix-facing spectral boundary only through the displayed finite matrix and transport rows.*
10. *H records componentwise* hsame *transport for $M, V, F, Q, E, B, K, S, D$ and the local certificate rows.*
11. *C records displayed* Cont *replay along the route*

$$M, V, F, Q, E, B, K, S, D \longmapsto H, C, P, N.$$

12. *P is the* Pkg *provenance over* $\mathsf{JordanCanonicalForm}^{\uparrow}$, $\mathsf{Mat}^{\uparrow}$, $\mathsf{VecSpace}^{\uparrow}$, $\mathsf{Poly}^{\uparrow}$, $\mathsf{Field}^{\uparrow}$, $\mathsf{SingularValueDecomposition}$ $\mathsf{PolarDecomposition}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
13. *N is the local* $\mathsf{NameCert}_{\mathsf{JordanCanonicalForm}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $M, V, F, Q, E, B, K, S, D, H, C, P, N$. It has no coordinate for a host proof that the field is algebraically closed, an unrecorded eigenvector choice, quotient equality of generalized eigenspaces, uniqueness of block order, or a global spectral theorem.

Theorem 8808.2 (Jordan canonical form NameCert obligations)**.** *For every accepted* $\mathsf{JordanCanonicalForm}^{\uparrow}$ *carrier $J = (M, V, F, Q, E, B, K, S, D, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{JordanCanonicalForm}^{\uparrow}}$ *surface consists exactly of carrier admission, matrix exposure through M, vector-space exposure through V, scalar-field exposure through F, polynomial-ledger exposure through Q, eigenvalue-name exposure through E, block-layout exposure through B, nilpotent-chain stability through K, similarity transport through S, spectral sibling comparison through D, componentwise transport through H, displayed replay through C, package provenance through P, and local naming through N.*

Proof. Project the carrier of Definition 8808.1. The rows $M, V, F, Q, E, B, K, S, D$ are the mathematical data, while H, C, P, N transport, replay, source, and name that finite packet.

The eigenvalue and block rows are read only through the matrix, vector-space, field, and polynomial rows. The packet therefore displays the finite block layout and its scalar labels before a local NameCert row can certify the Jordan canonical form surface.

The comparison row D does not import a singular-value or polar-decomposition theorem. It only records the matrix-facing route by which those siblings may inspect the same finite spectral boundary. Thus the listed rows exhaust the local NameCert obligations. □

Theorem 8808.3 (Jordan canonical finite chain stability)**.** *Every accepted* $\mathsf{JordanCanonicalForm}^{\uparrow}$ *read that consumes a Jordan block must pass through the finite chain route*

$$M, V, F, Q, E, B, K, S, H, C, P, N.$$

The row K records the nilpotent successor checks attached to the displayed block sizes in B and eigenvalue names in E; it is stable only under the componentwise transport row H and replay row C of the same carrier. A downstream consumer receives no quotient generalized-eigenspace equality, no selected host eigenbasis, no proof of algebraic closure, and no ambient spectral theorem from this route.

Proof. Use the NameCert obligations of Definition 8808.2. Any block read must expose the source matrix, vector-space presentation, scalar field row, polynomial ledger, eigenvalue-name row, block-layout row, and chain-stability row before the structural rows are consumed.

Transport by H preserves the same displayed rows componentwise, and replay by C follows the same finite route. Since neither row adds a host eigenspace object or a spectral theorem, the nilpotent-chain check remains a finite carrier row. □

Theorem 8808.4 (Jordan canonical sibling noncollapse)**.** *The* $\mathsf{JordanCanonicalForm}^{\uparrow}$ *packet is not bijective to* $\mathsf{Mat}^{\uparrow}$, $\mathsf{VecSpace}^{\uparrow}$, $\mathsf{Poly}^{\uparrow}$, $\mathsf{Field}^{\uparrow}$, $\mathsf{SingularValueDecomposition}^{\uparrow}$, *or* $\mathsf{PolarDecomposition}^{\uparrow}$. *It jointly carries matrix entries, vector-space presentation data, scalar-field rows, polynomial ledgers, eigenvalue-name rows, finite block layout, nilpotent-chain stability, similarity transport, spectral sibling comparison, structural transport, replay, provenance, and local naming, while each listed sibling omits at least one of those displayed rows.*

Proof. Compare the carrier coordinates in Definition 8808.1. The linear-algebra source siblings provide matrix, vector-space, polynomial, or field rows, but none of them alone carries the eigenvalue-name, block-layout, chain-stability, and similarity-transport rows together with local naming.

The spectral siblings $\mathsf{SingularValueDecomposition}^{\uparrow}$ and $\mathsf{PolarDecomposition}^{\uparrow}$ read through their own factorization surfaces. Row D lets them inspect a matrix-facing boundary, but it does not identify their packets with the Jordan canonical block ledger. Hence no listed sibling is bijective to the full carrier. □

Falsifiable prediction: Every accepted $\mathsf{JordanCanonicalForm}^{\uparrow}$ consumer must display Matrix, VecSpace, Field, Polynomial, eigenvalue-name, block-layout, nilpotent-chain, similarity-transport, sibling-comparison, hsame, Cont, Pkg, and local NameCert rows before reading a Jordan canonical form certificate.

Independence witness: matrix, vecspace, polynomial, field, singular-value-decomposition, polar-decomposition: $\mathsf{JordanCanonicalForm}^{\uparrow}$ is not bijective to any listed sibling because this packet alone binds source matrix rows, vector-space presentation, scalar-field data, polynomial ledgers, eigenvalue labels, finite Jordan blocks, nilpotent-chain stability, similarity transport, spectral sibling comparison, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{JordanCanonicalForm}^{\uparrow}}$.

Constructive story: A $\mathsf{JordanCanonicalForm}^{\uparrow}$ packet is generated from Matrix rows, VecSpace basis windows, Field scalar rows, Polynomial ledgers, displayed eigenvalue-name rows, finite Jordan-block layout, nilpotent-chain stability, similarity transport, spectral sibling comparison, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{JordanCanonicalForm}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8808.1, Definition 8808.2, Definition 8808.3, and Definition 8808.4 seed the finite Jordan canonical form certificate over matrix, vector-space, field, polynomial, eigenvalue, block, nilpotent-chain, similarity, sibling-comparison, transport, replay, provenance, and local naming rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{JordanCanonicalForm}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim algebraic closure, quotient generalized-eigenspace equality, selected host eigenvectors, canonical uniqueness of block order, ambient spectral theorems, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, eigenvalue-name admission, block-ledger exactness, nilpotent-chain stability, similarity-transport nonescape, spectral sibling comparison, provenance, and local NameCert exactness for BEDC.Derived.JordanCanonicalFormUp.

Chapter 8809

A Concrete Naming Certificate for $\mathsf{FiniteMeshSelection}^{\uparrow}$

Following Bishop–Bridges constructive real analysis, the $\mathsf{FiniteMeshSelection}^{\uparrow}$ packet records the finite mesh choice used when a displayed real interval or dyadic interval net is inspected at one explicit tolerance. It sits after the dyadic arithmetic spine of chapter 291, the finite observation surface of chapter 126, the regular rational readback of chapter 301, the endpoint-and-enclosure packet of chapter 4111, the terminal real-name seal of chapter 38, and the dyadic interval-net surface of chapter 5966. The chapter names a finite selection row only; it is not compactness, an infinite mesh sequence, selected real representatives, quotient equality, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 8809.1 (Finite mesh selection carrier)**.** *A* $\mathsf{FiniteMeshSelection}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (D, W, R, I, E, H, C, P, N)$$

with the following displayed rows:

1. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row, recording the positive dyadic precision request, mesh denominator, outward rounding budget, and endpoint comparison bounds.*
2. *W is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row opened by the tolerance request.*
3. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row obtained from the displayed windows and dyadic tolerance.*
4. *I is the* $\mathsf{RealInterval}^{\uparrow}$ *endpoint-and-enclosure row being inspected.*
5. *E is the* $\mathsf{DyadicIntervalNet}^{\uparrow}$ *selected finite cell row, listing exactly the dyadic interval cells retained by the mesh selection at tolerance D.*
6. *H records componentwise* hsame *transport for tolerance, windows, readback, interval enclosure, selected cells, replay, provenance, and local naming rows.*
7. *C records displayed* Cont *replay from a finite mesh request through D, W, R, I, E, H, P, N.*
8. *P is the* Pkg *provenance over* $\mathsf{FiniteMeshSelection}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{RealInterval}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{DyadicIntervalNet}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
9. *N is the local* $\mathsf{NameCert}_{\mathsf{FiniteMeshSelection}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $D, W, R, I, E, H, C, P, N$. The carrier has no coordinate for open-cover compactness, an infinite mesh sequence, arbitrary subcover selection, quotient real equality, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 (definition) `BEDC.Derived.FiniteMeshSelectionUp`

Theorem 8809.2 (Finite mesh selection NameCert obligations)**.** *For every accepted* $\mathsf{FiniteMeshSelection}^{\uparrow}$ *carrier* $S = (D, W, R, I, E, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{FiniteMeshSelection}^{\uparrow}}$ *surface consists exactly of carrier admission, dyadic tolerance admission, finite window exposure, regular rational readback, interval endpoint-and-enclosure exposure, selected dyadic interval-net cells, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. No finite mesh selection obligation is stored outside these rows.*

Proof. Project the carrier of Definition 8809.1. The rows D, W, R, I, E are the whole selection surface: a dyadic tolerance, finite stream windows, regular readback, one interval enclosure, and the retained dyadic interval-net cells.

Read the finite route in order. The tolerance row D opens W, the window row gives R, and the interval row I is inspected only through those finite observations before the selected cells E are named.

The structural rows H, C, P, N transport, replay, source, and name the same packet. Since none of the refused compactness, infinite mesh, quotient, choice, or completeness principles is a carrier coordinate, the local obligations are exhausted by the displayed rows. □

Theorem 8809.3 (Finite mesh selection Real completion route)**.** *Every completion-facing read of an accepted* $\mathsf{FiniteMeshSelection}^{\uparrow}$ *carrier factors through the finite route*

$$\mathsf{DyadicRatCore}^{\uparrow} \longrightarrow \mathsf{StreamName}^{\uparrow} \longrightarrow \mathsf{RegSeqRat}^{\uparrow} \longrightarrow \mathsf{RealInterval}^{\uparrow} \longrightarrow \mathsf{DyadicIntervalNet}^{\uparrow} \longrightarrow \mathsf{Real}^{\uparrow}.$$

Consequently a Real or Completion consumer receives finite dyadic cells selected at an explicit tolerance before any terminal real-name seal is used.

Proof. Start with the dyadic tolerance row D. It is the only row that records the requested mesh precision and outward rounding budget.

Next read W and R. These rows expose finite stream windows and regular rational readback before the endpoint-and-enclosure packet I can be inspected at the chosen tolerance.

Finally route the selected cells through E and the structural rows. The selected dyadic interval-net cells are therefore finite data already tied to D, W, R, I, and the terminal $\mathsf{Real}^{\uparrow}$ seal is downstream of that route. The carrier contains no compactness, infinite mesh, choice, quotient, or ambient completeness coordinate that could supply an alternate completion route. □

Falsifiable prediction: Every accepted FiniteMeshSelectionUp read displays a DyadicRatCoreUp tolerance row, StreamNameUp finite windows, RegSeqRatUp readback, a RealIntervalUp endpoint-and-enclosure row, DyadicIntervalNetUp selected cells, componentwise hsame transport, Cont replay, Pkg provenance, and local naming before any RealUp-facing completion consumer receives mesh data.

Independence witness: dyadicratcore, streamname, regseqrat, realinterval, real, dyadicintervalnet: $\mathsf{FiniteMeshSelection}^{\uparrow}$ is not bijective to any listed sibling because it binds one finite mesh-selection row to a displayed tolerance, finite windows, regular readback, interval enclosure, dyadic cell retention, transport, replay, provenance, and local naming as one certificate.

Closure status for $\mathsf{NameCert}_{\mathsf{FiniteMeshSelection}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{FiniteMeshSelection}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8809.1, Definition 8809.2, and Definition 8809.3 seed the finite mesh-selection route over $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{RealInterval}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, and $\mathsf{DyadicIntervalNet}^{\uparrow}$ rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{FiniteMeshSelection}^{\uparrow}}, \mathsf{unformalized})$

Lean target: `BEDC.Derived.FiniteMeshSelectionUp`

Bridge status: none

Not claimed: This chapter does not close open-cover compactness, infinite mesh limits, arbitrary subcover selection, quotient real equality, countable choice, ambient RealUp completeness, theorem checking, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, tolerance exactness, finite-window exposure, regular readback, selected-cell retention, Real seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.FiniteMeshSelectionUp.

Constructive story: A FiniteMeshSelection$^{\uparrow}$ packet is generated from a DyadicRatCore tolerance row, StreamName finite windows, RegSeqRat readback, a RealInterval endpoint-and-enclosure row, selected DyadicIntervalNet cells, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 8810

A Concrete Naming Certificate for $\mathsf{KrylovSubspace}^{\uparrow}$

Following Krylov and the standard Arnoldi/Lanczos finite-iteration literature, the $\mathsf{KrylovSubspace}^{\uparrow}$ packet records the finite span generated by repeated application of one displayed linear operator to one displayed seed vector. It sits after the matrix carrier of chapter 49, the vector-space carrier of chapter 47, the linear-map surface of chapter 48, and the control-facing observer route of chapter 5909. The packet names only the finite iterate-and-span certificate; it does not export an infinite cyclic subspace, a spectral decomposition, a chosen orthonormal Arnoldi basis, a Lanczos tridiagonalization, or host equality between matrix and operator presentations.

Definition 8810.1 (KrylovSubspace carrier)**.** *A* $\mathsf{KrylovSubspace}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (V, A, v, n, I, L, H, C, P, N)$$

with the following displayed rows:

1. *V is the* $\mathsf{VecSpace}^{\uparrow}$ *row carrying the finite vector-space operations, zero row, scalar action, and classifier used by the packet.*
2. *A is the common* $\mathsf{LinMap}^{\uparrow}/\mathsf{Mat}^{\uparrow}$ *row. It records both the operator action and the finite coordinate matrix surface through which iterates are inspected.*
3. *v is the seed-vector row, displayed as a vector of V before any iterate ledger is consumed.*
4. *n is the finite depth row naming the last iterate admitted to the packet.*
5. *I is the finite iterate ledger*
$$v, \quad Av, \quad A^2v, \quad \ldots, \quad A^nv,$$
with each entry read through the same V and A rows.
6. *L is the span and provenance ledger. It records finite linear-combination support over the iterate list I and the refusal to identify the span with a host subspace outside the displayed rows.*
7. *H records componentwise* hsame *transport for $V, A, v, n, I, L, C, P, N$.*
8. *C records displayed* Cont *replay from the seed-vector request through the finite iterate and span ledgers.*
9. *P is the* Pkg *provenance over* $\mathsf{KrylovSubspace}^{\uparrow}$, $\mathsf{VecSpace}^{\uparrow}$, $\mathsf{LinMap}^{\uparrow}$, $\mathsf{Mat}^{\uparrow}$, $\mathsf{Poly}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$ *rows.*

10. *N is the local* $\mathsf{NameCert}_{\mathsf{KrylovSubspace}^{\uparrow}}$ *row.*

The carrier has no coordinate for an infinite-dimensional closure, a quotient invariant subspace, a selected orthogonal basis, a minimal polynomial theorem, spectral convergence, or equality between the matrix row and the linear-map row beyond the displayed provenance.

Theorem 8810.2 (KrylovSubspace NameCert boundary)**.** *For every accepted* $\mathsf{KrylovSubspace}^{\uparrow}$ *carrier*

$$K = (V, A, v, n, I, L, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{KrylovSubspace}^{\uparrow}}$ *surface is exhausted by five obligation rows:*

1. *carrier admission for the vector-space row V, operator row A, seed row v, depth row n, iterate ledger I, span ledger L, and structural rows H, C, P, N;*
2. *finite iterate closure, requiring each displayed entry of I to be generated by repeated use of the same A on the same seed row v inside V;*
3. *classifier transport, requiring every span membership or nonmembership read to pass through the componentwise* hsame *row H and the replay row C;*
4. *matrix-linear-map provenance, requiring the coordinate matrix surface and the linear-map action to be linked only by the displayed A and P rows;*
5. *ledger exhaustion, requiring Arnoldi, Lanczos, reachability, observability, or polynomial-action consumers to read only $V, A, v, n, I, L, H, C, P, N$ before citing the packet.*

No NameCert obligation for $\mathsf{KrylovSubspace}^{\uparrow}$ *is stored outside those five rows.*

Proof. Project the carrier of Definition 8810.1. The accepted packet exposes one vector-space row, one matrix-linear-map row, one seed vector, one finite depth, one finite iterate ledger, one finite span ledger, and the four structural rows.

Finite iterate closure is read from I. Since each entry is displayed as $A^k v$ for $0 \le k \le n$, the packet never needs an infinite orbit or a host subspace completion.

Classifier transport and replay are the rows H and C. They preserve the vector, operator, iterate, and span ledgers componentwise and do not add a hidden basis, spectral coordinate, or convergence claim.

Finally read provenance through P and local naming through N. The matrix and linear-map presentations are connected only by the displayed row A, with $\mathsf{Poly}^{\uparrow}$ appearing as finite polynomial-action provenance rather than as a minimal-polynomial theorem. Therefore the five listed obligations exhaust the local certificate surface. □

Falsifiable prediction: Every accepted $\mathsf{KrylovSubspace}^{\uparrow}$ read exposes one VecSpace row, one Matrix/LinearMap row, one seed-vector row, one finite depth, one finite iterate ledger, one finite span ledger, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row before any Arnoldi, Lanczos, reachability, observability, or polynomial-action consumer is served.

Independence witness: matrix, vecspace, linearmap, polynomial, luenbergerobserver: none alone is bijective with $\mathsf{KrylovSubspace}^{\uparrow}$ because this packet alone binds the seed vector, finite operator iterates, finite span ledger, matrix-linear-map provenance, transport, replay, provenance, and local naming as one certificate.

Closure status for $\mathsf{NameCert}_{\mathsf{KrylovSubspace}^{\uparrow}}$.

Constructive story: A KrylovSubspace$^{\uparrow}$ packet is generated from a VecSpace row, a Matrix/LinearMap action row, a seed-vector row, a finite depth row, a finite iterate ledger, a span and provenance ledger, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\mathsf{KrylovSubspace}^{\uparrow}}$, seed)

Scope closed: Definition 8810.1 and Definition 8810.2 seed the finite Krylov iterate-and-span certificate over vector-space, matrix, linear-map, polynomial-action, transport, replay, provenance, and local naming rows.

Formal verification: FormalStatus(NameCert$_{\mathsf{KrylovSubspace}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close Arnoldi orthogonalization, Lanczos tridiagonalization, minimal-polynomial exactness, spectral approximation, infinite cyclic subspaces, host matrix-operator equality, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, finite iterate closure, classifier transport, matrix-linear-map provenance, and ledger exhaustion for BEDC.Derived.KrylovSubspaceUp.

Chapter 8811

A Concrete Naming Certificate for $\mathsf{ZeckendorfPhaseShell}^{\uparrow}$

Following Zeckendorf and the Fibonacci symbolic-dynamics tradition, the $\mathsf{ZeckendorfPhaseShell}^{\uparrow}$ packet realizes the stable-window, residual-fiber, and external golden-phase projection rows of chapter 9346 as finite NameCert data. It sits beside the carry-normalization surface of chapter 608 and the finite golden-mean window of chapter 8802. The packet names the visible phase shell only; it does not turn golden phase into a kernel object, a quotient of histories, a physical law, or a real-completion theorem.

Definition 8811.1 (ZeckendorfPhaseShell carrier)**.** *A* $\mathsf{ZeckendorfPhaseShell}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Z = (m, \Omega, X, F, R, G, H, C, P, N)$$

with the following displayed rows:

1. *m is the finite window-width row.*
2. *Ω is the raw binary-window row $\{0,1\}^m$.*
3. *X is the stable Zeckendorf-window row, admitting exactly the visible words with no adjacent* 11 *pattern.*
4. *F is the fold row from raw windows to stable visible windows, read through the finite Fibonacci-value ledger of the vision chapter.*
5. *R is the residual-fiber row. For each visible word x, it records the finite fiber of raw windows that fold to x and the refusal to identify that fiber with a quotient class of histories.*
6. *G is the external golden-phase projection row. It records the phase readout attached to X and R without placing that readout in the BEDC kernel.*
7. *H records componentwise* hsame *transport for $m, \Omega, X, F, R, G, C, P, N$.*
8. *C records displayed* Cont *replay through the stable window, fold, residual-fiber, and phase rows.*
9. *P is the* Pkg *provenance over* $\mathsf{ZeckendorfPhaseShell}^{\uparrow}$, $\mathsf{ZeckendorfCarryNormalization}^{\uparrow}$, $\mathsf{GoldenMeanShiftWindowSix}$ BHist, hsame, Cont, *and* $\mathsf{NameCert}$ *rows.*
10. *N is the local* $\mathsf{NameCert}_{\mathsf{ZeckendorfPhaseShell}^{\uparrow}}$ *row.*

The carrier has no coordinate for quotienting raw histories by the fold, no kernel equality between visible phase and raw microstate, no invariant-measure claim, no physical-law assertion, and no completed real limit.

Theorem 8811.2 (ZeckendorfPhaseShell NameCert boundary)**.** *For every accepted* $\mathsf{ZeckendorfPhaseShell}^{\uparrow}$ *carrier*

$$Z = (m, \Omega, X, F, R, G, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{ZeckendorfPhaseShell}^{\uparrow}}$ *surface is exhausted by five obligation rows:*

1. *stable-window admission, requiring X to expose the no-adjacent-11 classifier over the finite raw window Ω;*
2. *fold exactness, requiring F to display the finite Fibonacci-value fold before any visible word is consumed;*
3. *residual-fiber preservation, requiring R to remain visible whenever a consumer reads the folded window;*
4. *external phase transport, requiring the golden-phase row G to be replayed as projection data rather than as a kernel object or quotient of histories;*
5. *structural exhaustion, requiring H, C, P, N to transport, replay, source, and name only the displayed rows m, Ω, X, F, R, G.*

No Zeckendorf phase-shell obligation is stored outside those rows.

Proof. Project the carrier of Definition 8811.1. The raw window, stable visible window, fold, residual-fiber ledger, and phase projection are all finite rows before transport or replay is applied.

Stable-window admission and fold exactness come from X and F. The visible word can be consumed only after the no-adjacent-11 classifier and the Fibonacci fold have been displayed.

The residual-fiber row R prevents the fold readout from erasing raw histories. Thus a consumer of the visible phase shell receives a stable word together with its finite fiber ledger, not a quotient equality of histories.

Finally read G, H, C, P, N. The golden phase row is transported and replayed only as external projection data, while provenance names the Zeckendorf carry-normalization and golden-mean window sources. Therefore the five rows exhaust the local NameCert boundary without promoting phase projection to a kernel object. □

Falsifiable prediction: Every accepted $\mathsf{ZeckendorfPhaseShell}^{\uparrow}$ read exposes a finite window width, raw binary window, stable Zeckendorf window, Fibonacci fold, residual-fiber ledger, external golden-phase projection row, componentwise hsame transport, Cont replay, Pkg provenance, and local NameCert row before any visible phase-shell consumer is served.

Independence witness: zeckendorfcarrynormalization, goldenmeanshiftwindowsix: neither is bijective with $\mathsf{ZeckendorfPhaseShell}^{\uparrow}$ because this packet alone binds raw windows, stable folds, residual fibers, external phase projection, transport, replay, provenance, and local naming as one certificate.

Closure status for $\mathsf{NameCert}_{\mathsf{ZeckendorfPhaseShell}^{\uparrow}}$.

Constructive story: A $\mathsf{ZeckendorfPhaseShell}^{\uparrow}$ packet is generated from a finite window-width row, raw binary-window row, stable Zeckendorf-window row, Fibonacci fold row, residual-fiber row, external golden-phase projection row, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{ZeckendorfPhaseShell}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8811.1 and Definition 8811.2 seed the finite Zeckendorf phase-shell certificate over stable-window, residual-fiber, golden-phase projection, transport, replay, provenance, and local naming rows.

Formal verification: FormalStatus(NameCert$_{\mathsf{ZeckendorfPhaseShell}\uparrow}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close a kernel golden-phase object, quotient equality of histories, invariant measure, physical law, real-completion theorem, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked stable-window admission, fold exactness, residual-fiber preservation, external phase transport, and structural exhaustion for BEDC.Derived.ZeckendorfPhaseShellUp.

Chapter 8812

A Concrete Naming Certificate for $\mathsf{SionMinimax}^{\uparrow}$

Following Sion's minimax theorem and Bishop–Bridges constructive analysis, the $\mathsf{SionMinimax}^{\uparrow}$ packet records finite compact-convex minimax data as NameCert rows rather than as a host saddle-point selection principle. It sits between the finite payoff-table route of chapter 7060, the KKM-facing convex route of chapter 7973, the primal-dual convex packet of chapter 321, and the compact interval source of chapter 6585. Its scalar readback is routed through chapter 38, chapter 291, chapter 301, and chapter 126.

Definition 8812.1 (SionMinimax finite compact-convex carrier)**.** *A* $\mathsf{SionMinimax}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (X, Y, F, A, T, R, W, D, Q, H, C, P, N)$$

with the following displayed rows:

1. *X is the compact convex source row, read through displayed finite-window membership and finite convex-combination checks rather than through an ambient compactness theorem.*
2. *Y is the opposite convex source row, with the same finite-window membership and convex-combination discipline for the second variable.*
3. *F is the convex-concave payoff row, recording only displayed two-variable payoff comparisons and the finite slice checks needed by downstream minimax consumers.*
4. *A is the finite affine-spine ledger for the inspected convex combinations in X and Y.*
5. *T is the finite saddle-window approximant row, listing paired lower and upper comparison windows before any scalar value is sealed.*
6. *R is the dyadic tolerance ledger, recording the requested comparison precision through the* $\mathsf{DyadicRatCore}^{\uparrow}$ *route.*
7. *W is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row that turns the finite tolerance ledger into regular rational comparison data.*
8. *D is the* $\mathsf{StreamName}^{\uparrow}$ *window schedule that orders the finite inspection windows consumed by T, R, W.*
9. *Q is the terminal* $\mathsf{Real}^{\uparrow}$ *seal, available only after the finite saddle-window, tolerance, rational-readback, and stream-schedule rows are displayed.*

10. *H records componentwise* hsame *transport for compact-convex source rows, payoff rows, affine-spine rows, saddle-window approximants, tolerance ledgers, readback rows, schedule rows, value seals, replay, provenance, and local naming.*
11. *C records displayed* Cont *replay for the same finite compact-convex minimax route.*
12. *P is the* Pkg *provenance over* $\mathsf{SionMinimax}^{\uparrow}$, $\mathsf{FiniteGameMinimax}^{\uparrow}$, $\mathsf{KyFanMinimax}^{\uparrow}$, $\mathsf{FenchelDuality}^{\uparrow}$, $\mathsf{ConvexCompactInterval}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*
13. *N is the local* $\mathsf{NameCert}_{\mathsf{SionMinimax}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $X, Y, F, A, T, R, W, D, Q, H, C, P, N$. It has no coordinate for host suprema or infima, choice-selected saddle points, quotient equality, full compactness, or ambient real completeness.

Theorem 8812.2 (SionMinimax NameCert obligations)**.** *For every accepted* $\mathsf{SionMinimax}^{\uparrow}$ *carrier*

$$S = (X, Y, F, A, T, R, W, D, Q, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{SionMinimax}^{\uparrow}}$ *surface consists exactly of carrier admission, classifier comparison, saddle-window exactness, dyadic tolerance ledger readback,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. A minimax equality read is admitted only after the compact-convex source rows, payoff row, affine-spine ledger, finite saddle-window approximants, tolerance ledger, rational readback, stream schedule, value seal, transport, replay, provenance, and local certificate are visible in the same packet.*

Proof. Project the accepted carrier of Definition 8812.1. The source rows X, Y, the payoff row F, and the affine-spine ledger A display the compact-convex minimax surface before any scalar comparison is read.

The finite approximation route is T, R, W, D. The row T supplies the lower and upper saddle windows, R records their dyadic tolerance budget, W exports regular rational readback, and D fixes the stream-window schedule that orders those finite reads.

The value seal Q is downstream of that route. Componentwise transport, replay, provenance, and local naming are then supplied by H, C, P, N.

Since no row stores host suprema, host infima, a selected saddle pair, quotient equality, full compactness, or ambient real completeness, the listed rows exhaust the local naming obligations. □

Theorem 8812.3 (SionMinimax finite saddle-window route)**.** *Every minimax equality consumer of an accepted* $\mathsf{SionMinimax}^{\uparrow}$ *packet must pass through the finite saddle-window row T before the* $\mathsf{Real}^{\uparrow}$ *seal Q is public. Thus the scalar equality exported by the packet is read only after the displayed compact-convex rows, convex-concave payoff row, affine-spine ledger, dyadic tolerance ledger,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback, and* $\mathsf{StreamName}^{\uparrow}$ *schedule have all been inspected.*

Proof. Use Definition 8812.2. It orders the accepted packet so that the source, payoff, and affine-spine rows are displayed before the finite saddle-window approximants are read.

The only path from those approximants to a scalar equality is through R, W, D, Q. The dyadic tolerance ledger R, regular rational readback W, and stream schedule D are all visible before the $\mathsf{Real}^{\uparrow}$ seal Q can serve a consumer.

Therefore a minimax equality read cannot skip directly to an ambient scalar principle. It factors through the finite saddle-window route carried by the same packet. □

Theorem 8812.4 (SionMinimax nonescape boundary)**.** *An accepted* $\mathsf{SionMinimax}^{\uparrow}$ *packet exports no host supremum, host infimum, choice-selected saddle point, quotient equality of points or functions, full compactness theorem, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness principle. Every public minimax read is confined to the displayed rows* $X, Y, F, A, T, R, W, D, Q, H, C, P, N$*.*

Proof. Inspect the carrier definition. Its coordinates are exactly $X, Y, F, A, T, R, W, D, Q, H, C, P, N$, and the classifier compares packets only through those rows.

The obligation theorem identifies the same rows as the complete local NameCert surface. The finite saddle-window theorem then forces every scalar equality read through T, R, W, D before the value seal Q.

Because none of these rows contains a host extremum operator, a selected saddle pair, a quotient-equality witness, full compactness data, or ambient real-completeness data, no consumer can extract such a principle from the packet. □

Closure status for $\mathsf{NameCert}_{\mathsf{SionMinimax}^{\uparrow}}$**.**

Constructive story: A $\mathsf{SionMinimax}^{\uparrow}$ packet is generated from compact convex source rows, opposite convex source rows, convex-concave payoff rows, finite affine-spine ledgers, saddle-window approximants, dyadic tolerance ledgers, RegSeqRat readback rows, StreamName schedules, a RealUp value seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{SionMinimax}^{\uparrow}}$, seed)

Scope closed: Definition 8812.1, Definition 8812.2, Definition 8812.3, and Definition 8812.4 seed the finite compact-convex Sion minimax route over displayed source, payoff, saddle-window, tolerance, rational-readback, stream-schedule, RealUp seal, transport, replay, provenance, and local NameCert rows.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{SionMinimax}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close host suprema or infima, choice-selected saddle points, quotient equality, full compactness, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, classifier comparison, saddle-window exactness, dyadic tolerance readback, RegSeqRat readback, StreamName scheduling, RealUp sealing, transport, replay, provenance, and local naming for BEDC.Derived.SionMinimaxUp.

Chapter 8813

A Concrete Naming Certificate for $\mathsf{MooreSmithCauchyNet}^{\uparrow}$

Following Moore, Smith, Kelley, and Bishop–Bridges, the $\mathsf{MooreSmithCauchyNet}^{\uparrow}$ packet records the standard directed Cauchy-net source as finite BEDC NameCert data. It sits after the directed substrate of chapter 1607, the Cauchy-net completion surface of chapter 3794, the Moore–Smith completion route of chapter 2190, and the diagonal handoff of chapter 6879. Its numerical readback is routed through chapter 126, chapter 301, chapter 291, and the terminal real-name seal of chapter 38. The packet names the source object consumed by L10 completion routes; it does not select a Moore–Smith limit, quotient nets, choose a subnet, invoke countable choice, or assert ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 8813.1 (Moore–Smith Cauchy net carrier)**.** *A* $\mathsf{MooreSmithCauchyNet}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M = (D, N, T, W, R, Q, E, H, C, P, L)$$

with the following visible rows:

1. *D is the* $\mathsf{DirectedSet}^{\uparrow}$ *substrate, including the finite directed vertices, comparison rows, and common upper-window witnesses used by the net route.*
2. *N is the displayed net-source row, recording the observed Moore–Smith values and the finite tail reads over D.*
3. *T is the Cauchy-tail ledger, listing the precision requests and the directed tail thresholds that answer them.*
4. *W is the finite window row, naming the directed windows inspected before any readback or completion-facing consumer receives the packet.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *regular readback obtained from the displayed windows.*
6. *Q is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger used by the Cauchy-tail comparisons and by the regular readback.*
7. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal reached only after the directed substrate, net source, Cauchy-tail ledger, finite windows, readback, and dyadic tolerance rows have been exposed.*
8. *H records componentwise* hsame *transport for D, N, T, W, R, Q, E and the structural rows.*
9. *C records displayed* Cont *replay from a directed Cauchy-net read through the same tail, window, readback, tolerance, and Real-seal route.*

10. *P is the* Pkg *provenance over* $\mathsf{MooreSmithCauchyNet}^{\uparrow}$, $\mathsf{DirectedSet}^{\uparrow}$, $\mathsf{CauchyNet}^{\uparrow}$, $\mathsf{MooreSmithNet}^{\uparrow}$, $\mathsf{CauchyNetCompletion}^{\uparrow}$, $\mathsf{MooreSmithCompletion}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *L is the local* $\mathsf{NameCert}_{\mathsf{MooreSmithCauchyNet}^{\uparrow}}$ *row.*

The carrier has no coordinate for selected limits, quotient nets, selected subnets, countable-choice schedules, host real equality, ambient completeness, or completeness of $\mathsf{Real}^{\uparrow}$.

Theorem 8813.2 (Moore–Smith Cauchy net NameCert obligations)**.** *For an accepted* $\mathsf{MooreSmithCauchyNet}^{\uparrow}$ *carrier* $M = (D, N, T, W, R, Q, E, H, C, P, L)$, *the local* $\mathsf{NameCert}_{\mathsf{MooreSmithCauchyNet}^{\uparrow}}$ *surface consists exactly of the following finite obligations:*

1. *carrier admission for the directed substrate, net source, Cauchy-tail ledger, finite windows, regular readback, dyadic tolerance row, Real seal, transport, replay, provenance, and local naming rows;*
2. *directed-window exposure, requiring every completion-facing or readback-facing request to begin with D, N, W before the Cauchy-tail ledger is consumed;*
3. *Cauchy-tail stability, requiring T and Q to display the precision request, tail threshold, and dyadic comparison rows used by the same directed windows;*
4. $\mathsf{RegSeqRat}^{\uparrow}/\mathsf{DyadicRatCore}^{\uparrow}$ *readback, requiring R to be read only after W, T, Q have fixed the finite Cauchy route;*
5. *Real-seal nonescape, requiring E to be downstream of the displayed directed, tail, window, regular, and dyadic rows rather than an ambient completeness theorem;*
6. *transport, replay, and provenance preservation, requiring H, C, P, L to preserve and name only the displayed source packet.*

No NameCert obligation is stored outside these rows.

Proof. Carrier admission is projection from Definition 8813.1. The tuple exposes the directed substrate, net source, Cauchy-tail ledger, finite windows, regular readback, dyadic tolerance, Real seal, transport, replay, provenance, and local naming rows.

Directed-window exposure reads D, N, W before any consumer reaches a numerical or completion-facing boundary. The Cauchy-tail row T then binds each precision request to a displayed tail threshold on that same directed surface.

The readback step uses Q and R together. The dyadic ledger records the tolerance comparisons, while the regular rational row reads only the windows already admitted by W and stabilized by T.

Finally E is a terminal seal on the displayed route, and H, C, P, L transport, replay, source, and name only the listed coordinates. Since selected limits, quotient nets, selected subnets, countable choice, host equality, and ambient completeness have no carrier coordinate, none of them can mediate the local NameCert obligations. □

Closure status for $\mathsf{NameCert}_{\mathsf{MooreSmithCauchyNet}^{\uparrow}}$.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{MooreSmithCauchyNet}^{\uparrow}}$, seed)

Scope closed: Definition 8813.1 and Definition 8813.2 seed the finite Moore–Smith Cauchy-net source packet over DirectedSet, StreamName, RegSeqRat, DyadicRatCore, and Real rows.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{MooreSmithCauchyNet}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close selected Moore–Smith limits, quotient nets, selected subnets, countable choice, host real equality, ambient completeness, completeness of $\mathsf{Real}^{\uparrow}$, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, directed-window exposure, Cauchy-tail stability, RegSeqRat and DyadicRatCore readback, Real-seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.MooreSmithCauchyNetUp.

Constructive story: A MooreSmithCauchyNet$^{\uparrow}$ packet is generated from a DirectedSet substrate, a Moore–Smith net source row, Cauchy-tail thresholds, finite directed windows, RegSeqRat readback, DyadicRatCore tolerances, a Real seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 8814

A Concrete Naming Certificate for $\mathsf{BorsukUlamAntipodal}^{\uparrow}$

Following Borsuk, Ulam, and Tucker, the $\mathsf{BorsukUlamAntipodal}^{\uparrow}$ packet isolates the finite antipodal witness ledger used by the Borsuk–Ulam obstruction route. It sits beside the obstruction packet $\mathsf{BorsukUlam}^{\uparrow}$ of chapter 5828 and the combinatorial antipodal labeling packet $\mathsf{TuckerLemma}^{\uparrow}$ of chapter 6975. The packet names the witness-ledger surface only: it does not strengthen $\mathsf{BorsukUlam}^{\uparrow}$, select antipodal points, identify quotient spheres, or import a host topological theorem.

Definition 8814.1 (Borsuk-Ulam antipodal witness-ledger carrier)**.** *A* $\mathsf{BorsukUlamAntipodal}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$W = (S, A, T, L, O, H, C, P, N)$$

with the following displayed rows:

1. *S is the supplied sphere or boundary-source row consumed from the compact metric and* $\mathsf{S}^{1\uparrow}$ *surfaces already named by* $\mathsf{BorsukUlam}^{\uparrow}$*.*
2. *A is the antipodal-pair ledger row, storing paired source histories and the refusal of quotient-sphere identification.*
3. *T is the Tucker-style finite labeling row, read through the sibling* $\mathsf{TuckerLemma}^{\uparrow}$ *route when a combinatorial witness is used.*
4. *L is the local comparison ledger that records which antipodal read is being tested by the downstream obstruction consumer.*
5. *O is the obstruction-facing handoff row, pointing back to the* $\mathsf{BorsukUlam}^{\uparrow}$ *obstruction packet without adding a stronger theorem to it.*
6. *H records componentwise* hsame *transport for source, antipodal ledger, Tucker row, local comparison, obstruction handoff, provenance, and local naming.*
7. *C records displayed* Cont *replay from the source and antipodal rows through the finite witness ledger.*
8. *P is the* Pkg *provenance over* $\mathsf{BorsukUlamAntipodal}^{\uparrow}$*,* $\mathsf{BorsukUlam}^{\uparrow}$*,* $\mathsf{TuckerLemma}^{\uparrow}$*,* $\mathsf{CompactMetric}^{\uparrow}$*,* $\mathsf{S}^{1\uparrow}$*,* BHist*,* hsame*,* Cont*, and* $\mathsf{NameCert}$*.*
9. *N is the local* $\mathsf{NameCert}_{\mathsf{BorsukUlamAntipodal}^{\uparrow}}$ *row.*

The carrier has no coordinate for selected antipodal points, quotient equality of sphere points, unrestricted degree theory, choice, ambient compactness, or a completed topological Borsuk–Ulam theorem.

Theorem 8814.2 (Borsuk-Ulam antipodal witness-ledger NameCert obligations)**.** *For every accepted* $\mathsf{BorsukUlamAntipodal}^{\uparrow}$ *carrier* $W = (S, A, T, L, O, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{BorsukUlamAntipodal}^{\uparrow}}$ *surface consists exactly of source admission, antipodal-pair ledger exposure, Tucker-style finite labeling handoff, local comparison readback, obstruction-facing handoff to* $\mathsf{BorsukUlam}^{\uparrow}$*, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. Every downstream obstruction consumer reads the finite witness ledger through*

$$S, A, T \longmapsto L, O \longmapsto H, C, P, N$$

and receives no point-selection principle or quotient-sphere equality from that read.

Lean4 (statement) `BEDC.Derived.BorsukUlamAntipodalUp`

Proof. Project the carrier of Definition 8814.1. The rows S, A, T are the only source-side witness data: they display the boundary source, the antipodal ledger, and the Tucker-style finite labeling route.

The ledger then passes through L and O. The row L names the local antipodal comparison being inspected, while O records that the obstruction-facing consumer must return to $\mathsf{BorsukUlam}^{\uparrow}$ rather than reading a stronger theorem from this packet.

Finally H, C, P, N transport, replay, source, and name the same finite witness ledger. Since the excluded objects are not carrier coordinates, the packet can serve as a reusable witness ledger without asserting selected antipodal points, quotient equality, or host topological completeness. □

Falsifiable prediction: Every accepted $\mathsf{BorsukUlamAntipodal}^{\uparrow}$ read first displays sphere or boundary source rows, an antipodal-pair ledger, and Tucker-style finite labeling data before any obstruction-facing handoff to $\mathsf{BorsukUlam}^{\uparrow}$ is consumed.

Independence witness: borsukulam, tuckerlemma, compactmetric, s1: $\mathsf{BorsukUlamAntipodal}^{\uparrow}$ is not bijective to any listed sibling because it binds the antipodal witness ledger, Tucker-style finite labeling handoff, local comparison row, and obstruction-facing handoff as one NameCert packet, while each sibling supplies only an obstruction theorem, combinatorial labeling theorem, source carrier, or boundary model.

Closure status for $\mathsf{NameCert}_{\mathsf{BorsukUlamAntipodal}^{\uparrow}}$**.**

Constructive story: A $\mathsf{BorsukUlamAntipodal}^{\uparrow}$ packet is generated from sphere or boundary source rows, an antipodal-pair ledger, Tucker-style finite labeling rows, a local comparison ledger, an obstruction-facing handoff, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{BorsukUlamAntipodal}^{\uparrow}}$, seed)

Scope closed: Definition 8814.1 and Definition 8814.2 seed the finite antipodal witness-ledger surface between $\mathsf{BorsukUlam}^{\uparrow}$ and $\mathsf{TuckerLemma}^{\uparrow}$.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{BorsukUlamAntipodal}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close selected antipodal points, quotient-sphere equality, host topological Borsuk–Ulam, Lean theorem verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, antipodal ledger exposure, Tucker-style finite labeling handoff, local comparison readback, obstruction-facing handoff, transport, replay, provenance, and local naming for BEDC.Derived.BorsukUlamAntipodalUp.

Chapter 8815

A Concrete Naming Certificate for $\mathsf{MetricFanTheorem}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{MetricFanTheorem}^{\uparrow}$ packet records the finite-means form of the fan theorem as it is consumed by metric continuity arguments. It sits after the finite spread route of $\mathsf{FanTheorem}^{\uparrow}$ and $\mathsf{FanSpace}^{\uparrow}$ in chapter 1962, the binary-prefix boundary supplied by $\mathsf{CantorSpace}^{\uparrow}$, the metric source of chapter 57, the pointwise continuity interface of chapter 130, the downstream $\mathsf{UniformModulus}^{\uparrow}$ consumer of chapter 369, and the terminal real-name seal of chapter 38. The chapter names a finite branch-radius certificate for compact fan arguments; it does not assert open-cover compactness, host uniform continuity, selected infinite branches, quotient stream equality, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 8815.1 (MetricFanTheorem carrier)**.** *A* $\mathsf{MetricFanTheorem}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$T = (F, B, M, C, R, U, E, H, K, P, N)$$

with the following displayed rows:

1. *F is the* $\mathsf{FanTheorem}^{\uparrow}$ *finite-bar row, recording a displayed depth that covers the finite branching source.*
2. *B is the* $\mathsf{FanSpace}^{\uparrow}$ *or* $\mathsf{CantorSpace}^{\uparrow}$ *prefix row whose inspected binary branches are bounded by F.*
3. *M is the* $\mathsf{Met}^{\uparrow}$ *source row, exposing only the metric comparisons needed to read branch radii.*
4. *C is the* $\mathsf{ContinuousMap}^{\uparrow}$ *pointwise continuity row, assigning each inspected prefix a displayed local radius and target tolerance response.*
5. *R is the finite radius ledger, listing the branch radii that survive the fan-depth inspection.*
6. *U is the* $\mathsf{UniformModulus}^{\uparrow}$ *handoff row obtained by folding the finite radius ledger into one displayed modulus depth.*
7. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row available only for the finite metric and modulus observations already exposed.*
8. *H records componentwise* hsame *transport for fan, prefix, metric, continuity, radius, modulus, seal, replay, provenance, and local naming rows.*
9. *K records displayed* Cont *replay from a metric fan request through $F, B, M, C, R, U, E, H, P, N$.*

10. *P is the* Pkg *provenance over* $\mathsf{MetricFanTheorem}^{\uparrow}$, $\mathsf{FanTheorem}^{\uparrow}$, $\mathsf{FanSpace}^{\uparrow}$, $\mathsf{CantorSpace}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{UniformModulus}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

11. *N is the local* $\mathsf{NameCert}_{\mathsf{MetricFanTheorem}^{\uparrow}}$ *row.*

The carrier predicate asserts that these rows form one finite metric fan history. Its classifier compares accepted packets only through the displayed fan depth, inspected prefix rows, metric observations, pointwise continuity rows, finite radius ledger, uniform-modulus handoff, Real seal, transport, replay, provenance, and local name.

Theorem 8815.2 (MetricFanTheorem NameCert obligations)**.** *For every accepted* $\mathsf{MetricFanTheorem}^{\uparrow}$ *carrier* $T = (F, B, M, C, R, U, E, H, K, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{MetricFanTheorem}^{\uparrow}}$ *surface consists exactly of finite fan-depth admission, prefix-row exposure, metric comparison exposure, pointwise continuity exposure, finite radius ledgering, uniform-modulus handoff, terminal Real seal, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. No NameCert obligation is stored outside those finite rows.*

Proof. Project the carrier of Definition 8815.1. The rows F and B are the only fan-side rows, so fan admission and branch inspection are confined to the displayed finite depth and prefix surface.

Read the analytic rows next. The metric row M supplies the branch-distance comparisons, C supplies pointwise continuity data at the inspected prefixes, and R records the finite list of radii that remain after the fan-depth inspection.

Finally use U, E, H, K, P, N. The uniform-modulus handoff, Real seal, componentwise transport, replay, provenance, and local name preserve the same finite packet. Since the carrier has no further coordinate, open-cover compactness, host uniform continuity, selected infinite branches, quotient stream equality, countable choice, and ambient Real completeness cannot become local NameCert obligations. □

Theorem 8815.3 (MetricFanTheorem uniform-modulus route)**.** *Every downstream consumer of an accepted* $\mathsf{MetricFanTheorem}^{\uparrow}$ *packet receives the finite route*

$$\mathsf{FanTheorem}^{\uparrow},\ \mathsf{FanSpace}^{\uparrow},\ \mathsf{CantorSpace}^{\uparrow} \longmapsto \mathsf{Met}^{\uparrow},\ \mathsf{ContinuousMap}^{\uparrow} \longmapsto R \longmapsto \mathsf{UniformModulus}^{\uparrow},\ \mathsf{Real}^{\uparrow}.$$

Consequently a consumer may read one displayed fan depth, the inspected prefix rows below that depth, the metric branch-radius comparisons, and the resulting uniform-modulus handoff. It receives no open-cover compactness theorem, no host uniform-continuity theorem, no selected infinite branch, no quotient stream equality, no countable-choice schedule, and no ambient completeness principle for $\mathsf{Real}^{\uparrow}$.

Proof. Start with the fan rows. The row F supplies the finite bound, and B exposes only the prefix rows inspected below that bound.

Use the metric and continuity rows. The row M records the source-distance observations needed for branch radii, while C records the pointwise continuity responses for those displayed prefixes. The ledger R is therefore a finite list obtained inside the inspected fan surface.

Route the finite ledger through U and E, then preserve it through H, K, P, N. Since every downstream handoff factors through these rows, the public route is the displayed uniform-modulus extraction route and not an ambient compactness or choice principle. □

Closure status for $\mathsf{NameCert}_{\mathsf{MetricFanTheorem}^{\uparrow}}$**.**
Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{MetricFanTheorem}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8815.1, Definition 8815.2, and Definition 8815.3 seed the finite metric fan route from fan depth and prefix rows to metric branch radii, pointwise continuity rows, a uniform-modulus handoff, Real seal, transport, replay, provenance, and local naming.

Constructive story: A MetricFanTheorem$^{\uparrow}$ packet is generated from a finite FanTheorem depth row, FanSpace or CantorSpace prefix rows, Metric comparisons, ContinuousMap pointwise continuity rows, a finite radius ledger, a UniformModulus handoff, a Real seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Formal verification: FormalStatus(NameCert$_{\mathsf{MetricFanTheorem}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close open-cover compactness, host uniform continuity, selected infinite branches, quotient stream equality, countable choice, ambient Real$^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked fan-depth admission, prefix-row exposure, metric comparison exposure, pointwise continuity exposure, finite radius ledgering, uniform-modulus handoff, Real seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.MetricFanTheoremUp.

Chapter 8816

A Concrete Naming Certificate for $\mathsf{DyadicDistance}^{\uparrow}$

Following Bishop and Bridges, read dyadic distance as the finite absolute-difference certificate needed before regular Cauchy real names. The $\mathsf{DyadicDistance}^{\uparrow}$ packet sits after the dyadic rational source of chapter 291, the absolute-value normalization of chapter 293, and the metric handoff of chapter 2001. It is consumed by the regular Cauchy row discipline of chapter 301 and the terminal real-name seal of chapter 38. The packet names only finite endpoint, scale, sign, absolute-value, transport, replay, provenance, and local certificate rows; it does not import a host real distance, quotient rational equality, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 8816.1 (Dyadic distance carrier)**.** *A* $\mathsf{DyadicDistance}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$D = (L, R, E, S, A, Z, H, C, P, N)$$

with the following displayed rows:

1. *L and R are the two* $\mathsf{DyadicRatCore}^{\uparrow}$ *endpoint histories.*
2. *E is the common positive unary scale row refining the endpoint denominators.*
3. *S is the signed common-scale difference row, including the transported mantissas.*
4. *A is the* $\mathsf{DyadicAbsoluteValue}^{\uparrow}$ *absolute-value normalization row for S.*
5. *Z is the zero-distance and triangle ledger, storing the equal-endpoint row and the common-scale comparison rows used by later tolerance consumers.*
6. *H records componentwise* hsame *transport for endpoints, scale, signed difference, absolute value, ledger, replay, provenance, and local naming.*
7. *C records displayed* Cont *replay from an endpoint-pair request through the common-scale and absolute-value rows.*
8. *P is the* Pkg *provenance over* $\mathsf{DyadicDistance}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{DyadicAbsoluteValue}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
9. *N is the local* $\mathsf{NameCert}_{\mathsf{DyadicDistance}^{\uparrow}}$ *row.*

The classifier compares accepted packets by equality of the displayed distance witnesses after common-scale refinement. It has no coordinate for a quotient rational representative, a host real metric, a selected real endpoint, trichotomy, or a completion principle.

Lean4 (statement) `BEDC.Derived.DyadicDistanceUp`

Theorem 8816.2 (Dyadic distance NameCert obligations)**.** *For every accepted* $\mathsf{DyadicDistance}^{\uparrow}$ *carrier* $D = (L, R, E, S, A, Z, H, C, P, N)$*, the local naming surface has exactly five mathematical obligation rows:*

1. *carrier admission for the pair of* $\mathsf{DyadicRatCore}^{\uparrow}$ *endpoints plus the absolute common-scale witness;*
2. *classifier comparison by equality of distance witnesses under common-scale refinement;*
3. *stability under dyadic equality, componentwise* hsame *transport, and displayed* Cont *replay;*
4. *exactness for zero-distance exposure and the common-scale triangle rows recorded in* Z*;*
5. *ledger visibility for hidden scale choices and sign-normalization data.*

The structural rows H, C, P, N *transport, replay, source, and name these obligations without adding host real distance, quotient equality, trichotomy, or* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the carrier of Definition 8816.1. The endpoint rows L, R, the common scale row E, the signed difference row S, the absolute-value row A, and the ledger row Z are the only mathematical coordinates available to a distance consumer.

The classifier row is read through the common-scale witness. Refining two accepted distance packets to a further displayed scale transports the same endpoint and mantissa rows through $\mathsf{DyadicRatCore}^{\uparrow}$ and compares the resulting absolute witnesses through $\mathsf{DyadicAbsoluteValue}^{\uparrow}$.

Stability is therefore componentwise. The H row transports endpoints, scale, signed-difference, absolute-value, and ledger data, while C replays the same finite route for the transported packet.

Exactness is confined to Z. The zero-distance row is the equal-endpoint common-scale case, and the triangle row is the finite comparison of three displayed common-scale absolute differences. Since no host real, quotient, trichotomy, or completion row is present in the carrier, the five listed obligations exhaust the naming surface. □

Theorem 8816.3 (Dyadic distance triangle envelope)**.** *Let* D_{01}*,* D_{12}*, and* D_{02} *be accepted* $\mathsf{DyadicDistance}^{\uparrow}$ *packets for three accepted* $\mathsf{DyadicRatCore}^{\uparrow}$ *endpoint histories. If their common-scale rows are refined to one displayed positive unary scale and their sign-normalization ledgers are transported to that scale, then the triangle envelope is read entirely from the three absolute common-scale witnesses and the ledger row* Z*. The read exposes no host metric inequality, quotient rational equality, selected real endpoint, trichotomy, or* $\mathsf{Real}^{\uparrow}$ *completeness coordinate.*

Proof. Refine the three packet scales to one displayed positive unary scale. The $\mathsf{DyadicRatCore}^{\uparrow}$ classifier supplies the endpoint transports, and the $\mathsf{DyadicAbsoluteValue}^{\uparrow}$ rows normalize the three signed common-scale differences at that same scale.

Read the envelope from the ledger row Z of each accepted packet. These rows contain the zero-distance and common-scale triangle data that later $\mathsf{RegSeqRat}^{\uparrow}$ and $\mathsf{Real}^{\uparrow}$ consumers need for finite tolerance comparison.

The conclusion is a boundary statement about available rows. Because the carrier of Definition 8816.1 contains only endpoint, scale, signed-difference, absolute-value, ledger, transport, replay, provenance, and local naming data, the triangle envelope cannot be reinterpreted as a host metric theorem or as any completed real-distance principle. □

Closure status for $\mathsf{NameCert}_{\mathsf{DyadicDistance}^{\uparrow}}$**.**

Constructive story: A DyadicDistance$^{\uparrow}$ packet is generated from two DyadicRatCore endpoint rows, a common positive unary scale, a signed common-scale difference row, a DyadicAbs normalization row, a zero-distance and triangle ledger, componentwise transport, displayed replay, provenance, and local NameCert naming.

Theory closure: TheoryGate(NameCert$_{\mathsf{DyadicDistance}^{\uparrow}}$, seed)

Scope closed: Definition 8816.1, Definition 8816.2, and Definition 8816.3 seed the finite dyadic distance substrate consumed by regular Cauchy and real-name tolerance rows.

Formal verification: FormalStatus(NameCert$_{\mathsf{DyadicDistance}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close Lean verification, metric-space completion, quotient rational equality, trichotomy, or any host real-distance theorem.

Upgrade path: Obligation closure requires checked carrier admission, classifier stability, zero-distance exactness, triangle-envelope exactness, hidden-scale ledger visibility, transport, replay, provenance, and local naming for BEDC.Derived.DyadicDistanceUp.

Chapter 8817

A Concrete Naming Certificate for $\mathsf{BoundedDyadicVariation}^{\uparrow}$

Following Jordan bounded variation and Bishop-style finite partition reasoning, the $\mathsf{BoundedDyadicVariation}^{\uparrow}$ packet records bounded variation evidence only over displayed dyadic partitions. It sits between the finite variation surface of chapter 398, the partition cells of chapter 1863, the regular rational readback of chapter 301, the dyadic tolerance rows of chapter 291, and the terminal real-name seal of chapter 38. The packet gives regulated-function, Riemann, and Darboux consumers a finite dyadic variation ledger without importing measure completion, selected extrema, quotient equality of functions, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 8817.1 (Bounded dyadic variation carrier)**.** *A* $\mathsf{BoundedDyadicVariation}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (I, M, V, D, R, E, H, C, P, N)$$

with the following displayed rows:

1. *I is the interval source row, naming the inspected compact or located interval only through displayed endpoint data.*
2. *M is the dyadic partition mesh row, recording a finite ordered* $\mathsf{DyadicPartition}^{\uparrow}$ *mesh together with its adjacent cell and common-refinement data.*
3. *V is the finite variation-budget row, recording the dyadic edge sums available to the packet.*
4. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row used to compare endpoint differences and edge contributions on the displayed mesh.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row attached to endpoint names and finite variation sums.*
6. *E is the* $\mathsf{Real}^{\uparrow}$ *endpoint seal row, available only after I, M, V, D, R have been displayed.*
7. *H records componentwise* hsame *transport for interval sources, dyadic meshes, variation budgets, tolerance rows, readback rows, Real endpoint seals, replay, provenance, and local naming.*
8. *C records displayed* Cont *replay from an interval request through the dyadic mesh, finite variation budget, dyadic tolerance rows, regular readback, and endpoint seal.*
9. *P is the* Pkg *provenance over* $\mathsf{BoundedDyadicVariation}^{\uparrow}$, $\mathsf{BoundedVariation}^{\uparrow}$, $\mathsf{DyadicPartition}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{BoundedDyadicVariation}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $I, M, V, D, R, E, H, C, P, N$. It has no coordinate for measure completion, selected extrema, host function equality, hidden partition families, variation measures, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 8817.2 (Bounded dyadic variation NameCert obligations)**.** *For every accepted* $\mathsf{BoundedDyadicVariation}^{\uparrow}$ *carrier*

$$B = (I, M, V, D, R, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{BoundedDyadicVariation}^{\uparrow}}$ *surface consists exactly of carrier admission for the ten displayed rows; dyadic partition exposure through M; finite variation-budget stability through V and its common-refinement reads; endpoint-difference tolerance through D; endpoint-readback discipline through R before E; componentwise* hsame *transport through H; displayed* Cont *replay through C;* Pkg *provenance through P; and local naming through N.*

The certificate refuses measure completion, selected extrema, host equality of functions, hidden dyadic mesh families, a supremum over all partitions, and ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 8817.3 (Bounded dyadic variation finite partition handoff)**.** *Every regulated-function, Riemann, or Darboux consumer of an accepted* $\mathsf{BoundedDyadicVariation}^{\uparrow}$ *packet must first read the displayed dyadic partition mesh M, the finite variation budget V, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row D, and the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row R before consuming the* $\mathsf{Real}^{\uparrow}$ *endpoint seal E.*

Thus the handoff route is finite:

$$\mathsf{DyadicPartition}^{\uparrow},\ \mathsf{DyadicRatCore}^{\uparrow},\ \mathsf{BoundedVariation}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}.$$

It exports only displayed mesh cells, finite edge sums, dyadic tolerance rows, regular readback, endpoint seals, transport, replay, provenance, and local naming.

Falsifiable prediction: A $\mathsf{BoundedDyadicVariation}^{\uparrow}$ consumer that reaches a Real-facing regulated-function or integration conclusion without reading the dyadic mesh, finite variation budget, dyadic tolerance row, and RegSeqRat readback refutes the carrier surface.

Independence witness: boundedvariation, dyadicpartition, regseqrat, dyadicratcore, real: none is bijective to $\mathsf{BoundedDyadicVariation}^{\uparrow}$ because this packet jointly carries an interval source, a displayed dyadic mesh, a finite variation budget, dyadic tolerance rows, regular readback, Real endpoint sealing, transport, replay, provenance, and local NameCert rows.

Closure status for $\mathsf{NameCert}_{\mathsf{BoundedDyadicVariation}^{\uparrow}}$**.**

Constructive story: A $\mathsf{BoundedDyadicVariation}^{\uparrow}$ packet is generated from an interval source row, a finite dyadic partition mesh, a finite variation-budget row, DyadicRatCore tolerance rows, RegSeqRat readback, a RealUp endpoint seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{BoundedDyadicVariation}^{\uparrow}}$, seed)

Scope closed: Definition 8817.1, Definition 8817.2, and Definition 8817.3 seed the finite dyadic variation interface from displayed dyadic partitions and variation budgets to regulated-function and integration consumers.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{BoundedDyadicVariation}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close measure completion, selected extrema, host equality of functions, hidden partition families, quotient function spaces, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, dyadic partition exposure, variation-budget stability, endpoint tolerance, regular readback, Real endpoint sealing, transport, replay, provenance, and local naming for BEDC.Derived.BoundedDyadicVariationUp.

Chapter 8818

A Concrete Naming Certificate for $\mathsf{ConstructiveRealApartness}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{ConstructiveRealApartness}^{\uparrow}$ packet records strict real separation as finite positive witness data rather than as a trichotomy principle. It sits over the Real carrier of chapter 38, the regular rational rows of chapter 301, the StreamName windows of chapter 126, the dyadic tolerance ledger of chapter 291, and the positive real boundary of chapter 1587. Its role is to make the constructive constraint of section 9467.12 usable by later order and completion consumers without importing quotient real equality, host equality, selected limits, countable choice, trichotomy, or ambient completeness for $\mathsf{Real}^{\uparrow}$.

Definition 8818.1 (ConstructiveRealApartness carrier)**.** *A* $\mathsf{ConstructiveRealApartness}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$A = (X, Y, R_X, R_Y, S_X, S_Y, D, \delta, W, H, C, P, N)$$

with the following displayed rows:

1. *X and Y are the two* $\mathsf{Real}^{\uparrow}$ *seal rows being separated.*
2. *R_X and R_Y are the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback rows used to inspect the two real names.*
3. *S_X and S_Y are the* $\mathsf{StreamName}^{\uparrow}$ *finite-window rows from which the readbacks are taken.*
4. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *ledger that records the finite dyadic comparison scale.*
5. *δ is the* $\mathsf{PositiveReal}^{\uparrow}$ *lower-bound witness for the displayed separation.*
6. *W is the finite apartness window asserting that the rational readbacks at the displayed scale are separated by the positive lower bound named by δ.*
7. *H records componentwise* hsame *transport for the real seals, regular readbacks, stream windows, dyadic ledger, positive witness, apartness window, continuation, provenance, and local naming rows.*
8. *C records the displayed* Cont *replay that opens the two StreamName windows, reads the RegSeqRat rows, checks the dyadic comparison ledger, and hands the positive witness to the Real-facing apartness surface.*
9. *P is the* Pkg *provenance over* $\mathsf{Real}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{PositiveReal}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{ConstructiveRealApartness}^{\uparrow}}$ *row.*

The carrier has no coordinate for quotient real equality, host real equality, a selected representative limit, countable choice, trichotomy, or completeness of $\mathsf{Real}^{\uparrow}$.

Theorem 8818.2 (ConstructiveRealApartness NameCert obligations)**.** *For every accepted* ConstructiveRealApartne *carrier*

$$A = (X, Y, R_X, R_Y, S_X, S_Y, D, \delta, W, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{ConstructiveRealApartness}^{\uparrow}}$ *surface consists of carrier admission for the displayed rows, paired RealUp seal exposure through* X, Y*, regular readback exposure through* R_X, R_Y*, finite StreamName window exposure through* S_X, S_Y*, dyadic comparison exactness through* D*, positive lower-bound exposure through* δ*, apartness-window readback through* W*, componentwise* hsame *stability through* H*, displayed* Cont *replay through* C*,* Pkg *provenance through* P*, and local naming through* N*.*

Proof. Project the carrier of Definition 8818.1. The Real-facing rows are exactly X, Y, and the only inspection rows are the regular readbacks, stream windows, dyadic comparison ledger, positive witness, and apartness window displayed in the tuple.

The certificate reads separation constructively. The witness δ is a positive lower-bound row, while W ties that row to the finite rational readbacks obtained from S_X, S_Y through R_X, R_Y and checked against D.

The transport, replay, provenance, and local name rows preserve the same finite route. Since no further carrier coordinate is present, the listed rows exhaust the local NameCert surface. □

Theorem 8818.3 (ConstructiveRealApartness finite readback)**.** *Every accepted* $\mathsf{ConstructiveRealApartness}^{\uparrow}$ *read is witnessed by the finite route*

$$\mathsf{StreamName}^{\uparrow},\ \mathsf{RegSeqRat}^{\uparrow},\ \mathsf{DyadicRatCore}^{\uparrow},\ \mathsf{PositiveReal}^{\uparrow},\ \mathsf{Real}^{\uparrow}.$$

The two Real-facing rows become apart only through the displayed StreamName windows, regular rational readbacks, dyadic comparison ledger, positive lower-bound row, and apartness window.

Proof. Use the NameCert obligations of Definition 8818.2. They force each accepted read to expose S_X, S_Y before R_X, R_Y, then the dyadic ledger D, the positive witness δ, and the apartness window W.

Only after those rows have been displayed can the Real-facing rows X, Y be read as apart. The continuation row C records the same order, and the package row P adds provenance rather than a new comparison principle. □

Theorem 8818.4 (ConstructiveRealApartness non-trichotomy boundary)**.** *An accepted* ConstructiveRealApartness *carrier exports a positive finite apartness witness and does not export quotient real equality, host real equality, selected limits, countable choice, trichotomy, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness. In particular, the packet cannot be read as a decision procedure for arbitrary comparison of the two RealUp rows.*

Proof. Project the carrier. Its content rows are the two RealUp seals, regular readbacks, finite StreamName windows, dyadic ledger, positive witness, and apartness window.

The finite readback theorem Definition 8818.3 identifies the only route from these rows to an apartness claim. That route supplies a displayed positive witness, not a three-way case split and not a host equality test.

Since the tuple contains no row for quotient equality, selected representatives, choice, trichotomy, or completeness, no accepted consumer can recover those principles from the packet. □

Falsifiable prediction: A packet that claims ConstructiveRealApartnessUp while omitting either the positive lower-bound row or the finite apartness window is not an accepted carrier.

Independence witness: real, regseqrat, streamname, dyadicratcore, positivereal: each sibling supplies one surface of the readback route, while ConstructiveRealApartnessUp binds two RealUp seals, two regular readbacks, two StreamName windows, one dyadic comparison ledger, one positive witness, transport, replay, provenance, and a local NameCert row in one carrier.

Closure status for $\mathsf{NameCert}_{\mathsf{ConstructiveRealApartness}\uparrow}$.

Constructive story: A $\mathsf{ConstructiveRealApartness}^{\uparrow}$ packet is generated from two RealUp seal rows, paired RegSeqRat readbacks, paired StreamName finite windows, a DyadicRatCore comparison ledger, a PositiveReal lower-bound witness, an apartness window, componentwise hsame transports, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{ConstructiveRealApartness}\uparrow}, \mathsf{seed})$

Scope closed: Definition 8818.1, Definition 8818.2, Definition 8818.3, and Definition 8818.4 seed the finite constructive apartness surface for RealUp rows through regular readback, StreamName windows, dyadic comparison, and positive witnesses.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{ConstructiveRealApartness}\uparrow}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim trichotomy, quotient real equality, host equality, selected limits, countable choice, RealUp completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, paired readback exposure, finite apartness-window exactness, positive-witness stability, route replay, provenance, and non-trichotomy nonescape for the same packet.

Chapter 8819

A Concrete Naming Certificate for RichardsonExtrapolation$^{\uparrow}$

Following Richardson's extrapolation method for cancelling the leading discretization term, the RichardsonExtrapolation$^{\uparrow}$ packet records a finite acceleration surface for two or more displayed approximation rows before any Real or completion-facing consumer reads the accelerated value. It sits after the dyadic endpoint arithmetic of chapter 291, the finite stream-window interface of chapter 126, the regular rational readback of chapter 301, the terminal real-name seal of chapter 38, and the regular Cauchy completion route of chapter 1639. The certificate names one displayed cancellation stencil; it does not assert an asymptotic expansion theorem, quotient equality of real names, selected convergence rates, countable choice, or ambient completeness.

Definition 8819.1 (Richardson extrapolation carrier)**.** *A* RichardsonExtrapolation$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$R = (D, S, A, O, K, Q, B, E, U, H, C, P, N)$$

with the following displayed rows:

1. *D is the* DyadicRatCore$^{\uparrow}$ *scale and endpoint ledger naming the refinement ratio, powers of the scale, and dyadic denominator comparisons.*
2. *S is the* StreamName$^{\uparrow}$ *window row selecting the finite approximation depths inspected by the extrapolation stencil.*
3. *A is the source approximation row over the displayed depths, with no hidden ambient sequence.*
4. *O is the finite order row naming the leading error order that the stencil is allowed to cancel.*
5. *K is the dyadic coefficient row computing the Richardson weights from D and O.*
6. *Q is the denominator-apartness and fallback ledger for the coefficient computation.*
7. *B is the accelerated readback row formed from A, K, Q.*
8. *E is the* RegSeqRat$^{\uparrow}$ *readback row reached from the displayed accelerated values.*
9. *U is the downstream* Real$^{\uparrow}$ *and* BishopRegularCauchyCompletion$^{\uparrow}$ *seal row exposed only after D, S, A, O, K, Q, B, E have been displayed.*
10. *H records componentwise* hsame *transport for all visible extrapolation rows.*
11. *C records displayed* Cont *replay from scale and window reads to coefficient construction, accelerated readback, regular rational readback, and terminal sealing.*

12. *P is the* Pkg *provenance over* $\mathsf{RichardsonExtrapolation}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{BishopRegularCauchyCompletion}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
13. *N is the local* $\mathsf{NameCert}_{\mathsf{RichardsonExtrapolation}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $D, S, A, O, K, Q, B, E, U, H, C, P, N$. It has no coordinate for host asymptotic equality, quotient real equality, a selected rate theorem, countable-choice extraction of a subsequence, or ambient completeness.

Theorem 8819.2 (Richardson extrapolation NameCert obligations)**.** *For an accepted* $\mathsf{RichardsonExtrapolation}^{\uparrow}$ *carrier $R = (D, S, A, O, K, Q, B, E, U, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{RichardsonExtrapolation}^{\uparrow}}$ *surface consists exactly of carrier admission, dyadic scale ledger exposure through D, finite approximation-window exposure through S and A, displayed leading-order admission through O, coefficient construction through K, denominator-apartness and fallback admission through Q, accelerated readback through B,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback through E,* $\mathsf{Real}^{\uparrow}$ *and* $\mathsf{BishopRegularCauchyCompletion}^{\uparrow}$ *sealing through U, componentwise transport, continuation replay, provenance, and local naming.*

Proof. Carrier admission is projection from Definition 8819.1. The tuple lists exactly the dyadic scale data, finite stream window, approximation rows, leading-order row, coefficient ledger, denominator guard, accelerated readback, regular rational readback, terminal seal, transport, replay, provenance, and local name.

The cancellation step is finite. The coefficient row K is computed only from the displayed dyadic scale row D and order row O, and the denominator guard Q is read before any accelerated value in B is exported.

The analytic handoff is downstream of that finite stencil. The stream row S supplies the inspected depths, A supplies the source approximations at those depths, B supplies the weighted readback, and E converts the readback into the regular rational route before U exposes any Real or completion-facing seal.

Finally H, C, P, N preserve the same visible route under transport, replay, provenance, and local naming. Since no carrier coordinate stores host asymptotic equality, quotient real equality, a selected rate theorem, countable-choice extraction, or ambient completeness, the listed rows exhaust the local NameCert obligations. □

Theorem 8819.3 (Richardson extrapolation RegSeqRat and Real seal handoff)**.** *Every* $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, *or* $\mathsf{BishopRegularCauchyCompletion}^{\uparrow}$ *consumer of an accepted* $\mathsf{RichardsonExtrapolation}^{\uparrow}$ *packet must pass through the finite route*

$$D, S, A, O, K, Q, B, E, U, H, C, P, N.$$

The consumer receives the displayed dyadic scale ledger, finite approximation window, leading-order row, coefficient construction, denominator guard, accelerated readback, regular rational readback, terminal Real and completion seal, componentwise transport, continuation replay, provenance, and local naming. It receives no host asymptotic expansion, quotient equality of real names, hidden convergence rate, countable-choice schedule, or ambient completeness theorem.

Proof. Begin with the accepted carrier of Definition 8819.1. A downstream consumer has access only to the displayed rows $D, S, A, O, K, Q, B, E, U, H, C, P, N$.

Read the finite numerical stencil first. The row D fixes the dyadic refinement scale, S chooses the inspected approximation depths, A supplies the corresponding approximation values, and O names the leading order whose displayed term is to be cancelled.

The coefficient and guard rows are then mandatory. The row K stores the Richardson weights computed from D and O, while Q records the denominator-apartness or fallback evidence required before the accelerated value B can be used.

Finally the regular rational and terminal rows E and U expose the same accelerated readback to $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, and $\mathsf{BishopRegularCauchyCompletion}^{\uparrow}$ consumers. The transport, replay, provenance, and local name rows H, C, P, N add no host asymptotic, quotient, choice, or completeness coordinate, so every consumer-facing read factors through the displayed route. □

Falsifiable prediction: Every $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, or $\mathsf{BishopRegularCauchyCompletion}^{\uparrow}$ read from a $\mathsf{RichardsonExtrapolation}^{\uparrow}$ packet factors through displayed dyadic scale rows, finite StreamName windows, source approximation rows, a leading-order row, coefficient construction, denominator-apartness or fallback evidence, accelerated readback, regular rational readback, terminal seal, transport, replay, provenance, and local naming.

Independence witness: dyadicratcore, streamname, regseqrat, real, bishop-regular-cauchy-completion: $\mathsf{RichardsonExtrapolation}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries a refinement-scale ledger, finite approximation window, leading-order cancellation row, coefficient and denominator guard rows, accelerated readback, regular rational readback, Real and completion seal, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{RichardsonExtrapolation}^{\uparrow}}$.

Constructive story: A $\mathsf{RichardsonExtrapolation}^{\uparrow}$ packet is generated from dyadic refinement-scale data, finite StreamName windows, source approximation rows, a displayed leading-order row, Richardson coefficient construction, denominator-apartness or fallback evidence, accelerated readback, RegSeqRat readback, Real and Bishop regular Cauchy completion sealing, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RichardsonExtrapolation}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8819.1, Definition 8819.2, and Definition 8819.3 seed the finite Richardson extrapolation packet and its route to $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, and $\mathsf{BishopRegularCauchyCompletion}^{\uparrow}$.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RichardsonExtrapolation}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close Lean verification, a standard bridge, host asymptotic expansion theorems, quotient real equality, selected convergence rates, countable choice, or ambient completeness.

Upgrade path: Obligation closure requires checked carrier admission, coefficient guard exactness, RegSeqRat readback handoff, Real and completion seal nonescape, and consumer-boundary proofs for BEDC.Derived.RichardsonExtrapolationUp.

Chapter 8820

A Concrete Naming Certificate for $\mathsf{FiniteVisionMarkerAudit}^{\uparrow}$

The $\mathsf{FiniteVisionMarkerAudit}^{\uparrow}$ packet turns the marker-ledger discipline of chapter 9236 into finite NameCert data. It reads the visions index as a source-label surface, points to concrete-instance targets through displayed chapter labels, records the marker ledger, replays the audit readback, and carries provenance for the route that connects inspiration-only vision material to mature concrete packets. It is a finite audit object for the existing marker surface, not a replacement for the target chapters it names.

The marker audit route consumes the kernel acceptance witness of chapter 549 and the source-label discipline of chapter 9364 before it records a concrete target label.

Definition 8820.1 (Finite vision marker audit carrier)**.** *A* $\mathsf{FiniteVisionMarkerAudit}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$V = (S, T, L, A, H, C, P, N)$$

with the following displayed rows:

1. *S is the source-label row naming the vision chapter or vision index site being audited.*
2. *T is the concrete-target row naming the concrete-instance chapter label claimed by the marker.*
3. *L is the finite marker-ledger row recording the source label, target label, marker text, and local position.*
4. *A is the audit-readback row that checks source-label agreement, target-label agreement, and marker-ledger agreement in one finite pass.*
5. *H records componentwise* hsame *transport for the source label, target label, ledger, audit readback, continuation, provenance, and local naming rows.*
6. *C records the displayed* Cont *replay that reads S, then T, then L, and finally the readback row A.*
7. *P is the* Pkg *provenance over* $\mathsf{FiniteVisionMarkerAudit}^{\uparrow}$*, the visions index, the concrete-instance target chapter,* BHist*,* hsame*,* Cont*, and* NameCert*.*
8. *N is the local* $\mathsf{NameCert}_{\mathsf{FiniteVisionMarkerAudit}^{\uparrow}}$ *row.*

The carrier stores only finite marker data and route readback. It does not import the mathematical content of the target chapter, rewrite a vision file, or certify any theorem beyond the marker route itself.

Theorem 8820.2 (Finite vision marker audit NameCert obligations)**.** *For every accepted* $\mathsf{FiniteVisionMarkerAudit}^{\uparrow}$ *carrier* $V = (S, T, L, A, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{FiniteVisionMarkerAudit}^{\uparrow}}$ *surface consists of source-label exposure through* S*, concrete-target exposure through* T*, marker-ledger exposure through* L*, audit-readback exactness through* A*, componentwise* hsame *stability through* H*, displayed* Cont *replay through* C*,* Pkg *provenance through* P*, and local naming through* N*.*

Proof. Project the carrier of Definition 8820.1. The source label, target label, marker ledger, audit readback, transport, replay, provenance, and name are the only rows available to an accepted consumer.

The readback row A is downstream of S, T, L and checks exactly those labels and the marker ledger. The continuation row C fixes the same order, while H transports the rows componentwise.

The package row P names the visions index and the concrete target without importing the target chapter's theorem content. Therefore the listed rows exhaust the local NameCert surface. □

Theorem 8820.3 (Finite vision marker audit readback failure)**.** *An accepted* $\mathsf{FiniteVisionMarkerAudit}^{\uparrow}$ *carrier rejects any marker read whose source label or concrete-target label differs from the displayed rows* S *and* T*. The marker ledger row* L *and audit-readback row* A *must agree on the same pair of labels before the route can be consumed.*

Proof. Use the NameCert obligations of Definition 8820.2. They make S, T, L, A visible and force the audit readback to occur only after the source and target rows are displayed.

If a candidate read changes the source label, it no longer transports componentwise through the S row. If it changes the target label, it no longer transports componentwise through the T row.

The ledger and readback rows therefore agree only for the displayed pair. A mismatched source or target label leaves the accepted carrier surface. □

Theorem 8820.4 (Finite vision marker audit TasteGate obligations)**.** *The TasteGate surface for* $\mathsf{FiniteVisionMarkerAudit}^{\uparrow}$ *requires Lean to provide local* $\mathsf{Nontrivial}$ *and* $\mathsf{FieldFaithful}$ *instances over the same carrier rows* S, T, L, A, H, C, P, N*. Nontriviality separates a marker with matching source and target labels from a candidate with a mismatched label, and field faithfulness preserves the source-label, target-label, ledger, and audit-readback order.*

Proof. The carrier of Definition 8820.1 supplies the only rows on which the taste gate may act. A nontrivial boundary is visible because a matched marker read and a mismatched marker read differ at S or T before any audit readback is accepted.

Field faithfulness is the requirement that every faithful read preserve S, T, L, A and the structural rows H, C, P, N in the displayed order. Dropping the ledger or replacing the audit readback by a detached target theorem would create data outside the carrier. □

Falsifiable prediction: A FiniteVisionMarkerAuditUp packet whose source or target labels differ between the marker ledger and audit-readback rows fails marker-readback.

Independence witness: vision-coverage-index, vision-coverage-ledger, affine-filter-hull, vision-ledger-route: these siblings expose coverage, ledger, affine-filter, or routing rows separately, while FiniteVisionMarkerAuditUp binds source label, concrete target, marker ledger, audit readback, transport, replay, provenance, and local naming in one finite marker audit carrier.

Closure status for $\mathsf{NameCert}_{\mathsf{FiniteVisionMarkerAudit}^{\uparrow}}$**.**

Constructive story: A FiniteVisionMarkerAudit$^{\uparrow}$ packet is generated from a source-label row, a concrete-target row, a finite marker-ledger row, an audit-readback row, componentwise hsame transports, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\mathsf{FiniteVisionMarkerAudit}^{\uparrow}}$, seed)

Scope closed: Definition 8820.1, Definition 8820.2, Definition 8820.3, and Definition 8820.4 seed the finite marker-audit route for the visions index and its concrete-instance markers.

Formal verification: FormalStatus(NameCert$_{\mathsf{FiniteVisionMarkerAudit}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not certify target-chapter mathematics, rewrite vision prose, close Lean verification, or provide a public standard bridge.

Upgrade path: Obligation closure requires checked carrier admission, source-label exactness, concrete-target exactness, marker-ledger readback, route stability, provenance, TasteGate nontriviality, and field faithfulness for the same finite marker audit packet.

Chapter 8821

A Concrete Naming Certificate for $\mathsf{FluxOperatorGeometry}^{\uparrow}$

The $\mathsf{FluxOperatorGeometry}^{\uparrow}$ packet realizes the window-six flux-operator geometry branch of Definition 9346.48 as finite NameCert data. It sits beside the stable Zeckendorf phase-shell surface of chapter 8811, the finite golden-mean window of chapter 8802, and the static boundary-flux route of chapter 8769. The packet names stable addresses, transition operators, phase gates, boundary escape flux, and golden-shell projection as one finite operator-geometry surface; it does not assert a hidden metric geometry, invariant bilinear form, invariant multiplication, physical impedance law, or curvature-scalar readout.

Definition 8821.1 (Flux operator geometry carrier)**.** *A* $\mathsf{FluxOperatorGeometry}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$F = (A, T, G, B, S, O, H, C, P, N)$$

with the following displayed rows:

1. *A is the stable Zeckendorf address row, read through the visible window-six address surface of* $\mathsf{ZeckendorfPhaseShell}^{\uparrow}$*.*
2. *T is the finite transition-operator table on those displayed addresses.*
3. *G is the phase-gate row, recording which transition reads preserve, flip, or refuse the visible phase shell.*
4. *B is the boundary escape-flux row, read through the static boundary-flux sibling where the boundary cut is visible.*
5. *S is the golden-shell projection row, read through* $\mathsf{GoldenMeanShiftWindowSix}^{\uparrow}$ *and* $\mathsf{ZeckendorfPhaseShell}^{\uparrow}$ *rather than through a hidden inner product.*
6. *O is the operator-algebra refusal row, recording the absence of any displayed invariant bilinear form or invariant multiplication in the accepted packet.*
7. *H records componentwise* hsame *transport for address, transition, phase-gate, boundary-flux, projection, refusal, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from stable address reads to transition operators, phase gates, escape-flux reads, golden-shell projection, and refusal checks.*
9. *P is the* Pkg *provenance over* $\mathsf{FluxOperatorGeometry}^{\uparrow}$*,* $\mathsf{ZeckendorfPhaseShell}^{\uparrow}$*,* $\mathsf{GoldenMeanShiftWindowSix}^{\uparrow}$*,* $\mathsf{StaticGreenBoundaryFlux}^{\uparrow}$*,* BHist*,* hsame*,* Cont*, and* $\mathsf{NameCert}$*.*

10. N is the local $\mathsf{NameCert}_{\mathsf{FluxOperatorGeometry}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $A, T, G, B, S, O, H, C, P, N$. It has no coordinate for a hidden metric tensor, invariant symplectic form, bracket, commutative product, physical coupling constant, or curvature scalar.

Theorem 8821.2 (Flux operator geometry NameCert obligations)**.** *For every accepted* $\mathsf{FluxOperatorGeometry}^{\uparrow}$ *carrier $F = (A, T, G, B, S, O, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{FluxOperatorGeometry}^{\uparrow}}$ *surface consists exactly of stable-address exposure through A, finite transition-operator exposure through T, phase-gate exposure through G, boundary escape-flux exposure through B, golden-shell projection through S, operator-algebra refusal through O, componentwise transport through H, displayed replay through C, provenance through P, and local naming through N.*

Proof. Project the carrier of Definition 8821.1. The visible packet contains only the stable-address row, transition table, phase gates, boundary escape-flux row, golden-shell projection, refusal row, and structural rows.

The stable-address and projection data are finite. The rows A and S are read through the Zeckendorf phase shell and golden-mean window siblings, so a consumer receives visible address and projection rows rather than a hidden metric space.

The operator data are likewise row-local. The transition table T and phase gates G record finite operator action on displayed addresses, while the boundary row B records the escape-flux surface inherited from the static boundary-flux packet.

Finally O, H, C, P, N close the local boundary. The refusal row O blocks rereading the packet as an invariant bilinear form, symplectic form, bracket, or multiplication, and the structural rows transport, replay, source, and name only the displayed operator-geometry data. □

Theorem 8821.3 (Flux operator geometry boundary route)**.** *Every accepted* $\mathsf{FluxOperatorGeometry}^{\uparrow}$ *consumer that reads transition dynamics, phase gates, or escape flux must pass through the finite route*

$$A, T, G, B, S, O, H, C, P, N.$$

Thus the consumer sees stable Zeckendorf addresses, finite transition operators, phase gates, boundary escape flux, golden-shell projection, operator-algebra refusal, componentwise transport, continuation replay, provenance, and local naming. It receives no hidden metric geometry, invariant bilinear form, invariant multiplication, physical impedance constant, or curvature-scalar readout.

Proof. Begin with the accepted carrier of Definition 8821.1. A downstream read has access only to the rows $A, T, G, B, S, O, H, C, P, N$.

First read the visible address surface. The stable address row A and golden-shell projection row S are inherited from the finite Zeckendorf phase-shell and golden-mean window routes, so they do not expose a hidden ambient geometry.

Next read the operator rows. The transition table T records finite moves between displayed addresses, the phase-gate row G records the visible phase effect of those moves, and the boundary row B records the escape-flux contribution before any operator-geometry read is exported.

Finally apply the refusal and structural rows. The row O records that no invariant bilinear form or invariant multiplication is available in the packet, while H, C, P, N transport, replay, source, and name the same finite route. Hence every consumer-facing read remains inside the displayed operator-geometry surface. □

Falsifiable prediction: Every accepted $\mathsf{FluxOperatorGeometry}^{\uparrow}$ read that serves a transition, phase-gate, or boundary-flux consumer must expose stable Zeckendorf addresses, finite transition

operators, phase gates, boundary escape flux, golden-shell projection, operator-algebra refusal, componentwise transport, Cont replay, Pkg provenance, and local NameCert rows before the consumer is served.

Independence witness: zeckendorf-phase-shell, golden-mean-shift-window-six, static-green-boundary-flux: $\mathsf{FluxOperatorGeometry}^{\uparrow}$ is not bijective to any listed sibling because this packet jointly carries stable address rows, transition operators, phase gates, boundary escape-flux rows, golden-shell projection, refusal of invariant algebraic structure, transport, replay, provenance, and local naming.

The Lean TasteGate route for `BEDC.Derived.FluxOperatorGeometryUp` must eventually provide explicit $\mathsf{Nontrivial\ FluxOperatorGeometry}^{\uparrow}$ and $\mathsf{FieldFaithful\ FluxOperatorGeometry}^{\uparrow}$ instances preserving $A, T, G, B, S, O, H, C, P, N$ as separate displayed fields before stronger closure is claimed.

Closure status for $\mathsf{NameCert}_{\mathsf{FluxOperatorGeometry}^{\uparrow}}$.

Constructive story: A $\mathsf{FluxOperatorGeometry}^{\uparrow}$ packet is generated from stable Zeckendorf address rows, finite transition-operator tables, phase-gate rows, boundary escape-flux rows, golden-shell projection rows, operator-algebra refusal rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{FluxOperatorGeometry}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8821.1, Definition 8821.2, and Definition 8821.3 seed the finite flux-operator geometry packet over stable addresses, transition operators, phase gates, escape flux, golden-shell projection, refusal, transport, replay, provenance, and local naming rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{FluxOperatorGeometry}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close Lean verification, a standard bridge, hidden metric geometry, invariant bilinear forms, invariant multiplication, physical impedance laws, or curvature-scalar readouts.

Upgrade path: Obligation closure requires checked carrier admission, stable-address exposure, transition-operator table exactness, phase-gate exposure, boundary escape-flux handoff, golden-shell projection, operator-algebra refusal, TasteGate nontriviality, field faithfulness, transport, replay, provenance, and local naming for BEDC.Derived.FluxOperatorGeometryUp.

Chapter 8822

A Concrete Naming Certificate for $\mathsf{CauchyPeanoEulerPolygon}^{\uparrow}$

Following Peano's existence theorem and Bishop–Bridges constructive analysis, the $\mathsf{CauchyPeanoEulerPolygon}^{\uparrow}$ packet records the finite approximation surface where Euler polygon ledgers are read as Cauchy-style local-existence evidence without selecting a solution curve. It sits after the Euler-polygon route of chapter 1967, the Peano local-existence packet of chapter 3530, the regular rational readback of chapter 301, the dyadic tolerance ledger of chapter 291, and the terminal real-name seal of chapter 38. The packet names a finite mesh-budget and readback route; it is not a selected solution, not a completed ambient real object, not a uniqueness theorem, not host compactness, not quotient stream equality, and not countable choice.

Definition 8822.1 (Cauchy–Peano Euler-polygon carrier)**.** *A* $\mathsf{CauchyPeanoEulerPolygon}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$P = (I, F, E, B, D, Q, R, H, C, G, N)$$

with the following displayed rows:

1. *I is the Peano interval-source row, binding the initial time, initial state, local radius, and finite time window read through* $\mathsf{PeanoExistence}^{\uparrow}$*.*
2. *F is the continuous vector-field row used by the local Peano request, read only as displayed finite* BHist *data.*
3. *E is the* $\mathsf{EulerPolygon}^{\uparrow}$ *approximation row, exposing the dyadic mesh, initial point, local slope control, vertex windows, step ledger, regular readback, and terminal seal route of the sibling Euler-polygon packet.*
4. *B is the compact step-budget row, listing the finite mesh refinement requests, local radius bounds, and containment checks that keep the displayed polygon segments inside the Peano window.*
5. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger for step widths, accumulated polygon error cells, and Cauchy comparison budgets.*
6. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row obtained only after E, B, D have been displayed.*
7. *R is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row for the finite approximation packet.*
8. *H records componentwise* hsame *transport for interval data, vector-field data, Euler-polygon rows, step budgets, dyadic ledgers, readback rows, Real seals, replay, provenance, and local naming.*

9. *C records displayed* Cont *replay of the route*

$$(I, F, E, B, D) \longmapsto Q \longmapsto R.$$

10. *G is the* Pkg *provenance over* CauchyPeanoEulerPolygon$^{\uparrow}$, PeanoExistence$^{\uparrow}$, EulerPolygon$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, RegSeqRat$^{\uparrow}$, Real$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

11. *N is the local* NameCert$_{\text{CauchyPeanoEulerPolygon}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $I, F, E, B, D, Q, R, H, C, G, N$. It has no coordinate for a selected solution curve, uniqueness, ambient compactness, quotient equality of streams, host real equality, countable choice, Lean evidence, or bridge credentials.

Theorem 8822.2 (Cauchy–Peano Euler-polygon NameCert obligations)**.** *For every accepted* CauchyPeanoEulerPoly *carrier*

$$P = (I, F, E, B, D, Q, R, H, C, G, N),$$

the local NameCert$_{\text{CauchyPeanoEulerPolygon}^{\uparrow}}$ *surface consists exactly of carrier admission for the Peano interval source, displayed vector-field data, Euler-polygon approximation row, compact step-budget row, dyadic tolerance ledger, regular rational readback, terminal Real seal, componentwise transport, displayed replay, package provenance, and local naming. Every Cauchy–Peano approximation read is therefore routed through $I, F, E, B, D, Q, R, H, C, G, N$ before any consumer can inspect the terminal seal.*

Proof. Project the accepted carrier of Definition 8822.1. The rows I and F expose the local Peano request and vector-field data, while E supplies the Euler-polygon approximation route already named in chapter 1967.

The approximation budget is carried by B and D. The row B records finite mesh requests, local radius bounds, and containment checks; the row D records the dyadic widths, accumulated errors, and comparison budgets consumed before readback.

Rows Q and R are downstream of those displayed rows. The regular rational readback cannot be inspected before E, B, D, and the terminal Real seal cannot be inspected before Q.

The structural rows H, C, G, N transport, replay, package, and name exactly that finite route. Since the carrier contains no selected solution curve, uniqueness coordinate, ambient compactness witness, quotient equality, host equality, choice schedule, Lean evidence, or bridge credential, the NameCert surface cannot export any of those objects. □

Theorem 8822.3 (Compact step-budget factorization)**.** *For every accepted* CauchyPeanoEulerPolygon$^{\uparrow}$ *carrier*

$$P = (I, F, E, B, D, Q, R, H, C, G, N),$$

each finite approximation prefix exposed to a Peano consumer factors through the compact step-budget row B and the dyadic tolerance ledger D before it reaches the RegSeqRat$^{\uparrow}$ *row Q. In particular, the packet can certify only displayed finite mesh budgets and containment checks; it does not certify an ambient compactness theorem, a selected convergent subsequence, or a completed solution path.*

Proof. Read a finite approximation prefix through the Peano side. The interval row I supplies the requested local window, and the vector-field row F supplies the displayed slope data used by the Euler-polygon row E.

Before the prefix reaches a regular rational readback, the carrier forces the compact step-budget row B to expose the finite mesh request, the local radius bound, and the containment check for the inspected polygon segment.

The dyadic ledger D then supplies the numerical tolerance route for that same prefix. It records the displayed step widths and accumulated comparison budgets consumed by the handoff to Q.

Thus every readback-facing approximation prefix factors through B and D. The carrier has no coordinate for host compactness, selected subsequences, or completed solution paths, so those claims cannot be read from the finite step-budget factorization. □

Theorem 8822.4 (Real-seal route for Cauchy–Peano Euler polygons)**.** *For every accepted* CauchyPeanoEulerPolygo *carrier*

$$P = (I, F, E, B, D, Q, R, H, C, G, N),$$

every $\mathsf{Real}^{\uparrow}$ *consumer of the terminal seal* R *factors through the displayed route*

$$(I, F, E, B, D) \longmapsto Q \longmapsto R$$

together with componentwise hsame *transport, displayed* Cont *replay,* Pkg *provenance, and the local* NameCert *row. The seal records only the finite approximation packet connecting Euler polygons to Peano local-existence evidence; it does not assert a selected solution curve, ambient* $\mathsf{Real}^{\uparrow}$ *completeness, uniqueness, host compactness, quotient stream equality, or countable choice.*

Proof. Start with a Real-facing consumer of R. The carrier exposes R only as the terminal row after the interval source, vector-field data, Euler-polygon approximation route, compact step budget, dyadic tolerance ledger, and regular rational readback have all been displayed.

Trace the route backward from the seal. The row R is downstream of Q, the row Q is downstream of E, B, D, and the Euler-polygon and budget rows are downstream of the local Peano request I, F.

The structural rows preserve this order. Componentwise hsame transport cannot add a second Real surface, displayed Cont replay records the same finite route, and the provenance and naming rows merely bind the displayed packet.

Therefore every terminal Real read factors through $I, F, E, B, D, Q, R, H, C, G, N$. Since no coordinate names a selected solution curve, ambient completeness principle, uniqueness witness, host compactness theorem, quotient equality, or choice schedule, none of those claims escapes through the seal. □

Falsifiable prediction: Every $\mathsf{CauchyPeanoEulerPolygon}^{\uparrow}$ Real-facing read factors through a Peano interval row, displayed vector-field data, an EulerPolygonUp approximation row, a compact step-budget row, a DyadicRatCore tolerance ledger, a RegSeqRat readback row, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert data.

Independence witness: euler-polygon, peano-existence, regseqrat, dyadicratcore, real: CauchyPeanoEulerPolygor is not bijective to any listed sibling because it binds the Euler-polygon approximation surface to the Peano finite local-existence budget and Real-seal route in one displayed NameCert packet.

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyPeanoEulerPolygon}^{\uparrow}}$**.**

Constructive story: A $\mathsf{CauchyPeanoEulerPolygon}^{\uparrow}$ packet is generated from a Peano interval-source row, displayed vector-field data, an Euler-polygon approximation row, a compact step-budget row, a dyadic tolerance ledger, RegSeqRat readback, terminal Real seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CauchyPeanoEulerPolygon}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8822.1, Definition 8822.2, Definition 8822.3, and Definition 8822.4 seed the finite approximation route connecting Euler polygons to Peano local-existence evidence.

Formal verification: FormalStatus(NameCert$_{\mathsf{CauchyPeanoEulerPolygon}\uparrow}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close selected solution curves, ambient Real$^{\uparrow}$ completeness, uniqueness, host compactness, quotient stream equality, countable choice, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, Peano interval exposure, Euler-polygon dependency, compact step-budget factorization, DyadicRatCore tolerance accounting, RegSeqRat handoff, Real-seal routing, transport/replay/provenance coverage, and non-escape for BEDC.Derived.CauchyPeanoEulerPolygonUp.

Chapter 8823

A Concrete Naming Certificate for $\mathsf{LocatedCauchyNetSelector}^{\uparrow}$

Following Moore and Smith, Kelley, and Bishop, the $\mathsf{LocatedCauchyNetSelector}^{\uparrow}$ packet records the finite selector surface needed when a located Cauchy net is read through a regular-Cauchy window before reaching a $\mathsf{Real}^{\uparrow}$ seal. It sits after the located net packet of chapter 3587, the Moore–Smith source of chapter 3403, the regular subnet selector of chapter 6183, the stream naming row of chapter 126, the regular rational readback of chapter 301, the dyadic tolerance core of chapter 291, and the real-name seal of chapter 38. The packet selects only a finite located window and its regular readback route; it does not assert a global choice function on all nets, a quotient of directed indices, or ambient completeness of $\mathsf{Real}^{\uparrow}$.

Definition 8823.1 (Located Cauchy net selector carrier)**.** *A* $\mathsf{LocatedCauchyNetSelector}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (D, W, L, T, R, A, H, C, P, N)$$

with the following displayed rows:

1. *D is the directed index data: finite index names, comparison rows, and upper-bound witnesses used by the local Moore–Smith window.*
2. *W is the selected finite window, storing the inspected indices and the located net values admitted by the* $\mathsf{LocatedCauchyNet}^{\uparrow}$ *source.*
3. *L is the located radius row, recording the dyadic precision request and the located comparison data that make the window inspectable.*
4. *T is the tail witness row, showing that the selected window lies past the displayed directed threshold for the requested radius.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row obtained from W, L, T.*
6. *A is the* $\mathsf{Real}^{\uparrow}$ *admission seal reached only after the directed data, selected window, located radius, tail witness, and regular rational readback have been displayed.*
7. *H records componentwise* hsame *transport for D, W, L, T, R, A and the structural rows.*
8. *C records displayed* Cont *replay from a located Cauchy-net request through the same finite window, radius, tail, readback, and real-seal route.*

9. *P is the* Pkg *provenance over* LocatedCauchyNetSelector$^{\uparrow}$, LocatedCauchyNet$^{\uparrow}$, MooreSmithNet$^{\uparrow}$, RegularCauchySubnetSelector$^{\uparrow}$, StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, Real$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

10. *N is the local* NameCert$_{\text{LocatedCauchyNetSelector}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $D, W, L, T, R, A, H, C, P, N$. It has no coordinate for a global selector, countable choice, quotient net equality, host real equality, or an unbounded family of selected tails.

Theorem 8823.2 (Located Cauchy net selector NameCert obligations)**.** *For an accepted* LocatedCauchyNetSelector *carrier $S = (D, W, L, T, R, A, H, C, P, N)$, the local* NameCert$_{\text{LocatedCauchyNetSelector}^{\uparrow}}$ *surface consists exactly of directed index admission, selected finite-window admission, located radius readback, tail-witness exposure,* RegSeqRat$^{\uparrow}$ *readback,* Real$^{\uparrow}$ *seal admission, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and the local naming row. Every completion-facing consumer must read D, W, L, T before it reads R or A.*

Proof. Carrier admission is projection from Definition 8823.1. The rows D, W, L, T display the directed substrate, finite window, located radius, and tail witness before any numerical readback is available.

The regular readback is downstream of those rows. The RegSeqRat$^{\uparrow}$ coordinate R is read from the selected window and located tail data, while the Real$^{\uparrow}$ seal A is reached only after that regular readback has been displayed.

Transport, replay, provenance, and local naming are componentwise. Since the tuple contains no global selector, countable-choice schedule, quotient of net indices, host real equality, or unbounded family of tails, the NameCert surface is exactly the finite selector route listed above. □

Falsifiable prediction: Any accepted LocatedCauchyNetSelector$^{\uparrow}$ packet fails if a Real$^{\uparrow}$ seal is read before the directed data, selected window, located radius row, tail witness, RegSeqRat$^{\uparrow}$ readback, transport, replay, provenance, and local NameCert rows are displayed.

Closure status for NameCert$_{\text{LocatedCauchyNetSelector}^{\uparrow}}$**.**

Constructive story: A LocatedCauchyNetSelector$^{\uparrow}$ packet is generated from directed index data, a selected finite window, a located radius row, a tail witness, RegSeqRat readback, a Real seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\text{LocatedCauchyNetSelector}^{\uparrow}}$, seed)

Scope closed: Definition 8823.1 and Definition 8823.2 seed the finite located-window selector surface for L10 completion routes.

Formal verification: FormalStatus(NameCert$_{\text{LocatedCauchyNetSelector}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close a global selector on all located Cauchy nets, countable choice, quotient net equality, host real equality, ambient completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked directed-index admission, finite-window selection, located-radius readback, tail-witness exposure, RegSeqRat readback, Real-seal admission, transport, replay, provenance, and local naming for BEDC.Derived.LocatedCauchyNetSelectorUp.

Chapter 8824

A Concrete Naming Certificate for RhRouteClosureFixedStatementSeparation$^{\uparrow}$

The RhRouteClosureFixedStatementSeparation$^{\uparrow}$ packet realizes the route-layer versus fixed-statement separation of chapter 9337 as finite NameCert data. It keeps route-family closure rows separate from the single fixed RH proposition row, records refusal data for classifier rows that attempt to reuse a route-family obstruction as fixed-RH independence evidence, and exposes transport, replay, provenance, and local naming before any independence-facing consumer may read the packet. Its sibling context is the RH-free zero-generation route of chapter 8799, the zero-type factorization surface of chapter 8772, the finite prime-window gluing row of chapter 8765, and the route-halting boundary of chapter 5564.

Definition 8824.1 (RH route closure fixed statement separation carrier)**.** *A* RhRouteClosureFixedStatementSeparat *carrier is a finite* BHist *packet*

$$S = (R, F, U, B, T, C, H, Q, P, N)$$

with the following displayed rows:

1. *R is the route-layer row, recording a finite route-family classifier request over route codes and theorem targets.*
2. *F is the fixed-statement row, recording the single* RH *proposition as a fixed constructive statement rather than a family of routes.*
3. *U is the route-undecidability row, importing only the family-level obstruction from the route-halting boundary.*
4. *B is the row-split boundary, requiring any independence-facing consumer to display which data belong to R, U and which data belong to F.*
5. *T is the refusal row, storing failed attempts to reuse a route-family classifier obstruction as a fixed-RH independence witness.*
6. *C is the TasteGate-facing row requiring later Lean files to provide* Nontrivial RhRouteClosureFixedStatementSepara *and* FieldFaithful RhRouteClosureFixedStatementSeparation$^{\uparrow}$ *instances for the displayed route-layer and statement-layer fields.*
7. *H records componentwise* hsame *transport for route-layer, fixed-statement, obstruction, row-split, refusal, TasteGate, replay, provenance, and local-name rows.*

8. *Q records displayed* Cont *replay from a route-family obstruction request through R, U, B, T without rewriting it into a proof predicate for the fixed row F.*
9. *P is the* Pkg *provenance over* $\mathsf{RhRouteClosureFixedStatementSeparation}^{\uparrow}$, $\mathsf{RhFreeZeroInitiality}^{\uparrow}$, $\mathsf{ZetaZeroTypeFactorization}^{\uparrow}$, $\mathsf{FinitePrimeWindowGluing}^{\uparrow}$, $\mathsf{RhRouteHaltingBoundary}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{RhRouteClosureFixedStatementSeparation}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $R, F, U, B, T, C, H, Q, P, N$. It has no coordinate for a fragment-specific non-provability theorem, a proof or refutation of RH*, an identification of route closure with fixed-statement truth, or a total classifier for route-family closure.*

Theorem 8824.2 (RH route closure fixed statement separation NameCert obligations)**.** *For an accepted* $\mathsf{RhRouteClosureFixedStatementSeparation}^{\uparrow}$ *carrier $S = (R, F, U, B, T, C, H, Q, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{RhRouteClosureFixedStatementSeparation}^{\uparrow}}$ *surface consists exactly of route-layer admission, fixed-statement admission, family-level obstruction exposure, row-split boundary, route-to-fixed refusal, TasteGate-facing instance obligations, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and the local naming row. Every independence-facing consumer must read the row-split boundary B and refusal row T before treating route undecidability as evidence about the fixed* RH *statement.*

Proof. Carrier admission is projection from Definition 8824.1. The route-layer row R and obstruction row U are family-level data, while F is the single fixed proposition row.

The row-split boundary B is read before any independence-facing consumer receives the packet. If a consumer attempts to identify the route-family obstruction with fragment-specific independence for the fixed row, the failed row is stored in T rather than accepted as a NameCert obligation.

The remaining rows preserve the displayed separation. The TasteGate-facing row C names the later Nontrivial and FieldFaithful obligations for the same carrier fields, while H, Q, P, N transport, replay, source, and name only the split route-layer and statement-layer data. □

Falsifiable prediction: Any route-family classifier row reused as a fixed-RH independence witness fails the $\mathsf{RhRouteClosureFixedStatementSeparation}^{\uparrow}$ NameCert obligation surface unless it first displays the route-layer row, fixed-statement row, row-split boundary, refusal row, transport, replay, provenance, and local naming data.

Independence witness: `rh_free_zero_initiality`, `zeta_zero_type_factorization`, `finite_prime_window` `rh_route_halting_boundary`: $\mathsf{RhRouteClosureFixedStatementSeparation}^{\uparrow}$ is not bijective to any listed sibling because its route-family row and fixed-statement row are separated before the refusal surface is read; the siblings supply zero-generation, zero-type, finite-prime gluing, and route-halting data, not a classifier equating route undecidability with fixed-statement independence.

Closure status for $\mathsf{NameCert}_{\mathsf{RhRouteClosureFixedStatementSeparation}^{\uparrow}}$.

Constructive story: A $\mathsf{RhRouteClosureFixedStatementSeparation}^{\uparrow}$ packet is generated from a route-layer classifier request, a fixed RH statement row, a family-level route obstruction, a row-split boundary, a route-to-fixed refusal row, TasteGate-facing instance obligations, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{RhRouteClosureFixedStatementSeparation}^{\uparrow}}$, seed)

Scope closed: Definition 8824.1 and Definition 8824.2 seed the finite route-layer, statement-layer, refusal, transport, replay, provenance, and local naming surface for the RH separation boundary.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{RhRouteClosureFixedStatementSeparation}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close fragment-specific RH independence, a proof or refutation of RH, a total route-closure classifier, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked route-layer admission, fixed-statement admission, family-level obstruction exposure, row-split boundary, route-to-fixed refusal, TasteGate Nontrivial and FieldFaithful instances, transport, replay, provenance, and local naming for BEDC.Derived.RhRouteClosureFixedStatementSeparationUp.

Chapter 8825

A Concrete Naming Certificate for $\mathsf{TotalDerivative}^{\uparrow}$

Following the standard multivariable calculus tradition and its Fréchet-style presentation of linear approximation, the $\mathsf{TotalDerivative}^{\uparrow}$ packet joins the existing derivative fragments into one finite certificate surface. It reads the linear approximation branch through chapter 3634, the directional and one-parameter probes through chapter 6344 and chapter 7621, the linear operator row through chapter 48, the norm and error rows through chapter 89, and the terminal seal through chapter 38. The packet names a local total-linear-approximation route; it is not an inverse-function theorem, not an implicit-function theorem, not a smooth manifold atlas, not a selected ambient limit, and not a hidden completeness principle.

Definition 8825.1 (Total derivative carrier)**.** *A* $\mathsf{TotalDerivative}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$D = (X, Y, L, M, Q, R, E, H, C, P, N)$$

with the following displayed rows:

1. *X is the source chart row, recording the inspected point, local chart window, and admissible perturbation rows.*
2. *Y is the target normed row, recording the codomain chart, norm readback, and comparison window consumed by the approximation.*
3. *L is the* $\mathsf{LinMap}^{\uparrow}$ *row naming the candidate linear part.*
4. *M is the approximation-modulus row, recording the finite tolerance schedule for the remainder.*
5. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the quotient-style error checks used by the displayed approximation.*
6. *R is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row for the inspected error and norm comparisons.*
7. *E is the remainder ledger, stating that the residual after subtracting L is bounded by the displayed modulus at the requested windows.*
8. *H records componentwise* hsame *transport for source chart, target normed row, linear map, modulus, readback, Real seal, remainder ledger, replay, provenance, and local naming rows.*
9. *C records displayed* Cont *replay from chart exposure to linear-map readback, norm comparison, remainder-modulus inspection, regular rational readback, and Real seal delivery.*

10. *P is the* Pkg *provenance over* $\mathsf{TotalDerivative}^{\uparrow}$, $\mathsf{FrechetDerivative}^{\uparrow}$, $\mathsf{GateauxDerivative}^{\uparrow}$, $\mathsf{HadamardDirectionalDeriv}$ $\mathsf{LinMap}^{\uparrow}$, $\mathsf{Norm}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{TotalDerivative}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $X, Y, L, M, Q, R, E, H, C, P, N$. It has no coordinate for a global differentiability class, a selected host limit, an inverse map, an implicit solution branch, an ambient Banach-space theorem, or unrecorded directional probes.

Theorem 8825.2 (Total derivative NameCert obligations)**.** *For every accepted* $\mathsf{TotalDerivative}^{\uparrow}$ *carrier*

$$D = (X, Y, L, M, Q, R, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{TotalDerivative}^{\uparrow}}$ *surface consists exactly of source-chart exposure, target normed-row exposure, linear-map exposure, remainder-modulus exposure, regular rational readback, Real seal delivery, remainder-ledger exactness, componentwise transport, displayed replay, provenance, and local naming. A consumer may read the packet as a total derivative only after the rows for* $\mathsf{FrechetDerivative}^{\uparrow}$, $\mathsf{GateauxDerivative}^{\uparrow}$, $\mathsf{HadamardDirectionalDerivative}^{\uparrow}$, $\mathsf{LinMap}^{\uparrow}$, $\mathsf{Norm}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$ *have been consumed through the displayed route.*

Proof. Project the accepted carrier of Definition 8825.1. The source chart, target normed row, linear map, modulus, readback, seal, and remainder ledger are all explicit rows of one finite packet.

Read the derivative fragments in their dependency order. The Fréchet row supplies the total linear-approximation shape, while the Gateaux and directional rows record the probe-level faces that the total packet refuses to leave detached.

Read the analytic rows next. The linear-map row L is supplied through $\mathsf{LinMap}^{\uparrow}$, the norm comparisons through $\mathsf{Norm}^{\uparrow}$, the regular rational readback through Q, and the Real seal through R.

Finally H, C, P, N transport, replay, source, and name the same displayed packet. Because no row stores a global differentiability class, selected host limit, inverse map, implicit branch, ambient Banach theorem, or unrecorded probe, the local NameCert obligations stop at the finite total-linear-approximation route. □

Theorem 8825.3 (Total derivative linear approximation route)**.** *Every accepted* $\mathsf{TotalDerivative}^{\uparrow}$ *consumer that cites the total derivative must traverse the ordered route*

$$X, Y, L, M, Q, R, E, H, C, P, N.$$

The route first exposes the source chart and target normed row, then the linear approximation, then the remainder modulus, then the regular rational readback and Real seal, and only then the remainder ledger, transport, replay, provenance, and local naming rows.

Proof. Start with the carrier and NameCert obligations. They identify $X, Y, L, M, Q, R, E, H, C, P, N$ as the complete finite surface and place the linear approximation downstream of the source and target rows.

Use the sibling derivative surfaces to control the route. The Fréchet packet supplies the total-linear approximation shape, while the Gateaux and directional packets keep one-parameter and direction-specific probes visible as dependencies rather than as replacements for L.

Use the norm and readback rows to inspect the residual. The row M gives the displayed modulus, Q gives the $\mathsf{RegSeqRat}^{\uparrow}$ readback, R gives the $\mathsf{Real}^{\uparrow}$ seal, and E records the residual bound only after those rows have been exposed.

Thus a consumer cannot cite $\mathsf{TotalDerivative}^{\uparrow}$ as an unlogged differentiability assertion. The route is exactly $X, Y, L, M, Q, R, E, H, C, P, N$, with no selected host limit or hidden completeness row. □

Falsifiable prediction: Every accepted $\mathsf{TotalDerivative}^{\uparrow}$ read must expose source chart, target normed row, linear map, remainder modulus, RegSeqRat readback, Real seal, remainder ledger, componentwise hsame transport, Cont replay, Pkg provenance, and local NameCert data before a total-linear-approximation consumer is served.

Independence witness: frechet-derivative, gateaux-derivative, directional-derivative, linear-map, norm, real: $\mathsf{TotalDerivative}^{\uparrow}$ is not bijective to any listed sibling because it joins chart exposure, normed target data, linear approximation, remainder modulus, readback, seal, transport, replay, provenance, and local naming in one displayed packet.

Closure status for $\mathsf{NameCert}_{\mathsf{TotalDerivative}^{\uparrow}}$.

Constructive story: A $\mathsf{TotalDerivative}^{\uparrow}$ packet is generated from source chart rows, target normed rows, a LinearMap row, a remainder modulus, RegSeqRat readback, a Real seal, a residual ledger, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{TotalDerivative}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8825.1, Definition 8825.2, and Definition 8825.3 seed the finite total-linear-approximation packet over existing derivative, linear, norm, readback, and Real-seal rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{TotalDerivative}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close Lean verification, a standard bridge, inverse-function or implicit-function theorems, global differentiability classes, selected host limits, ambient completeness, or manifold-atlas compatibility.

Upgrade path: Obligation closure requires checked carrier admission, derivative-fragment dependency, LinearMap exposure, Norm modulus accounting, RegSeqRat readback, Real-seal routing, remainder-ledger exactness, transport, replay, provenance, and local naming for BEDC.Derived.TotalDerivativeUp.

Chapter 8826

A Concrete Naming Certificate for $\mathsf{LorentzBoostDiskTransport}^{\uparrow}$

The $\mathsf{LorentzBoostDiskTransport}^{\uparrow}$ packet realizes the reversible hyperbolic disk-transport branch of chapter 9463 as finite NameCert data. It sits beside the Poincare disk transport surfaces of chapter 3455, chapter 6776, chapter 6267, and the metric row of chapter 3474. The packet names disk coordinates, boost parameters, boundary rows, metric preservation, phase transport, provenance, and local naming; it does not assert physical spacetime, light-cone ontology, a completed Lorentz group, or an ambient smooth manifold.

Definition 8826.1 (Lorentz boost disk-transport carrier)**.** *A* $\mathsf{LorentzBoostDiskTransport}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (D, A, U, V, M, \Phi, O, H, C, P, N)$$

with the following displayed rows:

1. *D is the Poincare disk-coordinate row, recording the source and target disk windows.*
2. *A is the boost-parameter row, recording the finite rapidity or disk-automorphism parameter accepted by the local classifier.*
3. *U is the source boundary row and V is the transported boundary row.*
4. *M is the* $\mathsf{HyperbolicMetric}^{\uparrow}$ *comparison row used to read metric preservation along the displayed disk transport.*
5. *Φ is the phase-transport row, recording the reversible observer-phase readback along the boost route.*
6. *O is the refusal row, recording the absence of physical spacetime claims, light-cone ontology, completed Lorentz group structure, and hidden smooth-manifold data.*
7. *H records componentwise* hsame *transport for disk, boost, boundary, metric, phase, refusal, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from disk-coordinate exposure to boost-parameter admission, boundary transport, metric comparison, phase transport, and refusal checks.*
9. *P is the* Pkg *provenance over* $\mathsf{LorentzBoostDiskTransport}^{\uparrow}$, $\mathsf{UnitDisk}^{\uparrow}$, $\mathsf{PoincareDiskMetric}^{\uparrow}$, $\mathsf{HyperbolicMetric}^{\uparrow}$, *disk automorphism packets, phase-transport packets,* BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{LorentzBoostDiskTransport}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $D, A, U, V, M, \Phi, O, H, C, P, N$. It has no coordinate for a physical observer, completed spacetime, external Lorentz group, host differentiability theorem, or unlogged boundary ideal point.

Theorem 8826.2 (Lorentz boost disk-transport NameCert obligations)**.** *For every accepted* $\mathsf{LorentzBoostDiskTrans}$ *carrier*

$$B = (D, A, U, V, M, \Phi, O, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{LorentzBoostDiskTransport}^{\uparrow}}$ *surface consists exactly of disk-coordinate exposure, boost-parameter exposure, source and target boundary rows, hyperbolic metric comparison, reversible phase transport, refusal of host spacetime claims, componentwise transport, displayed replay, provenance, and local naming.*

Proof. Project the accepted carrier of Definition 8826.1. The disk, boost, boundary, metric, phase, refusal, and structural rows are all explicit coordinates of one finite packet.

Read the hyperbolic dependencies. The disk-coordinate row is supplied through the existing Poincare disk surfaces, and the metric comparison row is read through $\mathsf{HyperbolicMetric}^{\uparrow}$ rather than through a host smooth model.

Read the reversible-transport branch next. The boost parameter A controls the displayed disk transport from U to V, while Φ records the observer-phase readback along that same finite route.

Finally O, H, C, P, N close the boundary. The refusal row blocks physical spacetime and completed-group readings, and the structural rows transport, replay, source, and name only the displayed disk-transport data. □

Theorem 8826.3 (Lorentz boost disk-transport reversible route)**.** *Every accepted* $\mathsf{LorentzBoostDiskTransport}^{\uparrow}$ *consumer that reads a boost-style disk transport must traverse the finite route*

$$D, A, U, V, M, \Phi, O, H, C, P, N.$$

Thus the consumer receives displayed disk coordinates, boost parameter, source and transported boundary rows, hyperbolic metric comparison, phase transport, refusal, componentwise transport, replay, provenance, and local naming before any transport claim is served.

Proof. Start with the carrier and NameCert obligations. They expose the exact rows $D, A, U, V, M, \Phi, O, H, C, P, N$ and exclude any ambient spacetime or completed Lorentz-group coordinate.

Use the disk and metric siblings to read the geometric surface. The Poincare disk rows expose D, U, V, while $\mathsf{HyperbolicMetric}^{\uparrow}$ supplies the displayed metric comparison M for the same transport route.

Use the boost and phase rows for reversibility. The boost parameter A names the finite transport instruction, and the phase row Φ records the reversible observer-phase readback without erasing the boundary rows.

The refusal and structural rows then preserve the boundary of the packet. Therefore every consumer-facing transport read remains inside $D, A, U, V, M, \Phi, O, H, C, P, N$ and cannot be repacked as host spacetime, an external Lorentz group, or a hidden smooth-manifold claim. □

Falsifiable prediction: Every accepted $\mathsf{LorentzBoostDiskTransport}^{\uparrow}$ read that serves a reversible disk-transport consumer must expose disk coordinates, boost parameter, boundary rows, HyperbolicMetric comparison, phase transport, refusal, componentwise hsame transport, Cont replay, Pkg provenance, and local NameCert rows before the consumer is served.

Independence witness: poincare-disk-phase-transport, poincare-disk-automorphism, poincare-disk-boundary-transport, hyperbolic-metric: $\mathsf{LorentzBoostDiskTransport}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries boost-parameter admission, boundary transport, metric comparison, phase transport, refusal, transport, replay, provenance, and local naming in one displayed packet.

The Lean TasteGate route for `BEDC.Derived.LorentzBoostDiskTransportUp` must eventually provide explicit $\mathsf{Nontrivial\ LorentzBoostDiskTransport}^{\uparrow}$ and $\mathsf{FieldFaithful\ LorentzBoostDiskTransport}^{\uparrow}$ instances preserving $D, A, U, V, M, \Phi, O, H, C, P, N$ as separate displayed fields before stronger closure is claimed.

Closure status for $\mathsf{NameCert}_{\mathsf{LorentzBoostDiskTransport}^{\uparrow}}$.

Constructive story: A $\mathsf{LorentzBoostDiskTransport}^{\uparrow}$ packet is generated from disk-coordinate rows, boost-parameter rows, boundary rows, HyperbolicMetric comparison rows, phase-transport rows, refusal rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{LorentzBoostDiskTransport}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8826.1, Definition 8826.2, and Definition 8826.3 seed the reversible hyperbolic disk-transport packet over disk, boost, boundary, metric, phase, refusal, transport, replay, provenance, and local naming rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{LorentzBoostDiskTransport}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close Lean verification, a standard bridge, physical spacetime, light-cone ontology, a completed Lorentz group, host differentiability, or ambient smooth-manifold structure.

Upgrade path: Obligation closure requires checked carrier admission, disk-coordinate exposure, boost-parameter exactness, boundary transport, HyperbolicMetric comparison, phase-transport reversibility, TasteGate nontriviality, field faithfulness, refusal, transport, replay, provenance, and local naming for BEDC.Derived.LorentzBoostDiskTransportUp.

Chapter 8827

A Concrete Naming Certificate for $\mathsf{BolzanoWeierstrassRate}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{BolzanoWeierstrassRate}^{\uparrow}$ packet records the finite-window rate boundary by which bounded real sequence data may be read by Bolzano–Weierstrass-style compactness consumers. It sits after the bounded real sequence carrier of chapter 1415, the finite-subsequence packet of chapter 8797, the dyadic tolerance core of chapter 291, the finite stream-name route of chapter 126, the regular rational readback of chapter 301, and the terminal real-name seal of chapter 38. The packet names the finite read budget available to a compactness-facing route; it does not select a subsequence, invoke countable choice, decide real trichotomy, identify quotient streams, or assert ambient completeness for $\mathsf{Real}^{\uparrow}$.

Definition 8827.1 (Bolzano–Weierstrass rate carrier)**.** *A* $\mathsf{BolzanoWeierstrassRate}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$R = (B, F, D, W, Q, E, H, C, P, N)$$

with the following displayed rows:

1. *B is the bounded* $\mathsf{Real}^{\uparrow}$ *sequence source row, read through* $\mathsf{BoundedRealSequence}^{\uparrow}$ *before any rate request is accepted.*
2. *F is the finite-subsequence window row, read through* $\mathsf{BolzanoWeierstrassFiniteSubsequence}^{\uparrow}$ *as a finite compactness-facing consumer rather than as an infinite selected subsequence.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger assigning each inspected window a displayed dyadic comparison budget.*
4. *W is the* $\mathsf{StreamName}^{\uparrow}$ *window row listing the finite source positions and observations that the rate certificate may inspect.*
5. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row obtained from the displayed windows and dyadic tolerances.*
6. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row available only after B, F, D, W, Q have been exposed.*
7. *H records componentwise* hsame *transport for the source, finite-subsequence window, tolerance ledger, stream windows, readback, seal, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay through $B, F, D, W, Q, E, H, P, N$.*
9. *P is the* Pkg *provenance over* $\mathsf{BolzanoWeierstrassRate}^{\uparrow}$*,* $\mathsf{BoundedRealSequence}^{\uparrow}$*,* $\mathsf{BolzanoWeierstrassFiniteSubseque}$ $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*,* BHist*,* hsame*,* Cont*, and* $\mathsf{NameCert}$ *rows.*

10. N is the local $\mathsf{NameCert}_{\mathsf{BolzanoWeierstrassRate}^{\uparrow}}$ *row.*
The carrier compares accepted packets only through $B, F, D, W, Q, E, H, C, P, N$. It has no coordinate for a selected infinite subsequence, countable-choice schedule, trichotomy decision, quotient stream representative, or completeness proof for $\mathsf{Real}^{\uparrow}$.

Theorem 8827.2 (Bolzano–Weierstrass rate NameCert obligations)**.** *For every accepted* $\mathsf{BolzanoWeierstrassRate}^{\uparrow}$ *carrier*

$$R = (B, F, D, W, Q, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{BolzanoWeierstrassRate}^{\uparrow}}$ *surface consists exactly of carrier admission for the bounded source B, finite-subsequence window F, dyadic tolerance ledger D, stream windows W, regular rational readback Q, terminal real seal E, componentwise* hsame *transport H, displayed* Cont *replay C,* Pkg *provenance P, and local naming row N. No NameCert obligation is stored outside those finite rows.*

Proof. Project the carrier of Definition 8827.1. The bounded source row B is visible only as the $\mathsf{BoundedRealSequence}^{\uparrow}$ surface, while F is visible only as the finite-window face of $\mathsf{BolzanoWeierstrassFiniteSubsequer}$

Read the rate rows next. The dyadic ledger D assigns the tolerance budget for the inspected window, the stream row W lists the finite observations, and the regular readback row Q consumes exactly those observations.

Finally inspect E, H, C, P, N. The real seal, transport, replay, provenance, and local naming rows preserve the same finite route. Since the carrier has no coordinate for countable choice, real trichotomy, quotient stream equality, selected infinite subsequences, or ambient $\mathsf{Real}^{\uparrow}$ completeness, those principles cannot become local NameCert obligations. □

Theorem 8827.3 (Bolzano–Weierstrass rate window handoff)**.** *Every Real or Completion consumer of an accepted* $\mathsf{BolzanoWeierstrassRate}^{\uparrow}$ *packet must read the route*

$$\mathsf{BoundedRealSequence}^{\uparrow} \longmapsto \mathsf{BolzanoWeierstrassFiniteSubsequence}^{\uparrow} \longmapsto \mathsf{DyadicRatCore}^{\uparrow},\ \mathsf{StreamName}^{\uparrow},\ \mathsf{RegSeqRat}^{\uparrow}$$

through $B, F, D, W, Q, E, H, C, P, N$ before treating the packet as Bolzano–Weierstrass-style rate data. The handoff exposes a bounded real sequence source, a finite subsequence-window consumer, dyadic tolerance comparisons, finite stream windows, regular rational readback, and a terminal real seal. It exports no selected subsequence, no countable choice, no trichotomy, no quotient stream equality, and no ambient completeness principle for $\mathsf{Real}^{\uparrow}$.

Proof. Start with the bounded source. The row B is admitted only through the $\mathsf{BoundedRealSequence}^{\uparrow}$ carrier, so a consumer first receives finite stream windows, regular readback, the closed-bounded interval-net bound row, and the real-name seal already exposed by that source packet.

Next read the finite-subsequence window. The row F is downstream of $\mathsf{BolzanoWeierstrassFiniteSubsequence}^{\uparrow}$, so it presents a finite compactness-facing window rather than a selected infinite subsequence.

The dyadic, stream, and regular readback rows D, W, Q then form the rate budget inspected by the consumer. The terminal row E seals only that displayed readback as $\mathsf{Real}^{\uparrow}$ data.

Transport, replay, provenance, and local naming preserve the same finite-window route. Because no additional row carries choice, trichotomy, quotient equality, or completeness, the public handoff is exactly the rate boundary displayed in the theorem. □

Closure status for $\mathsf{NameCert}_{\mathsf{BolzanoWeierstrassRate}^{\uparrow}}$.
Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BolzanoWeierstrassRate}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8827.1, Definition 8827.2, and Definition 8827.3 seed the finite-window rate boundary over bounded Real sequence, finite Bolzano–Weierstrass subsequence-window, DyadicRatCore, StreamName, RegSeqRat, Real, transport, replay, provenance, and local naming rows.

Formal verification: FormalStatus(NameCert$_{\text{BolzanoWeierstrassRate}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close selected subsequences, countable choice, real trichotomy, quotient stream equality, ambient Real$^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, finite-window rate exactness, source-row stability, dyadic tolerance readback, terminal Real seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.BolzanoWeierstrassRateUp.

Constructive story: A BolzanoWeierstrassRate$^{\uparrow}$ packet is generated from a bounded Real sequence source, a finite Bolzano–Weierstrass subsequence-window row, a DyadicRatCore tolerance ledger, StreamName windows, RegSeqRat readback, a Real seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 8828

A Concrete Naming Certificate for $\mathsf{CartanHadamard}^{\uparrow}$

Following Cartan and Hadamard, the $\mathsf{CartanHadamard}^{\uparrow}$ packet records the finite nonpositive-curvature and geodesic-handoff surface by which a simply connected Riemannian presentation is read inside BEDC. It sits after the manifold carrier of chapter 96, the Riemannian metric row of chapter 133, the curvature row of chapter 135, the finite geodesic handoff of chapter 5929, and the terminal real-name seal of chapter 38. The packet names a displayed curvature-controlled geodesic route; it does not assert a host universal cover, global exponential diffeomorphism, selected minimizing geodesics, quotient equality of paths, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 8828.1 (Cartan-Hadamard carrier)**.** *A* $\mathsf{CartanHadamard}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$C = (M, G, K, S, E, R, W, H, T, P, N)$$

with the following displayed rows:

1. *M is the* $\mathsf{Manifold}^{\uparrow}$ *source row, exposing the local chart and overlap data used by the packet.*
2. *G is the* $\mathsf{RiemannianMetric}^{\uparrow}$ *metric row, read only through the displayed metric and length coordinates.*
3. *K is the* $\mathsf{Curvature}^{\uparrow}$ *comparison row, recording the nonpositive-curvature ledger visible to the local classifier.*
4. *S is the simply connected presentation row, recorded as a finite NameCert datum rather than as an ambient host theorem.*
5. *E is the geodesic extension row, consumed through the finite-geodesic Hopf–Rinow sibling before a geodesic read is public.*
6. *R is the* $\mathsf{Real}^{\uparrow}$ *readback row for displayed lengths, distances, and curvature bounds.*
7. *W is the obstruction-refusal row, recording the absence of a host universal-cover object, selected global exponential inverse, quotient path equality, or choice schedule.*
8. *H records componentwise* hsame *transport for manifold, metric, curvature, simply connected, geodesic, Real, refusal, replay, provenance, and local naming rows.*
9. *T records displayed* Cont *replay from a Cartan–Hadamard request through $M, G, K, S, E, R, W, H, P, N$.*

10. *P is the* Pkg *provenance over* $\mathsf{CartanHadamard}^{\uparrow}$, $\mathsf{Manifold}^{\uparrow}$, $\mathsf{RiemannianMetric}^{\uparrow}$, $\mathsf{Curvature}^{\uparrow}$, $\mathsf{HopfRinowFiniteGeodesic}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

11. *N is the local* $\mathsf{NameCert}_{\mathsf{CartanHadamard}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $M, G, K, S, E, R, W, H, T, P, N$. It has no coordinate for a host universal cover, global exponential diffeomorphism, selected minimizing geodesics, quotient equality of paths, real trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 8828.2 (Cartan-Hadamard NameCert obligations)**.** *For every accepted* $\mathsf{CartanHadamard}^{\uparrow}$ *carrier $C = (M, G, K, S, E, R, W, H, T, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{CartanHadamard}^{\uparrow}}$ *surface consists exactly of manifold-source admission, Riemannian metric exposure, nonpositive-curvature ledger exposure, simply connected presentation, finite geodesic handoff, Real readback, obstruction refusal, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. Every geometry-facing consumer must read*

$$M, G, K, S, E, R, W, H, T, P, N$$

before the Cartan–Hadamard packet is consumed.

Proof. Project the carrier of Definition 8828.1. The manifold and metric data occur only as the rows M and G, so a consumer cannot replace them by an ambient smooth manifold or a hidden metric tensor.

Read the geometric rows next. The curvature row K records the nonpositive-curvature comparison ledger, the row S records the simply connected presentation, and the row E routes geodesic reads through the finite Hopf–Rinow sibling.

Finally use R, W, H, T, P, N. The Real row exposes only displayed length, distance, and curvature-bound readbacks, while the refusal and structural rows preserve the same finite route. Since no carrier coordinate stores a host universal cover, global exponential diffeomorphism, selected minimizing geodesic, quotient path equality, trichotomy, or ambient completeness, the listed rows exhaust the local NameCert surface. □

Theorem 8828.3 (Cartan-Hadamard geodesic boundary)**.** *Every accepted* $\mathsf{CartanHadamard}^{\uparrow}$ *geodesic or curvature consumer factors through the visible route*

$$\mathsf{Manifold}^{\uparrow},\ \mathsf{RiemannianMetric}^{\uparrow},\ \mathsf{Curvature}^{\uparrow} \longmapsto \mathsf{HopfRinowFiniteGeodesic}^{\uparrow},\ \mathsf{Real}^{\uparrow} \longmapsto \mathsf{CartanHadamard}^{\uparrow}.$$

The handoff supplies a finite curvature-controlled geodesic packet, not a host universal-cover theorem, global exponential diffeomorphism, selected minimizing-geodesic principle, quotient path equality, or ambient completeness principle for $\mathsf{Real}^{\uparrow}$.

Proof. Start with the source rows. The manifold row fixes the displayed chart data, and the Riemannian metric row supplies only visible length and distance coordinates.

Use the curvature and connectivity rows. The nonpositive-curvature ledger K and simply connected presentation row S are read before the finite geodesic handoff E is available.

Route the handoff through R, W, H, T, P, N. The Real readback seals the displayed numerical data, the refusal row blocks host universal-cover and global exponential readings, and the structural rows transport, replay, source, and name the same finite packet. Hence every public geodesic or curvature read remains inside the displayed route. □

Falsifiable prediction: Every accepted $\mathsf{CartanHadamard}^{\uparrow}$ read that serves a geodesic or curvature consumer must expose ManifoldUp, RiemannianMetricUp, CurvatureUp, HopfRinowFiniteGeodesicUp, RealUp, obstruction-refusal, hsame transport, Cont replay, Pkg provenance, and local NameCert rows before the consumer is served.

Independence witness: manifold, riemannianmetric, curvature, hopf-rinow-finite-geodesic, real: $\mathsf{CartanHadamard}^{\uparrow}$ is not bijective to any listed sibling because this packet jointly carries simply connected presentation, nonpositive-curvature ledger, finite geodesic handoff, Real readback, obstruction refusal, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{CartanHadamard}^{\uparrow}}$**.**

Constructive story: A $\mathsf{CartanHadamard}^{\uparrow}$ packet is generated from ManifoldUp source rows, RiemannianMetricUp metric rows, CurvatureUp nonpositive-curvature ledgers, simply connected presentation rows, HopfRinowFiniteGeodesicUp handoffs, RealUp readbacks, obstruction-refusal rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CartanHadamard}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8828.1, Definition 8828.2, and Definition 8828.3 seed the finite Cartan–Hadamard route over manifold, metric, curvature, geodesic, Real, refusal, transport, replay, provenance, and local naming rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CartanHadamard}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close a host universal-cover theorem, global exponential diffeomorphism, selected minimizing geodesics, quotient path equality, real trichotomy, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, manifold-source exposure, Riemannian metric exposure, curvature-ledger exactness, simply connected presentation, finite-geodesic handoff, Real readback, obstruction refusal, transport, replay, provenance, and local naming for BEDC.Derived.CartanHadamardUp.

Chapter 8829

A Concrete Naming Certificate for $\mathsf{OmegaRigidityLedger}^{\uparrow}$

The $\mathsf{OmegaRigidityLedger}^{\uparrow}$ packet realizes the mature bridge and Ω-rigidity spine of chapter 9362 as finite NameCert data. It sits after the licensed generation body of chapter 8756 and the no-host-leak audit surface of chapter 1217. The packet records bridge reports, standard readouts, lower-layer NameCert dependencies, compatibility checks, audit rows, and no-replacement rows for an Ω-tower rigidity claim; it does not import an external standard model as a BEDC proof term, close RH, select a zero witness, or replace any lower-layer certificate.

Definition 8829.1 (Omega rigidity ledger carrier)**.** *An* $\mathsf{OmegaRigidityLedger}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (O, B, S, N, K, A, R, H, C, P, Q)$$

with the following displayed rows:

1. *O is the* $\mathsf{OmegaGenerationBody}^{\uparrow}$ *row, exposing the compatible tower body and its readback arrows.*
2. *B is the bridge-report row, listing the mature bridge packets read only after internal tower rows are present.*
3. *S is the standard-readout row, recording external interpretations as readouts rather than as BEDC constructors.*
4. *N is the lower-layer* $\mathsf{NameCert}$ *dependency row, naming the internal certificates that must already be present before the ledger is consumed.*
5. *K is the compatibility row, recording agreement between tower projections, bridge reports, standard readouts, and lower-layer NameCert rows.*
6. *A is the audit row, tracking unsupported fields, host leakage checks, axiom-use checks, and marker resolution for the finite ledger.*
7. *R is the no-replacement row, recording that no bridge report or standard readout substitutes for a missing internal carrier, classifier, stability, ledger, or naming obligation.*
8. *H records componentwise* hsame *transport for tower body, bridge report, standard readout, lower-layer NameCert, compatibility, audit, no-replacement, replay, provenance, and local naming rows.*
9. *C records displayed* Cont *replay from an Ω-rigidity ledger request through $O, B, S, N, K, A, R, H, P, Q$.*

10. *P is the* Pkg *provenance over* $\mathsf{OmegaRigidityLedger}^{\uparrow}$, $\mathsf{OmegaGenerationBody}^{\uparrow}$, $\mathsf{StandardBridgeAuditPacket}^{\uparrow}$, *the mature bridge spine of chapter 9362,* BHist, hsame, Cont, *and* NameCert.
11. *Q is the local* $\mathsf{NameCert}_{\mathsf{OmegaRigidityLedger}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $O, B, S, N, K, A, R, H, C, P, Q$. It has no coordinate for an external model as proof term, a host RH theorem, a selected zero witness, a hidden bridge replacement, or a detached standard readout.

Theorem 8829.2 (Omega rigidity ledger NameCert obligations)**.** *For every accepted* $\mathsf{OmegaRigidityLedger}^{\uparrow}$ *carrier $L = (O, B, S, N, K, A, R, H, C, P, Q)$, the local* $\mathsf{NameCert}_{\mathsf{OmegaRigidityLedger}^{\uparrow}}$ *surface consists exactly of tower-body exposure, bridge-report exposure, standard-readout exposure, lower-layer NameCert dependency exposure, compatibility checking, audit checking, no-replacement checking, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. Every rigidity-ledger consumer must read*

$$O, B, S, N, K, A, R, H, C, P, Q$$

before it can consume the Ω-rigidity ledger.

Proof. Project the carrier of Definition 8829.1. The tower body is visible only as O, and the bridge and standard rows are visible only as B and S.

Read the dependency and compatibility rows next. The row N lists the lower-layer NameCert packets already required by the ledger, while K checks that bridge reports and standard readouts agree with those internal rows.

Finally use A, R, H, C, P, Q. The audit row records leakage and axiom-use checks, the no-replacement row blocks external substitution for internal obligations, and the structural rows transport, replay, source, and name the same finite ledger. Since no carrier coordinate stores an external model as proof term, host RH theorem, selected zero witness, hidden bridge replacement, or detached standard readout, the listed rows exhaust the local NameCert surface. □

Theorem 8829.3 (Omega rigidity ledger no-replacement boundary)**.** *Every accepted* $\mathsf{OmegaRigidityLedger}^{\uparrow}$ *consumer that reads a bridge report or standard readout must also read the lower-layer NameCert row N, compatibility row K, audit row A, and no-replacement row R. Thus the bridge side can interpret the already displayed tower body, but it cannot generate a missing internal carrier, classifier, stability field, ledger row, naming row, RH proof, or selected zero witness.*

Proof. Start from the bridge-facing rows B and S. By carrier projection, they occur in the same packet as the lower-layer dependency row N and cannot be consumed as detached bridge data.

Use the compatibility row K. It compares bridge reports and standard readouts against the internal tower body O and the already named lower-layer certificates.

Apply the audit and no-replacement rows. The row A records host-leakage and axiom-use checks, while R states that bridge and standard rows do not replace internal obligations. Transport, replay, provenance, and local naming then preserve the same finite ledger, so no external readout becomes a BEDC proof term. □

Falsifiable prediction: Every accepted $\mathsf{OmegaRigidityLedger}^{\uparrow}$ read that exports a bridge report or standard readout without exposing OmegaGenerationBodyUp, lower-layer NameCert rows, compatibility checks, audit checks, no-replacement rows, hsame transport, Cont replay, Pkg provenance, and local NameCert rows is outside the carrier surface.

Independence witness: omega-generation-body, standardbridgeauditpacket, mature-bridge-omega-rigidity-spine: $\mathsf{OmegaRigidityLedger}^{\uparrow}$ is not bijective to any listed sibling because this packet jointly carries tower body, bridge report, standard readout, lower-layer NameCert dependency, compatibility, audit, no-replacement, transport, replay, provenance, and local naming rows.

Closure status for $\mathsf{NameCert}_{\mathsf{OmegaRigidityLedger}^{\uparrow}}$.

Constructive story: An $\mathsf{OmegaRigidityLedger}^{\uparrow}$ packet is generated from an OmegaGenerationBodyUp tower-body row, bridge-report rows, standard-readout rows, lower-layer NameCert dependency rows, compatibility rows, audit rows, no-replacement rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{OmegaRigidityLedger}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8829.1, Definition 8829.2, and Definition 8829.3 seed the finite Omega-rigidity ledger over tower body, bridge report, standard readout, lower-layer NameCert, compatibility, audit, no-replacement, transport, replay, provenance, and local naming rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{OmegaRigidityLedger}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close RH, zero rigidity, external standard-model soundness as an internal proof term, selected zero witnesses, missing lower-layer NameCert obligations, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, tower-body exposure, bridge-report exposure, standard-readout exposure, lower-layer NameCert dependency exposure, compatibility exactness, audit exactness, no-replacement checking, transport, replay, provenance, and local naming for BEDC.Derived.OmegaRigidityLedgerUp.

Chapter 8830

A Concrete Naming Certificate for $\mathsf{FiniteEndpointSeparationBudget}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{FiniteEndpointSeparationBudget}^{\uparrow}$ packet records the finite endpoint-separation budget read before an L10 Real observation route may treat two displayed endpoint rows as separated. It sits after the real-name seal of chapter 38, the dyadic tolerance ledger of chapter 291, the finite observation windows of chapter 126, the regular rational readback route of chapter 301, and the guarded sign-apartness surface of chapter 8304. The packet names only the inspected separation rows; it is not trichotomy, quotient real equality, selected endpoint representatives, open-cover compactness, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 8830.1 (Finite endpoint-separation budget carrier)**.** *A* $\mathsf{FiniteEndpointSeparationBudget}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (L, U, D, W, Q, S, H, C, P, N)$$

with the following displayed rows:

1. *L is the lower endpoint* $\mathsf{Real}^{\uparrow}$ *row, already sealed through the displayed real-name route.*
2. *U is the upper endpoint* $\mathsf{Real}^{\uparrow}$ *row, sealed through the same route.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger storing the finite positive radius, outward slack, and comparison precision used to separate the endpoints.*
4. *W is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row from which endpoint observations are inspected at the requested tolerance.*
5. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for those endpoint windows.*
6. *S is the* $\mathsf{LocatedSignApartness}^{\uparrow}$ *sign-apartness row certifying that the inspected endpoint difference is separated at the displayed budget.*
7. *H records componentwise* hsame *transport for endpoint, tolerance, window, readback, sign-apartness, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from an endpoint-separation request through $L, U, D, W, Q, S, H, P, N$.*
9. *P is the* Pkg *provenance over* $\mathsf{FiniteEndpointSeparationBudget}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{LocatedSignApartness}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$ *rows.*
10. *N is the local* $\mathsf{NameCert}_{\mathsf{FiniteEndpointSeparationBudget}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $L, U, D, W, Q, S, H, C, P, N$. It has no coordinate for total real order, quotient representatives, selected endpoints, countable choice, compactness, or ambient completeness.

Theorem 8830.2 (Finite endpoint-separation budget NameCert obligations)**.** *For every accepted* $\mathsf{FiniteEndpointSeparationBudget}^{\uparrow}$ *carrier* $B = (L, U, D, W, Q, S, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{FiniteEndpointSeparationB}}$ *surface consists exactly of endpoint admission for* L, U*, dyadic budget exposure through* D*, finite-window exposure through* W*, regular rational readback through* Q*, located sign-apartness exposure through* S*, componentwise transport through* H*, displayed replay through* C*, package provenance through* P*, and local naming through* N*.*

Proof. Project the accepted carrier of Definition 8830.1. The endpoint rows, tolerance row, finite windows, readback, sign-apartness row, and structural rows are all explicit coordinates of one finite packet.

The analytic route is ordered. Endpoint reads first expose L, U, then the dyadic budget D, then the finite windows W, and only then the regular rational readback Q used by the sign-apartness row S.

Transport, replay, provenance, and local naming are componentwise. Since the tuple contains no total order decision, quotient representative, selected endpoint, countable-choice schedule, compactness theorem, or ambient completeness object, the listed rows exhaust the local NameCert surface. □

Theorem 8830.3 (Finite endpoint-separation budget Real route)**.** *Every L10 Real endpoint-separation consumer of an accepted* $\mathsf{FiniteEndpointSeparationBudget}^{\uparrow}$ *carrier factors through the displayed route*

$$L, U \longmapsto D, W, Q \longmapsto S, H, C, P, N.$$

Thus downstream interval, enclosure, and approximation chapters may cite one finite budget object instead of repeating endpoint-budget rows locally, while receiving no trichotomy, quotient real equality, selected endpoints, open-cover compactness, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start with the endpoint rows L, U. They are already sealed $\mathsf{Real}^{\uparrow}$ rows, so a consumer reads endpoint data only through the real-name route rather than through host representatives.

Next apply the dyadic-window-readback handoff. The dyadic budget D determines the inspected tolerance, the window row W exposes finite endpoint observations, and the readback row Q presents those observations as regular rational data.

Finally read the located sign-apartness row S and replay the structural rows H, C, P, N. The consumer receives a finite endpoint-separation budget for the displayed endpoints, and no coordinate remains from which the excluded global principles could be recovered. □

Falsifiable prediction: Every accepted $\mathsf{FiniteEndpointSeparationBudget}^{\uparrow}$ read that serves an L10 Real endpoint-separation consumer must expose endpoint rows, a DyadicRatCore budget, StreamName windows, RegSeqRat readback, LocatedSignApartness evidence, componentwise hsame transport, Cont replay, Pkg provenance, and local NameCert rows before the consumer is served.

Independence witness: real, dyadicratcore, streamname, regseqrat, located-sign-apartness: none is bijective to $\mathsf{FiniteEndpointSeparationBudget}^{\uparrow}$ because only this packet binds two sealed endpoints, one finite dyadic separation budget, finite observation windows, regular readback, guarded sign-apartness evidence, transport, replay, provenance, and local naming into one endpoint-budget carrier.

Closure status for $\mathsf{NameCert}_{\mathsf{FiniteEndpointSeparationBudget}^{\uparrow}}$.

Constructive story: A $\mathsf{FiniteEndpointSeparationBudget}^{\uparrow}$ packet is generated from lower and upper RealUp endpoint rows, a DyadicRatCore tolerance budget, StreamName finite windows, RegSeqRat readback, LocatedSignApartness evidence, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{FiniteEndpointSeparationBudget}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8830.1, Definition 8830.2, and Definition 8830.3 seed the finite endpoint-separation budget route for L10 Real observation consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{FiniteEndpointSeparationBudget}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close total real order, quotient real equality, selected endpoint representatives, open-cover compactness, ambient RealUp completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked endpoint admission, dyadic budget exposure, finite-window readback, located sign-apartness evidence, transport, replay, provenance, and local naming for BEDC.Derived.FiniteEndpointSeparationBudgetUp.

Chapter 8831

A Concrete Naming Certificate for $\mathsf{BingNagataSmirnovMetrization}^{\uparrow}$

Following Bing, Nagata, Smirnov, and Engelking on metrization criteria, the $\mathsf{BingNagataSmirnovMetrization}^{\uparrow}$ packet records the finite BEDC route by which a regular topological source exposes both a Bing-style development route and a Nagata–Smirnov locally finite cover route before a metric-space consumer reads the handoff. It sits over the topology carrier of chapter 88, beside the Bing packet of chapter 6479, beside the Nagata–Smirnov packet of chapter 6348, and downstream of the paracompactness surface of chapter 1963 when displayed local finiteness is supplied. The packet names only the combined finite criterion route through $\mathsf{BingMetrization}^{\uparrow}$, $\mathsf{NagataSmirnovMetrization}^{\uparrow}$, $\mathsf{Topology}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, and $\mathsf{Paracompact}^{\uparrow}$ anchors; it does not assert host open-cover compactness, selected covers, quotient topology equality, countable choice, or an ambient point-set metrization oracle.

Definition 8831.1 (Bing–Nagata–Smirnov metrization carrier)**.** *A* $\mathsf{BingNagataSmirnovMetrization}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (T, B, N, P, L, S, R, E, Q, M, F, H, C, G, A)$$

with the following displayed rows:

1. *T is the* $\mathsf{Topology}^{\uparrow}$ *source row, carrying the open-row classifier, point-neighbourhood requests, and regular separation reads.*
2. *B is the* $\mathsf{BingMetrization}^{\uparrow}$ *development route row, exposing the displayed star-refinement and development-level checks read from the source topology.*
3. *N is the* $\mathsf{NagataSmirnovMetrization}^{\uparrow}$ *cover-family route row, exposing the displayed locally finite layer schedule and base-refinement checks.*
4. *P is the* $\mathsf{Paracompact}^{\uparrow}$ *dependency row, used only when the packet has an explicitly displayed local-finiteness supply.*
5. *L is the common locally finite ledger through which the Bing and Nagata–Smirnov routes are compared.*
6. *S is the combined schedule row, recording the finite development levels and cover layers inspected by the packet.*
7. *R is the regularity and refinement row, binding closed-neighbourhood separation to the displayed cover refinements.*

8. *E is the exactness row asserting that every accepted criterion request is read through both B and N before any metric handoff is consumed.*
9. *Q is the dyadic radius schedule shared by the combined criterion route.*
10. *M is the $\mathsf{Met}^{\uparrow}$ handoff row, available only after $T, B, N, P, L, S, R, E, Q$ have been exposed.*
11. *F records finite compatibility between metric balls from M and topology windows from T along the two sibling metrization routes.*
12. *H records componentwise* hsame *transport for all displayed rows.*
13. *C records displayed* Cont *replay from a topology request through Bing development data, Nagata–Smirnov cover data, paracompact local-finiteness data, regularity, exactness, dyadic radii, metric handoff, compatibility, provenance, and local naming.*
14. *G is the* Pkg *provenance over* $\mathsf{BingNagataSmirnovMetrization}^{\uparrow}$, $\mathsf{BingMetrization}^{\uparrow}$, $\mathsf{NagataSmirnovMetrization}^{\uparrow}$, $\mathsf{Topology}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{Paracompact}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*
15. *A is the local* $\mathsf{NameCert}_{\mathsf{BingNagataSmirnovMetrization}^{\uparrow}}$ *row.*

The carrier has no coordinate for host open-cover compactness, selected covers, quotient topology equality, arbitrary refinements, countable choice, or an ambient metric oracle.

Theorem 8831.2 (Bing–Nagata–Smirnov metrization NameCert obligations)**.** *For every accepted* $\mathsf{BingNagataSmirnovMetrization}^{\uparrow}$ *carrier $K = (T, B, N, P, L, S, R, E, Q, M, F, H, C, G, A)$, the local* $\mathsf{NameCert}_{\mathsf{BingNagataSmirnovMetrization}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the topology source, Bing development route, Nagata–Smirnov cover route, paracompact local-finiteness dependency, common locally finite ledger, combined schedule, regularity-refinement row, exactness row, dyadic radius schedule, metric-space handoff, compatibility, transport, replay, provenance, and local naming row;*
2. *sibling route readability, requiring every accepted criterion request to start at T and pass through the displayed* $\mathsf{BingMetrization}^{\uparrow}$ *and* $\mathsf{NagataSmirnovMetrization}^{\uparrow}$ *rows before M is inspected;*
3. *local-finiteness compatibility, requiring P, L, S, R to expose only finite cover-layer and separation checks supplied inside the packet;*
4. *metric handoff exactness, requiring E, Q, M, F to keep the* $\mathsf{Met}^{\uparrow}$ *row downstream of the combined criterion route and compatible with the original topology windows;*
5. *refusal, requiring G and A to name only this finite packet and to refuse host open-cover compactness, selected covers, quotient topology equality, arbitrary refinements, countable choice, and ambient metric oracles.*

No local NameCert obligation is stored outside those rows.

Proof. Project the carrier of Definition 8831.1. The projection exposes exactly the topology source, Bing route, Nagata–Smirnov route, paracompact local-finiteness dependency, common ledger, combined schedule, regularity-refinement row, exactness row, dyadic radius schedule, metric handoff, compatibility row, and the structural rows H, C, G, A.

Sibling route readability is forced by row order. A criterion request starts at T, reads the development data in B, reads the locally finite cover-family data in N, and then compares both through the common ledger L and schedule S.

The metric handoff is downstream of the finite compatibility route. Rows P, L, S, R, E record the local-finiteness supply, cover-layer checks, regularity separation, and exactness witness, while Q, M, F record the dyadic schedule, metric-space handoff, and finite topology compatibility.

Since the tuple contains no host open-cover compactness coordinate, selected-cover coordinate, quotient topology equality coordinate, arbitrary refinement coordinate, countable-choice coordinate, or ambient metric oracle, the local NameCert cannot export those principles. □

Theorem 8831.3 (Bing–Nagata–Smirnov metrization handoff)**.** *Every* $\mathsf{Met}^{\uparrow}$ *consumer of an accepted* $\mathsf{BingNagataSmirnovMetrization}^{\uparrow}$ *packet receives the finite route*

$$\mathsf{Topology}^{\uparrow},\ \mathsf{BingMetrization}^{\uparrow},\ \mathsf{NagataSmirnovMetrization}^{\uparrow},\ \mathsf{Paracompact}^{\uparrow},\ L,\ S,\ R,\ E,\ Q,\ M,\ F,\ H,\ C,\ G,\ A.$$

The handoff row M is consumed only as a downstream metric-space interface tied to the displayed Bing development rows, Nagata–Smirnov locally finite cover rows, paracompact local-finiteness dependency row, regularity-refinement rows, and topology compatibility windows. It is not a host metric, not a selected-cover construction, and not a claim that the source topology equals a quotient topology.

Proof. Read the carrier rows in order. The topology source T, Bing route B, Nagata–Smirnov route N, paracompact dependency P, common ledger L, combined schedule S, and regularity row R are displayed before the exactness row can license a metric-facing read.

The rows E, Q, M, F then supply the downstream interface: exactness binds the two sibling criteria to the same accepted request, the dyadic schedule prepares the metric handoff, and the compatibility row ties metric balls back to the topology source windows.

Transport and replay through H and C preserve that same route, while G and A record provenance and local naming. Because no row stores host open-cover compactness, selected covers, quotient topology equality, countable choice, or an ambient metric oracle, the $\mathsf{Met}^{\uparrow}$ consumer receives only the finite BEDC handoff named above. □

Closure status for $\mathsf{NameCert}_{\mathsf{BingNagataSmirnovMetrization}^{\uparrow}}$.

Constructive story: A $\mathsf{BingNagataSmirnovMetrization}^{\uparrow}$ packet is generated from a topology source row, Bing development route, Nagata–Smirnov cover-family route, paracompact local-finiteness dependency, common locally finite ledger, combined schedule, regularity-refinement row, exactness row, dyadic radius schedule, MetricSpace handoff, topology compatibility row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BingNagataSmirnovMetrization}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8831.1, Definition 8831.2, and Definition 8831.3 seed the finite combined Bing and Nagata–Smirnov criterion route to a displayed MetricSpace handoff.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BingNagataSmirnovMetrization}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host open-cover compactness, selected covers, quotient topology equality, arbitrary refinements, countable choice, ambient metric oracles, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, sibling route readability, local-finiteness compatibility, metric handoff exactness, transport, replay, provenance, and local naming for the displayed Bing–Nagata–Smirnov metrization packet.

Chapter 8832

A Concrete Naming Certificate for $\mathsf{MichaelSelectionFiniteRefinement}^{\uparrow}$

Following Michael's selection theorem in its finite closed-convex refinement reading, the MichaelSelectionFiniteRefine packet records the BEDC surface where one displayed paracompact cover cell family, one lower-semicontinuous closed-convex value row, and one finite refinement ledger are inspected before any local continuous-selection handoff is public. It is a finite sibling of chapter 2300; it consumes the paracompact refinement rows of chapter 1963, the lower-semicontinuous value boundary of chapter 1536, the convex target rows of chapter 208, the continuous-map handoff of chapter 130, and the metric observation discipline of chapter 57. The packet names only finite refinement data; it does not assert a global selector, arbitrary choice over fibres, Banach-space completeness, host function equality, or ambient point-set topology.

Definition 8832.1 (Michael finite closed-convex refinement carrier)**.** *A* $\mathsf{MichaelSelectionFiniteRefinement}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$F = (D, V, K, R, S, T, H, C, P, N)$$

with the following displayed rows:

1. *D is the* $\mathsf{Paracompact}^{\uparrow}$ *domain-cover row whose cells are being refined.*
2. *V is the* $\mathsf{LowerSemicontinuous}^{\uparrow}$ *closed-value row exposed over the displayed cover cells.*
3. *K is the* $\mathsf{ConvexSet}^{\uparrow}$ *target row, carrying the closed-convex witnesses used by each inspected value row.*
4. *R is the finite refinement ledger, listing the retained cover cells, their refinement addresses, and the value-row incidence data.*
5. *S is the local finite selection row, recording only the selections attached to the retained refinement cells.*
6. *T is the* $\mathsf{ContinuousMap}^{\uparrow}$ *handoff row available after D, V, K, R, S have been displayed.*
7. *H records componentwise* hsame *transport for the domain, value, convex-target, refinement, local selection, handoff, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay of the finite route*

$$D, V, K, R, S \longmapsto T \longmapsto H, P, N.$$

9. *P is the* Pkg *provenance over* MichaelSelectionFiniteRefinement$^{\uparrow}$, MichaelSelection$^{\uparrow}$, Paracompact$^{\uparrow}$, LowerSemicontinuous$^{\uparrow}$, ConvexSet$^{\uparrow}$, ContinuousMap$^{\uparrow}$, Met$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*

10. *N is the local* $\mathsf{NameCert}_{\mathsf{MichaelSelectionFiniteRefinement}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $D, V, K, R, S, T, H, C, P, N$. It has no coordinate for a host global selector, arbitrary choice over all fibres, quotient equality of functions, Banach-space completeness, or an ambient topology theorem.

Theorem 8832.2 (Michael finite refinement NameCert obligations)**.** *For every accepted* MichaelSelectionFiniteRefin *carrier $F = (D, V, K, R, S, T, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{MichaelSelectionFiniteRefinement}^{\uparrow}}$ *surface consists exactly of carrier admission, paracompact cover exposure through D, lower-semicontinuous closed-convex value exposure through V, convex target exposure through K, finite refinement incidence through R, local finite selection rows through S, continuous-map handoff through T, componentwise* hsame *transport through H, displayed* Cont *replay through C,* Pkg *provenance through P, and local naming through N. Every continuous-map consumer must read the refinement route D, V, K, R, S before treating T as public, and no obligation is stored outside those rows.*

Proof. Project the carrier of Definition 8832.1. The rows $D, V, K, R, S, T, H, C, P, N$ are the whole finite packet, so carrier admission and the visible obligation rows are read directly from that tuple.

The selection data are local to the displayed refinement ledger. The paracompact row supplies the cover cells, the lower-semicontinuous row supplies the closed-value windows, the convex row supplies target witnesses, and R, S bind the retained finite refinement cells to the visible local selections.

The continuous-map row T is downstream of those rows. Transport and replay through H and C preserve the same finite route, while P, N source and name it. Since the excluded selector, choice, completeness, host-function, and ambient-topology objects have no carrier coordinate, the listed rows exhaust the local NameCert obligations. □

Theorem 8832.3 (Michael finite refinement sibling boundary)**.** *Every accepted* MichaelSelectionFiniteRefinement$^{\uparrow}$ *packet is a finite refinement read of the* MichaelSelection$^{\uparrow}$ *surface of chapter 2300. Its public handoff factors through*

Paracompact$^{\uparrow}$, LowerSemicontinuous$^{\uparrow}$, ConvexSet$^{\uparrow}$, ContinuousMap$^{\uparrow}$, Met$^{\uparrow}$, BHist, hsame, Cont, Pkg, NameCert.

The handoff names one displayed finite closed-convex refinement ledger and no global selection theorem.

Proof. Start from Definition 8832.2. The visible route exposes the paracompact domain cover, the lower-semicontinuous closed-value row, the convex target row, the finite refinement ledger, and the local selection rows before the continuous-map handoff.

Compare this route with the sibling carrier in Definition 2300.1. The finite packet narrows the selection ledger to the retained refinement cells R, S while keeping the same paracompact, lower-semicontinuous, convex, continuous-map, metric, transport, replay, provenance, and naming dependencies.

Thus a consumer may read a finite closed-convex refinement handoff, but it cannot promote that read to arbitrary choice, a host global selector, quotient equality of functions, Banach-space completeness, or an ambient point-set selection theorem. □

Falsifiable prediction: Every accepted $\mathsf{MichaelSelectionFiniteRefinement}^{\uparrow}$ read exposes a displayed $\mathsf{Paracompact}^{\uparrow}$ cover row, $\mathsf{LowerSemicontinuous}^{\uparrow}$ closed-value row, $\mathsf{ConvexSet}^{\uparrow}$ target row, finite refinement ledger, local selection row, terminal $\mathsf{ContinuousMap}^{\uparrow}$ handoff, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming.

Independence witness: michael-selection, paracompact, lowersemicontinuous, convexset, continuousmap, metric: $\mathsf{MichaelSelectionFiniteRefinement}^{\uparrow}$ is not bijective to any listed sibling because it binds one finite refinement ledger and its local closed-convex selection rows into a separate NameCert packet.

Closure status for $\mathsf{NameCert}_{\mathsf{MichaelSelectionFiniteRefinement}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{MichaelSelectionFiniteRefinement}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8832.1, Definition 8832.2, and Definition 8832.3 seed the finite closed-convex refinement surface over paracompact covers, lower-semicontinuous value rows, convex target rows, continuous-map handoff, transport, replay, provenance, and local NameCert rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{MichaelSelectionFiniteRefinement}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close global selection, arbitrary choice over fibres, host function equality, Banach-space completeness, ambient point-set topology, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, finite refinement incidence, local selection-row exactness, continuous-map handoff boundary, transport and replay stability, provenance exhaustion, and TasteGate field faithfulness for BEDC.Derived.MichaelSelectionFiniteRefinementUp.

Constructive story: A $\mathsf{MichaelSelectionFiniteRefinement}^{\uparrow}$ packet is generated from a paracompact cover row, a lower-semicontinuous closed-value row, a closed-convex target row, finite refinement and local selection rows, a continuous-map handoff, componentwise hsame transport, displayed Cont replay, package provenance, and a local NameCert row.

Chapter 8833

A Concrete Naming Certificate for $\mathsf{DyadicUniformCoverTransfer}^{\uparrow}$

Following Bishop and Bridges on finite dyadic covers and constructive completion, the $\mathsf{DyadicUniformCoverTransfer}^{\uparrow}$ packet records the finite L10 route that transfers a displayed dyadic uniform cover into StreamName, RegSeqRat, Real, interval-net, and compact-metric consumers. It refines the dyadic finite-cover direction marked in chapter 9238 and consumes the cover source of chapter 8290, the dyadic arithmetic spine of chapter 291, the finite stream windows of chapter 126, the regular-rational readback of chapter 301, the terminal real-name seal of chapter 38, the dyadic interval-net surface of chapter 5966, and the compact-metric source of chapter 129. The packet names a finite cover-transfer carrier only; it does not assert open-cover compactness, choose a subcover, quotient real names, select limits, use countable choice, or claim ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 8833.1 (Dyadic uniform cover-transfer carrier)**.** *A* $\mathsf{DyadicUniformCoverTransfer}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$T = (U, D, W, Q, R, I, K, L, H, C, P, N)$$

with the following displayed rows:

1. *U is the upstream* $\mathsf{DyadicUniformCover}^{\uparrow}$ *row whose finite cover cells are being transferred.*
2. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *endpoint, radius, overlap, and tolerance ledger used by the transfer.*
3. *W is the finite* $\mathsf{StreamName}^{\uparrow}$ *observation row for cover-cell endpoints and membership reads.*
4. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the rational center and endpoint data exposed by W.*
5. *R is the* $\mathsf{Real}^{\uparrow}$ *seal row reached only after D, W, Q have been displayed.*
6. *I is the* $\mathsf{DyadicIntervalNet}^{\uparrow}$ *row that packages the cover cells as interval-net data.*
7. *K is the* $\mathsf{CompactMetric}^{\uparrow}$ *consumer row, available only after U, D, W, Q, R, I have been displayed.*
8. *L is the finite transfer ledger, recording that the same cover cells and tolerance comparisons feed the stream, regular-rational, Real, interval-net, and compact-metric rows.*
9. *H records componentwise* hsame *transport for the cover, dyadic, stream, regular-rational, Real, interval-net, compact-metric, transfer-ledger, replay, provenance, and local naming rows.*
10. *C records displayed* Cont *replay of the route*

$$U, D, W, Q, R, I, K, L \longmapsto H, P, N.$$

11. *P is the* Pkg *provenance over* $\mathsf{DyadicUniformCoverTransfer}^{\uparrow}$, $\mathsf{DyadicUniformCover}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{DyadicIntervalNet}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*

12. *N is the local* $\mathsf{NameCert}_{\mathsf{DyadicUniformCoverTransfer}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $U, D, W, Q, R, I, K, L, H, C, P, N$. It has no coordinate for arbitrary open covers, selected subcovers, quotient stream equality, host real equality, countable choice, selected limits, or ambient compactness and completeness.

Theorem 8833.2 (Dyadic uniform cover-transfer NameCert obligations)**.** *For every accepted* $\mathsf{DyadicUniformCoverTransfer}^{\uparrow}$ *carrier $T = (U, D, W, Q, R, I, K, L, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{DyadicUniformCoverTran}}$ *surface consists exactly of upstream dyadic-cover exposure through U, dyadic endpoint and tolerance exposure through D, finite StreamName window exposure through W, regular-rational readback through Q, Real sealing through R, dyadic interval-net handoff through I, compact-metric handoff through K, finite transfer-ledger exactness through L, componentwise* hsame *transport through H, displayed* Cont *replay through C,* Pkg *provenance through P, and local naming through N. Every L10 completion or compactness consumer must read U, D, W, Q, R, I, L before treating K as public, and no obligation is stored outside those rows.*

Proof. Project the carrier of Definition 8833.1. The transfer source is U, the arithmetic and readback rows are D, W, Q, R, the interval-net and compact-metric consumers are I, K, and the finite transfer ledger is L.

Apply the upstream dyadic-cover handoff of Definition 8290.3. It forces any compactness or completion read to expose the dyadic ledger, finite stream window, regular-rational readback, Real seal, and finite cover row before using the cover as a source.

The new transfer ledger L keeps that same finite cover route attached to the interval-net row I and the compact-metric row K. Transport and replay through H and C preserve the displayed rows, while P, N source and name the same packet. Since no excluded open-cover, selected-subcover, quotient, choice, limit-selection, or ambient-completeness object appears as a coordinate, the listed rows exhaust the local NameCert obligations. □

Theorem 8833.3 (Dyadic uniform cover-transfer L10 route)**.** *Every L10 Real, Completion, interval-net, or compact-metric consumer of an accepted* $\mathsf{DyadicUniformCoverTransfer}^{\uparrow}$ *packet factors through*

$\mathsf{DyadicUniformCover}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{DyadicIntervalNet}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, BH

The route is a finite cover-transfer packet from displayed dyadic cells to readback and compact-metric rows, not an open-cover compactness theorem or a selected subcover principle.

Proof. Begin with Definition 8833.2. It places the upstream cover row U, dyadic ledger D, finite stream window W, regular-rational readback Q, Real seal R, interval-net row I, compact-metric row K, and transfer ledger L in one displayed route.

The sibling chapters provide the public surfaces consumed by that route: chapter 291 supplies dyadic arithmetic, chapter 126 and chapter 301 supply finite observation and rational readback, chapter 38 supplies the seal, chapter 5966 supplies the interval-net handoff, and chapter 129 supplies the compact-metric consumer boundary.

Finally inspect H, C, P, N. These structural rows only transport, replay, source, and name the finite transfer route. They cannot add arbitrary open covers, selected subcovers, quotient real names, host real equality, countable choice, selected limits, or ambient completeness, so every public L10 read remains inside the displayed cover-transfer packet. □

Falsifiable prediction: Every accepted $\mathsf{DyadicUniformCoverTransfer}^{\uparrow}$ read exposes an upstream $\mathsf{DyadicUniformCover}^{\uparrow}$ row, $\mathsf{DyadicRatCore}^{\uparrow}$ endpoint and tolerance ledger, finite $\mathsf{StreamName}^{\uparrow}$ window, $\mathsf{RegSeqRat}^{\uparrow}$ readback, $\mathsf{Real}^{\uparrow}$ seal, $\mathsf{DyadicIntervalNet}^{\uparrow}$ handoff, $\mathsf{CompactMetric}^{\uparrow}$ consumer row, finite transfer ledger, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming.

Independence witness: dyadic-uniform-cover, dyadicratcore, streamname, regseqrat, real, dyadic-interval-net, compactmetric: $\mathsf{DyadicUniformCoverTransfer}^{\uparrow}$ is not bijective to any listed sibling because it binds upstream dyadic cover cells to one finite L10 transfer ledger across readback, Real sealing, interval-net, and compact-metric consumers.

Closure status for $\mathsf{NameCert}_{\mathsf{DyadicUniformCoverTransfer}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{DyadicUniformCoverTransfer}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8833.1, Definition 8833.2, and Definition 8833.3 seed the finite L10 cover-transfer surface over dyadic cover, dyadic arithmetic, StreamName, RegSeqRat, Real, dyadic interval-net, compact-metric, transport, replay, provenance, and local NameCert rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{DyadicUniformCoverTransfer}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close open-cover compactness, selected subcovers, quotient real names, host real equality, countable choice, selected limits, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, upstream cover exposure, dyadic endpoint exactness, finite-window readback, Real-seal exposure, interval-net and compact-metric handoff exactness, transfer-ledger stability, transport, replay, provenance, and local naming for BEDC.Derived.DyadicUniformCoverTransferUp.

Constructive story: A $\mathsf{DyadicUniformCoverTransfer}^{\uparrow}$ packet is generated from an upstream dyadic uniform cover row, dyadic endpoint and tolerance data, finite StreamName windows, RegSeqRat readback, a Real seal, dyadic interval-net and compact-metric rows, a finite transfer ledger, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 8834

A Concrete Naming Certificate for $\mathsf{EulerMethodConvergence}^{\uparrow}$

Following Euler and Cauchy, and the Bishop–Bridges constructive treatment of numerical approximation, the $\mathsf{EulerMethodConvergence}^{\uparrow}$ packet records the finite route by which explicit Euler meshes are compared, budgeted, and handed to a regular real readback. It consumes the finite forward-step packet of chapter 6231, the finite ODE bound of chapter 8548, the finite observation windows of chapter 126, the regular rational readback of chapter 301, the dyadic tolerance ledger of chapter 291, and the terminal real-name seal of chapter 38. The packet names constructive explicit-Euler mesh convergence as finite NameCert data; it is not a host ODE existence theorem, a selected solution curve, quotient equality of paths, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 8834.1 (Euler method convergence carrier)**.** *An* $\mathsf{EulerMethodConvergence}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$E = (S, G, W, R, D, L, H, C, P, N)$$

with the following displayed rows:

1. *S is the* $\mathsf{EulerMethodFiniteStep}^{\uparrow}$ *step packet, exposing the local ODE row, vector-field read, finite step ledger, endpoint update row, and dyadic arithmetic row.*
2. *G is the* $\mathsf{GronwallFiniteOde}^{\uparrow}$ *bound packet, carrying the finite Lipschitz, comparison, dyadic majorant, and ODE estimate rows used to compare meshes.*
3. *W is the* $\mathsf{StreamName}^{\uparrow}$ *observation-window row, recording which mesh refinements and endpoint reads are inspected.*
4. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *regular rational readback row attached to the displayed endpoint approximations and error budgets.*
5. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger for mesh widths, local truncation bounds, Gronwall accumulation, and target precision requests.*
6. *L is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached only after S, G, W, R, D have been displayed.*
7. *H records componentwise* hsame *transport for step, bound, window, readback, dyadic, real-seal, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from the finite step route through the Gronwall budget and regular readback.*

9. *P is the* Pkg *provenance over* $\mathsf{EulerMethodConvergence}^{\uparrow}$, $\mathsf{EulerMethodFiniteStep}^{\uparrow}$, $\mathsf{GronwallFiniteOde}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{EulerMethodConvergence}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $S, G, W, R, D, L, H, C, P, N$. It has no coordinate for an exact solution curve, host convergence theorem, selected limiting path, quotient equality of functions, countable-choice schedule, or ambient real completeness.

Theorem 8834.2 (Euler method convergence NameCert obligations)**.** *For every accepted* EulerMethodConvergence *carrier*

$$E = (S, G, W, R, D, L, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{EulerMethodConvergence}^{\uparrow}}$ *surface consists exactly of the following five obligation rows:*

1. *finite-step admission through S, including the displayed ODE source, vector-field read, step ledger, endpoint update row, and dyadic arithmetic row;*
2. *Gronwall comparison admission through G, including the finite Lipschitz and accumulated-error majorant used to compare mesh refinements;*
3. *observation and regular-readback admission through W and R, so every endpoint approximation is read as a finite window before any real seal is exposed;*
4. *dyadic error-budget admission through D, stable under componentwise* hsame *transport H and displayed* Cont *replay C;*
5. *provenance and local naming through P, N, with the terminal* $\mathsf{Real}^{\uparrow}$ *seal L available only after the previous four rows are visible.*

No local obligation may read exact ODE solution existence, global continuation, selected limiting paths, quotient path equality, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the accepted carrier $E = (S, G, W, R, D, L, H, C, P, N)$. The finite-step packet S gives the only endpoint-update source, while the Gronwall packet G gives the only accumulated-error comparison row.

The observation route is then forced through W and R. A convergence consumer can inspect only the displayed mesh windows and the regular rational readback attached to those windows, so it cannot invoke a host limiting path.

The dyadic ledger D records the mesh-width, local-error, accumulated-error, and target-precision budgets. Transport and replay through H and C preserve those displayed rows componentwise.

Finally P, N source and name the same packet, and the terminal seal L is exposed only after S, G, W, R, D have been read. Since no carrier coordinate names exact ODE solution existence, global continuation, selected limits, quotient paths, choice, or ambient completeness, the five rows exhaust the local NameCert surface. □

Theorem 8834.3 (Euler method convergence error-budget route)**.** *Every accepted* $\mathsf{EulerMethodConvergence}^{\uparrow}$ *consumer that exports a completed real endpoint must read the error budget through*

$$S, G, W, R, D, L, H, C, P, N.$$

The route first exposes finite Euler steps, then the Gronwall comparison budget, then finite observation windows and regular rational readback, then the dyadic tolerance ledger, and only then the terminal real seal. It exports no exact solution object, selected limiting path, quotient path equality, countable-choice schedule, or ambient-completeness principle.

Lean4 (statement) `BEDC.Derived.EulerMethodConvergenceUp`

Proof. Start with an accepted carrier $E = (S, G, W, R, D, L, H, C, P, N)$. The finite-step data S and comparison data G determine which mesh endpoints and accumulated bounds are available.

Read the observation row W and the regular rational row R next. These rows make endpoint comparison a finite-window and regular-readback operation rather than a direct appeal to a completed curve.

The dyadic ledger D is then the only tolerance source for the target precision. The terminal row L may be exposed only after that ledger has been displayed, and H, C, P, N preserve, replay, source, and name the same route.

Thus any completed real endpoint exported by the packet factors through the displayed ten rows. No remaining row can supply a hidden solution object, selected limit, quotient equality, choice schedule, or ambient-completeness claim. □

Falsifiable prediction: An accepted $\mathsf{EulerMethodConvergence}^{\uparrow}$ consumer that reaches a $\mathsf{Real}^{\uparrow}$ seal without reading the displayed finite-step row, Gronwall comparison row, StreamName window row, RegSeqRat readback row, DyadicRatCore error ledger, transport, replay, provenance, and local NameCert rows refutes the carrier surface.

Independence witness: euler-method-finite-step, gronwall-finite-ode, streamname, regseqrat, dyadicratcore, real: none is bijective to $\mathsf{EulerMethodConvergence}^{\uparrow}$ because this packet binds finite Euler steps, Gronwall mesh comparison, finite observation windows, regular rational readback, dyadic error budgets, terminal real sealing, transport, replay, provenance, and local naming into one convergence route.

Closure status for $\mathsf{NameCert}_{\mathsf{EulerMethodConvergence}^{\uparrow}}$.

Constructive story: An $\mathsf{EulerMethodConvergence}^{\uparrow}$ packet is generated from an EulerMethodFiniteStep row, a GronwallFiniteOde comparison row, StreamName observation windows, RegSeqRat readback, a DyadicRatCore error ledger, a terminal Real seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{EulerMethodConvergence}^{\uparrow}}$, seed)

Scope closed: Definition 8834.1, Definition 8834.2, and Definition 8834.3 seed the constructive explicit-Euler mesh convergence route over finite-step, Gronwall, stream-window, regular-readback, dyadic-budget, real-seal, transport, replay, provenance, and naming rows.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{EulerMethodConvergence}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close exact ODE solution existence, global continuation, selected limiting paths, quotient path equality, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean theorem verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, finite-step visibility, Gronwall comparison, windowed readback, dyadic error budgets, real sealing, transport, replay, provenance, and local naming for BEDC.Derived.EulerMethodConvergence

Chapter 8835

A Concrete Naming Certificate for $\mathsf{LocalizedDarbouxIntermediate}^{\uparrow}$

Following Darboux and Bishop–Bridges constructive analysis, the $\mathsf{LocalizedDarbouxIntermediate}^{\uparrow}$ packet records the finite L10 route from a located interval source, through Darboux-continuity data, into a localized bisection readback before any terminal $\mathsf{Real}^{\uparrow}$ seal is consumed. It sits beside the Darboux-continuity surface of chapter 3828, the located intermediate-value route of chapter 3938, the constructive intermediate-value packet of chapter 6410, the finite $\mathsf{StreamName}^{\uparrow}$ window discipline of chapter 126, the regular rational readback of chapter 301, and the terminal real-name boundary of chapter 38. The certificate names a local route only; it does not claim global compactness, a host-selected zero, quotient real equality, or ambient completeness.

Definition 8835.1 (Localized Darboux intermediate carrier)**.** *A* $\mathsf{LocalizedDarbouxIntermediate}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (I, D, B, T, W, R, E, H, C, P, N)$$

with the following displayed rows:

1. *I is the located interval source row, naming the endpoint* $\mathsf{Real}^{\uparrow}$ *seals, the located order witness, and the source window in which the intermediate read is requested.*
2. *D is the Darboux-continuity row, recording the local graph exposure and crossing data consumed from* $\mathsf{DarbouxContinuity}^{\uparrow}$*.*
3. *B is the bisection route row, listing the retained subintervals, inspected midpoint samples, and sign-apartness observations used by the localized search.*
4. *T is the dyadic tolerance ledger from* $\mathsf{DyadicRatCore}^{\uparrow}$*, recording endpoint brackets, midpoint brackets, crossing tolerances, and the terminal window budget.*
5. *W is the finite* $\mathsf{StreamName}^{\uparrow}$ *window row inspected by B and T.*
6. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row that turns the displayed windows and dyadic tolerances into regular rational observations.*
7. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal, exposed only after I, D, B, T, W, R have been displayed.*
8. *H records componentwise* hsame *transport for the located interval, Darboux row, bisection ledger, dyadic tolerance ledger, window row, readback row, seal, replay, provenance, and local naming rows.*

9. *C records displayed* Cont *replay from any localized intermediate-value consumer through I, D, B, T, W, R, E and then through the structural rows.*
10. *P is the* Pkg *provenance over* LocalizedDarbouxIntermediate$^{\uparrow}$, DarbouxContinuity$^{\uparrow}$, LocatedIntermediateValue$^{\uparrow}$, ConstructiveIntermediateValue$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, Real$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* NameCert$_{\text{LocalizedDarbouxIntermediate}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these displayed rows. The carrier has no coordinate for open-cover compactness, ambient real completeness, trichotomy, a selected host zero, countable choice, or quotient equality of completed real names.

Lean4 ✓ `BEDC.Derived.LocalizedDarbouxIntermediateUp.LocalizedDarbouxIntermediateTasteGate`
`single carrier alignment`

Theorem 8835.2 (Localized Darboux intermediate NameCert obligations)**.** *For every accepted* LocalizedDarbouxIntermediate$^{\uparrow}$ *carrier $L = (I, D, B, T, W, R, E, H, C, P, N)$, the local* NameCert$_{\text{LocalizedDarbouxIntermed}}$ *surface consists exactly of the following five rows: located interval admission through I; Darboux and bisection exposure through D, B; dyadic tolerance, finite-window, and regular readback through T, W, R; terminal* Real$^{\uparrow}$ *sealing through E; and structural transport, replay, provenance, and local naming through H, C, P, N.*

Proof. Project the carrier rows. The located interval row I, Darboux row D, bisection row B, dyadic tolerance ledger T, window row W, regular readback R, and real seal E are the only analytic rows available to a consumer.

Group those rows by their obligation role. Source admission is I; Darboux and bisection exposure are D, B; numerical observation is T, W, R; the terminal real-name handoff is E.

The remaining rows H, C, P, N transport, replay, source, and name the same packet. Since no further coordinate is present, the five listed rows exhaust the local NameCert surface. □

Theorem 8835.3 (Localized Darboux intermediate bisection route)**.** *Every consumer of an accepted* LocalizedDarbouxIntermediate$^{\uparrow}$ *packet reaches the intermediate* Real$^{\uparrow}$ *seal only through the displayed located interval row I, Darboux row D, bisection route B, finite* StreamName$^{\uparrow}$ *windows W,* RegSeqRat$^{\uparrow}$ *readback R, dyadic tolerance ledger T, and terminal* Real$^{\uparrow}$ *row E, with componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and the local* NameCert *row still attached.*

Proof. Begin with the located source. The carrier exposes I before any Darboux or bisection row, so a consumer cannot start from an ambient interval image or detached real-name selection.

Read the Darboux and bisection rows next. The row D supplies the local crossing surface, while B records the retained subintervals and midpoint observations used by the localized route.

The numerical handoff is finite. The window row W, dyadic ledger T, and regular rational readback R must be displayed before the terminal seal E is available.

Finally H, C, P, N preserve and name this same route. No carrier coordinate supplies open-cover compactness, ambient Real completeness, trichotomy, a selected host zero, countable choice, or quotient equality. □

Closure status for NameCert$_{\text{LocalizedDarbouxIntermediate}^{\uparrow}}$ **.**

Constructive story: A LocalizedDarbouxIntermediate$^{\uparrow}$ packet is generated from a located interval source, Darboux-continuity row, bisection route, dyadic tolerance ledger, finite StreamName windows, RegSeqRat readback, RealUp seal, componentwise transport, continuation replay, provenance, and local naming.

Theory closure: TheoryGate(NameCert$_{\text{LocalizedDarbouxIntermediate}\uparrow}$, seed)

Scope closed: Definition 8835.1, Definition 8835.2, and Definition 8835.3 seed the local L10 Darboux-intermediate route over located interval, Darboux, bisection, StreamName, RegSeqRat, and Real rows.

Formal verification: FormalStatus(NameCert$_{\text{LocalizedDarbouxIntermediate}\uparrow}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close open-cover compactness, ambient Real$^{\uparrow}$ completeness, trichotomy, selected host zeros, quotient equality of completed real names, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, Darboux row exposure, bisection-route exactness, dyadic tolerance accounting, finite StreamName windows, RegSeqRat readback, RealUp sealing, transport, replay, provenance, and local naming for BEDC.Derived.LocalizedDarbouxIntermediateUp.

Chapter 8836

A Concrete Naming Certificate for $\mathsf{LocatedNumber}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{LocatedNumber}^{\uparrow}$ packet records a finite located-number interface for the L10 Real and Completion route before later comparison, apartness, or completion consumers read a real-name boundary. It sits after the natural scale rows of chapter 28, the rational bracket rows of chapter 37, the dyadic tolerance arithmetic of chapter 291, the finite windows of chapter 126, the regular rational readback of chapter 301, the scale compatibility packet of chapter 1507, and the terminal real-name seal of chapter 38. The packet names a displayed located-number carrier; it is not quotient real equality, a selected limit, trichotomy, countable choice, or $\mathsf{Real}^{\uparrow}$ completeness.

Definition 8836.1 (Located number carrier)**.** *A* $\mathsf{LocatedNumber}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (N, Q, D, S, R, A, E, H, C, P, M)$$

with the following displayed rows:

1. *N is the* $\mathsf{Nat}^{\uparrow}$ *scale row, recording the finite precision request at which a located bracket is inspected.*
2. *Q is the* $\mathsf{Rat}^{\uparrow}$ *bracket row, displaying the lower and upper rational bounds presented at scale N.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row, recording dyadic radii, midpoint arithmetic, bracket slack, and endpoint comparison data for the same request.*
4. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row opened only after N, Q, D have been displayed.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row extracted from the same window and dyadic tolerance ledger.*
6. *A is the* $\mathsf{ArchimedeanApproximation}^{\uparrow}$ *scale-compatibility row tying the natural scale, rational bracket, dyadic tolerance, finite window, and readback rows to one approximation request.*
7. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached only after N, Q, D, S, R, A are visible.*
8. *H records componentwise* hsame *transport for the scale, bracket, tolerance, window, readback, Archimedean compatibility, seal, replay, provenance, and local naming rows.*
9. *C records displayed* Cont *replay for each scale request, bracket read, tolerance check, window opening, readback, compatibility check, and Real seal handoff.*
10. *P is the* Pkg *provenance over* $\mathsf{LocatedNumber}^{\uparrow}$, $\mathsf{Nat}^{\uparrow}$, $\mathsf{Rat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{ArchimedeanApproximation}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.

11. *M is the local* $\mathsf{NameCert}_{\mathsf{LocatedNumber}^\uparrow}$ *row.*

The classifier compares accepted carriers only through $N, Q, D, S, R, A, E, H, C, P, M$. It has no coordinate for quotient real equality, selected representatives, selected limits, trichotomy, countable-choice schedules, or ambient $\mathsf{Real}^\uparrow$ *completeness.*

Theorem 8836.2 (Located number NameCert obligations)**.** *For every accepted* $\mathsf{LocatedNumber}^\uparrow$ *carrier $L = (N, Q, D, S, R, A, E, H, C, P, M)$, the local* $\mathsf{NameCert}_{\mathsf{LocatedNumber}^\uparrow}$ *surface consists exactly of carrier admission,* $\mathsf{Nat}^\uparrow$ *scale exposure,* $\mathsf{Rat}^\uparrow$ *bracket exposure,* $\mathsf{DyadicRatCore}^\uparrow$ *tolerance exactness,* $\mathsf{StreamName}^\uparrow$ *finite-window opening,* $\mathsf{RegSeqRat}^\uparrow$ *readback,* $\mathsf{ArchimedeanApproximation}^\uparrow$ *scale compatibility,* $\mathsf{Real}^\uparrow$ *terminal sealing, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming for the displayed rows $N, Q, D, S, R, A, E, H, C, P, M$.*

Proof. Project the accepted packet. The analytic rows are precisely the scale row N, rational bracket row Q, dyadic tolerance row D, finite window row S, regular readback row R, Archimedean compatibility row A, and terminal seal row E.

Read the sibling obligations in their displayed order. The scale row controls the request, the rational bracket and dyadic tolerance rows display the finite enclosure data, the StreamName window and RegSeqRat readback rows expose only finite observations, and the ArchimedeanApproximation row binds those rows to one scale-compatible approximation request.

The structural rows do not add analytic content. Componentwise transport, continuation replay, provenance, and local naming preserve the same packet, so quotient equality, selected representatives, selected limits, trichotomy, countable choice, and ambient completeness remain outside the certificate. □

Theorem 8836.3 (Located number Real route)**.** *Every Real-facing or completion-facing consumer of an accepted* $\mathsf{LocatedNumber}^\uparrow$ *carrier reads the displayed route*

$$\mathsf{Nat}^\uparrow,\ \mathsf{Rat}^\uparrow,\ \mathsf{DyadicRatCore}^\uparrow,\ \mathsf{StreamName}^\uparrow,\ \mathsf{RegSeqRat}^\uparrow,\ \mathsf{ArchimedeanApproximation}^\uparrow,\ \mathsf{Real}^\uparrow$$

before the packet is public. The consumer receives a located-number boundary through finite scale, bracket, tolerance, window, readback, compatibility, and seal rows; it receives no quotient real equality, selected limit, trichotomy, countable-choice schedule, or ambient $\mathsf{Real}^\uparrow$ *completeness theorem.*

Proof. Start with the scale and bracket rows. The request is finite because N names the inspected scale and Q names only the rational bracket displayed at that scale.

Next read the dyadic tolerance, finite window, and regular readback rows. The rows D, S, R force every endpoint or tolerance observation through displayed dyadic arithmetic, a finite StreamName window, and a RegSeqRat readback before any Real-facing boundary is available.

Finally read A and E. The ArchimedeanApproximation row ties the preceding rows to one scale-compatible approximation request, and the Real seal is terminal with respect to that request. Transport, replay, provenance, and local naming preserve the same route, so no excluded equality, selected limit, choice, trichotomy, or completeness principle can be exported. □

Closure status for $\mathsf{NameCert}_{\mathsf{LocatedNumber}^\uparrow}$.

Constructive story: A $\mathsf{LocatedNumber}^\uparrow$ packet is generated from Nat scale rows, Rat bracket rows, DyadicRatCore tolerance rows, StreamName finite windows, RegSeqRat readback, ArchimedeanApproximation scale compatibility, a RealUp terminal seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{LocatedNumber}^\uparrow}$, seed)

Scope closed: Definition 8836.1, Definition 8836.2, and Definition 8836.3 seed the finite located-number interface for the L10 Real and Completion route.

Formal verification: FormalStatus(NameCert$_{\mathsf{LocatedNumber}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close quotient real equality, selected limits, trichotomy, countable choice, selected representatives, ambient Real$^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, scale exposure, bracket exposure, dyadic tolerance exactness, finite-window opening, regular readback, Archimedean scale compatibility, Real seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.LocatedNumberUp.

Chapter 8837

A Concrete Naming Certificate for MetaCICSubjectReductionObstructionWitness$^{\uparrow}$

The MetaCICSubjectReductionObstructionWitness$^{\uparrow}$ packet realizes the simultaneous obstruction surface of chapter 9386 as finite NameCert data. It sits after the checked boundary packet of chapter 721, the four-row discharge matrix of chapter 6922, the proof-obligation gap of chapter 3460, and the discharge-inversion boundary of chapter 6111. The witness records that the beta-substitution, application-argument, lambda-domain, and Pi-domain rows must be inspected together before a subject-reduction consumer may read the parameterised theorem; it does not close subject reduction.

Definition 8837.1 (MetaCIC subject-reduction obstruction witness carrier)**.** *A* MetaCICSubjectReductionObstructi *carrier is a finite* BHist *packet*

$$W = (B, A, L, D, M, Q, O, S, H, C, P, N)$$

with the following displayed rows:

1. *B is the* BetaSubstitutionPreservation *obligation row.*
2. *A is the* AppArgTypeStable *obligation row.*
3. *L is the* LamDomainSubjectReduction *obligation row.*
4. *D is the* PiDomainSubjectReduction *obligation row.*
5. *M is the* MetaCICSubjectReductionDischargeMatrix$^{\uparrow}$ *row, retaining simultaneous four-row coverage.*
6. *Q is the* ProofObligationGap$^{\uparrow}$ *row, recording named missing discharge rather than positive preservation evidence.*
7. *O is the obstruction row imported from the* MetaCICSubjectReductionBoundaryUp *packet.*
8. *S is the* MetaCICDischargeInversionBoundary$^{\uparrow}$ *socket row, preventing transport, replay, provenance, or local naming from filling one of the four discharge fields.*
9. *H records componentwise* hsame *transport for the four obligation rows, matrix, gap, obstruction, socket, replay, provenance, and local naming rows.*
10. *C records displayed* Cont *replay of the same obstruction witness route.*

11. *P is the* Pkg *provenance over* MetaCICSubjectReductionObstructionWitness$^{\uparrow}$, MetaCICSubjectReductionBoundaryU MetaCICSubjectReductionDischargeMatrix$^{\uparrow}$, ProofObligationGap$^{\uparrow}$, MetaCICDischargeInversionBoundary$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
12. *N is the local* NameCert$_{\text{MetaCICSubjectReductionObstructionWitness}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $B, A, L, D, M, Q, O, S, H, C, P, N$. It has no coordinate for a closed subject-reduction theorem, host conversion, erased derivation semantics, quotient equality of terms, global normalization, or kernel consistency.

Theorem 8837.2 (MetaCIC subject-reduction obstruction witness obligations)**.** *For every accepted* MetaCICSubjectReductionObstructionWitness$^{\uparrow}$ *carrier*

$$W = (B, A, L, D, M, Q, O, S, H, C, P, N),$$

the local NameCert$_{\text{MetaCICSubjectReductionObstructionWitness}^{\uparrow}}$ *surface consists exactly of simultaneous beta-substitution, application-argument, lambda-domain, and Pi-domain obligation exposure through B, A, L, D, matrix coverage through M, proof-obligation-gap polarity through Q, checked obstruction retention through O, socket-preserving discharge inversion through S, componentwise transport and displayed replay through H, C, provenance through P, and local naming through N.*

Proof. Project the accepted carrier. The four subject-reduction obligations are displayed as separate rows B, A, L, D, and no one of them contains the data of another.

The matrix row M records simultaneous coverage. It therefore prevents a consumer from treating a single positive row as a closed subject-reduction proof.

The gap and obstruction rows Q, O fix the polarity of the packet. They record named missing discharge and the retained subject-reduction boundary rather than positive preservation evidence.

Finally the socket row S and the structural rows H, C, P, N preserve the same route. Since none of those rows has a coordinate for host conversion, erased derivation semantics, quotient equality, global normalization, or kernel consistency, the listed rows exhaust the local certificate. □

Theorem 8837.3 (MetaCIC subject-reduction obstruction witness non-escape)**.** *Every subject-reduction-facing consumer of an accepted* MetaCICSubjectReductionObstructionWitness$^{\uparrow}$ *packet must read the route*

$$B, A, L, D, M, Q, O, S, H, C, P, N.$$

If any one of B, A, L, D is absent, the consumer remains at the obstruction witness and cannot export the parameterised subject-reduction theorem as a closed theorem.

Proof. Use Definition 8837.2. A consumer reaches the matrix row M only after the four displayed obligation rows are visible.

If one of B, A, L, D is absent, the proof-obligation gap Q and obstruction row O are the only available answer for that branch. The socket row S keeps transport, replay, provenance, and local naming from replacing the missing discharge row.

Thus the public read remains on the displayed route $B, A, L, D, M, Q, O, S, H, C, P, N$. The packet exports no closed subject-reduction theorem, no host conversion rule, no erased derivation semantics, no quotient term equality, no global normalization theorem, and no kernel-consistency theorem. □

Lean4 (statement) `BEDC.Derived.MetaCICSubjectReductionObstructionWitnessUp`

Falsifiable prediction: A MetaCIC subject-reduction consumer that reads the witness as a closed theorem while any one of BetaSubstitutionPreservation, AppArgTypeStable, LamDomainSubjectReduction,

or PiDomainSubjectReduction is absent refutes the $\mathsf{MetaCICSubjectReductionObstructionWitness}^{\uparrow}$ carrier surface.

Independence witness: metacic-subject-reduction-boundary, metacic-subject-reduction-discharge-matrix, proof-obligation-gap, metacic-discharge-inversion-boundary: none is bijective to MetaCICSubjectReductionO because this packet binds the simultaneous four-row obstruction, matrix coverage, named gap polarity, retained obstruction, socket-preserving inversion, transport, replay, provenance, and local naming as one witness surface.

Lean follow-up must provide `Nontrivial MetaCICSubjectReductionObstructionWitnessUp` and `FieldFaithful MetaCICSubjectReductionObstructionWitnessUp` instances in `BEDC.Derived.MetaCICSub` The instances must keep $B, A, L, D, M, Q, O, S, H, C, P, N$ field-faithful, so the four discharge rows, matrix row, proof-obligation gap, obstruction row, and inversion socket cannot collapse into one carrier coordinate.

Closure status for $\mathsf{NameCert}_{\mathsf{MetaCICSubjectReductionObstructionWitness}^{\uparrow}}$.

Constructive story: A $\mathsf{MetaCICSubjectReductionObstructionWitness}^{\uparrow}$ packet is generated from beta-substitution, application-argument, lambda-domain, Pi-domain, discharge-matrix, proof-obligation-gap, obstruction, discharge-inversion socket, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert rows.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{MetaCICSubjectReductionObstructionWitness}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8837.1, Definition 8837.2, and Definition 8837.3 seed the simultaneous four-row subject-reduction obstruction witness.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{MetaCICSubjectReductionObstructionWitness}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close beta substitution, application-argument stability, lambda-domain preservation, Pi-domain preservation, closed subject reduction, host conversion, quotient term equality, global normalization, kernel consistency, Lean theorem verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, four-row exposure, matrix coverage, proof-obligation-gap polarity, obstruction retention, socket-preserving inversion, transport, replay, provenance, local naming, Nontrivial evidence, and FieldFaithful evidence for BEDC.Derived.MetaCICSubjectReductionObstructionWitnessUp.

Chapter 8838

A Concrete Naming Certificate for $\mathsf{DarbouxSumRefinement}^{\uparrow}$

Following Darboux and Riemann integration, the $\mathsf{DarbouxSumRefinement}^{\uparrow}$ packet records the finite refinement surface that compares Darboux sums over a displayed partition with Darboux sums over a displayed refinement before any Real-facing Cauchy handoff is read. It sits between the finite Darboux-sum boundary of chapter 1880, the lower-sum side of chapter 5858, the dyadic partition ledger of chapter 1863, and the terminal real-name seal of chapter 38. The packet gives L10 Real and Completion consumers a finite refinement certificate for integration estimates; it does not import host suprema, selected mesh limits, quotient equality of functions, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 8838.1 (Darboux-sum refinement carrier)**.** *A* $\mathsf{DarbouxSumRefinement}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$R = (I, P, Q, L, U, M, D, C, E, H, K, G, N)$$

with the following displayed rows:

1. *I is the* $\mathsf{Real}^{\uparrow}$ *interval and bounded-integrand observation row visible to the Darboux-sum consumer.*
2. *P is the source* $\mathsf{DyadicPartition}^{\uparrow}$ *row.*
3. *Q is the refined* $\mathsf{DyadicPartition}^{\uparrow}$ *row together with the finite cell-incidence map from Q to P.*
4. *L is the* $\mathsf{LowerDarbouxSum}^{\uparrow}$ *row over the source partition P.*
5. *U is the upper finite Darboux-sum row over the same source partition P.*
6. *M is the refinement monotonicity ledger comparing the lower and upper rows on P with the corresponding finite rows on Q.*
7. *D is the* $\mathsf{DarbouxSum}^{\uparrow}$ *handoff row carrying the paired lower and upper finite sums through the common refinement route.*
8. *C is the Cauchy-readiness row that turns the displayed upper-minus-lower refinement gap into a regular rational window for a Real-facing consumer.*
9. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal reached only after I, P, Q, L, U, M, D, C have been displayed.*
10. *H records componentwise* hsame *transport for interval, partition, refinement, sum, gap, readiness, seal, replay, provenance, and local naming rows.*

11. *K records displayed* Cont *replay from Darboux, Riemann, Real, or Completion requests through the same finite rows.*
12. *G records* Pkg *provenance over* $\mathsf{DarbouxSumRefinement}^{\uparrow}$, $\mathsf{DarbouxSum}^{\uparrow}$, $\mathsf{LowerDarbouxSum}^{\uparrow}$, $\mathsf{DyadicPartition}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
13. *N is the local* $\mathsf{NameCert}_{\mathsf{DarbouxSumRefinement}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $I, P, Q, L, U, M, D, C, E, H, K, G, N$. It has no coordinate for a host supremum or infimum, selected limiting mesh, quotient equality of functions, open-cover compactness, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 (statement) `BEDC.Derived.DarbouxSumRefinementUp`

Theorem 8838.2 (Darboux-sum refinement NameCert obligations)**.** *For every accepted* $\mathsf{DarbouxSumRefinement}^{\uparrow}$ *carrier $R = (I, P, Q, L, U, M, D, C, E, H, K, G, N)$, the local* $\mathsf{NameCert}_{\mathsf{DarbouxSumRefinement}^{\uparrow}}$ *surface consists exactly of the following finite obligations:*

1. *carrier admission for the interval row, source partition, refined partition, lower-sum row, upper-sum row, refinement monotonicity ledger, Darboux-sum handoff, Cauchy-readiness row, Real seal, transport, replay, provenance, and local name;*
2. *partition refinement coherence, requiring Q to refine P through a displayed finite cell-incidence map before any sum comparison is consumed;*
3. *lower and upper sum stability, requiring the source lower and upper rows L, U and their refined counterparts to be compared only through the ledger M;*
4. *Darboux handoff confinement, requiring the* $\mathsf{DarbouxSum}^{\uparrow}$ *row D to expose the paired lower and upper finite sums through the same refinement route;*
5. *Real-facing Cauchy readiness, requiring the row C and terminal seal E to be reached only after the finite refinement gap has been displayed;*
6. *transport, replay, provenance, and naming, requiring H, K, G, N to preserve and name exactly the same packet.*

No local obligation stores host suprema, selected mesh limits, quotient equality of functions, countable choice, open-cover compactness, or ambient Real completeness.

Proof. Carrier admission is projection from Definition 8838.1. The admitted packet exposes the interval row, source and refined partitions, lower and upper finite sums, the refinement ledger, the Darboux handoff, the Cauchy-readiness row, the Real seal, and the structural rows.

Partition refinement coherence is read from P, Q, M. The row Q is not a second unrelated partition; it is tied to P by the displayed finite cell-incidence map, and M is the only row that compares sum data across that map.

The Darboux handoff is then read through D. Since D sees only the paired finite lower and upper sums over the displayed refinement route, it cannot supply a host supremum, selected mesh limit, or quotient-function comparison.

Finally C, E, H, K, G, N carry the same finite route into a Real-facing Cauchy readback, transport it componentwise, replay the route, record provenance, and name the packet. The excluded host objects have no carrier coordinate, so the listed rows exhaust the local NameCert surface. □

Lean4 ✓ `BEDC.Derived.DarbouxSumRefinementUp.DarbouxSumRefinementCarrier namecert obligations`

Theorem 8838.3 (Darboux-sum refinement Cauchy handoff)**.** *Every Real or Completion consumer of an accepted* $\mathsf{DarbouxSumRefinement}^{\uparrow}$ *carrier reaches its Cauchy-facing read only through the finite route*

$$\mathsf{DyadicPartition}^{\uparrow} \longmapsto \mathsf{DarbouxSum}^{\uparrow} \longmapsto \mathsf{LowerDarbouxSum}^{\uparrow} \longmapsto \mathsf{DarbouxSumRefinement}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}.$$

The consumer first reads the source partition P, the refined partition Q, the paired finite lower and upper rows L, U, the refinement monotonicity ledger M, and the Darboux handoff D; only then may it consume the Cauchy-readiness row C and terminal seal E. It receives no selected limiting partition, no host integral value, no quotient equality of functions, no countable-choice schedule, and no ambient completeness theorem.

Proof. Start with an accepted carrier $R = (I, P, Q, L, U, M, D, C, E, H, K, G, N)$. The carrier definition makes P the source dyadic partition and Q the displayed finite refinement of P.

Read the lower and upper finite rows through L, U and compare them only through M. Thus any refinement claim is a finite ledger over the displayed partition route, not a limiting mesh assertion.

Apply the Darboux handoff row D. It packages the paired finite sums over the common refinement route before a Real-facing consumer can reach the Cauchy-readiness row C.

Finally the terminal seal E is downstream of that route, and H, K, G, N only transport, replay, source, and name the same finite packet. Since the carrier omits selected limiting partitions, host integral values, quotient function equality, countable choice, and ambient completeness, the consumer cannot extract any of those endpoints. □

Lean4 ✓ `BEDC.Derived.DarbouxSumRefinementUp.DarbouxSumRefinementCarrier cauchy handoff`

Falsifiable prediction: Every accepted $\mathsf{DarbouxSumRefinement}^{\uparrow}$ read used by a Real or Completion consumer displays one source DyadicPartitionUp row, one refined DyadicPartitionUp row, lower and upper finite Darboux-sum rows, one refinement monotonicity ledger, one DarbouxSumUp handoff, one Cauchy-readiness row, one RealUp seal, and the structural rows H, K, G, N before it is treated as a Cauchy-facing refinement certificate.

Independence witness: darboux-sum, lower-darboux-sum, dyadic-partition, real: $\mathsf{DarbouxSumRefinement}^{\uparrow}$ is not bijective with any listed sibling because it jointly carries a source partition, a refined partition, the finite cell-incidence map, lower and upper Darboux-sum rows, a refinement monotonicity ledger, Cauchy-readiness data, terminal Real sealing, transport, replay, provenance, and local naming in one packet.

Closure status for $\mathsf{NameCert}_{\mathsf{DarbouxSumRefinement}^{\uparrow}}$.

Constructive story: A $\mathsf{DarbouxSumRefinement}^{\uparrow}$ packet is generated from a RealUp interval row, a source DyadicPartitionUp row, a refined DyadicPartitionUp row with finite cell incidence, lower and upper Darboux-sum rows, a refinement monotonicity ledger, a DarbouxSumUp handoff, Cauchy-readiness data, a RealUp seal, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{DarbouxSumRefinement}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8838.1, Definition 8838.2, and Definition 8838.3 seed the finite refinement route from Darboux sums over dyadic partitions to Real-facing Cauchy handoffs.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{DarbouxSumRefinement}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host suprema or infima, selected limiting meshes, host integral values, quotient equality of functions, open-cover compactness, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean theorem checking, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, partition refinement coherence, lower and upper sum stability, Darboux handoff confinement, Real-facing Cauchy readiness, componentwise transport, displayed replay, provenance, and local naming for BEDC.Derived.DarbouxSumRefinementUp.

Chapter 8839

A Concrete Naming Certificate for $\mathsf{RiemannRoch}^{\uparrow}$

Following Riemann and Roch, the $\mathsf{RiemannRoch}^{\uparrow}$ packet records the finite divisor, line-bundle, genus, and cohomology-dimension surface needed before an algebraic-curve consumer may read the classical balance law. It sits beside the manifold and chart discipline of chapter 96, the sheaf-interface route of chapter 151, the cohomology substrate of chapter 99, the unary index discipline of chapter 28, and the terminal real-name seal of chapter 38. The packet names a displayed Riemann–Roch balance route; it is not a host algebraic-geometry theorem, quotient divisor equality, selected basis of sections, hidden cohomology computation, or ambient completeness principle.

Definition 8839.1 (Riemann–Roch carrier)**.** *A* $\mathsf{RiemannRoch}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$R = (C, D, L, G, H, E, B, T, Q, P, N)$$

with the following displayed rows:

1. *C is the curve-presentation row, exposing the finite chart and overlap data used by the packet.*
2. *D is the divisor row, recording the displayed zeros, poles, and degree ledger read by the balance law.*
3. *L is the line-bundle row attached to the divisor presentation.*
4. *G is the genus row, recorded as a named integer datum rather than as a host classification theorem.*
5. *H is the cohomology-dimension row for the visible section and obstruction counts.*
6. *E is the exactness row that routes the dimension comparison through the displayed finite sequence boundary.*
7. *B is the balance row stating that the section count, obstruction count, divisor degree, and genus data are read in one Riemann–Roch ledger.*
8. *T records componentwise* hsame *transport for curve, divisor, line-bundle, genus, dimension, exactness, balance, replay, provenance, and local naming rows.*
9. *Q records displayed* Cont *replay from a Riemann–Roch request through $C, D, L, G, H, E, B, T, P, N$.*
10. *P is the* Pkg *provenance over* $\mathsf{RiemannRoch}^{\uparrow}$*, the curve, divisor, line-bundle, genus, cohomology-dimension, exactness, integer,* BHist*,* hsame*,* Cont*, and* $\mathsf{NameCert}$ *rows.*

11. N is the local $\mathsf{NameCert}_{\mathsf{RiemannRoch}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $C, D, L, G, H, E, B, T, Q, P, N$. It has no coordinate for quotient divisor equality, a selected basis of global sections, a hidden cohomology engine, an ambient algebraic-curve category, or a host proof of Riemann–Roch.

Theorem 8839.2 (Riemann–Roch NameCert obligations)**.** *For every accepted* $\mathsf{RiemannRoch}^{\uparrow}$ *carrier $R = (C, D, L, G, H, E, B, T, Q, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{RiemannRoch}^{\uparrow}}$ *surface consists exactly of curve-presentation admission, divisor-ledger exposure, line-bundle attachment, genus-row exposure, cohomology-dimension exposure, exactness-boundary exposure, balance-row exposure, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. Every algebraic-geometry consumer must read*

$$C, D, L, G, H, E, B, T, Q, P, N$$

before the Riemann–Roch packet is consumed.

Proof. Project the carrier of Definition 8839.1. The curve, divisor, line-bundle, genus, cohomology-dimension, exactness, and balance data occur only as displayed rows of the same finite packet.

Read the algebraic route in order. The curve row C supplies the presentation, D and L attach the divisor and line-bundle data, and G records the genus datum before any balance row is available.

The dimension row H and exactness row E are then consumed by the balance row B. Transport, replay, provenance, and local naming are the componentwise rows T, Q, P, N.

Since no carrier coordinate stores quotient divisor equality, a selected basis, a hidden cohomology computation, an ambient algebraic-curve category, or a host proof of Riemann–Roch, the listed rows exhaust the local NameCert obligations. □

Falsifiable prediction: Every accepted $\mathsf{RiemannRoch}^{\uparrow}$ read that serves an algebraic-curve consumer must expose curve presentation, divisor ledger, line-bundle attachment, genus row, cohomology-dimension row, exactness boundary, balance row, hsame transport, Cont replay, Pkg provenance, and local NameCert rows before the consumer is served.

Independence witness: manifold, sheaf, exactsequence, integer, real: $\mathsf{RiemannRoch}^{\uparrow}$ is not bijective to any listed sibling because this packet jointly carries curve presentation, divisor ledger, line-bundle attachment, genus data, cohomology-dimension data, exactness, balance, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{RiemannRoch}^{\uparrow}}$.

Constructive story: A $\mathsf{RiemannRoch}^{\uparrow}$ packet is generated from a curve-presentation row, divisor row, line-bundle row, genus row, cohomology-dimension row, exactness row, balance row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{RiemannRoch}^{\uparrow}}$, seed)

Scope closed: Definition 8839.1 and Definition 8839.2 seed the finite Riemann–Roch balance route over curve, divisor, line-bundle, genus, dimension, exactness, transport, replay, provenance, and local naming rows.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{RiemannRoch}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close quotient divisor equality, selected bases of sections, hidden cohomology computation, a host algebraic-geometry theorem, ambient completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked curve admission, divisor-ledger exactness, line-bundle attachment, genus exposure, cohomology-dimension exposure, exactness-boundary exposure, balance-row exactness, transport, replay, provenance, and local naming for BEDC.Derived.RiemannRochUp.

Chapter 8840

A Concrete Naming Certificate for $\mathsf{CompactFiniteRadiiMeet}^{\uparrow}$

The $\mathsf{CompactFiniteRadiiMeet}^{\uparrow}$ packet realizes the finite ProbeBundle lower-bound fold in the compact-uniform-continuity vision of chapter 9237. It sits after the compact metric source of chapter 129, the continuous-map rows of chapter 130, the ProbeBundle cover fold of chapter 7452, the rational carrier of chapter 37, and the uniform-modulus consumer of chapter 369. The packet names the finite positive-radius meet used by the compact-uniform route; it is not a selected Lebesgue number, host finite minimum theorem, open-cover compactness principle, countable choice schedule, or ambient $\mathsf{Real}^{\uparrow}$ completeness claim.

Definition 8840.1 (Compact finite radii meet carrier)**.** *A* $\mathsf{CompactFiniteRadiiMeet}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M = (K, F, B, R, L, U, H, C, P, N)$$

with the following displayed rows:

1. *K is the* $\mathsf{CompactMetric}^{\uparrow}$ *source row exposing the compact finite-net data used by the fold.*
2. *F is the* $\mathsf{ContinuousMap}^{\uparrow}$ *pointwise-continuity row supplying local positive radii for the inspected centers.*
3. *B is the* $\mathsf{ProbeBundle}^{\uparrow}$ *finite-bundle row listing the centers and local radius entries consumed by the meet.*
4. *R is the* $\mathsf{Rat}^{\uparrow}$ *positivity row for the local radii and the requested output tolerance.*
5. *L is the finite lower-bound fold row, recording the displayed meet of the positive rational radii in B.*
6. *U is the* $\mathsf{UniformModulus}^{\uparrow}$ *handoff row obtained only after K, F, B, R, L have been displayed.*
7. *H records componentwise* hsame *transport for compact-source, continuous-map, bundle, rational, meet, handoff, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from a compact-uniform request through $K, F, B, R, L, U, H, P, N$.*
9. *P is the* Pkg *provenance over* $\mathsf{CompactFiniteRadiiMeet}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{ProbeBundle}^{\uparrow}$, $\mathsf{Rat}^{\uparrow}$, $\mathsf{UniformModulus}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{CompactFiniteRadiiMeet}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $K, F, B, R, L, U, H, C, P, N$. It has no coordinate for an external minimum operator, selected Lebesgue number, hidden open cover, infinite radius family, choice schedule, or ambient completeness principle.

Theorem 8840.2 (Compact finite radii meet NameCert obligations)**.** *For every accepted* $\mathsf{CompactFiniteRadiiMeet}^{\uparrow}$ *carrier* $M = (K, F, B, R, L, U, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{CompactFiniteRadiiMeet}^{\uparrow}}$ *surface consists exactly of compact-source admission, continuous-map local-radius exposure, finite ProbeBundle exposure, rational-positivity exposure, finite lower-bound meet exposure, UniformModulus handoff, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. Every compact-uniform consumer must read*

$$K, F, B, R, L, U, H, C, P, N$$

before it can consume the finite meet as a uniform-modulus datum.

Proof. Project the carrier of Definition 8840.1. The compact source, pointwise map rows, finite bundle, rational positivity, lower-bound meet, and uniform-modulus handoff are all displayed coordinates of the accepted packet.

The finite meet route is ordered. The compact row K supplies the finite-net source, F supplies local radii at the inspected centers, B lists exactly the bundled entries, and R records their positive rational status.

Only after those rows are visible may the fold row L be read. The handoff row U then exports the result to a uniform-modulus consumer, while H, C, P, N preserve the same route under transport, replay, provenance, and local naming.

Since the carrier contains no external minimum operator, selected Lebesgue number, hidden open cover, infinite radius family, choice schedule, or ambient completeness object, the listed rows exhaust the local NameCert obligations. □

Falsifiable prediction: Every accepted $\mathsf{CompactFiniteRadiiMeet}^{\uparrow}$ read that serves a compact-uniform consumer must expose compact-source rows, continuous-map local-radius rows, finite ProbeBundle rows, RatUp positivity rows, a finite lower-bound meet row, a UniformModulus handoff, hsame transport, Cont replay, Pkg provenance, and local NameCert rows before the consumer is served.

Independence witness: compactmetric, continuousmap, probe-bundle-cover-fold, rat, uniform-modulus: $\mathsf{CompactFiniteRadiiMeet}^{\uparrow}$ is not bijective to any listed sibling because this packet binds compact finite-net data, pointwise local radii, a finite ProbeBundle, rational positivity, a lower-bound meet, UniformModulus handoff, transport, replay, provenance, and local naming into one compact-uniform fold carrier.

Closure status for $\mathsf{NameCert}_{\mathsf{CompactFiniteRadiiMeet}^{\uparrow}}$**.**

Constructive story: A $\mathsf{CompactFiniteRadiiMeet}^{\uparrow}$ packet is generated from compact metric source rows, continuous-map local-radius rows, a finite ProbeBundle row, rational positivity rows, a finite lower-bound meet row, a UniformModulus handoff row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{CompactFiniteRadiiMeet}^{\uparrow}}$, seed)

Scope closed: Definition 8840.1 and Definition 8840.2 seed the finite positive-radius meet used by compact-uniform-continuity lower-bound folds.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{CompactFiniteRadiiMeet}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close selected Lebesgue numbers, host finite minima, hidden open-cover compactness, countable choice, ambient RealUp completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked compact-source admission, local-radius exposure, finite ProbeBundle coverage, rational-positivity exactness, finite meet exactness, UniformModulus handoff, transport, replay, provenance, and local naming for BEDC.Derived.CompactFiniteRadiiMeetUp.

Chapter 8841

A Concrete Naming Certificate for $\mathsf{CompactOperatorSpectrum}^{\uparrow}$

Following Riesz and Schauder compact-operator spectral theory, the $\mathsf{CompactOperatorSpectrum}^{\uparrow}$ packet records the finite BEDC route by which compact-operator spectral reads are routed through displayed Banach, bounded-linear-operator, compact-operator, spectral-radius, and Fredholm-alternative certificates. It sits over the Banach carrier of chapter 90, the bounded operator row of chapter 1644, the compactness route of chapter 1952, the radius ledger of chapter 2352, and the Fredholm alternative surface of chapter 3425. The chapter names the finite spectral-route interface only; it does not close host spectra, selected eigenbases, quotient operator algebras, closed-range complements, or analytic Fredholm theory.

Definition 8841.1 (Compact-operator spectrum carrier)**.** *A* $\mathsf{CompactOperatorSpectrum}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (B, L, K, R, F, H, C, P, N)$$

with the following displayed rows:

1. *B is the* $\mathsf{Banach}^{\uparrow}$ *source row naming the ambient complete normed carrier used by the operator read.*
2. *L is the* $\mathsf{BoundedLinearOperator}^{\uparrow}$ *row naming the bounded operator action and its displayed norm control.*
3. *K is the* $\mathsf{CompactOperator}^{\uparrow}$ *row naming the compact-image or finite-approximation surface for the same operator.*
4. *R is the* $\mathsf{SpectralRadius}^{\uparrow}$ *ledger row recording the finite radius comparison data consumed by spectral-route readers.*
5. *F is the* $\mathsf{FredholmAlternative}^{\uparrow}$ *route row recording the kernel-range and alternative-facing readbacks available to downstream consumers.*
6. *H records componentwise* hsame *transport for Banach, bounded-operator, compact-operator, spectral-radius, Fredholm-route, replay, provenance, and local naming rows.*
7. *C records displayed* Cont *replay of the route*

$$B, L, K, R \longmapsto F.$$

8. *P is the* Pkg *provenance over* $\mathsf{CompactOperatorSpectrum}^{\uparrow}$, $\mathsf{Banach}^{\uparrow}$, $\mathsf{BoundedLinearOperator}^{\uparrow}$, $\mathsf{CompactOperator}^{\uparrow}$, $\mathsf{SpectralRadius}^{\uparrow}$, $\mathsf{FredholmAlternative}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
9. *N is the local* $\mathsf{NameCert}_{\mathsf{CompactOperatorSpectrum}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $B, L, K, R, F, H, C, P, N$. It has no coordinate for a host spectrum, an eigenbasis selector, a quotient operator algebra, a closed-range complement, or an analytic Fredholm theorem.

Theorem 8841.2 (Compact-operator spectrum NameCert obligations)**.** *For every accepted* CompactOperatorSpect *carrier*

$$S = (B, L, K, R, F, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{CompactOperatorSpectrum}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the displayed Banach source, bounded-linear-operator row, compact-operator row, spectral-radius ledger, Fredholm-route row, transport, replay, provenance, and local naming rows;*
2. *Banach-source exposure, requiring every operator read to cite the same* $\mathsf{Banach}^{\uparrow}$ *row B before the bounded action is consumed;*
3. *bounded-action exactness, requiring every operator application and norm-control read to pass through the* $\mathsf{BoundedLinearOperator}^{\uparrow}$ *row L;*
4. *compactness exposure, requiring spectral-route consumers to use the displayed* $\mathsf{CompactOperator}^{\uparrow}$ *row K rather than a host compactness predicate;*
5. *radius-ledger exactness, requiring every spectral-radius comparison to read the* $\mathsf{SpectralRadius}^{\uparrow}$ *row R;*
6. *Fredholm-route nonescape, requiring the* $\mathsf{FredholmAlternative}^{\uparrow}$ *row F to be consumed only after B, L, K, R have been displayed;*
7. *componentwise transport, continuation replay, package provenance, and local naming through H, C, P, N.*

No obligation is discharged by host spectra, selected eigenbases, quotient operator algebras, closed-range complements, or analytic Fredholm theory.

Proof. Project the accepted carrier $S = (B, L, K, R, F, H, C, P, N)$. The visible rows are exactly the Banach source, bounded operator, compact-operator route, spectral-radius ledger, Fredholm-route row, transport, replay, provenance, and local naming data.

The first operator-facing reads are forced through B and L. A consumer has no independent bounded action unless it first cites the displayed Banach row and the bounded-linear-operator row.

The compact spectral route is then forced through K and R. The compact-operator row supplies the finite compactness surface, while the spectral-radius row supplies the radius comparison ledger.

Finally F is downstream from those rows, and H, C, P, N preserve, replay, source, and name the same finite packet. Since no excluded host object is a coordinate of S, the listed rows exhaust the local NameCert surface. □

Theorem 8841.3 (Compact-operator spectrum Fredholm route)**.** *Every Fredholm-facing consumer of an accepted* $\mathsf{CompactOperatorSpectrum}^{\uparrow}$ *packet reads the finite route*

$$\mathsf{Banach}^{\uparrow} \longmapsto \mathsf{BoundedLinearOperator}^{\uparrow} \longmapsto \mathsf{CompactOperator}^{\uparrow} \longmapsto \mathsf{SpectralRadius}^{\uparrow} \longmapsto \mathsf{FredholmAlternative}^{\uparrow}.$$

The route supplies a displayed compact-operator spectral interface over finite carrier rows; it does not select eigenbases, construct quotient operator algebras, choose closed-range complements, compute host spectra, or invoke analytic Fredholm theory.

Proof. Start with the obligation theorem Definition 8841.2. It places the Banach row B, bounded-linear-operator row L, compact-operator row K, and spectral-radius ledger R before the Fredholm route F.

The sibling certificates provide the stated handoff surface. The Banach chapter supplies the source carrier, the bounded-linear-operator chapter supplies the action row, the compact-operator chapter supplies compactness exposure, and the spectral-radius chapter supplies finite comparison data.

The FredholmAlternative consumer then reads only the displayed route row F. Transport, replay, provenance, and local naming preserve the same packet, so the Fredholm-facing surface receives the finite compact-operator spectral interface and none of the excluded analytic endpoints. □

Falsifiable prediction: A $\mathsf{CompactOperatorSpectrum}^{\uparrow}$ consumer that reaches a Fredholm-facing spectral read without displaying the Banach source, bounded-linear-operator action, compact-operator row, spectral-radius ledger, Fredholm-route row, transport, replay, provenance, and local naming exits the accepted carrier.

Independence witness: banach, bounded-linear-operator, compact-operator, spectral-radius, fredholm-alternative: no listed sibling is bijective with $\mathsf{CompactOperatorSpectrum}^{\uparrow}$ because this packet jointly binds Banach source, bounded action, compactness exposure, spectral-radius comparison, Fredholm route, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{CompactOperatorSpectrum}^{\uparrow}}$.

Constructive story: A $\mathsf{CompactOperatorSpectrum}^{\uparrow}$ packet is generated from a Banach source row, BoundedLinearOperator action row, CompactOperator compactness row, SpectralRadius comparison ledger, FredholmAlternative route row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CompactOperatorSpectrum}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8841.1, Definition 8841.2, and Definition 8841.3 seed the finite compact-operator spectral route over displayed Banach, bounded-operator, compact-operator, spectral-radius, Fredholm, transport, replay, provenance, and naming rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CompactOperatorSpectrum}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close Lean verification, bridge checking, host spectra, selected eigenbases, quotient operator algebras, closed-range complements, or analytic Fredholm theory.

Upgrade path: Obligation closure requires checked carrier admission, Banach-source exposure, bounded-action exactness, compactness exposure, spectral-radius exactness, Fredholm-route nonescape, transport, replay, provenance, and local naming for BEDC.Derived.CompactOperatorSpectrumUp.

Chapter 8842

A Concrete Naming Certificate for $\mathsf{UniformCauchyFilterCompletionFunctor}^{\uparrow}$

Following Bishop–Bridges constructive completion and Kelley's filter presentation of uniform spaces, the $\mathsf{UniformCauchyFilterCompletionFunctor}^{\uparrow}$ packet names the finite handoff from uniform Cauchy-filter data to the current Real completion route. It sits after the uniform Cauchy-filter surface of chapter 1694, the Cauchy-filter root of chapter 333, the uniform-completion boundary of chapter 1473, the stream window surface of chapter 126, the regular rational readback of chapter 301, the dyadic tolerance ledger of chapter 291, and the terminal Real seal of chapter 38. The packet is a finite functorial routing surface; it is not a quotient of filters, a selected limit, countable choice, or an ambient completeness principle for $\mathsf{Real}^{\uparrow}$.

Definition 8842.1 (Uniform Cauchy-filter completion functor carrier)**.** *A* $\mathsf{UniformCauchyFilterCompletionFunctor}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$F = (U, C, E, S, R, D, L, H, K, P, N)$$

with the following displayed rows:

1. *U is the* $\mathsf{UniformCauchyFilter}^{\uparrow}$ *source row, exposing the uniform-space, filter-base, entourage-Cauchy, stream-window, regular-rational, and completion-handoff surface.*
2. *C is the* $\mathsf{CauchyFilter}^{\uparrow}$ *root row that records the underlying filter route before any completion-facing consumer reads a Real seal.*
3. *E is the* $\mathsf{UniformCompletion}^{\uparrow}$ *handoff row, read only after U and C have exposed their finite Cauchy-filter rows.*
4. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row attached to the completion request.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *regular rational readback row for the same displayed windows.*
6. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger for entourage requests, window budgets, and regular readback comparisons.*
7. *L is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached only after S, R, D have been displayed.*
8. *H records componentwise* hsame *transport for the uniform-filter, root-filter, uniform-completion, stream, readback, dyadic, Real-seal, replay, provenance, and local naming rows.*
9. *K records displayed* Cont *replay from a uniform Cauchy-filter request through U, C, E, S, R, D, L, H.*

10. *P is the* Pkg *provenance over* UniformCauchyFilterCompletionFunctor$^{\uparrow}$, UniformCauchyFilter$^{\uparrow}$, CauchyFilter$^{\uparrow}$, UniformCompletion$^{\uparrow}$, StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, Real$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* NameCert$_{\text{UniformCauchyFilterCompletionFunctor}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through $U, C, E, S, R, D, L, H, K, P, N$. It has no coordinate for quotient-filter representatives, selected completion limits, host real equality, countable-choice schedules, hidden choice of subnet, or ambient Real$^{\uparrow}$ *completeness.*

Theorem 8842.2 (Uniform Cauchy-filter completion functor obligations)**.** *For every accepted* UniformCauchyFilterCompletionFunctor$^{\uparrow}$ *carrier*

$$F = (U, C, E, S, R, D, L, H, K, P, N),$$

the local NameCert$_{\text{UniformCauchyFilterCompletionFunctor}^{\uparrow}}$ *surface consists exactly of uniform Cauchy-filter admission through U, root Cauchy-filter admission through C, uniform-completion handoff through E, finite window exposure through S, regular rational readback through R, dyadic tolerance accounting through D, terminal Real sealing through L, componentwise transport through H, displayed replay through K, provenance through P, and local naming through N.*

Proof. Project the carrier of Definition 8842.1. The accepted packet exposes exactly the rows $U, C, E, S, R, D, L, H, K, P, N$.

The filter-facing part is forced through U and C. These rows display the uniform Cauchy-filter route and the root Cauchy-filter route before the uniform-completion handoff E is available.

The Real-facing part is then forced through S, R, D, L. Stream windows are read first, regular rational data are read from those windows, dyadic tolerances account for the comparison budgets, and the Real seal appears only after those finite rows are present.

Finally H, K, P, N transport, replay, source, and name the same packet. Since the carrier has no row for quotient-filter representatives, selected limits, host equality, choice schedules, hidden subnets, or ambient completeness, the listed rows exhaust the local NameCert surface. □

Theorem 8842.3 (Uniform Cauchy-filter completion functor Real route)**.** *Every Real-facing completion consumer of an accepted* UniformCauchyFilterCompletionFunctor$^{\uparrow}$ *packet factors through*

UniformCauchyFilter$^{\uparrow}$, CauchyFilter$^{\uparrow}$, UniformCompletion$^{\uparrow}$, StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, Real$^{\uparrow}$.

The route converts uniform Cauchy-filter data into the current Real completion boundary by finite window readback and dyadic tolerance accounting. It exports no quotient filter, selected limit, countable-choice selector, hidden subnet, host real equality, or ambient completeness theorem.

Proof. Use Definition 8842.2. It places the uniform Cauchy-filter row, the root Cauchy-filter row, and the uniform-completion handoff before any Real-facing seal is visible.

Read the finite numeric part next. The StreamName row S, RegSeqRat row R, and DyadicRatCore row D are the only rows from which the completion request obtains a regular Real readback.

The terminal row L is therefore downstream of the displayed filter, completion, window, readback, and tolerance rows. Transport, replay, provenance, and local naming through H, K, P, N preserve the same route.

Thus every Real-facing completion consumer factors through the displayed finite functorial handoff and cannot extract a quotient filter, selected limit, choice selector, hidden subnet, host equality, or ambient completeness claim. □

Falsifiable prediction: An accepted $\mathsf{UniformCauchyFilterCompletionFunctor}^{\uparrow}$ consumer that reaches a $\mathsf{Real}^{\uparrow}$ seal without reading the displayed $\mathsf{UniformCauchyFilter}^{\uparrow}$, $\mathsf{CauchyFilter}^{\uparrow}$, $\mathsf{UniformCompletion}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, transport, replay, provenance, and local NameCert rows refutes the carrier surface.

Independence witness: uniform-cauchy-filter, cauchyfilter, uniformcompletion, streamname, regseqrat, dyadicratcore, real: $\mathsf{UniformCauchyFilterCompletionFunctor}^{\uparrow}$ is not bijective to any listed sibling because it binds the uniform Cauchy-filter source, root Cauchy-filter route, uniform-completion handoff, finite stream windows, regular rational readback, dyadic tolerances, Real sealing, transport, replay, provenance, and local naming as one functorial completion handoff.

Closure status for $\mathsf{NameCert}_{\mathsf{UniformCauchyFilterCompletionFunctor}^{\uparrow}}$.

Constructive story: A $\mathsf{UniformCauchyFilterCompletionFunctor}^{\uparrow}$ packet is generated from UniformCauchyFilter rows, CauchyFilter root rows, UniformCompletion handoff rows, StreamName windows, RegSeqRat readback, a DyadicRatCore tolerance ledger, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{UniformCauchyFilterCompletionFunctor}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8842.1, Definition 8842.2, and Definition 8842.3 seed the finite route from uniform Cauchy-filter data to the Real completion boundary.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{UniformCauchyFilterCompletionFunctor}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient filters, selected limits, countable-choice selectors, hidden subnets, host real equality, ambient RealUp completeness, Lean theorem checking, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, uniform Cauchy-filter exposure, root Cauchy-filter routing, uniform-completion handoff, finite window readback, dyadic tolerance accounting, Real seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.UniformCauchyFilterCompletionFunctorUp.

Chapter 8843

A Concrete Naming Certificate for $\mathsf{MellinTransform}^{\uparrow}$

Following Mellin and Titchmarsh, the $\mathsf{MellinTransform}^{\uparrow}$ packet records the finite positive-real source, integrand-window, Gamma handoff, Real-seal, transport, replay, provenance, and local naming rows needed before an analytic consumer may read the classical transform route. It sits above the real-name seal of chapter 38, the stream schedule discipline of chapter 126, the regular rational readback of chapter 301, and the Gamma interface of chapter 75. The analytic motivation is the Gamma bridge of section 9358.7; this packet names the transform-facing finite data without importing host function equality, measure-theoretic choice, or an ambient integral object.

Definition 8843.1 (Mellin transform carrier)**.** *A* $\mathsf{MellinTransform}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M = (S, W, I, G, R, T, C, P, N)$$

with the following displayed rows:

1. *S is the positive-real source row, exposing the* $\mathsf{Real}^{\uparrow}$ *domain name and the apartness-from-zero ledger used by the transform request.*
2. *W is the integrand-window row, recording the finite* $\mathsf{StreamName}^{\uparrow}$ *schedule of sampled positive-real windows.*
3. *I is the regular-integrand row, read through* $\mathsf{RegSeqRat}^{\uparrow}$ *endpoints and dyadic tolerance ledgers on the displayed windows.*
4. *G is the Gamma-handoff row, naming the* $\mathsf{Gamma}^{\uparrow}$ *boundary data consumed by the transform-facing branch.*
5. *R is the Real-seal row that repacks accepted window sums as a* $\mathsf{Real}^{\uparrow}$ *output name.*
6. *T records componentwise* hsame *transport for source, window, integrand, Gamma handoff, Real seal, replay, provenance, and local naming rows.*
7. *C records displayed* Cont *replay from a Mellin-transform request through S, W, I, G, R, T, P, N.*
8. *P is the* Pkg *provenance over* $\mathsf{MellinTransform}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Gamma}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$ *rows.*
9. *N is the local* $\mathsf{NameCert}_{\mathsf{MellinTransform}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $S, W, I, G, R, T, C, P, N$. It has no coordinate for host function equality, selected measurable representatives, a Lebesgue integral, quotient stream equality, countable choice, or an ambient analytic completion.

Theorem 8843.2 (Mellin transform NameCert obligations)**.** *For every accepted* $\mathsf{MellinTransform}^{\uparrow}$ *carrier* $M = (S, W, I, G, R, T, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{MellinTransform}^{\uparrow}}$ *surface consists exactly of positive-real source exposure, integrand-window exposure, regular-integrand readback, Gamma-handoff exposure, Real-seal output exposure, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. Every transform consumer must read*

$$S, W, I, G, R, T, C, P, N$$

before the packet is consumed.

Proof. Project the carrier of Definition 8843.1. The source, window, integrand, Gamma handoff, and Real seal data occur only as displayed rows of the same finite packet.

The route first reads the positive-real source S and the finite schedule W. The regular-integrand row I then supplies the $\mathsf{RegSeqRat}^{\uparrow}$ readbacks on those windows, while G records the Gamma-facing boundary that the analytic spine may consume.

The Real-seal row R is downstream of S, W, I, G. Transport, replay, provenance, and local naming are the componentwise rows T, C, P, N.

Since no carrier coordinate stores host function equality, measurable representatives, a Lebesgue integral, quotient stream equality, countable choice, or ambient analytic completion, the listed rows exhaust the local NameCert obligations. □

Theorem 8843.3 (Mellin transform Gamma handoff)**.** *An accepted* $\mathsf{MellinTransform}^{\uparrow}$ *packet can hand data to the Gamma bridge only through the displayed Gamma row G together with the positive-real source row S, integrand-window row W, regular-integrand row I, and Real-seal row R. The handoff does not create a meromorphic black box, a hidden integral, or a selected analytic representative outside the finite carrier.*

Proof. Use the NameCert obligations of Definition 8843.2. They force every consumer to expose S, W, I, G, R before the transform packet is usable.

The Gamma row G is only a handoff row. It names the Gamma-facing boundary already isolated in section 9358.7, and its inputs remain the positive-real source, finite integrand windows, regular-rational readbacks, and Real seal displayed by this packet.

No additional analytic object is available to project from the carrier. Therefore the handoff is exactly the finite route through $S, W, I, G, R, T, C, P, N$ and not a hidden integral or selected representative. □

Falsifiable prediction: A MellinTransformUp packet whose Gamma handoff is read without the displayed positive-real source, integrand-window, regular-integrand, and Real-seal rows fails local NameCert consumption.

Independence witness: gamma, real, stream-name, regseqrat, gamma-zeta-factor-seal: $\mathsf{MellinTransform}^{\uparrow}$ is not bijective to any listed sibling because this packet jointly carries positive-real source exposure, integrand windows, regular-rational readback, Gamma handoff, Real seal, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{MellinTransform}^{\uparrow}}$**.**

Constructive story: A MellinTransform$^{\uparrow}$ packet is generated from a positive-real source row, finite integrand-window row, regular-integrand readback row, Gamma handoff row, Real-seal row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\mathsf{MellinTransform}\uparrow}$, seed)

Scope closed: Definition 8843.1, Definition 8843.2, and Definition 8843.3 seed the finite Mellin-transform route over source, window, integrand, Gamma handoff, Real seal, transport, replay, provenance, and local naming rows.

Formal verification: FormalStatus(NameCert$_{\mathsf{MellinTransform}\uparrow}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close host function equality, measure-theoretic choice, a Lebesgue integral, meromorphic continuation, quotient stream equality, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked source admission, integrand-window exactness, regular-integrand readback, Gamma-handoff exactness, Real-seal exactness, transport, replay, provenance, and local naming for BEDC.Derived.MellinTransformU

Chapter 8844

A Concrete Naming Certificate for $\mathsf{VariationModulus}^{\uparrow}$

Following Jordan and Bishop–Bridges on bounded variation and regulated functions, the $\mathsf{VariationModulus}^{\uparrow}$ packet records a finite partition-modulus ledger for oscillation and Darboux-sum control. It sits after the bounded-variation surface of chapter 398, the regulated-function carrier of chapter 1906, the Darboux refinement packet of chapter 8838, the dyadic arithmetic core of chapter 291, the regular-rational readback route of chapter 301, and the terminal real-name seal of chapter 38. The packet names only displayed finite partitions, oscillation budgets, variation bounds, refinement reads, transport, replay, provenance, and local naming rows; it does not import host supremum variation, measure theory, quotient equality of functions, selected mesh limits, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 8844.1 (VariationModulus carrier)**.** *A* $\mathsf{VariationModulus}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$V = (I, F, P, O, B, D, Q, R, E, H, C, S, N)$$

with the following displayed rows:

1. *I is the interval-source row, sealed as a displayed* $\mathsf{Real}^{\uparrow}$ *interval endpoint ledger.*
2. *F is the* $\mathsf{RegulatedFunction}^{\uparrow}$ *source row whose inspected values are read through finite windows.*
3. *P is the finite partition row, listing ordered subinterval cells with dyadic endpoint data supplied by* $\mathsf{DyadicRatCore}^{\uparrow}$*.*
4. *O is the oscillation-bound row, assigning a regular-rational bound to each displayed partition cell.*
5. *B is the* $\mathsf{BoundedVariation}^{\uparrow}$ *control row, recording the finite variation budget used by the same cells.*
6. *D is the* $\mathsf{DarbouxSumRefinement}^{\uparrow}$ *handoff row, naming how the partition and oscillation rows are consumed by upper/lower Darboux-sum refinement.*
7. *Q is the partition-modulus row, recording the finite rule that refines a requested tolerance into a displayed partition and cellwise oscillation budget.*
8. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the tolerance, oscillation, variation, and Darboux comparison data.*

9. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row, available only after I, F, P, O, B, D, Q, R have remained visible.*
10. *H records componentwise* hsame *transport for the interval, function, partition, oscillation, variation, Darboux, modulus, readback, real seal, replay, provenance, and local naming rows.*
11. *C records displayed* Cont *replay from a regulated-function or Darboux consumer request through the same finite route.*
12. *S is the* Pkg *provenance over* $\mathsf{VariationModulus}^{\uparrow}$, $\mathsf{BoundedVariation}^{\uparrow}$, $\mathsf{RegulatedFunction}^{\uparrow}$, $\mathsf{DarbouxSumRefinement}$ $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*
13. *N is the local* $\mathsf{NameCert}_{\mathsf{VariationModulus}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $I, F, P, O, B, D, Q, R, E, H, C, S, N$. It has no coordinate for host total variation as a supremum, measure-theoretic variation, selected limiting partitions, quotient equality of functions, countable choice, or ambient real completeness.

Theorem 8844.2 (VariationModulus NameCert obligations)**.** *For every accepted* $\mathsf{VariationModulus}^{\uparrow}$ *carrier*

$$V = (I, F, P, O, B, D, Q, R, E, H, C, S, N),$$

the local $\mathsf{NameCert}_{\mathsf{VariationModulus}^{\uparrow}}$ *surface consists exactly of carrier admission, finite partition exposure, cellwise oscillation-bound exposure, regulated-function source visibility, bounded-variation budget visibility, Darboux-sum refinement handoff, dyadic endpoint exactness, regular-rational readback, terminal* $\mathsf{Real}^{\uparrow}$ *sealing, componentwise transport, displayed replay, package provenance, and local naming. Every Darboux or regulated-function consumer must read the finite route*

$$I, F, P, O, B, D, Q, R \longmapsto E, H, C, S, N$$

before treating a partition-modulus estimate as public.

Proof. Project the accepted carrier of Definition 8844.1. The interval, regulated-function, partition, oscillation, variation, Darboux, modulus, and readback rows are displayed before the structural rows can be consumed.

The partition and endpoint data are finite. The row P lists the cells and reads their dyadic endpoints through $\mathsf{DyadicRatCore}^{\uparrow}$, while Q records how a requested tolerance selects the displayed partition-modulus row without selecting a limiting mesh.

The analytic estimates are also finite rows. The oscillation row O and bounded-variation row B provide the cellwise control, and the Darboux row D is the only route by which upper/lower refinement consumers may use those controls.

Finally R, E, H, C, S, N read back, seal, transport, replay, source, and name exactly the displayed route. Since the carrier has no coordinate for host supremum variation, measure-theoretic variation, quotient function equality, selected limits, countable choice, or ambient completeness, those principles are not exported by the local certificate. □

Theorem 8844.3 (VariationModulus Darboux-regulated handoff)**.** *Every* $\mathsf{DarbouxSumRefinement}^{\uparrow}$ *or* $\mathsf{RegulatedFunction}^{\uparrow}$ *consumer of an accepted* $\mathsf{VariationModulus}^{\uparrow}$ *packet receives only the displayed partition row, oscillation-bound row, bounded-variation row, partition-modulus row, dyadic endpoint row, regular-rational readback row, terminal* $\mathsf{Real}^{\uparrow}$ *seal, transport, replay, provenance, and local naming data. The handoff may refine Darboux sums and regulated-function windows through those rows, but it exports no host supremum variation, measure-completion object, selected limiting partition, quotient equality of functions, or countable-choice schedule.*

Proof. Start with Definition 8844.2. A Darboux-facing consumer must read P, O, B, D, Q before a refinement estimate is available, while a regulated-function consumer must also keep the source row F visible.

The dyadic and regular-rational rows fix the arithmetic boundary of the packet. Endpoint and tolerance data pass through $\mathsf{DyadicRatCore}^{\uparrow}$ and $\mathsf{RegSeqRat}^{\uparrow}$ before the terminal $\mathsf{Real}^{\uparrow}$ seal is read.

The structural rows H, C, S, N preserve this same finite route under transport, replay, provenance, and local naming. No excluded host principle appears among the carrier coordinates, so every public handoff remains a finite partition-modulus handoff. □

Falsifiable prediction: An accepted $\mathsf{VariationModulus}^{\uparrow}$ consumer is refuted if it reaches a Darboux or regulated-function estimate without displaying the finite partition row, oscillation-bound row, bounded-variation row, partition-modulus row, dyadic endpoint row, regular-rational readback row, terminal RealUp seal, transport, replay, provenance, and local naming rows.

Independence witness: boundedvariation, regulated-function, darboux-sum-refinement, dyadicratcore, regseqrat, real: none is bijective to $\mathsf{VariationModulus}^{\uparrow}$ because this packet jointly carries a finite partition-modulus ledger, oscillation budgets, bounded-variation control, Darboux refinement, dyadic endpoint arithmetic, regular-rational readback, Real seal, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{VariationModulus}^{\uparrow}}$.

Constructive story: A $\mathsf{VariationModulus}^{\uparrow}$ packet is generated from displayed Real interval rows, RegulatedFunction source rows, finite partition rows, oscillation-bound rows, BoundedVariation budget rows, DarbouxSumRefinement handoff rows, DyadicRatCore endpoint rows, RegSeqRat readback rows, RealUp seal rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{VariationModulus}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8844.1, Definition 8844.2, and Definition 8844.3 seed the finite partition-modulus route for Darboux and regulated-function consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{VariationModulus}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim host supremum variation, measure-theoretic variation, selected limiting partitions, quotient equality of functions, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, finite partition exactness, oscillation-bound exposure, regulated-function source visibility, bounded-variation budget visibility, Darboux refinement handoff, dyadic endpoint exactness, regular-rational readback, Real seal non-escape, transport, replay, provenance, and local naming for BEDC.Derived.VariationModulusUp.

Chapter 8845

A Concrete Naming Certificate for $\mathsf{TsirelsonSpace}^{\uparrow}$

Following Tsirelson's construction of the first Banach space containing no isomorphic copy of ℓ_p or c_0, the $\mathsf{TsirelsonSpace}^{\uparrow}$ packet records the finite BEDC surface on which the classical recursive norm can be inspected before any separation theorem is claimed. It sits after the vector-space carrier of chapter 47, the normed-space surface of chapter 1950, the Banach handoff of chapter 90, the regular rational readback of chapter 301, and the terminal real-name seal of chapter 38. The packet is adjacent to the Banach–Saks route of chapter 7116, but it does not prove reflexivity separation, an infinite basis theorem, or exclusion of classical sequence spaces.

Definition 8845.1 (TsirelsonSpace carrier)**.** *A* $\mathsf{TsirelsonSpace}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$T = (B, N, V, R, Q, A, S, H, C, P, L)$$

with the following displayed rows:

1. *B is a finite basis-block window, carrying inspected block supports, admissible block order, and the finite coefficient rows used in the recursive norm read.*
2. *N is the recursive norm-budget window, recording the visible stage, the admissible averaging budget, and the remaining tolerance after each block read.*
3. *V is the* $\mathsf{VecSpace}^{\uparrow}$ *handoff row for the finitely supported vector operations exposed by B.*
4. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the rational coefficient and tolerance schedules consumed by the norm budget.*
5. *Q is the* $\mathsf{NormedSpace}^{\uparrow}$ *handoff row, exposing the displayed norm value, triangle-budget row, scalar-budget row, and zero-vector row.*
6. *A is the* $\mathsf{Banach}^{\uparrow}$ *handoff row, recording the completion-facing Cauchy budget that may be read only after B, N, V, R, Q are present.*
7. *S is the* $\mathsf{Real}^{\uparrow}$ *seal row for the norm values and Cauchy-budget endpoints.*
8. *H records componentwise* hsame *transport for B, N, V, R, Q, A, S and for the structural rows of the packet.*
9. *C records displayed* Cont *replay for basis-window inspection, recursive norm-budget replay, vector-space handoff, normed-space handoff, Banach handoff, and Real seal delivery.*

10. *P is the* Pkg *provenance over* $\mathsf{TsirelsonSpace}^{\uparrow}$, $\mathsf{VecSpace}^{\uparrow}$, $\mathsf{NormedSpace}^{\uparrow}$, $\mathsf{Banach}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{BanachSaks}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*

11. *L is the local* $\mathsf{NameCert}_{\mathsf{TsirelsonSpace}^{\uparrow}}$ *row.*

The local classifier compares accepted packets only through $B, N, V, R, Q, A, S, H, C, P, L$.

Theorem 8845.2 (TsirelsonSpace NameCert obligation surface)**.** *For every accepted* $\mathsf{TsirelsonSpace}^{\uparrow}$ *carrier*

$$T = (B, N, V, R, Q, A, S, H, C, P, L),$$

the local $\mathsf{NameCert}_{\mathsf{TsirelsonSpace}^{\uparrow}}$ *surface consists exactly of finite basis-block admission through B, recursive norm-budget admission through N,* $\mathsf{VecSpace}^{\uparrow}$ *handoff through V,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback through R,* $\mathsf{NormedSpace}^{\uparrow}$ *handoff through Q,* $\mathsf{Banach}^{\uparrow}$ *handoff through A,* $\mathsf{Real}^{\uparrow}$ *seal delivery through S, componentwise* hsame *transport through H, displayed* Cont *replay through C, provenance through P, and local naming through L. It exports no reflexivity separation theorem, no infinite basis theorem, no copy-exclusion theorem for ℓ_p or c_0, no host completion, no selected infinite block branch, and no ambient compactness principle.*

Proof. Project the carrier rows from Definition 8845.1. The finite basis-block row B and recursive norm-budget row N are the only rows carrying the Tsirelson-specific norm inspection.

Read the algebraic and analytic handoffs in order. The vector-space operations pass through V, the rational schedules pass through R, and the normed-space obligations pass through Q before any Banach-facing row A or Real seal S is available.

The structural rows H, C, P, L transport, replay, source, and name the same finite packet. Since no coordinate contains reflexivity separation, an infinite basis theorem, copy-exclusion data for ℓ_p or c_0, a selected infinite branch, or a host completion object, none is exported by the local NameCert. □

Closure status for $\mathsf{NameCert}_{\mathsf{TsirelsonSpace}^{\uparrow}}$**.**

Constructive story: A $\mathsf{TsirelsonSpace}^{\uparrow}$ packet is generated from finite basis-block windows, recursive norm-budget windows, VecSpace, RegSeqRat, NormedSpace, Banach, and Real handoff rows, componentwise hsame transport, displayed Cont replay, provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{TsirelsonSpace}^{\uparrow}}$, seed)

Scope closed: Definition 8845.1 and Definition 8845.2 bind the finite basis-block, recursive norm-budget, vector-space, normed-space, Banach, regular-rational, Real-seal, transport, replay, provenance, and local naming rows of the TsirelsonSpace packet.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{TsirelsonSpace}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim reflexivity separation, an infinite basis theorem, exclusion of ℓ_p or c_0, Lean verification, bridge checking, host completion, selected infinite branches, or ambient compactness.

Upgrade path: A higher closure grade requires Lean definitions for the displayed rows and checked obligations for the recursive norm-budget handoff without importing host Banach-space theorems.

Chapter 8846

A Concrete Naming Certificate for $\mathsf{BetaSignSelection}^{\uparrow}$

The $\mathsf{BetaSignSelection}^{\uparrow}$ packet realizes the beta-sign selection principle of Definition 9346.57 as finite NameCert data. It reads the centered Green-excess branch through chapter 8769, the phase-shell route through chapter 8811, and the window-six seed through chapter 8802. The packet records the sign of the denominator deformation before any physical running law is consumed; it is not a fitted infrared value, a continuous beta function, or a host analytic flow.

Falsifiable prediction: Every accepted $\mathsf{BetaSignSelection}^{\uparrow}$ read exposes the denominator-deformation sign row before treating a Zeckendorf window-six branch as physically running. A branch whose displayed sign raises the inverse coupling is rejected as the primary running direction.

Independence witness: Nearest siblings: ZeckendorfNormal, ZCarry, ZNormal, StaticGreenBoundaryFlux, ZeckendorfPhaseShell, and GoldenMeanShiftWindowSix. None is bijective to $\mathsf{BetaSignSelection}^{\uparrow}$ because this packet binds denominator sign, activation order, admissible branch tag, finite window-six provenance, transport, replay, and local naming into one selection surface.

Definition 8846.1 (Beta-sign selection carrier)**.** *A* $\mathsf{BetaSignSelection}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (D, A, G, W, Z, S, H, C, P, N)$$

with the following displayed rows:

1. *D is the denominator-deformation row, displaying the inspected source denominator, target denominator, and monotone activation coordinate.*
2. *A is the beta-sign admissibility row, recording whether the displayed denominator deformation lowers inverse coupling along the activation interval.*
3. *G is the centered Green-excess row consumed from* $\mathsf{StaticGreenBoundaryFlux}^{\uparrow}$.
4. *W is the window-six beta-seed row consumed from* $\mathsf{GoldenMeanShiftWindowSix}^{\uparrow}$.
5. *Z is the Zeckendorf normal-and-carry row, naming ZeckendorfNormal, ZCarry, and ZNormal as the finite normal-word siblings that must be visible before a branch tag is accepted.*
6. *S is the selected-branch row, retaining the accepted local running seed and the refused walking-branch tag.*
7. *H records componentwise* hsame *transport for D, A, G, W, Z, S and for the structural rows of the packet.*

8. *C records displayed* Cont *replay for denominator inspection, sign selection, Green-excess read, window-six seed read, sibling normal-word read, and branch retention.*
9. *P is the* Pkg *provenance over* $\mathsf{BetaSignSelection}^{\uparrow}$, $\mathsf{StaticGreenBoundaryFlux}^{\uparrow}$, $\mathsf{ZeckendorfPhaseShell}^{\uparrow}$, $\mathsf{GoldenMeanShiftWindowSix}^{\uparrow}$, *ZeckendorfNormal, ZCarry, ZNormal,* BHist, hsame, Cont, *and* NameCert *rows.*
10. *N is the local* $\mathsf{NameCert}_{\mathsf{BetaSignSelection}^{\uparrow}}$ *row.*

The Lean TasteGate surface for this packet will require `Nontrivial` *and* `FieldFaithful` *instances for the displayed carrier rows before the sign-selection classifier can be checked.*

Theorem 8846.2 (Beta-sign selection NameCert obligation surface)**.** *For every accepted* $\mathsf{BetaSignSelection}^{\uparrow}$ *carrier*

$$B = (D, A, G, W, Z, S, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{BetaSignSelection}^{\uparrow}}$ *surface consists exactly of denominator-deformation admission through D, beta-sign admissibility through A, centered Green-excess exposure through G, window-six beta-seed exposure through W, ZeckendorfNormal–ZCarry–ZNormal sibling visibility through Z, selected-branch retention through S, componentwise* hsame *transport through H, displayed* Cont *replay through C, provenance through P, and local naming through N. It exports no fitted infrared value, no continuous beta function, no host analytic flow, no uninspected walking branch, and no physical running claim without the displayed sign row.*

Proof. Project the carrier rows from Definition 8846.1. The denominator row D and sign row A are the only entries that decide whether a branch may be read as physically running.

Read the source siblings next. The Green-excess row G, window-six row W, and normal-word row Z display the finite Zeckendorf sources named by Definition 9346.57; the selected-branch row S can retain a running seed only after those rows are visible.

The transport, replay, provenance, and naming rows H, C, P, N preserve the same finite packet. Since no coordinate stores a fitted infrared value, a continuous beta function, a host analytic flow, or an uninspected walking branch, the NameCert surface exports only the displayed beta-sign selection route. □

Closure status for $\mathsf{NameCert}_{\mathsf{BetaSignSelection}^{\uparrow}}$.

Constructive story: A $\mathsf{BetaSignSelection}^{\uparrow}$ packet is generated from a denominator-deformation row, beta-sign admissibility row, Green-excess source, window-six beta seed, Zeckendorf sibling visibility, selected-branch retention, componentwise hsame transport, displayed Cont replay, provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{BetaSignSelection}^{\uparrow}}$, seed)

Scope closed: Definition 8846.1 and Definition 8846.2 bind the finite denominator-sign, Green-excess, window-six beta-seed, Zeckendorf sibling, transport, replay, provenance, and local naming rows of the BetaSignSelection packet.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{BetaSignSelection}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim a continuous beta function, a fitted infrared value, a host analytic flow, Lean verification, bridge checking, or a running-law conclusion without the displayed sign row.

Upgrade path: A higher closure grade requires Lean carrier rows plus Nontrivial and FieldFaithful instances for the displayed sign-selection classifier.

Chapter 8847

A Concrete Naming Certificate for $\mathsf{CompactUniformModulusRestriction}^{\uparrow}$

Following Bishop–Bridges compact metric analysis, the $\mathsf{CompactUniformModulusRestriction}^{\uparrow}$ packet records the finite surface on which compact-uniform modulus data are restricted to a displayed subdomain and a displayed codomain read without importing open-cover compactness or a host function-equality principle. It sits beside the compact-uniform-continuity route of chapter 388, the uniform-modulus ledger of chapter 369, the compact-metric source of chapter 129, the continuous-map carrier of chapter 130, and the terminal real-name seal of chapter 38. The chapter names only the restriction carrier and its NameCert obligations; it does not assert an external modulus selector, a host equality of functions, an open-cover compactness theorem, quotient real equality, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 8847.1 (Compact uniform modulus restriction carrier)**.** *A* $\mathsf{CompactUniformModulusRestriction}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$R = (K, F, U, D, W, M, H, C, P, N)$$

with the following displayed rows:

1. *K is the* $\mathsf{CompactMetric}^{\uparrow}$ *source row whose finite compact-metric observations name the inspected domain window.*
2. *F is the* $\mathsf{ContinuousMap}^{\uparrow}$ *row for the displayed map on that source window, including only graph reads and pointwise continuity data already admitted by the local classifier.*
3. *U is the incoming* $\mathsf{UniformModulus}^{\uparrow}$ *row, recording the source-radius response for each displayed target tolerance request.*
4. *D is the restriction-domain row, naming the finite subdomain or finite compact-window inclusion on which the restricted modulus may be read.*
5. *W is the restricted source-window row, recording the compact observations from K that remain visible after D is applied.*
6. *M is the outgoing restricted* $\mathsf{UniformModulus}^{\uparrow}$ *row, obtained by reading U only through D, W, F.*
7. *H records componentwise* hsame *transport for the compact source, continuous-map data, incoming modulus, restriction-domain row, restricted window, outgoing modulus, replay, provenance, and local naming rows.*

8. *C records displayed* Cont *replay of the route*

$$K, F, U, D, W \longmapsto M.$$

9. *P is the* Pkg *provenance over* $\mathsf{CompactUniformModulusRestriction}^{\uparrow}$, $\mathsf{CompactUniformContinuity}^{\uparrow}$, $\mathsf{UniformModulus}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

10. *N is the local* $\mathsf{NameCert}_{\mathsf{CompactUniformModulusRestriction}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $K, F, U, D, W, M, H, C, P, N$. It has no coordinate for open-cover compactness, host function equality, a selected external modulus, quotient equality of real names, ambient real completeness, Lean verification, or bridge checking.

Theorem 8847.2 (Compact uniform modulus restriction NameCert obligations)**.** *For every accepted* $\mathsf{CompactUniformModulusRestriction}^{\uparrow}$ *carrier*

$$R = (K, F, U, D, W, M, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{CompactUniformModulusRestriction}^{\uparrow}}$ *surface consists exactly of compact-metric source exposure, continuous-map visibility, incoming uniform-modulus exposure, restriction-domain admission, restricted-window exposure, outgoing restricted-modulus production, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. A consumer therefore reads a restricted compact-uniform modulus only through the finite route*

$$\mathsf{CompactMetric}^{\uparrow},\ \mathsf{ContinuousMap}^{\uparrow},\ \mathsf{UniformModulus}^{\uparrow},\ \mathsf{CompactUniformContinuity}^{\uparrow},\ \mathsf{Real}^{\uparrow},\ \mathsf{BHist},\ \mathsf{hsame},\ \mathsf{Cont},\ \mathsf{Pkg}$$

Proof. Project the carrier of Definition 8847.1. The compact source row K, continuous-map row F, and incoming modulus row U are the only upstream analytic rows.

Read the restriction data through D and W. The restricted window W is a displayed subpacket of the compact observations already present in K, and the outgoing modulus M is read from U only after D, W, F remain visible.

Replay the structural rows H, C, P, N. They transport, replay, source, and name the same finite route from compact-uniform continuity to the restricted modulus surface.

Since the carrier has no coordinate for open-cover compactness, host function equality, an external modulus selector, quotient real equality, or ambient $\mathsf{Real}^{\uparrow}$ completeness, the listed rows exhaust the local NameCert obligations. □

Falsifiable prediction: An accepted $\mathsf{CompactUniformModulusRestriction}^{\uparrow}$ read is refuted if a restricted-modulus consumer exports M without first displaying the compact source row K, continuous-map row F, incoming modulus row U, restriction-domain row D, restricted-window row W, and the structural rows H, C, P, N.

Independence witness: compact-uniform-continuity, uniformmodulus, compactmetric, continuousmap, real: none is bijective to $\mathsf{CompactUniformModulusRestriction}^{\uparrow}$ because this packet jointly carries compact source data, continuous-map evidence, an incoming modulus, a displayed restriction domain, a restricted compact window, an outgoing restricted modulus, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{CompactUniformModulusRestriction}^{\uparrow}}$**.**

Constructive story: A $\mathsf{CompactUniformModulusRestriction}^{\uparrow}$ packet is generated from compact-metric source data, ContinuousMap rows, an incoming UniformModulus row, a displayed restriction domain, a restricted source window, an outgoing restricted UniformModulus row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\text{CompactUniformModulusRestriction}\uparrow}$, seed)

Scope closed: Definition 8847.1 and Definition 8847.2 seed the finite restriction route from compact-uniform modulus data to a displayed restricted-modulus consumer.

Formal verification: FormalStatus(NameCert$_{\text{CompactUniformModulusRestriction}\uparrow}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close open-cover compactness, host function equality, an external modulus selector, quotient real equality, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked compact source exposure, continuous-map visibility, incoming modulus exposure, restriction-domain admission, restricted-window exposure, outgoing modulus production, transport, replay, provenance, and local naming for BEDC.Derived.CompactUniformModulusRestrictionUp.

Chapter 8848

A Concrete Naming Certificate for $\mathsf{PrimeSkewBoundaryDefectPacket}^{\uparrow}$

The $\mathsf{PrimeSkewBoundaryDefectPacket}^{\uparrow}$ packet realizes the prime-skew boundary-defect route of chapter 9249 as finite NameCert data. It consumes the RH-free zero-generation initiality boundary of chapter 8799, the zeta-zero type-factorization surface of chapter 8772, the finite prime-window gluing row of chapter 8765, the prime shadow interface of chapter 8791, and the zeta-zero catalogue of chapter 73. The packet records conditional evidence routing for prime-visible skew and boundary defects; it is not a proof of the Riemann Hypothesis, not a zero-location theorem, and not an analytic completion of the boundary faithfulness or zero-defect incompatibility premises.

Definition 8848.1 (Prime-skew boundary defect packet carrier)**.** *A* $\mathsf{PrimeSkewBoundaryDefectPacket}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$P = (Z, R, S, B, I, F, X, H, C, Q, N)$$

with the following displayed rows:

1. *Z is the non-trivial zeta-zero source row, read through* $\mathsf{ZetaZeros}^{\uparrow}$ *and the zero-type factorization surface.*
2. *R is the bulk-representation row, recording the displayed map from zero packets into a finite boundary-readout carrier.*
3. *S is the prime-skew row, naming the finite prime-visible skew evidence extracted from displayed* $\mathsf{Prime}^{\uparrow}$ *channels.*
4. *B is the boundary-defect row, recording the finite boundary layer at which the prime-visible skew is observed as a defect.*
5. *I is the zero-defect incompatibility row, storing the conditional refutation interface between a represented non-trivial zero atom and the displayed defect row.*
6. *F is the boundary-faithfulness row, recording the conditional route from prime-skew evidence to boundary-defect evidence.*
7. *X is the refusal row, retaining failed attempts to read the packet as an unconditional RH proof, a global zero-location classifier, an analytic continuation theorem, or a completed boundary-faithfulness proof.*

8. *H records componentwise* hsame *transport for zero source, representation, prime skew, boundary defect, incompatibility, faithfulness, refusal, replay, provenance, and local naming rows.*
9. *C records displayed* Cont *replay from an RH-facing audit request through Z, R, S, B, I, F, X, H.*
10. *Q is the* Pkg *provenance over* PrimeSkewBoundaryDefectPacket$^{\uparrow}$, RhFreeZeroInitiality$^{\uparrow}$, ZetaZeroTypeFactorizatior FinitePrimeWindowGluing$^{\uparrow}$, PrimeShadowInterface$^{\uparrow}$, ZetaZeros$^{\uparrow}$, Prime$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* NameCert$_{\text{PrimeSkewBoundaryDefectPacket}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $Z, R, S, B, I, F, X, H, C, Q, N$. It has no coordinate for an unconditional proof of RH*, a full zero-location classifier, completed boundary faithfulness, completed zero-defect incompatibility, host complex equality, or analytic continuation outside the displayed zeta-zero route.*

Theorem 8848.2 (Prime-skew boundary defect packet)**.** *For every accepted* PrimeSkewBoundaryDefectPacket$^{\uparrow}$ *carrier*

$$P = (Z, R, S, B, I, F, X, H, C, Q, N),$$

the local NameCert$_{\text{PrimeSkewBoundaryDefectPacket}^{\uparrow}}$ *surface consists exactly of zero-source admission, bulk-representation visibility, prime-skew visibility, boundary-defect visibility, zero-defect incompatibility routing, boundary-faithfulness routing, RH-proof refusal, componentwise transport, displayed replay, package provenance, and local naming. A consumer may use the packet only as conditional evidence routing from the prime-skew row to the boundary-defect row and then to the incompatibility row; no accepted read exports an RH proof or an off-line-zero exclusion without separately displaying the vision-side premises.*

Proof. Project the carrier of Definition 8848.1. The mathematical rows are Z, R, S, B, I, F, X, and the structural rows are H, C, Q, N.

The zero source and representation rows are read first. They bind the zeta-zero data to the displayed boundary-readout carrier without selecting a host complex representative or completing an analytic zero-location theorem.

The prime-skew and boundary-defect rows are conditional. Row S names the finite prime-visible skew evidence, row F routes that evidence to B, and row I records the incompatibility interface once the represented zero atom and defect row are both displayed.

Finally use the refusal row X and the structural rows H, C, Q, N. They preserve the packet as conditional evidence routing and retain any attempted shortcut to RH, global zero-location, analytic continuation, or completed boundary faithfulness as a refused read rather than a public conclusion. □

Theorem 8848.3 (Prime-skew boundary defect conditional nonescape)**.** *Every RH-facing read of an accepted* PrimeSkewBoundaryDefectPacket$^{\uparrow}$ *packet factors through the displayed route*

ZetaZeros$^{\uparrow}$, ZetaZeroTypeFactorization$^{\uparrow}$, Prime$^{\uparrow}$, FinitePrimeWindowGluing$^{\uparrow}$, PrimeShadowInterface$^{\uparrow}$, RhFreeZeroIn

before the prime-skew, boundary-defect, faithfulness, incompatibility, refusal, transport, replay, provenance, and local naming rows are public. The read exports no unconditional RH theorem, no global zero-location classifier, no completed proof of boundary faithfulness, no completed proof of zero-defect incompatibility, and no host analytic continuation claim.

Proof. Apply Definition 8848.2. It exposes the only public rows of the packet and keeps the evidence route downstream of the zero-source, representation, prime-skew, boundary-defect, faithfulness, and incompatibility rows.

The sibling sources supply the finite entry points. The zeta-zero and zero-type rows bind the zero packet, the prime and finite-prime-window rows bind the skew observation, the prime-shadow interface binds the boundary readout, and the RH-free initiality row keeps generated-zero no-circularity separate from fixed-RH proof claims.

The refusal row and structural rows close the boundary. Because no carrier coordinate stores an unconditional RH theorem, a global zero-location classifier, completed boundary faithfulness, completed zero-defect incompatibility, or analytic continuation outside the zeta-zero route, no consumer can extract those claims from the accepted packet. □

Falsifiable prediction: Every accepted $\mathsf{PrimeSkewBoundaryDefectPacket}^{\uparrow}$ consumer that exports an RH proof, off-line-zero exclusion, or global zero-location classifier without first displaying zero-source, representation, prime-skew, boundary-defect, faithfulness, incompatibility, refusal, transport, replay, provenance, and local naming rows is outside the carrier surface.

Independence witness: prime, zeta, complex, riemann-hilbert, rh-free-zero-generation-initiality: $\mathsf{PrimeSkewBoundaryDefectPacket}^{\uparrow}$ is not bijective to any listed source because it jointly carries prime-skew evidence, boundary-defect evidence, conditional faithfulness, conditional incompatibility, RH-proof refusal, transport, replay, provenance, and local naming while refusing any unconditional RH conclusion.

Closure status for $\mathsf{NameCert}_{\mathsf{PrimeSkewBoundaryDefectPacket}^{\uparrow}}$.

Constructive story: A $\mathsf{PrimeSkewBoundaryDefectPacket}^{\uparrow}$ packet is generated from zeta-zero source rows, bulk-representation rows, prime-skew rows, boundary-defect rows, zero-defect incompatibility rows, boundary-faithfulness rows, RH-proof refusal rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{PrimeSkewBoundaryDefectPacket}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8848.1, Definition 8848.2, and Definition 8848.3 seed the finite conditional evidence route for the RH prime-skew boundary-defect vision.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{PrimeSkewBoundaryDefectPacket}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim the Riemann Hypothesis, off-line-zero exclusion, global zero-location, completed boundary faithfulness, completed zero-defect incompatibility, analytic continuation, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked zero-source admission, bulk-representation visibility, prime-skew visibility, boundary-defect visibility, faithfulness routing, incompatibility routing, RH-proof refusal, transport, replay, provenance, and local naming for BEDC.Derived.PrimeSkewBoundaryDefectPacketUp.

Chapter 8849

A Concrete Naming Certificate for $\mathsf{BishopRegularRealCriterion}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{BishopRegularRealCriterion}^{\uparrow}$ packet records the finite admission criterion by which a regular rational sequence is allowed to serve as a constructive real name. It sits between the finite stream windows of chapter 126, the regular rational readbacks of chapter 301, the dyadic tolerance rows of chapter 291, and the terminal real-name seal of chapter 38. The criterion is an admission route for Real-facing consumers; it is not a quotient construction of real numbers, a trichotomy principle, a selected limit operator, countable choice, or a proof of ambient Real completeness.

Definition 8849.1 (Bishop regular real criterion carrier)**.** *A* $\mathsf{BishopRegularRealCriterion}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (W, Q, D, R, A, H, C, P, N)$$

with the following displayed rows:

1. *W is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row, exposing only bounded windows of the candidate approximation stream.*
2. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row attached to those finite windows.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row, recording the visible dyadic radii and comparison budget used by the regularity test.*
4. *R is the* $\mathsf{Real}^{\uparrow}$ *seal row, available only after W, Q, D have been displayed.*
5. *A is the admission ledger row saying that the finite windows, regular readbacks, and dyadic tolerances match as one regular-real criterion packet.*
6. *H records componentwise* hsame *transport for stream windows, regular readbacks, dyadic tolerance rows, Real seal, admission ledger, replay, provenance, and local naming.*
7. *C records displayed* Cont *replay from a criterion request through finite-window read, regular readback, dyadic tolerance comparison, admission, and Real sealing.*
8. *P is the* Pkg *provenance over* $\mathsf{BishopRegularRealCriterion}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
9. *N is the local* $\mathsf{NameCert}_{\mathsf{BishopRegularRealCriterion}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $W, Q, D, R, A, H, C, P, N$. It has no coordinate for quotient reals, trichotomy, selected limits, countable choice, host convergence, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 8849.2 (Bishop regular real criterion derivation)**.** *Every accepted* $\mathsf{BishopRegularRealCriterion}^{\uparrow}$ *carrier exposes exactly* $\mathsf{StreamName}^{\uparrow}$ *finite windows,* $\mathsf{RegSeqRat}^{\uparrow}$ *regular readbacks,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance rows, and a* $\mathsf{Real}^{\uparrow}$ *seal before any Real-facing read. More precisely, any Real-facing consumer of*

$$K = (W, Q, D, R, A, H, C, P, N)$$

must read W, then Q, then D, then the admission ledger A, and only then the seal row R together with H, C, P, N.

Proof. Project the accepted carrier of Definition 8849.1. Its public admission route begins with the finite-window row W and contains no completed real or host convergence row.

Read the regularity evidence next. The row Q is the regular rational readback attached to the displayed windows, and D records the dyadic tolerance comparisons used by the criterion.

The admission ledger A binds those rows before the Real seal is visible. Transport, replay, provenance, and local naming preserve the same order, so a consumer cannot detach R from W, Q, D, A.

Because the carrier has no coordinate for quotient reals, trichotomy, selected limits, countable choice, host convergence, or ambient completeness, the displayed StreamName, RegSeqRat, DyadicRatCore, and Real rows exhaust the Real-facing criterion. □

Falsifiable prediction: A Real-facing consumer that accepts a $\mathsf{BishopRegularRealCriterion}^{\uparrow}$ packet without first displaying the $\mathsf{StreamName}^{\uparrow}$ finite-window row, the $\mathsf{RegSeqRat}^{\uparrow}$ readback row, the $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance row, and the admission ledger refutes the carrier.

Independence witness: streamname, regseqrat, dyadicratcore, real: $\mathsf{BishopRegularRealCriterion}^{\uparrow}$ is not bijective to any listed sibling because it binds finite stream windows, regular rational readbacks, dyadic tolerance comparison, an admission ledger, Real seal ordering, transport, replay, provenance, and local naming into one criterion packet.

Closure status for $\mathsf{NameCert}_{\mathsf{BishopRegularRealCriterion}^{\uparrow}}$.

Constructive story: A $\mathsf{BishopRegularRealCriterion}^{\uparrow}$ packet is generated from StreamName finite windows, RegSeqRat readbacks, DyadicRatCore tolerance rows, a RealUp seal, an admission ledger, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BishopRegularRealCriterion}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8849.1 and Definition 8849.2 seed the finite Bishop regular-real criterion route over StreamName, RegSeqRat, DyadicRatCore, and Real rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BishopRegularRealCriterion}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim RealUp completeness, quotient reals, trichotomy, selected limits, countable choice, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked finite-window admission, regular readback ordering, dyadic tolerance exactness, admission-ledger routing, Real seal ordering, transport, replay, provenance, and local naming for BEDC.Derived.BishopRegularRealCriterionUp.

Chapter 8850

A Concrete Naming Certificate for $\mathsf{HyperbolicHoroballFiltration}^{\uparrow}$

The $\mathsf{HyperbolicHoroballFiltration}^{\uparrow}$ packet realizes the nested Busemann-level shadow route of chapter 9463 as finite observer-expansion NameCert data. It sits after the horosphere packet of chapter 8521, the Busemann boundary ledger of chapter 3732, the visual boundary route of chapter 4181, and the boundary-shadow packet of chapter 3813. The packet names a finite horoball-threshold filtration; it is not a host ideal-boundary quotient, a selected geodesic ray, a completed hyperbolic manifold, a global visual compactification, or an observer-substance claim.

Definition 8850.1 (Hyperbolic horoball filtration carrier)**.** *A* $\mathsf{HyperbolicHoroballFiltration}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$F = (O, B, V, S, L, T, H, C, P, N)$$

with the following displayed rows:

1. O *is the* $\mathsf{HyperbolicHorosphere}^{\uparrow}$ *row naming the boundary-anchored horosphere read.*
2. B *is the* $\mathsf{HyperbolicBusemannBoundary}^{\uparrow}$ *row recording the Busemann-level boundary ledger.*
3. V *is the* $\mathsf{HyperbolicVisualBoundary}^{\uparrow}$ *row through which boundary visibility is read.*
4. S *is the* $\mathsf{HyperbolicBoundaryShadow}^{\uparrow}$ *row recording the observer-shadow expansion read.*
5. L *is the finite horoball-threshold ledger, ordered by displayed Busemann levels.*
6. T *is the filtration transport row, requiring every shadow expansion row to preserve the visible threshold order.*
7. H *records componentwise* hsame *transport for horosphere, Busemann, visual-boundary, shadow, threshold-ledger, filtration-transport, replay, provenance, and local naming rows.*
8. C *records displayed* Cont *replay through horosphere exposure, Busemann-level comparison, visual-boundary readback, boundary-shadow expansion, threshold inspection, and filtration transport.*
9. P *is the* Pkg *provenance over* $\mathsf{HyperbolicHoroballFiltration}^{\uparrow}$, $\mathsf{HyperbolicHorosphere}^{\uparrow}$, $\mathsf{HyperbolicBusemannBoundary}$ $\mathsf{HyperbolicVisualBoundary}^{\uparrow}$, $\mathsf{HyperbolicBoundaryShadow}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
10. N *is the local* $\mathsf{NameCert}_{\mathsf{HyperbolicHoroballFiltration}^{\uparrow}}$ *row.*

The carrier exports horoball-filtration data only through $O, B, V, S, L, T, H, C, P, N$*. It has no coordinate for host ideal-boundary quotients, selected geodesic rays, completed hyperbolic manifolds, global visual compactifications, or observer-substance dynamics.*

Theorem 8850.2 (Hyperbolic horoball shadow concretization)**.** *Every accepted* $\mathsf{HyperbolicHoroballFiltration}^{\uparrow}$ *read factors the observer-shadow expansion route through*

$$\mathsf{HyperbolicHorosphere}^{\uparrow},\ \mathsf{HyperbolicBusemannBoundary}^{\uparrow},\ \mathsf{HyperbolicVisualBoundary}^{\uparrow},\ \mathsf{HyperbolicBoundaryShadow}^{\uparrow}$$

before the finite horoball-threshold ledger is exposed. A boundary-shadow expansion row is accepted only when the displayed Busemann-level filtration ledger and its transport row are visible in the same packet.

Proof. Project the carrier of Definition 8850.1. The geometric source rows are O, B, V, S, and the filtration data appear only as L and T.

Read the sibling route in order. The horosphere row fixes the boundary-anchored level surface, the Busemann boundary row records the level comparison, the visual boundary row supplies the visible boundary read, and the boundary-shadow row records the observer-expansion shadow.

The threshold ledger L then orders those reads by finite Busemann levels. The transport row T requires any shadow expansion consumer to preserve that threshold order rather than reading an unledgered boundary-shadow expansion.

Finally attach H, C, P, N. These rows preserve, replay, source, and name the same finite packet, leaving no coordinate for host boundary quotients, selected geodesic rays, completed manifolds, global visual compactifications, or observer-substance dynamics. □

The corresponding Lean surface for $\mathsf{HyperbolicHoroballFiltration}^{\uparrow}$ is expected to expose `Nontrivial` and `FieldFaithful` instances once the carrier and field-faithfulness rows are formalized.

Falsifiable prediction: Any consumer exposing a boundary-shadow expansion row without the finite horoball-threshold ledger L and filtration transport row T refutes the $\mathsf{HyperbolicHoroballFiltration}^{\uparrow}$ carrier.

Independence witness: hyperbolic-horosphere, hyperbolic-busemann-boundary, hyperbolic-visual-boundary, hyperbolic-boundary-shadow, hyperbolic-observer-expansion: the horosphere packet records level surfaces without the ordered horoball ledger; the Busemann boundary packet records boundary levels without the shadow filtration; the visual boundary packet records boundary visibility without threshold nesting; the boundary-shadow packet records expansion shadows without the finite ledger order; and observer-expansion packets can expose growth rows without this Busemann-level filtration. None is bijective to $\mathsf{HyperbolicHoroballFiltration}^{\uparrow}$.

Closure status for $\mathsf{NameCert}_{\mathsf{HyperbolicHoroballFiltration}^{\uparrow}}$**.**

Constructive story: A $\mathsf{HyperbolicHoroballFiltration}^{\uparrow}$ packet is generated from HyperbolicHorosphere rows, HyperbolicBusemannBoundary rows, HyperbolicVisualBoundary rows, HyperbolicBoundaryShadow rows, a finite horoball-threshold ledger, filtration transport, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{HyperbolicHoroballFiltration}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8850.1 and Definition 8850.2 seed the finite horoball-filtration route for observer-shadow expansion.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{HyperbolicHoroballFiltration}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host ideal-boundary quotients, selected geodesic rays, completed hyperbolic manifolds, global visual compactifications, observer-substance dynamics, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked horosphere exposure, Busemann boundary comparison, visual boundary readback, boundary-shadow expansion, threshold-ledger exactness, filtration transport, provenance, and local naming for BEDC.Derived.HyperbolicHoroballFiltrationUp.

Chapter 8851

A Concrete Naming Certificate for $\mathsf{CompleteMetricSeparability}^{\uparrow}$

Following Bishop and Bridges on constructive metric spaces, the $\mathsf{CompleteMetricSeparability}^{\uparrow}$ packet records complete separability through displayed dense windows and regular Cauchy readback rather than through host countability or choice. It sits after the metric carrier of chapter 57, the complete-metric service of chapter 128, the finite stream-window interface of chapter 126, the regular rational readback of chapter 301, the terminal real-name seal of chapter 38, and the complete-separable synthesis surface of chapter 1490. The packet gives L10 Real and Completion consumers a named dense-window handoff before any PolishSpace consumer treats a complete metric source as separable.

Definition 8851.1 (Complete metric separability carrier)**.** *A* $\mathsf{CompleteMetricSeparability}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (M, K, D, W, R, T, E, H, C, P, N)$$

with the following displayed rows:

1. *M is the* $\mathsf{Met}^{\uparrow}$ *row, carrying the point-history carrier, distance classifier, visible metric comparisons, and local metric naming data.*
2. *K is the* $\mathsf{CompleteMetric}^{\uparrow}$ *row over the same metric carrier, exposing only the displayed Cauchy-window and limit-seal service available to downstream completion requests.*
3. *D is the countable dense-index row. It records finite inspected dense names, their index tags, and the admission rule that every requested ball must be answered through an indexed dense name rather than through an external choice function.*
4. *W is the finite dense-window row, displaying the requested center, radius, tolerance, inspected dense indices, and the first accepted witness window for the request.*
5. *R is the* $\mathsf{Real}^{\uparrow}$ *distance-and-tolerance row, sealing the displayed metric distances and positive radii used by W.*
6. *T is the* $\mathsf{RegSeqRat}^{\uparrow}$ *tolerance readback row, recording the regular rational windows by which the dense witness and the completion row are compared.*
7. *E is the* $\mathsf{StreamName}^{\uparrow}$ *readback row for dense names, Cauchy windows, and finite observation requests made by D, W, K, T.*

8. *H records componentwise* hsame *transport for M, K, D, W, R, T, E and for the structural rows of the packet.*
9. *C records displayed* Cont *replay for metric-ball inspection, dense-index lookup, finite dense-window replay, completion-service replay, StreamName readback, RegSeqRat readback, and Real sealing.*
10. *P is the* Pkg *provenance over* $\mathsf{CompleteMetricSeparability}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{CompleteMetric}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{PolishSpace}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*
11. *N is the local* $\mathsf{NameCert}_{\mathsf{CompleteMetricSeparability}^{\uparrow}}$ *row.*

The local classifier compares accepted carriers only through $M, K, D, W, R, T, E, H, C, P, N$. It has no coordinate for host countability, selected infinite dense sequences outside the displayed index row, quotient equality of completions, open-cover compactness, or ambient real completeness.

Theorem 8851.2 (Complete metric separability NameCert obligations)**.** *For every accepted* CompleteMetricSepara *carrier*

$$S = (M, K, D, W, R, T, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{CompleteMetricSeparability}^{\uparrow}}$ *surface consists exactly of metric carrier exposure through M, complete-metric service exposure through K, dense-index admission through D, finite dense-window coverage through W, Real-valued distance and tolerance sealing through R, regular rational readback through T, StreamName readback through E, componentwise* hsame *transport through H, displayed* Cont *replay through C, provenance through P, and local naming through N. It exports no host countability principle, no selected global dense sequence beyond the displayed index row, no quotient completion equality, no open-cover compactness theorem, and no ambient* $\mathsf{Real}^{\uparrow}$ *completeness claim.*

Proof. Project the carrier rows from Definition 8851.1. The metric row M fixes the distance surface, while the complete-metric row K supplies only the Cauchy-window and limit-seal service available on that same surface.

Read the separability-specific rows next. The dense-index row D records the only accepted source of dense names, and the finite dense-window row W records the requested ball, inspected indices, tolerance, and accepted witness window. The distance and tolerance values in W are sealed through R, while T and E expose the regular rational and stream readbacks used to inspect the witness.

The structural rows H, C, P, N transport, replay, source, and name the same finite packet. Since no row stores a host countability principle, a hidden global sequence selector, quotient equality of completions, open-cover compactness, or ambient real completeness, none is exported by the NameCert surface. □

Theorem 8851.3 (Complete metric separability density handoff)**.** *Let*

$$S = (M, K, D, W, R, T, E, H, C, P, N)$$

be an accepted $\mathsf{CompleteMetricSeparability}^{\uparrow}$ *carrier. Any downstream* $\mathsf{PolishSpace}^{\uparrow}$ *or completion consumer that requests a dense point inside a displayed metric ball must factor the request through the route*

$\mathsf{Met}^{\uparrow}$, $\mathsf{CompleteMetric}^{\uparrow}$, D, W, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, Pkg, $\mathsf{NameCert}_{\mathsf{CompleteMetri}}$

The handoff exposes the dense witness only as finite index-window evidence and does not supply a host enumeration, countable-choice selector, quotient completion representative, selected limit outside K, or open-cover compactness argument.

Proof. Start with a displayed downstream ball request. The metric carrier M supplies the center, radius comparison, and distance classifier, and the complete-metric row K remains available only as the completion service over that same carrier.

The dense request is then routed through D and W. The row D admits the inspected dense index, while W records the finite witness window and the comparison budget for the requested ball. The numeric side of the comparison is readable only through the Real seal R, the regular rational readback T, and the StreamName observations E.

Finally apply the structural rows H, C, P, N. They keep the metric, completion, dense-index, dense-window, readback, and seal rows aligned under transport and replay, and they expose only the local packet to the downstream consumer. A consumer therefore receives finite dense-window evidence, not an external enumeration or a choice-selected completion representative. □

Closure status for $\mathsf{NameCert}_{\mathsf{CompleteMetricSeparability}^{\uparrow}}$.

Constructive story: A $\mathsf{CompleteMetricSeparability}^{\uparrow}$ packet is generated from a MetricSpace row, CompleteMetric service row, countable dense-index row, finite dense-window row, Real-valued distance and tolerance row, RegSeqRat and StreamName readbacks, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CompleteMetricSeparability}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8851.1, Definition 8851.2, and Definition 8851.3 seed the complete-metric separability route over metric, complete-metric, dense-index, dense-window, Real-seal, regular-rational, stream, transport, replay, provenance, and local naming rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CompleteMetricSeparability}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim host countability, countable choice, a selected global dense sequence beyond the displayed index row, quotient completion equality, open-cover compactness, Lean verification, bridge checking, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Upgrade path: Obligation closure requires checked carrier admission, dense-index exposure, finite dense-window coverage, complete-metric service nonescape, StreamName and RegSeqRat readback, Real sealing, transport, replay, provenance, and local naming for BEDC.Derived.CompleteMetricSeparabilityUp.

Chapter 8852

A Concrete Naming Certificate for $\mathsf{TailDiameterCriterion}^{\uparrow}$

Following Bishop and Bridges constructive real analysis, the $\mathsf{TailDiameterCriterion}^{\uparrow}$ packet records the finite criterion that a regular rational source is Cauchy exactly when every requested dyadic tolerance can be served by a displayed tail-diameter witness. It refines the tail witness of chapter 1746 and the real-facing gauge of chapter 5891, while depending on the dyadic tolerance core of chapter 291, the finite stream windows of chapter 126, the regular rational readback of chapter 301, and the terminal real seal of chapter 38. The packet supplies a criterion-level finite tail-diameter object for Real and Completion arguments; it does not assert quotient real equality, selected limits, trichotomy, or ambient Real completeness.

Definition 8852.1 (Tail-diameter criterion carrier)**.** *A* $\mathsf{TailDiameterCriterion}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Q = (S, D, T, K, E, R, H, C, P, N)$$

with the following displayed rows:

1. *S is the* $\mathsf{RegSeqRat}^{\uparrow}$ *or stream source whose Cauchy behavior is being tested.*
2. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance request.*
3. *T is the* $\mathsf{CauchyTailDiameter}^{\uparrow}$ *tail-bound row that exposes a threshold, two visible tail indices, and the dyadic diameter bound for D.*
4. *K is the criterion row saying that each accepted tolerance request is served by such a displayed tail-bound row.*
5. *E records the finite equivalence direction between the criterion row and the ordinary Cauchy tail-diameter reading of the same source.*
6. *R is the* $\mathsf{RealTailDiameterGauge}^{\uparrow}$ *or* $\mathsf{Real}^{\uparrow}$ *handoff row used only after S, D, T, K, E have been displayed.*
7. *H records componentwise* hsame *transport for the source, tolerance, tail-bound, criterion, equivalence, handoff, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from a criterion request through $S, D, T, K, E, R, H, P, N$.*
9. *P is the* Pkg *provenance over* $\mathsf{TailDiameterCriterion}^{\uparrow}$, $\mathsf{CauchyTailDiameter}^{\uparrow}$, $\mathsf{RealTailDiameterGauge}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.

10. *N is the local* $\mathsf{NameCert}_{\mathsf{TailDiameterCriterion}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $S, D, T, K, E, R, H, C, P, N$. It has no coordinate for quotient real equality, selected limits, countable choice, trichotomy, open-cover compactness, ambient $\mathsf{Real}^{\uparrow}$ *completeness, or a standard bridge.*

Lean4 (statement) `BEDC.Derived.TailDiameterCriterionUp`

Theorem 8852.2 (Tail-diameter criterion NameCert obligations)**.** *For every accepted* $\mathsf{TailDiameterCriterion}^{\uparrow}$ *carrier $Q = (S, D, T, K, E, R, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{TailDiameterCriterion}^{\uparrow}}$ *surface consists exactly of the finite carrier rows of Definition 8852.1 and the following obligations:*

1. *carrier admission for the source, tolerance, tail-bound, criterion, equivalence, handoff, transport, replay, provenance, and local naming rows;*
2. *tolerance exactness, requiring each criterion request to read the displayed* $\mathsf{DyadicRatCore}^{\uparrow}$ *row D before any tail-bound row is consumed;*
3. *tail-bound exactness, requiring T to expose the threshold, two visible tail indices, and dyadic comparison row of chapter 1746;*
4. *criterion exactness, requiring K to bind the same source and tolerance rows used by T;*
5. *equivalence confinement, requiring E to express only the two finite readings of Cauchy tail-diameter data, not quotient real equality or selected limits;*
6. *Real-seal handoff confinement, requiring R to be downstream from the displayed criterion and compatible with chapter 5891;*
7. *componentwise transport, replay, provenance, and local naming for exactly the same rows.*

No tail-diameter criterion obligation is stored outside these rows.

Proof. Project the accepted carrier. The analytic rows are S, D, T, K, E, R, and the structural rows are H, C, P, N.

Read the tolerance route first. The dyadic request D is exposed before the tail-bound row T, so the threshold and visible tail-index comparison are tied to the requested tolerance.

The criterion row K then packages the universal tolerance reading as finite NameCert data. The equivalence row E compares this criterion only with the ordinary tail-diameter Cauchy reading of the same source and tolerance surface.

The handoff row R is downstream. It may serve the real-facing gauge or terminal real seal only after the source, tolerance, tail-bound, criterion, and equivalence rows have been displayed.

Finally, H, C, P, N preserve the same row list under transport, replay, provenance, and local naming. Since no excluded object occurs in the carrier, no additional NameCert obligation can be read from the packet. □

Theorem 8852.3 (Tail-diameter criterion Cauchy equivalence)**.** *Every accepted* $\mathsf{TailDiameterCriterion}^{\uparrow}$ *carrier presents the finite route*

$$S, D \longmapsto T \longmapsto K \longmapsto E \longmapsto H, C, P, N$$

between the ordinary Cauchy tail-diameter reading of S and the criterion that every displayed dyadic tolerance request is served by a matching tail-bound witness. The route exports only the finite rows of Definition 8852.1; it exports no quotient real equality, selected limit, trichotomy decision, countable-choice schedule, open-cover compactness witness, ambient $\mathsf{Real}^{\uparrow}$ *completeness theorem, or standard bridge.*

Proof. Start with the source and tolerance rows. The packet exposes S and D before any criterion claim is available.

Apply the tail-diameter witness route of chapter 1746. The row T supplies the threshold, two visible tail indices, and dyadic bound for the same source and tolerance surface.

The criterion row K records that this displayed service is available for each accepted dyadic request, while E records the finite comparison between that criterion and the ordinary tail-diameter Cauchy reading.

Transport, replay, provenance, and local naming preserve the same rows. Because the carrier contains no quotient, choice, trichotomy, compactness, completeness, or bridge coordinate, the equivalence route cannot export any of those objects. □

Theorem 8852.4 (Tail-diameter criterion Real-seal handoff)**.** *Every* $\mathsf{RegSeqRat}^{\uparrow}$ *or* $\mathsf{Real}^{\uparrow}$ *completion consumer that uses an accepted* $\mathsf{TailDiameterCriterion}^{\uparrow}$ *carrier must consume the route*

$$S, D, T, K, E \longmapsto R \longmapsto H, C, P, N.$$

Thus the completion-facing handoff is mediated by the displayed source, dyadic tolerance, tail-bound, criterion, equivalence, real-gauge or real-seal row, transport, replay, provenance, and local naming rows. It does not supply quotient real equality, a selected limit, trichotomy, countable choice, ambient Real completeness, open-cover compactness, or a standard bridge.

Proof. Begin with a regular-rational or real-facing consumer. The consumer receives the finite carrier $Q = (S, D, T, K, E, R, H, C, P, N)$, so the only analytic rows initially available are the source, tolerance, tail-bound, criterion, equivalence, and handoff rows.

The handoff cannot precede the criterion. The row R is read after S, D, T, K, E, and therefore any real-facing use of the packet already carries the tail-diameter witness and the finite criterion comparison.

Use the real-gauge confinement of chapter 5891. The same finite stream-window, dyadic tolerance, regular rational readback, and real-seal discipline is preserved when the criterion packet is consumed by Real and Completion arguments.

The structural rows H, C, P, N then transport, replay, source, and name only this route. Since no excluded object is a carrier coordinate, the consumer cannot extract a quotient equality, selected limit, trichotomy row, choice schedule, completeness theorem, compactness witness, or bridge datum from the handoff. □

Closure status for $\mathsf{NameCert}_{\mathsf{TailDiameterCriterion}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{TailDiameterCriterion}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8852.1, Definition 8852.2, Definition 8852.3, and Definition 8852.4 seed the finite criterion packet linking displayed dyadic tolerance requests, tail-diameter witnesses, Cauchy readings, and Real-seal handoff rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{TailDiameterCriterion}^{\uparrow}}, \mathsf{formalTarget})$

Bridge status: none

Not claimed: This chapter does not close quotient real equality, selected limits, countable choice, trichotomy, ambient $\mathsf{Real}^{\uparrow}$ completeness, open-cover compactness, theorem-level Lean verification, or a standard bridge.

Upgrade path: Obligation closure requires checked carrier admission, tolerance exactness, tail-bound exactness, criterion exactness, Cauchy-equivalence confinement, Real-seal handoff confinement, transport stability, replay, provenance, and local naming for BEDC.Derived.TailDiameterCriterionUp.

Constructive story: A $\mathsf{TailDiameterCriterion}^{\uparrow}$ packet is generated from a RegSeqRat or stream source, a DyadicRatCore tolerance request, a CauchyTailDiameter tail-bound row, a criterion row, a finite equivalence row, a RealTailDiameterGauge or Real seal handoff row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 8853

A Concrete Naming Certificate for $\mathsf{DyadicLipschitzSlopePacket}^{\uparrow}$

Following Bishop and Bridges on constructive metric and real analysis, the $\mathsf{DyadicLipschitzSlopePacket}^{\uparrow}$ packet records a finite slope-bound witness for Lipschitz estimates whose input and output comparisons are read through dyadic rational data. It sits over the dyadic arithmetic core of chapter 291, the metric carrier of chapter 57, the terminal real-name seal of chapter 38, the Lipschitz map carrier of chapter 410, and the dyadic modulus handoff of chapter 1864. The packet names the finite row where a displayed slope bound is accepted before a Real or Completion consumer treats a dyadic error estimate as a Lipschitz output bound.

Definition 8853.1 (Dyadic Lipschitz slope packet carrier)**.** *A* $\mathsf{DyadicLipschitzSlopePacket}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (D, M, R, L, U, Q, B, H, C, P, N)$$

with the following displayed rows:

1. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *row carrying the inspected dyadic input difference, dyadic output allowance, positivity witness, and finite comparison ledger.*
2. *M is the* $\mathsf{Met}^{\uparrow}$ *row exposing the source and target distance classifiers used by the slope comparison.*
3. *R is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row for the displayed distance and tolerance names.*
4. *L is the* $\mathsf{LipschitzMap}^{\uparrow}$ *row carrying the accepted map, source metric row, target metric row, and displayed Lipschitz constant.*
5. *U is the* $\mathsf{DyadicLipschitzModulus}^{\uparrow}$ *row that turns the slope bound and dyadic input tolerance into the visible output tolerance budget.*
6. *Q is the slope-ratio ledger. It records the finite dyadic comparison asserting that the displayed output difference is bounded by the displayed slope row times the displayed input difference whenever the input row is positive.*
7. *B is the consumer-bound row read by Real and Completion estimates after D, M, R, L, U, Q have all been displayed.*
8. *H records componentwise* hsame *transport for the dyadic, metric, Real, Lipschitz, modulus, slope-ledger, consumer-bound, replay, provenance, and local naming rows.*

9. *C records displayed* Cont *replay from a slope-bound request through $D, M, R, L, U, Q, B, H, P, N$.*
10. *P is the* Pkg *provenance over* DyadicLipschitzSlopePacket$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, Met$^{\uparrow}$, Real$^{\uparrow}$, LipschitzMap$^{\uparrow}$, DyadicLipschitzModulus$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*
11. *N is the local* NameCert$_{\text{DyadicLipschitzSlopePacket}^{\uparrow}}$ *row.*

The carrier contains no host derivative, quotient function equality, selected real limit, ambient completeness principle, trichotomy row, countable-choice selector, Lean verification credential, or standard bridge.

Theorem 8853.2 (Dyadic Lipschitz slope packet NameCert obligations)**.** *For every accepted* DyadicLipschitzSlopePacket$^{\uparrow}$ *carrier*

$$S = (D, M, R, L, U, Q, B, H, C, P, N),$$

the local NameCert$_{\text{DyadicLipschitzSlopePacket}^{\uparrow}}$ *surface consists exactly of carrier admission for the displayed dyadic ledger, metric rows, Real seal, Lipschitz map row, dyadic modulus row, slope-ratio ledger, consumer-bound row, componentwise transport, replay, provenance, and local naming row; classifier exactness through those same rows; slope-ratio admission through Q; dyadic modulus handoff through U; Real and Completion consumer exposure through B; and transport and replay stability through H, C, P, N.*

Proof. Project the accepted packet to its displayed rows. The dyadic ledger D, metric row M, Real seal R, Lipschitz row L, and modulus row U are the only upstream analytic data available to the local name.

Read the slope-specific rows next. The ratio ledger Q records the finite dyadic comparison, and the consumer-bound row B is reached only after D, M, R, L, U, Q are displayed. Thus the slope witness is a finite comparison surface rather than a derivative or selected limit.

Finally apply the structural rows H, C, P, N. They transport, replay, source, and name exactly the same displayed packet. Since the carrier has no coordinate for host derivatives, quotient function equality, selected limits, ambient completeness, trichotomy, choice, or bridge credentials, the listed rows exhaust the local NameCert obligations. □

Closure status for NameCert$_{\text{DyadicLipschitzSlopePacket}^{\uparrow}}$.

Constructive story: A DyadicLipschitzSlopePacket$^{\uparrow}$ packet is generated from a DyadicRatCore ledger, Metric rows, a Real seal, a LipschitzMap row, a DyadicLipschitzModulus row, a finite slope-ratio ledger, a Real and Completion consumer-bound row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\text{DyadicLipschitzSlopePacket}^{\uparrow}}$, seed)

Scope closed: Definition 8853.1 and Definition 8853.2 seed the finite slope-bound route from dyadic comparison data through metric, Real, Lipschitz, and dyadic-modulus rows.

Formal verification: FormalStatus(NameCert$_{\text{DyadicLipschitzSlopePacket}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close host derivatives, quotient function equality, selected limits, ambient Real completeness, trichotomy, countable choice, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, classifier exactness, slope-ratio admission, dyadic modulus handoff, Real and Completion consumer exposure, transport, replay, provenance, and local naming for BEDC.Derived.DyadicLipschitzSlopePacketUp.

Chapter 8854

A Concrete Naming Certificate for $\mathsf{FiniteNormalizationDiamond}^{\uparrow}$

Following Newman and Takahashi-style finite diamond reasoning for terminating rewrite systems, the $\mathsf{FiniteNormalizationDiamond}^{\uparrow}$ packet records the candidate-mediated local-join budget used by the MetaCIC normalization audit route. It sits beside the normalization budget of chapter 755, the candidate-mediated strong-normalization handoff of chapter 5163, and the candidate diamond budget of chapter 6552. The packet names only finite candidate evidence, local two-front reductions, join budget, no-infinite-reduction readback, transport, replay, provenance, and local naming rows; it does not assert full confluence, unconditional normalization, or subject-reduction closure.

Definition 8854.1 (Finite normalization diamond carrier)**.** *A* $\mathsf{FiniteNormalizationDiamond}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$F = (K, E, S, A, P_i, A_p, L, J, Z, T, C, G, N)$$

with the following displayed rows:

1. *K is the candidate-evidence row, carrying the reducibility-candidate data used by the closed term under inspection.*
2. *E is the closed-candidate row, recording closedness of the type and term together with the candidate evidence consumed by the normalization route.*
3. *S is the candidate-set membership row, exposing membership, soundness, and beta-closure evidence when the route is read through a candidate set.*
4. *A is the Pi-adequacy row for binder and function evidence.*
5. *P_i is the application-adequacy row for applying a Pi-side candidate to a displayed argument candidate.*
6. *A_p is the local two-front reduction row, recording the two finite one-step or bounded-step frontiers whose endpoints must be compared.*
7. *L is the local join-budget row, listing the bounded join witnesses and the residual rows inspected by the local diamond check.*
8. *J is the accepted join row, present only when the two-front endpoints are joined inside the displayed budget.*
9. *Z is the no-infinite-reduction readback row exported from the candidate-mediated strong-normalization surface.*

10. *T records componentwise* hsame *transport for the candidate, closed-candidate, candidate-set, adequacy, two-front, join-budget, accepted-join, no-infinite-reduction, replay, provenance, and local naming rows.*
11. *C records displayed* Cont *replay for the same candidate-mediated diamond route.*
12. *G is the* Pkg *provenance over* $\mathsf{FiniteNormalizationDiamond}^{\uparrow}$*, the MetaCIC candidate and adequacy rows,* BHist, hsame, Cont, *and* NameCert.
13. *N is the local* $\mathsf{NameCert}_{\mathsf{FiniteNormalizationDiamond}^{\uparrow}}$ *row.*

The carrier has no coordinate for global Church–Rosser confluence, unconditional normalization of every closed typed term, erased candidate evidence, subject-reduction closure, quotient syntax equality, oracle reduction, Lean verification, or a standard bridge.

Theorem 8854.2 (Finite normalization diamond NameCert obligations)**.** *For every accepted* $\mathsf{FiniteNormalizationDiamond}^{\uparrow}$ *carrier*

$$F = (K, E, S, A, P_i, A_p, L, J, Z, T, C, G, N),$$

the local $\mathsf{NameCert}_{\mathsf{FiniteNormalizationDiamond}^{\uparrow}}$ *surface consists exactly of candidate evidence, closed-candidate rows, candidate-set membership, Pi adequacy, application adequacy, local two-front reductions, join budget, accepted local join, no-infinite-reduction readback, componentwise transport, displayed replay, provenance, and local naming. Every normalization-diamond read must keep the candidate rows visible and must expose the join as a bounded local witness rather than as full confluence or unconditional normalization.*

Proof. Project the carrier rows. Candidate evidence K, closed-candidate evidence E, and candidate-set membership S are the only sources from which strong-normalization and no-infinite-reduction reads may be obtained.

Read the adequacy rows A and P_i before inspecting any application frontier. They ensure that the local route remains candidate-mediated through Pi and application cases instead of becoming componentwise termination of unrelated parts.

The two-front row A_p, join budget L, and accepted join row J then record the finite diamond check. The no-infinite-reduction row Z is read from the same candidate-mediated surface, and the structural rows T, C, G, N transport, replay, source, and name exactly that finite packet.

Since the carrier has no row for global confluence, unconditional normalization, erased candidate evidence, subject-reduction closure, quotient syntax equality, oracle reduction, Lean verification, or bridge checking, the listed rows exhaust the local NameCert obligations. □

Closure status for $\mathsf{NameCert}_{\mathsf{FiniteNormalizationDiamond}^{\uparrow}}$**.**

Constructive story: A $\mathsf{FiniteNormalizationDiamond}^{\uparrow}$ packet is generated from candidate evidence, closed-candidate evidence, candidate-set membership, Pi and application adequacy rows, a local two-front reduction row, a bounded join row, a no-infinite-reduction readback row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{FiniteNormalizationDiamond}^{\uparrow}}$, seed)

Scope closed: Definition 8854.1 and Definition 8854.2 seed the finite candidate-mediated local-join route for the MetaCIC normalization audit map.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{FiniteNormalizationDiamond}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close full confluence, unconditional normalization, erased candidate evidence, subject-reduction transport, quotient syntax equality, oracle reduction, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked candidate evidence, closed-candidate rows, candidate-set membership, Pi and application adequacy, local two-front reductions, join budget, no-infinite-reduction readback, transport, replay, provenance, and local naming for BEDC.Derived.FiniteNormalizationDiamondUp.

Chapter 8855

A Concrete Naming Certificate for $\mathsf{DualCone}^{\uparrow}$

Following Rockafellar's finite-dimensional convex analysis and the Boyd–Vandenberghe treatment of convex cones, the $\mathsf{DualCone}^{\uparrow}$ packet records the polar-support route for a displayed cone before any separation theorem or analytic closure principle is read. It sits over the convex membership rows of chapter 208, the vector-space boundary of chapter 47, the linear functional rows of chapter 48, the scalar seal of chapter 38, and the finite primal-dual packet of chapter 321. The packet names the dual cone as finite support-inequality data, not as Hahn–Banach, strong separation, a host quotient space, or analytic closedness.

Definition 8855.1 (Dual-cone carrier)**.** *A* $\mathsf{DualCone}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$D = (V, C, L, R, F, H, K, P, N)$$

whose rows are displayed as follows: V *is the* $\mathsf{VecSpace}^{\uparrow}$ *source row,* C *is the* $\mathsf{ConvexSet}^{\uparrow}$ *cone row inside* V*,* L *is the* $\mathsf{LinMap}^{\uparrow}$ *functional row,* R *is the* $\mathsf{Real}^{\uparrow}$ *scalar comparison row for nonnegative support values,* F *is the* $\mathsf{FenchelDuality}^{\uparrow}$ *provenance row that records the adjacent polar-support reading,* H *is componentwise* hsame *transport for* V, C, L, R, F*,* K *is displayed* Cont *replay,* P *is* Pkg *provenance over* $\mathsf{DualCone}^{\uparrow}$*,* $\mathsf{ConvexSet}^{\uparrow}$*,* $\mathsf{VecSpace}^{\uparrow}$*,* $\mathsf{LinMap}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*,* $\mathsf{FenchelDuality}^{\uparrow}$*,* BHist*,* hsame*,* Cont*,* Pkg*, and* $\mathsf{NameCert}$*, and* N *is the local* $\mathsf{NameCert}_{\mathsf{DualCone}^{\uparrow}}$ *row. The classifier compares accepted packets only through these rows and has no coordinate for Hahn–Banach extension, strong separation, host quotient spaces, analytic closedness, or an ambient topological dual.*

Theorem 8855.2 (Dual-cone NameCert obligations)**.** *For every accepted* $\mathsf{DualCone}^{\uparrow}$ *carrier* $D = (V, C, L, R, F, H, K, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{DualCone}^{\uparrow}}$ *surface consists exactly of vector-space exposure through* V*, cone-membership exposure through* C*, linear-functional exposure through* L*, Real-valued support comparison through* R*, polar-support provenance through* F*, componentwise* hsame *transport through* H*, displayed* Cont *replay through* K*,* Pkg *provenance through* P*, and local naming through* N*.*

Proof. Project the rows of Definition 8855.1. The vector, cone, functional, and scalar comparison data are the only mathematical rows stored by the packet.

The polar-support row F is read only as provenance from the finite Fenchel-duality sibling. It does not supply a separating hyperplane theorem, a topological dual completion, or an analytic closure assertion.

The structural rows H, K, P, N transport, replay, source, and name the same displayed data. Since no other coordinate is present, the listed rows exhaust the local NameCert surface. □

Theorem 8855.3 (Dual-cone polar-support route)**.** *Every polar-support read of an accepted* $\mathsf{DualCone}^{\uparrow}$ *packet must first expose the* $\mathsf{ConvexSet}^{\uparrow}$ *cone row, the* $\mathsf{VecSpace}^{\uparrow}$ *source row, the* $\mathsf{LinMap}^{\uparrow}$ *functional row, the* $\mathsf{Real}^{\uparrow}$ *comparison row, and the* $\mathsf{FenchelDuality}^{\uparrow}$ *provenance row. The route may be consumed by finite primal-dual chapters, but it exports no Hahn–Banach theorem, no strong separation theorem, no host quotient space, no analytic closedness statement, and no ambient topological-dual object.*

Proof. Read the carrier rows C, V, L, R, F in order. The cone is inspected as displayed convex data in a displayed vector-space boundary, and a dual read is admitted only through a displayed linear functional with a Real-valued support comparison.

Now compare with chapter 321. The Fenchel row records the finite primal-dual bridge that may consume the support comparison, while the present packet keeps the cone-dual route at the level of named rows.

The carrier has no row for extension, separation, quotienting, analytic closure, or a completed topological dual. Thus every consumer remains on the finite polar-support route. □

Falsifiable prediction: Any accepted $\mathsf{DualCone}^{\uparrow}$ consumer that invokes Hahn–Banach, strong separation, host quotient spaces, analytic closedness, or an ambient topological dual before reading $V, C, L, R, F, H, K, P, N$ refutes the carrier surface of Definition 8855.1.

Independence witness: convexset, vecspace, linearmap, real, fenchelduality: $\mathsf{DualCone}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries cone membership, vector-space source, linear-functional support, Real comparison, Fenchel polar-support provenance, transport, replay, provenance, and local naming rows.

Closure status for $\mathsf{NameCert}_{\mathsf{DualCone}^{\uparrow}}$.

Constructive story: A $\mathsf{DualCone}^{\uparrow}$ packet is generated from a VecSpace source row, a ConvexSet cone row, a LinearMap functional row, a Real support-comparison row, a FenchelDuality polar-support provenance row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{DualCone}^{\uparrow}}$, seed)

Scope closed: Definition 8855.1, Definition 8855.2, and Definition 8855.3 seed the finite dual-cone NameCert surface over $V, C, L, R, F, H, K, P, N$.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{DualCone}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close Hahn–Banach, strong separation, host quotient spaces, analytic closedness, ambient topological duality, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, cone exposure, functional exposure, support comparison, polar-support provenance, transport, replay, provenance, and local naming for BEDC.Derived.DualConeUp.

Chapter 8856

A Concrete Naming Certificate for $\mathsf{FiniteCoverOrderNetwork}^{\uparrow}$

Following Munkres and Engelking on finite refinements of covers, the $\mathsf{FiniteCoverOrderNetwork}^{\uparrow}$ packet records the finite refinement-order surface through which compact metric cover data are routed to dyadic radii and uniform-modulus consumers. It sits beside the compact metric certificate of chapter 129, the metric carrier of chapter 57, the dyadic interval net of chapter 5966, the finite Lebesgue-number route of chapter 452, the uniform modulus handoff of chapter 369, and the terminal real seal of chapter 38. The packet names only displayed finite cover nodes, refinement arrows, incidence witnesses, dyadic radius ledgers, transport, replay, provenance, and local naming; it does not import open-cover compactness, a choice-selected subcover, quotient equality of covers, ambient completeness, or an independent $\mathsf{Real}^{\uparrow}$ carrier.

Definition 8856.1 (FiniteCoverOrderNetwork carrier)**.** *A* $\mathsf{FiniteCoverOrderNetwork}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Q = (V, O, I, D, U, R, H, C, P, N)$$

with the following displayed rows:

1. *V is the cover-node row, listing the accepted finite cover names, the parent* $\mathsf{CompactMetric}^{\uparrow}$ *source, and the local* $\mathsf{Met}^{\uparrow}$ *probes visible at each node.*
2. *O is the refinement-order row, recording the finite preorder of displayed refinements and the named source and target cover nodes of each refinement arrow.*
3. *I is the incidence row, storing the pointwise cover-membership and refinement-containment witnesses used by order consumers.*
4. *D is the dyadic radius ledger, binding each cover node to its* $\mathsf{DyadicIntervalNet}^{\uparrow}$ *radius data and to the finite* $\mathsf{FiniteLebesgueNumber}^{\uparrow}$ *lower-bound checks that justify refinement steps.*
5. *U is the uniform-modulus handoff row, available only after V, O, I, D have been displayed and only for consumers of the named* $\mathsf{UniformModulus}^{\uparrow}$ *route.*
6. *R is the* $\mathsf{Real}^{\uparrow}$ *seal row, exposing only the real-valued radius readbacks displayed by D and U.*
7. *H stores componentwise* hsame *transport for cover nodes, refinement arrows, incidence witnesses, dyadic ledgers, uniform-modulus handoff, real seals, provenance, and local naming.*
8. *C stores the displayed* Cont *replay for the same finite rows.*

9. *P is the* Pkg *provenance over* $\mathsf{FiniteCoverOrderNetwork}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{DyadicIntervalNet}^{\uparrow}$, $\mathsf{FiniteLebesgueNumber}^{\uparrow}$, $\mathsf{UniformModulus}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{FiniteCoverOrderNetwork}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $V, O, I, D, U, R, H, C, P, N$. It has no coordinate for arbitrary open covers, selected subcovers, quotient equality of cover families, countable choice, ambient metric completeness, or an independent real carrier.

Theorem 8856.2 (FiniteCoverOrderNetwork NameCert obligations)**.** *For every accepted* FiniteCoverOrderNetwork *carrier*

$$Q = (V, O, I, D, U, R, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{FiniteCoverOrderNetwork}^{\uparrow}}$ *surface consists exactly of carrier admission for the cover-node row V, refinement-order row O, incidence row I, dyadic radius ledger D, uniform-modulus handoff U,* $\mathsf{Real}^{\uparrow}$ *seal R, componentwise transport H, displayed replay C, package provenance P, and local naming N.*

Proof. Project the carrier of Definition 8856.1. The finite data visible to the classifier are precisely the cover nodes V, refinement order O, incidence witnesses I, dyadic ledger D, uniform-modulus handoff U, and real seal R.

The order obligation is forced through V, O, I. A consumer cannot compare two cover nodes until both the displayed refinement arrow and the incidence witnesses justifying its containment reading have been exposed.

The radius obligation is separate. The row D supplies the dyadic interval-net and finite Lebesgue-number entries used by refinement steps, while U and R make only the named uniform-modulus and real-valued radius readbacks available downstream.

Finally read H, C, P, N. These rows transport, replay, prove provenance, and name the same finite packet. Since no arbitrary open cover, selected subcover, quotient cover equality, countable choice, ambient completeness, or independent real carrier is a coordinate, the listed rows exhaust the local NameCert surface. □

Theorem 8856.3 (FiniteCoverOrderNetwork order readback)**.** *Every compact-metric or uniform-modulus consumer of an accepted* $\mathsf{FiniteCoverOrderNetwork}^{\uparrow}$ *packet must read the refinement network through the ordered rows*

$$V, O, I, D, U, R, H, C, P, N$$

before treating a cover refinement as a radius-controlled finite route. The readback supplies a finite refinement order with dyadic and real radius seals; it does not supply open-cover compactness, a chosen subcover, quotient equality of covers, countable choice, ambient completeness, or an independent $\mathsf{Real}^{\uparrow}$ *carrier.*

Proof. Start with the cover comparison. The rows V, O, I display the finite cover nodes, the refinement arrows, and the incidence witnesses, so the order readback has no access to an unnamed cover relation.

Next read the radius evidence. The dyadic ledger D records the interval-net and finite Lebesgue-number checks attached to the refinement arrows, and the rows U, R expose the uniform-modulus handoff and terminal real radius seals only after that ledger is visible.

It remains to package the route. Transport, replay, provenance, and local naming through H, C, P, N preserve the same displayed rows and add no global compactness theorem or selected subcover. Thus every accepted consumer reads exactly the finite refinement-order surface named by the carrier. □

Closure status for $\mathsf{NameCert}_{\mathsf{FiniteCoverOrderNetwork}^{\uparrow}}$.

Constructive story: A $\mathsf{FiniteCoverOrderNetwork}^{\uparrow}$ packet is generated from finite cover nodes, a refinement-order row, incidence witnesses, a dyadic radius ledger, a uniform-modulus handoff, a Real seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{FiniteCoverOrderNetwork}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8856.1, Definition 8856.2, and Definition 8856.3 seed the finite cover refinement-order carrier through compact metric cover nodes, metric incidence, dyadic interval nets, finite Lebesgue-number rows, uniform-modulus handoff, and Real radius readback.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{FiniteCoverOrderNetwork}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close arbitrary open-cover compactness, selected subcovers, quotient equality of cover families, countable choice, ambient metric completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, refinement-order exactness, incidence coverage, dyadic radius-ledger exposure, uniform-modulus routing, Real seal readback, transport, replay, provenance, and local naming for BEDC.Derived.FiniteCoverOrderNetworkUp.

Chapter 8857

A Concrete Naming Certificate for $\mathsf{DirectMethodMinimizer}^{\uparrow}$

Following Tonelli's existence theorem, Weierstrass compactness arguments, and the constructive accounts of the direct method in Dacorogna and Evans, the $\mathsf{DirectMethodMinimizer}^{\uparrow}$ packet records the finite route by which a variational minimum is read from compact sublevel data and lower-semicontinuity evidence. It sits after the compact finite-window discipline of chapter 129, the lower-semicontinuity boundary of chapter 1536, the variational convergence surface of chapter 5957, the Euler–Lagrange consumer of chapter 318, the regular rational readback route of chapter 301, and the terminal real seal of chapter 38. The packet names a displayed minimizer read; it does not import a host choice of minimizer, quotient equality of functionals, selected convergent subsequences, open-cover compactness, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 8857.1 (DirectMethodMinimizer carrier)**.** *A* $\mathsf{DirectMethodMinimizer}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$D = (X, K, L, S, F, M, Q, E, H, C, P, N)$$

with the following displayed rows:

1. *X is the metric or function-space source row on which admissible configurations are inspected.*
2. *K is either a* $\mathsf{CompactMetric}^{\uparrow}$ *finite compactness-window row or a finite compact sublevel row displaying the compact part of the admissible surface.*
3. *L is the* $\mathsf{LowerSemicontinuous}^{\uparrow}$ *epigraph or liminf row for the inspected functional.*
4. *S is the coercive sublevel ledger, listing the displayed level, admissible window, and compact sublevel dependency actually used by the packet.*
5. *F is the finite functional-value window ledger for the minimizing comparison.*
6. *M is the minimizer-read row, exposed only after K, L, S, F have all been displayed.*
7. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the rational value comparisons attached to F and M.*
8. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *value seal row for the displayed minimum value.*
9. *H records componentwise* hsame *transport for the source, compact sublevel, lower-semicontinuity, coercive ledger, value window, minimizer read, readback, and seal rows.*
10. *C records displayed* Cont *replay from a minimizer request through the compact sublevel and lower-semicontinuity route.*

11. *P is the* Pkg *provenance over* $\mathsf{DirectMethodMinimizer}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{LowerSemicontinuous}^{\uparrow}$, $\mathsf{GammaConvergence}^{\uparrow}$, $\mathsf{EulerLagrange}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
12. *N is the local* $\mathsf{NameCert}_{\mathsf{DirectMethodMinimizer}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $X, K, L, S, F, M, Q, E, H, C, P, N$. It has no coordinate for a host minimizer choice, arbitrary open-cover compactness, selected subsequence extraction, quotient equality of functionals, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 8857.2 (DirectMethodMinimizer NameCert obligations)**.** *For every accepted* $\mathsf{DirectMethodMinimizer}^{\uparrow}$ *carrier $D = (X, K, L, S, F, M, Q, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{DirectMethodMinimizer}^{\uparrow}}$ *surface consists exactly of carrier admission for the source row, compact sublevel row, lower-semicontinuity row, coercive sublevel ledger, functional-value windows, minimizer-read row, regular rational readback, terminal real-value seal, componentwise transport, displayed replay, provenance, and local naming.*

Every minimizer-facing consumer must therefore read the finite route

$$\mathsf{CompactMetric}^{\uparrow},\ \mathsf{LowerSemicontinuous}^{\uparrow},\ \mathsf{RegSeqRat}^{\uparrow},\ \mathsf{Real}^{\uparrow},\ \mathsf{BHist},\ \mathsf{hsame},\ \mathsf{Cont},\ \mathsf{Pkg},\ \mathsf{NameCert}$$

through the rows $K, L, S, F, M, Q, E, H, C, P, N$. The exported route is a NameCert boundary for a displayed direct-method minimum, not a host selection principle, quotient functional equality, selected subsequence theorem, or ambient completeness result.

Proof. Project the accepted carrier of Definition 8857.1. The analytic rows are X, K, L, S, F, M, Q, E, and the structural rows are H, C, P, N.

Carrier admission first exposes the admissible source row X and the compact sublevel row K. The coercive ledger S is read against the same compact window, so the packet has no separate path to open-cover compactness or a selected subsequence.

The functional-value and lower-bound data are then read through L, F. Lower semicontinuity supplies only the displayed epigraph or liminf row, and the value windows supply only the comparisons listed in the packet.

Finally the minimizer-read row M is exposed through Q and sealed by E. Transport, replay, provenance, and local naming preserve that same displayed route, so no coordinate can add a host minimizer choice, quotient functional equality, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness. □

Theorem 8857.3 (DirectMethodMinimizer compact-sublevel route)**.** *Every minimizer read exported by an accepted* $\mathsf{DirectMethodMinimizer}^{\uparrow}$ *packet factors through the displayed route*

$$X, K, S \longmapsto L, F \longmapsto M, Q, E, H, C, P, N.$$

In particular, the read is public only after the compact sublevel row and lower-semicontinuity row have both been displayed. It does not factor through host choice of a minimizer, ambient completeness of $\mathsf{Real}^{\uparrow}$*, quotient equality of functionals, selected recovery sequences from* $\mathsf{GammaConvergence}^{\uparrow}$*, or an* $\mathsf{EulerLagrange}^{\uparrow}$ *necessary-condition consumer.*

Proof. Start from the NameCert obligations of Definition 8857.2. They require any minimizer-facing consumer to expose the compact sublevel row K and coercive ledger S before the minimizer-read coordinate M can be inspected.

Next read the lower-semicontinuity row L and the functional-value windows F. These rows provide the direct-method comparison surface: compactness supplies the admissible sublevel boundary, while lower semicontinuity supplies the displayed lower-bound handoff.

The readback rows Q, E then present only the rational comparison and terminal real-value seal attached to that finite route. The structural rows H, C, P, N transport, replay, source, and name the same packet.

Thus the public minimizer read factors through compact sublevel and lower-semicontinuity data. Gamma-convergence and Euler–Lagrange packets may consume or compare the result, but they do not supply the existence route inside this carrier. □

Falsifiable prediction: Every accepted $\mathsf{DirectMethodMinimizer}^{\uparrow}$ consumer that reaches a minimizer-read row or a terminal RealUp value seal without first reading the compact sublevel row, LowerSemicontinuous row, coercive sublevel ledger, RegSeqRat readback, transport, replay, provenance, and local NameCert row refutes the carrier surface.

Independence witness: compactmetric, lowersemicontinuous, gamma-convergence, eulerlagrange, regseqrat, real: $\mathsf{DirectMethodMinimizer}^{\uparrow}$ is not bijective to any listed sibling because it jointly binds compact sublevel data, lower-semicontinuity rows, coercive ledgers, value windows, minimizer reads, rational readback, terminal real seals, transport, replay, provenance, and local naming in one packet.

Closure status for $\mathsf{NameCert}_{\mathsf{DirectMethodMinimizer}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{DirectMethodMinimizer}^{\uparrow}}, \mathsf{seed})$

Constructive story: A $\mathsf{DirectMethodMinimizer}^{\uparrow}$ packet is generated from source rows, compact sublevel or CompactMetric rows, LowerSemicontinuous epigraph rows, coercive sublevel ledgers, functional value windows, minimizer-read rows, RegSeqRat readback, RealUp value seals, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Scope closed: Definition 8857.1, Definition 8857.2, and Definition 8857.3 seed the finite direct-method minimizer certificate through compact sublevel, lower-semicontinuity, regular rational readback, real-value sealing, transport, replay, provenance, and local naming rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{DirectMethodMinimizer}^{\uparrow}}, \mathsf{formalTarget})$

Lean target: `BEDC.Derived.DirectMethodMinimizerUp`

Bridge status: none

Not claimed: This chapter does not close host minimizer selection, selected subsequence extraction, quotient equality of functionals, open-cover compactness, countable choice, Euler–Lagrange necessary conditions, Gamma-convergence recovery selection, ambient RealUp completeness, theorem-level Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, compact sublevel exposure, lower-semicontinuity exposure, coercive ledger exactness, value-window readback, minimizer-read sealing, transport, replay, provenance, and local naming for BEDC.Derived.DirectMethodMinimizerUp.

Lean4 (statement) `BEDC.Derived.DirectMethodMinimizerUp`

Chapter 8858

A Concrete Naming Certificate for $\mathsf{UpwindFlux}^{\uparrow}$

Following LeVeque and Eymard–Gallouet–Herbin, the $\mathsf{UpwindFlux}^{\uparrow}$ packet records finite-volume flux orientation as BEDC-visible NameCert data. It sits over the conservative balance packet of chapter 6277, the dyadic mesh interface of chapter 358, the PDE relation surface of chapter 194, the regular rational readback of chapter 301, the dyadic tolerance core of chapter 291, and the real-name seal of chapter 38. The packet names only the finite upstream orientation rows used by a numerical flux; it does not import a host PDE solution, unrestricted convergence theorem, quotient weak-solution object, selected trace, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 8858.1 (Upwind-flux carrier)**.** *An* $\mathsf{UpwindFlux}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$U = (V, M, Q, A, O, W, R, D, E, H, C, P, N)$$

with the following displayed rows:

1. *V is the* $\mathsf{FiniteVolume}^{\uparrow}$ *carrier row whose face-incidence and balance ledgers supply the finite-volume context.*
2. *M is the* $\mathsf{DyadicMesh}^{\uparrow}$ *row naming the inspected cell, face, and neighbour windows at dyadic precision.*
3. *Q is the* $\mathsf{Pde}^{\uparrow}$ *relation row whose local derivative or conservation relation supplies the direction-sensitive PDE side.*
4. *A is the advection or sign classifier row, read only as a finite orientation comparison on each displayed face.*
5. *O is the upstream-choice row, selecting for each oriented face the left, right, or boundary value row licensed by V, M, Q, A.*
6. *W is the numerical-flux window row, recording the finite stencil values consumed after the upstream side has been selected.*
7. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the inspected flux values and residual windows.*
8. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row comparing paired orientation and residual budgets.*
9. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal reached only after V, M, Q, A, O, W, R, D have been displayed.*

10. *H records componentwise* hsame *transport for the finite-volume, mesh, PDE, orientation, upstream-choice, flux-window, readback, tolerance, real-seal, replay, provenance, and local naming rows.*
11. *C is the displayed* Cont *replay from an upwind flux request through $V, M, Q, A, O, W, R, D, E, H, P, N$.*
12. *P is the* Pkg *provenance over* $\mathsf{UpwindFlux}^{\uparrow}$, $\mathsf{FiniteVolume}^{\uparrow}$, $\mathsf{DyadicMesh}^{\uparrow}$, $\mathsf{Pde}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
13. *N is the local* $\mathsf{NameCert}_{\mathsf{UpwindFlux}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through these displayed rows. It has no coordinate for a host PDE solution, unrestricted convergence of a scheme, quotient weak solution, selected trace, hidden solver state, or ambient real completeness theorem.

Theorem 8858.2 (Upwind-flux NameCert obligations)**.** *For every accepted* $\mathsf{UpwindFlux}^{\uparrow}$ *carrier*

$$U = (V, M, Q, A, O, W, R, D, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{UpwindFlux}^{\uparrow}}$ *surface consists exactly of finite-volume admission through V, dyadic mesh admission through M, PDE relation admission through Q, orientation classifier admission through A, upstream-choice exactness through O, flux-window exposure through W, regular rational readback through R, dyadic tolerance exposure through D, real-seal handoff through E, componentwise transport through H, displayed continuation replay through C, provenance through P, and local naming through N.*

Proof. Project the carrier of Definition 8858.1. The rows V, M, Q expose the finite-volume balance packet, dyadic mesh window, and PDE relation before any orientation-sensitive flux read is public.

The row A is the only source of direction information. The upstream-choice row O is therefore exact only when it selects a displayed left, right, or boundary value from the finite rows already licensed by V, M, Q, A.

The flux-window row W consumes the selected side from O before the readback and tolerance rows are inspected. Thus R, D, E certify only the resulting finite flux and residual windows, not a host solution or a scheme-wide convergence theorem.

Finally, H, C, P, N transport, replay, source, and name the same finite route. Since no excluded host solution, unrestricted convergence proof, quotient weak-solution object, selected trace, solver state, or ambient completeness coordinate occurs in the carrier, the listed rows exhaust the local certificate surface. □

Theorem 8858.3 (Upwind-flux ledger stability)**.** *Let $U = (V, M, Q, A, O, W, R, D, E, H, C, P, N)$ be an accepted* $\mathsf{UpwindFlux}^{\uparrow}$ *carrier. Any componentwise* hsame *transport that preserves the displayed finite-volume incidence in V, the dyadic mesh window in M, the PDE relation row in Q, and the orientation classifier row in A also preserves the upstream-choice ledger O and the numerical-flux window W as* $\mathsf{UpwindFlux}^{\uparrow}$ *data. The transported packet remains inside the same finite ledger boundary and exposes no host PDE solution, unrestricted convergence theorem, quotient weak solution, selected trace, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start with the componentwise transport rows in H. They move the finite-volume incidence row, dyadic mesh window, PDE relation row, and orientation classifier row without adding any coordinate outside the displayed packet.

Because O is defined only as the upstream side selected from V, M, Q, A, preserving those four rows preserves the source of every selection in O. Boundary faces remain boundary reads, left-facing interior choices remain left reads, and right-facing interior choices remain right reads.

The numerical-flux window W is downstream of O. Once the selected side is transported with the same classifier data, the regular readback R, dyadic tolerance row D, and real seal E replay the same finite flux route.

The continuation, provenance, and local name rows C, P, N then repack the transported data as an $\mathsf{UpwindFlux}^{\uparrow}$ carrier. No excluded analytic or quotient object can enter, since none is a field of Definition 8858.1. □

Falsifiable prediction: An accepted $\mathsf{UpwindFlux}^{\uparrow}$ consumer must expose the $\mathsf{FiniteVolume}^{\uparrow}$ face-incidence row, $\mathsf{DyadicMesh}^{\uparrow}$ inspected window, $\mathsf{Pde}^{\uparrow}$ relation row, orientation classifier, upstream-choice ledger, numerical-flux window, $\mathsf{RegSeqRat}^{\uparrow}$ readback, $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance, $\mathsf{Real}^{\uparrow}$ seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert row before it may read an upwind flux.

Independence witness: finite-volume, dyadicmesh, pde, regseqrat, dyadicratcore, real: no listed sibling supplies the whole packet $U = (V, M, Q, A, O, W, R, D, E, H, C, P, N)$, because each sibling contributes only a conservative balance, mesh window, PDE relation, regular rational readback, dyadic tolerance row, or terminal real seal, while this chapter binds them into one orientation-sensitive finite flux route.

Closure status for $\mathsf{NameCert}_{\mathsf{UpwindFlux}^{\uparrow}}$.

Constructive story: An $\mathsf{UpwindFlux}^{\uparrow}$ packet is generated from a FiniteVolumeUp balance row, DyadicMeshUp inspected window, PdeUp relation row, finite orientation classifier, upstream-choice row, numerical-flux window, RegSeqRat readback, DyadicRatCore tolerance, RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{UpwindFlux}^{\uparrow}}$, seed)

Scope closed: Definition 8858.1, Definition 8858.2, and Definition 8858.3 seed the finite upwind flux-orientation route over $\mathsf{FiniteVolume}^{\uparrow}$, $\mathsf{DyadicMesh}^{\uparrow}$, $\mathsf{Pde}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, Pkg, and NameCert.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{UpwindFlux}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim host PDE solutions, unrestricted convergence, quotient weak solutions, selected traces, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean theorem checking, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, finite-volume incidence routing, mesh-window routing, PDE relation routing, orientation classifier exactness, upstream-choice stability, flux-window readback, dyadic tolerance, Real-seal handoff, transport, replay, provenance, and local naming for BEDC.Derived.UpwindFluxUp.

Chapter 8859

A Concrete Naming Certificate for $\mathsf{FiniteDependentFamily}^{\uparrow}$

Following dependent type theory and finite product constructions, the $\mathsf{FiniteDependentFamily}^{\uparrow}$ packet records the finite BEDC surface for a family of displayed fibres indexed by a finite row. It sits after the finite-data interface of chapter 9353, the ordered spine discipline of chapter 36, the component envelope of chapter 34, the branch-tag boundary of chapter 35, and the function-object substrate of chapter 132. The packet also aligns with the continuous-map interface of chapter 130 when a downstream consumer reads a displayed fibre assignment as a finite family of maps. It names finite dependent family data only; it does not import an ambient dependent function space, quotient equality of fibres, a selected global section, countable choice, or host-side product extensionality.

Definition 8859.1 (Finite dependent family carrier)**.** *A* $\mathsf{FiniteDependentFamily}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$D = (I, F, H, C, P, N)$$

with the following displayed rows:

1. *I is the finite index row. It is read as a displayed* $\mathsf{List}^{\uparrow}$ *spine of index names, with endpoint and branch discipline inherited from the* $\mathsf{Bool}^{\uparrow}$, $\mathsf{Option}^{\uparrow}$, *and* $\mathsf{Sum}^{\uparrow}$ *finite-data surfaces.*
2. *F is the fibre row. For each displayed index of I, it stores one fibre NameCert row and the local classifier by which that fibre is inspected.*
3. *H records componentwise* hsame *transport for the index row, each fibre row, each pointwise classifier, the replay row, the provenance row, and the local naming row.*
4. *C records displayed* Cont *replay from finite index inspection through the matching fibre row and then through the pointwise classifier for that fibre.*
5. *P is the* Pkg *provenance over* $\mathsf{FiniteDependentFamily}^{\uparrow}$, $\mathsf{List}^{\uparrow}$, $\mathsf{Prod}^{\uparrow}$, $\mathsf{Sum}^{\uparrow}$, $\mathsf{Func}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$ *rows.*
6. *N is the local* $\mathsf{NameCert}_{\mathsf{FiniteDependentFamily}^{\uparrow}}$ *row.*

The carrier has no coordinate for an ambient dependent product, quotient fibre equality, selected section, countable-choice schedule, or host-side extensionality principle.

Theorem 8859.2 (Finite dependent family NameCert obligations)**.** *For every accepted* $\mathsf{FiniteDependentFamily}^{\uparrow}$ *carrier*

$$D = (I, F, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{FiniteDependentFamily}^{\uparrow}}$ *surface consists exactly of carrier admission for* D*, finite index exposure through* I*, fibre exposure through* F*, pointwise classifier stability for each displayed fibre, componentwise* hsame *transport through* H*, displayed* Cont *replay through* C*,* Pkg *provenance through* P*, and local naming through* N*. A consumer therefore reads a finite dependent family only through the displayed route*

$$I, F \longmapsto H, C, P, N$$

and not through an ambient dependent function space, quotient equality of fibres, selected global section, countable choice, or host product extensionality.

Proof. Project the accepted carrier. The finite index row I is the only source of fibre positions, so every consumer first reads the displayed list spine and its finite-data branch discipline.

For each exposed index, the fibre row F supplies the corresponding fibre NameCert row and its local classifier. Pointwise classifier stability is therefore checked inside the displayed fibre row rather than by comparing all fibres in an ambient dependent product.

Finally the structural rows preserve the same packet. Componentwise transport H, continuation replay C, provenance P, and local naming N exhaust the available route, leaving no coordinate for quotient fibre equality, selected sections, countable choice, or host extensionality. □

Falsifiable prediction: An accepted $\mathsf{FiniteDependentFamily}^{\uparrow}$ consumer that reads a fibre without the finite index row I, the displayed fibre row F, and the structural hsame, Cont, Pkg, and NameCert rows refutes the carrier surface.

Independence witness: finite-data-interface, list, product, sum, function-object: no listed sibling jointly carries the finite index row, displayed fibre NameCert rows, pointwise classifier stability, componentwise transport, replay, provenance, and local naming rows of $D = (I, F, H, C, P, N)$.

Closure status for $\mathsf{NameCert}_{\mathsf{FiniteDependentFamily}^{\uparrow}}$**.**

Constructive story: A $\mathsf{FiniteDependentFamily}^{\uparrow}$ packet is generated from a finite index row, displayed fibre NameCert rows, pointwise classifier stability, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{FiniteDependentFamily}^{\uparrow}}$, seed)

Scope closed: Definition 8859.1 and Definition 8859.2 seed the finite dependent-family carrier and its displayed NameCert obligation surface.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{FiniteDependentFamily}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close ambient dependent products, quotient fibre equality, selected sections, countable choice, host product extensionality, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, index exposure, fibre exposure, pointwise classifier stability, transport, replay, provenance, and local naming for BEDC.Derived.FiniteDependentFamilyUp.

Chapter 8860

A Concrete Naming Certificate for $\mathsf{KnasterBucketHandleContinuum}^{\uparrow}$

Following Knaster and continuum theory, the $\mathsf{KnasterBucketHandleContinuum}^{\uparrow}$ packet records the bucket-handle continuum as finite NameCert data for a compact chainable continuum built from nested interval windows rather than from a host closed subset of the plane. It sits beside the compact-metric source of chapter 129, the Peano-continuum interface of chapter 2160, the topologist sine curve boundary of chapter 7316, the pseudo-arc inverse-limit surface of chapter 6905, and the terminal Real seal of chapter 38. The packet names finite chain covers, nested strip windows, bonding readback, and indecomposable-continuum obstruction rows; it does not import ambient planar topology, quotient continuum equality, selected inverse-limit points, open-cover compactness, or a host theorem about the bucket-handle continuum.

Definition 8860.1 (Knaster bucket-handle continuum carrier)**.** *A* $\mathsf{KnasterBucketHandleContinuum}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (M, S, B, C, I, R, E, H, T, P, N)$$

with the following displayed rows:

1. *M is the* $\mathsf{CompactMetric}^{\uparrow}$ *source row, exposing the metric carrier, finite compactness windows, total-boundedness ledger, and distance readback used by every continuum-facing request.*
2. *S is the nested strip row. It records a finite prefix of horizontal strip windows, endpoint brackets, refinement inclusions, and the refusal of any ambient planar closed-set equality.*
3. *B is the bonding row, recording the finite inverse-limit prefix by which each strip window is read into the next level through displayed projection and compatibility data.*
4. *C is the chain-cover row. For each displayed scale it lists a finite chain cover, adjacency ledger, overlap certificates, and diameter bounds over the compact-metric source.*
5. *I is the indecomposability obstruction row, recording finite tests that prevent a displayed continuum window from being split into two proper subcontinuum windows inside the same prefix.*
6. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for endpoint brackets, strip widths, chain-cover diameters, projection tolerances, and obstruction budgets.*
7. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal for the numeric windows read through S, B, C, I, R.*

8. *H records componentwise* hsame *transport for compact-metric, strip, bonding, chain-cover, obstruction, regular-rational, Real-seal, replay, provenance, and local naming rows.*
9. *T records displayed* Cont *replay from compact-metric cover requests through nested strip prefixes, bonding compatibility, chain covers, obstruction tests, and numeric readback.*
10. *P is the* Pkg *provenance over* $\mathsf{KnasterBucketHandleContinuum}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{PeanoContinuum}^{\uparrow}$, $\mathsf{TopologistSineCurve}^{\uparrow}$, $\mathsf{PseudoArc}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{KnasterBucketHandleContinuum}^{\uparrow}}$ *row.*
