The classifier compares accepted packets only through $M, S, B, C, I, R, E, H, T, P, N$. It has no coordinate for ambient planar subsets, host closed-set equality, quotient continuum equality, selected inverse-limit representatives, countable choice, open-cover compactness, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 8860.2 (Knaster bucket-handle continuum NameCert obligations)**.** *For every accepted* $\mathsf{KnasterBucketHandleContinuum}^{\uparrow}$ *carrier*

$$K = (M, S, B, C, I, R, E, H, T, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{KnasterBucketHandleContinuum}^{\uparrow}}$ *surface consists exactly of compact-metric source admission through M, nested strip-window admission through S, bonding-prefix compatibility through B, finite chain-cover coverage through C, indecomposability obstruction exposure through I, regular rational tolerance readback through R, terminal Real sealing through E, componentwise transport through H, displayed replay through T, provenance through P, and local naming through N.*

Every continuum-facing consumer must read these rows before it may use the packet as bucket-handle continuum evidence. No obligation row is discharged by an ambient planar subset, host closed-set equality, quotient continuum equality, selected inverse-limit representative, countable-choice schedule, open-cover compactness theorem, or ambient $\mathsf{Real}^{\uparrow}$ *completeness principle.*

Proof. Project the carrier of Definition 8860.1. The compact-metric row M is the only source of metric and compactness data, so every later strip, bonding, chain-cover, or obstruction read is measured over the same displayed carrier.

Read the constructive bucket-handle rows next. The strip row S stores only finite nested strip windows, and the bonding row B records finite projection compatibility between those windows. Thus the packet uses displayed inverse-limit-style readback rather than a host closed subset of the plane.

The chainability and indecomposability data are then separated. The row C lists finite chain covers with adjacency, overlap, and diameter certificates; the row I records finite obstruction tests against splitting a displayed continuum window into two proper subcontinuum windows. The numeric side of both rows is read through R before the Real seal E is consumed.

Finally H, T, P, N transport, replay, source, and name the same finite packet. Since the refused principles have no carrier coordinate and no replay edge, the displayed rows exhaust the local NameCert surface. □

Theorem 8860.3 (Knaster bucket-handle continuum chainable handoff)**.** *Every chainable-continuum read of an accepted* $\mathsf{KnasterBucketHandleContinuum}^{\uparrow}$ *packet factors through*

$$\mathsf{CompactMetric}^{\uparrow},\quad S,\quad B,\quad C,\quad I,\quad \mathsf{RegSeqRat}^{\uparrow},\quad \mathsf{Real}^{\uparrow},\quad \mathsf{BHist},\quad \mathsf{hsame},\quad \mathsf{Cont},\quad \mathsf{Pkg},\quad \mathsf{NameCert}_{\mathsf{KnasterBuc}}$$

The handoff exposes the bucket-handle continuum only as finite nested strip prefixes, bonding compatibility, chain-cover rows, indecomposability obstruction rows, regular-rational readback, and Real

sealing. It exports no ambient planar topology, quotient continuum equality, selected inverse-limit point, open-cover compactness theorem, countable-choice selector, or ambient completeness claim.

Proof. Begin with the compact-metric source. The row M supplies the metric carrier and finite compactness windows before any continuum-facing read may inspect the strip or chain-cover data.

The bucket-handle-specific route then reads S and B. These rows display finite nested strip prefixes and bonding compatibility, so a downstream consumer obtains a finite prefix route rather than a selected inverse-limit point or host planar subset.

Next the consumer reads C and I. Chain covers in C provide the scale-by-scale chainable handoff, while obstruction windows in I keep the indecomposable-continuum boundary visible inside the same prefix. The tolerance and endpoint data for both rows pass through $\mathsf{RegSeqRat}^{\uparrow}$ readback and the terminal $\mathsf{Real}^{\uparrow}$ seal.

The structural rows H, T, P, N preserve this route under transport, replay, provenance, and local naming. Therefore the handoff stays inside the displayed finite packet and cannot export the refused ambient principles. □

Falsifiable prediction: An accepted $\mathsf{KnasterBucketHandleContinuum}^{\uparrow}$ consumer that reads a chain-cover row without first displaying the compact-metric source, nested strip prefix, bonding compatibility, regular-rational tolerance readback, Real seal, transport, replay, provenance, and local NameCert rows refutes the carrier surface.

Independence witness: compactmetric, peano-continuum, topologist-sine-curve, pseudo-arc, real: $\mathsf{KnasterBucketHandleContinuum}^{\uparrow}$ is not bijective to any listed sibling because it binds nested strip prefixes, bonding compatibility, chain-cover rows, indecomposability obstruction rows, regular-rational readback, Real sealing, transport, replay, provenance, and local naming in one carrier.

Closure status for $\mathsf{NameCert}_{\mathsf{KnasterBucketHandleContinuum}^{\uparrow}}$.

Constructive story: A $\mathsf{KnasterBucketHandleContinuum}^{\uparrow}$ packet is generated from CompactMetricUp source rows, nested strip prefix rows, bonding compatibility rows, finite chain-cover rows, indecomposability obstruction rows, RegSeqRatUp tolerance readback, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{KnasterBucketHandleContinuum}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8860.1, Definition 8860.2, and Definition 8860.3 seed the finite bucket-handle continuum route over compact-metric, nested-strip, bonding, chain-cover, obstruction, readback, and naming rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{KnasterBucketHandleContinuum}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim ambient planar topology, quotient continuum equality, selected inverse-limit points, open-cover compactness, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, nested strip-window exposure, bonding-prefix compatibility, finite chain-cover coverage, indecomposability obstruction exposure, tolerance readback, transport, replay, provenance, and local naming for BEDC.Derived.KnasterBucketHandleContinuumUp.

Chapter 8861

A Concrete Naming Certificate for $\mathsf{BumpFunction}^{\uparrow}$

Following Urysohn's lemma, Tietze extension, and the partition-of-unity tradition, the $\mathsf{BumpFunction}^{\uparrow}$ packet records the finite certificate surface for a locally supported nonzero continuous real-valued function without importing host function equality, choice-selected supports, or ambient $\mathsf{Real}^{\uparrow}$ completeness. It sits beside the separating-function route of **??**, the extension route of chapter 1956, the locally finite gluing route of chapter 3369, the real-name seal of chapter 38, and the pointwise continuity carrier of chapter 130.

Definition 8861.1 (Bump-function carrier)**.** *A* $\mathsf{BumpFunction}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (L, S, V, Z, F, R, H, C, P, N)$$

with the following displayed rows:

1. *L is the local source row, naming the displayed neighborhood, closed core, or finite localization data on which the bump is requested.*
2. *S is the support row, recording the finite support boundary and its inclusion in the chosen local region.*
3. *V is the vanishing-boundary row, stating that reads outside the displayed support boundary return the zero real-name seal.*
4. *Z is the nonzero local witness, displayed inside the source row before any downstream support consumer may use the bump.*
5. *F is the* $\mathsf{ContinuousMap}^{\uparrow}$ *row for the named real-valued map.*
6. *R is the* $\mathsf{Real}^{\uparrow}$ *seal row through which zero, nonzero, and boundary values are read.*
7. *H records componentwise* hsame *transport for the source, support, vanishing-boundary, nonzero witness, continuous-map, real-seal, provenance, and local naming rows.*
8. *C records the displayed* Cont *replay from local source data through support control and pointwise continuous-map reads into the real-value seal.*
9. *P is the* Pkg *provenance over* $\mathsf{BumpFunction}^{\uparrow}$, $\mathsf{UrysohnLemma}^{\uparrow}$, $\mathsf{TietzeExtension}^{\uparrow}$, $\mathsf{PartitionOfUnity}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$ *rows.*
10. *N is the local* $\mathsf{NameCert}_{\mathsf{BumpFunction}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $L, S, V, Z, F, R, H, C, P, N$. It has no coordinate for host equality of functions, a choice-selected support, a global support oracle, quotient real equality, or ambient completeness of $\mathsf{Real}^{\uparrow}$.

Theorem 8861.2 (Bump-function NameCert obligations)**.** *For an accepted* $\mathsf{BumpFunction}^{\uparrow}$ *carrier*

$$B = (L, S, V, Z, F, R, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{BumpFunction}^{\uparrow}}$ *surface consists of carrier admission, local source exposure through L, support exposure through S, vanishing-boundary exposure through V, nonzero local witness exposure through Z, continuous-map exposure through F, real-name reads through R, componentwise* hsame *transport through H, displayed* Cont *replay through C,* Pkg *provenance through P, and local naming through N.*

Proof. Project the carrier of Definition 8861.1. The local source, support, vanishing boundary, nonzero witness, continuous-map row, real seal, transport, replay, provenance, and local name are all visible coordinates of one finite packet.

Read the analytic obligations in order. The source row L fixes the local region, S records the support boundary inside that region, V records the zero behavior at the boundary, and Z records the local nonzero witness before the downstream consumer treats the map as a bump.

Finally F, R, H, C, P, N preserve the same displayed route as continuous real-valued data. The sibling routes through $\mathsf{UrysohnLemma}^{\uparrow}$, $\mathsf{TietzeExtension}^{\uparrow}$, and $\mathsf{PartitionOfUnity}^{\uparrow}$ explain the traditional sources of such packets, while the carrier itself exports only the listed finite rows. □

Theorem 8861.3 (Bump-function support non-escape)**.** *Every* $\mathsf{BumpFunction}^{\uparrow}$ *consumer reading an accepted carrier*

$$B = (L, S, V, Z, F, R, H, C, P, N)$$

must expose the local source row L, support row S, vanishing-boundary row V, nonzero witness Z, $\mathsf{ContinuousMap}^{\uparrow}$ *row F, and* $\mathsf{Real}^{\uparrow}$ *seal R before it can use the bump as locally supported real-valued data. The packet exports no host function equality, selected support set, global support oracle, quotient real equality, countable choice, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness principle.*

Proof. The NameCert obligations of Definition 8861.2 enumerate every row available to a downstream consumer. In particular, support control is not separate from the displayed packet: it is the row S together with the vanishing-boundary row V and the local witness Z.

The continuous-map and real-value reads are also downstream of the same packet. A consumer reaches F and R only through L, S, V, Z and then through the transport, replay, provenance, and naming rows.

Since the carrier has no coordinate for host function equality, selected supports, global support oracles, quotient equality, countable choice, or ambient completeness, none of these can be recovered from an accepted $\mathsf{BumpFunction}^{\uparrow}$ packet. □

Falsifiable prediction: A claimed bump-function packet with no displayed support row, no vanishing-boundary row, or no nonzero local witness is not an accepted BumpFunctionUp carrier.

Independence witness: urysohnlemma, tietzeextension, partitionofunity, continuousmap, real: these sibling chapters supply separating, extending, gluing, continuity, and real-value rows, while BumpFunctionUp binds them around a local support and nonzero witness, so no row-preserving bijection exists.

Closure status for $\mathsf{NameCert}_{\mathsf{BumpFunction}^{\uparrow}}$.

Constructive story: A BumpFunction$^{\uparrow}$ packet is generated from a local source row, a displayed support row, vanishing-boundary data, a nonzero local witness, a ContinuousMap row, a Real seal, componentwise hsame transport, Cont replay, package provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\mathsf{BumpFunction}^{\uparrow}}$, obligation)

Scope closed: Definition 8861.1, Definition 8861.2, and Definition 8861.3 bind the finite bump-function carrier and its local support boundary over source, support, vanishing, witness, ContinuousMap, Real, transport, replay, provenance, and naming rows.

Formal verification: FormalStatus(NameCert$_{\mathsf{BumpFunction}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close host function equality, choice-selected supports, global support oracles, quotient real equality, ambient Real$^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Scoped closure requires explicit routing of local source, support, vanishing-boundary, nonzero witness, ContinuousMap, Real seal, hsame transport, Cont replay, Pkg provenance, and local NameCert rows against the cited sibling surfaces.

Chapter 8862

A Concrete Naming Certificate for $\mathsf{UniformCauchyFunctionLimit}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{UniformCauchyFunctionLimit}^{\uparrow}$ packet records the finite certificate by which a uniformly Cauchy family of Cauchy-name maps is handed to a limit-function reader without selecting a host function or appealing to ambient completeness. It sits after the Cauchy-name transformer boundary of chapter 1401, the real-valued uniform Cauchy family surface of chapter 1830, the shared endpoint criterion of chapter 6029, the regular rational readback row of chapter 301, and the terminal real-name seal of chapter 38. The packet names the displayed rows by which a completion-facing consumer may read a limit candidate, not a quotient function, selected pointwise limit, choice schedule, host continuity theorem, or ambient $\mathsf{Real}^{\uparrow}$ completeness principle.

Definition 8862.1 (Uniform Cauchy function limit carrier)**.** *A* $\mathsf{UniformCauchyFunctionLimit}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (F, Q, M, S, R, E, H, C, P, N)$$

with the following displayed rows:

1. *F is the finite Cauchy-name map family row, listing the inspected maps, source Cauchy-name windows, and target value windows.*
2. *Q is the* $\mathsf{RealFunctionUniformCauchy}^{\uparrow}$ *row, recording that the same displayed tolerance request controls every retained source window and family index.*
3. *M is the* $\mathsf{CauchyContinuousMap}^{\uparrow}$ *boundary row, ensuring each inspected map is read through finite stream windows, regular rational image rows, dyadic tolerance ledgers, and a real-seal handoff.*
4. *S is the* $\mathsf{UniformLimitCauchyCriterion}^{\uparrow}$ *row, joining the shared uniform Cauchy evidence to the limit-endpoint read.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row opened from the displayed map-family windows before the terminal seal is inspected.*
6. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row for the limit candidate, available only after F, Q, M, S, R have been displayed.*
7. *H records componentwise* hsame *transport for the family row, uniform Cauchy row, Cauchy-continuous map boundary, criterion row, readback row, seal row, replay, provenance, and local naming.*

8. *C records displayed* Cont *replay from a limit-function request through $F, Q, M, S, R, E, H, P, N$.*
9. *P is the* Pkg *provenance over* $\mathsf{UniformCauchyFunctionLimit}^{\uparrow}$, $\mathsf{CauchyContinuousMap}^{\uparrow}$, $\mathsf{RealFunctionUniformCauchy}$ $\mathsf{UniformLimitCauchyCriterion}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{UniformCauchyFunctionLimit}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $F, Q, M, S, R, E, H, C, P, N$. It has no coordinate for host function equality, quotient Cauchy-name maps, selected pointwise limits, countable-choice selectors, global function-space completeness, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 8862.2 (Uniform Cauchy function limit NameCert obligations)**.** *For every accepted* $\mathsf{UniformCauchyFunctionLimit}^{\uparrow}$ *carrier*

$$L = (F, Q, M, S, R, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{UniformCauchyFunctionLimit}^{\uparrow}}$ *surface consists exactly of carrier admission for the finite Cauchy-name map family, real-function uniform Cauchy row, Cauchy-continuous map boundary, uniform-limit Cauchy criterion row, regular rational readback, terminal real seal, componentwise transport, displayed replay, provenance, and local naming. Every limit read must display the shared uniform Cauchy evidence Q, the Cauchy-continuous map boundary M, and the criterion row S before R and E can be consumed.*

Proof. Project the carrier of Definition 8862.1. The only admitted rows are $F, Q, M, S, R, E, H, C, P, N$, so the local certificate has no place to store an external limit function or a host equality proof.

The uniform Cauchy and continuity obligations are the rows Q and M. Their placement before S, R, E forces the family comparison and map-readback surfaces to be displayed before any endpoint seal is reached.

The criterion row S connects those rows to the limit endpoint. The regular rational readback R and terminal seal E then provide the Real-facing route, while H, C, P, N transport, replay, source, and name the same finite packet. □

Theorem 8862.3 (Uniform Cauchy function limit Real seal)**.** *Let $L = (F, Q, M, S, R, E, H, C, P, N)$ be an accepted* $\mathsf{UniformCauchyFunctionLimit}^{\uparrow}$ *carrier. Any* $\mathsf{Real}^{\uparrow}$*-facing read of the limit candidate factors through the displayed route*

$$\mathsf{CauchyContinuousMap}^{\uparrow} \longmapsto \mathsf{RealFunctionUniformCauchy}^{\uparrow} \longmapsto \mathsf{UniformLimitCauchyCriterion}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{R}$$

using the rows M, Q, S, R, E together with transport, replay, provenance, and local naming. The seal cannot be reached from a quotient function, a selected pointwise limit, a countable-choice schedule, or an ambient completeness argument.

Proof. Read the endpoint rows in Definition 8862.1. The seal E is downstream of the map boundary M, uniform Cauchy row Q, criterion row S, and regular readback R.

Replay the request through C. The replay route exposes exactly those rows before the seal is visible, and componentwise transport through H preserves the same dependency order.

The provenance row P sources only the listed packet rows. Therefore a Real-facing consumer receives the displayed route to E and no detached quotient function, selected pointwise limit, choice schedule, or ambient completeness datum. □

Theorem 8862.4 (Uniform Cauchy function limit continuity handoff)**.** *Every continuity-facing consumer of an accepted* $\mathsf{UniformCauchyFunctionLimit}^{\uparrow}$ *packet must first inspect the* $\mathsf{CauchyContinuousMap}^{\uparrow}$

row M, the RealFunctionUniformCauchy$^{\uparrow}$ *row Q, and the* UniformLimitCauchyCriterion$^{\uparrow}$ *row S. The packet therefore hands forward a finite Cauchy-name continuity boundary for the limit candidate, not a host-level proof of continuity over completed reals.*

Proof. The continuity-facing data are the rows M, Q, S in the carrier. They record the map boundary, the shared uniform Cauchy control, and the limit criterion before any regular readback or Real seal is exported.

Use the replay row C and transport row H to present the same rows to downstream consumers. Since P and N source and name only this finite packet, the consumer cannot replace the handoff by a host function on completed reals.

Thus the limit packet exposes a Cauchy-name continuity boundary, while host-level continuity, quotient function equality, selected limits, and completeness remain outside the local certificate. □

Closure status for NameCert$_{\text{UniformCauchyFunctionLimit}^{\uparrow}}$.

Theory closure: TheoryGate(NameCert$_{\text{UniformCauchyFunctionLimit}^{\uparrow}}$, seed)

Scope closed: Definition 8862.1, Definition 8862.2, Definition 8862.3, and Definition 8862.4 seed the finite certificate for uniform Cauchy limits of Cauchy-name maps through CauchyContinuousMap, RealFunctionUniformCauchy, UniformLimitCauchyCriterion, RegSeqRat, Real, transport, replay, provenance, and local NameCert rows.

Formal verification: FormalStatus(NameCert$_{\text{UniformCauchyFunctionLimit}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close host function equality, quotient Cauchy-name maps, selected pointwise limits, countable choice, global function-space completeness, ambient Real$^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, uniform Cauchy row stability, Cauchy-continuous map boundary exactness, criterion routing, RegSeqRat readback, Real-seal handoff, transport, replay, provenance, and local naming for BEDC.Derived.UniformCauchyFunctionLimitUp.

Constructive story: A UniformCauchyFunctionLimit$^{\uparrow}$ packet is generated from a finite Cauchy-name map family, RealFunctionUniformCauchy evidence, a CauchyContinuousMap boundary, UniformLimitCauchyCriterion routing, RegSeqRat readback, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 8863

A Concrete Naming Certificate for $\mathsf{BlakersMassey}^{\uparrow}$

Following Blakers and Massey on homotopy excision, the $\mathsf{BlakersMassey}^{\uparrow}$ packet records the finite BEDC surface by which two highly connected subobject rows and their intersection row are handed to an excision consumer. It sits after the $\mathsf{Homotopy}^{\uparrow}$ deformation surface of chapter 156, the $\mathsf{SimplicialSet}^{\uparrow}$ face-and-degeneracy ledger of chapter 157, the $\mathsf{Homology}^{\uparrow}$ chain-read surface of chapter 98, the van Kampen finite pushout route of chapter 8419, and the suspension connectivity handoff of chapter 8477. The packet names a displayed homotopy-excision handoff only; it does not import ambient model-category factorization, quotient topology, selected homotopy groups, a spectral sequence, or a host Blakers–Massey theorem.

Definition 8863.1 (Blakers–Massey carrier)**.** *A* $\mathsf{BlakersMassey}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (X, A, C, I, S, H_*, V, F, T, R, P, N)$$

with the following displayed rows:

1. *X is the ambient gluing row, recording the finite union or pushout window whose two subobject faces are inspected.*
2. *A and C are the two subobject rows, read through* $\mathsf{Homotopy}^{\uparrow}$ *deformation data and through the local face ledger of the ambient packet.*
3. *I is the intersection row, recording the displayed overlap, endpoint compatibility, and basepoint or boundary rows shared by A and C.*
4. *S is the* $\mathsf{SimplicialSet}^{\uparrow}$ *row carrying the finite face, horn, and degeneracy itinerary used to display the excision square.*
5. *H_* is the* $\mathsf{Homology}^{\uparrow}$ *read window used only as a finite chain-level sanity check for the inspected degrees.*
6. *V is the* $\mathsf{VanKampen}^{\uparrow}$ *sibling row, recording the already displayed pushout route for fundamental group style reads before higher homotopy-excision vocabulary is consumed.*
7. *F is the* $\mathsf{FreudenthalSuspension}^{\uparrow}$ *sibling row, recording the stable-range connectivity handoff used when a suspension-facing consumer asks for the same excision boundary.*
8. *T records componentwise* hsame *transport for the ambient, subobject, overlap, simplicial, homotopy, homology, van Kampen, Freudenthal, replay, provenance, and local naming rows.*

9. *R records displayed* Cont *replay from an excision request through $X, A, C, I, S, H_*, V, F, T, P, N$.*
10. *P is the* Pkg *provenance over* $\mathsf{BlakersMassey}^{\uparrow}$, $\mathsf{Homotopy}^{\uparrow}$, $\mathsf{SimplicialSet}^{\uparrow}$, $\mathsf{Homology}^{\uparrow}$, $\mathsf{VanKampen}^{\uparrow}$, $\mathsf{FreudenthalSuspension}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*
11. *N is the local* $\mathsf{NameCert}_{\mathsf{BlakersMassey}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $X, A, C, I, S, H_*, V, F, T, R, P, N$. It has no coordinate for a host homotopy pushout theorem, selected homotopy-group element, quotient space, model-category cofibration replacement, spectral-sequence convergence claim, or unbounded connectivity proof.

Theorem 8863.2 (Blakers–Massey NameCert obligations)**.** *For every accepted* $\mathsf{BlakersMassey}^{\uparrow}$ *carrier*

$$B = (X, A, C, I, S, H_*, V, F, T, R, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{BlakersMassey}^{\uparrow}}$ *surface consists exactly of ambient gluing admission through X, subobject exposure through A and C, intersection exposure through I, finite simplicial itinerary exposure through S, homotopy deformation reads through the displayed sibling rows, homology-window sanity checks through H_*, van Kampen pushout handoff through V, Freudenthal suspension handoff through F, componentwise transport through T, displayed replay through R, provenance through P, local naming through N, and non-escape from those displayed rows.*

Proof. Project the accepted carrier. The rows X, A, C, I supply the ambient square, the two subobject faces, and the overlap boundary, while S supplies the finite simplicial itinerary used to inspect that square.

Read the sibling rows in dependency order. The homotopy-facing data is consumed through the displayed $\mathsf{Homotopy}^{\uparrow}$ rows attached to A, C, I; the $\mathsf{Homology}^{\uparrow}$ row H_* supplies only a finite chain-read window; the $\mathsf{VanKampen}^{\uparrow}$ row V supplies the lower pushout route; and the $\mathsf{FreudenthalSuspension}^{\uparrow}$ row F supplies the suspension connectivity handoff.

Finally apply the structural rows. Transport T and replay R preserve exactly the rows already listed, and P, N only source and name the packet. Since the carrier has no coordinate for ambient quotient topology, chosen homotopy groups, model-category replacement, spectral-sequence convergence, or a host Blakers–Massey theorem, none of those objects can be exported by the local NameCert surface. □

Theorem 8863.3 (Blakers–Massey excision handoff)**.** *Every excision-facing consumer of an accepted* $\mathsf{BlakersMassey}^{\uparrow}$ *packet must read the route*

$$X, A, C, I, S \longmapsto H_*, V, F \longmapsto T, R, P, N$$

before treating the packet as a homotopy-excision boundary. The handoff preserves the displayed $\mathsf{Homotopy}^{\uparrow}$, $\mathsf{SimplicialSet}^{\uparrow}$, $\mathsf{Homology}^{\uparrow}$, $\mathsf{VanKampen}^{\uparrow}$, *and* $\mathsf{FreudenthalSuspension}^{\uparrow}$ *sibling rows, and it exports no ambient Blakers–Massey theorem, no quotient-space construction, no selected homotopy class, no hidden connectivity range, and no bridge certificate.*

Proof. Begin with the carrier rows of Definition 8863.1. The excision request starts with the ambient gluing row X, the two subobject rows A, C, the overlap row I, and the finite simplicial route S.

Apply the NameCert obligations from Definition 8863.2. They force the consumer to expose the homotopy, simplicial, homology, van Kampen, and Freudenthal sibling rows before any excision vocabulary is public.

The handoff is therefore row-preserving. The rows H_*, V, F are read as displayed dependency anchors, not as ambient theorem oracles; T, R, P, N then transport, replay, source, and name the same finite packet.

Because the packet contains no quotient-space constructor, selected homotopy-class row, hidden connectivity-range row, standard bridge row, or host theorem row, the consumer receives only the finite homotopy-excision boundary named by $X, A, C, I, S, H_*, V, F, T, R, P, N$. □

Falsifiable prediction: Any accepted $\mathsf{BlakersMassey}^{\uparrow}$ consumer that cites homotopy excision without first displaying the overlap row I, the simplicial route S, and the sibling rows $\mathsf{Homotopy}^{\uparrow}$, $\mathsf{SimplicialSet}^{\uparrow}$, $\mathsf{Homology}^{\uparrow}$, $\mathsf{VanKampen}^{\uparrow}$, and $\mathsf{FreudenthalSuspension}^{\uparrow}$ refutes the carrier surface of Definition 8863.1.

Independence witness: homotopy, simplicialset, homology, van-kampen, freudenthal-suspension: none is bijective to $\mathsf{BlakersMassey}^{\uparrow}$, because this packet alone binds the two-face gluing row, overlap row, finite simplicial itinerary, homology sanity window, van Kampen pushout route, Freudenthal connectivity handoff, componentwise transport, replay, provenance, and local NameCert rows into one homotopy-excision surface.

Closure status for $\mathsf{NameCert}_{\mathsf{BlakersMassey}^{\uparrow}}$.

Constructive story: A $\mathsf{BlakersMassey}^{\uparrow}$ packet is generated from an ambient gluing row, two subobject rows, an overlap row, a finite SimplicialSet route, a Homology read window, VanKampen and FreudenthalSuspension handoff rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BlakersMassey}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8863.1, Definition 8863.2, and Definition 8863.3 seed the finite homotopy-excision route over Homotopy, SimplicialSet, Homology, VanKampen, FreudenthalSuspension, BHist, hsame, Cont, Pkg, and NameCert rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BlakersMassey}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close the classical Blakers–Massey theorem, quotient topology, selected homotopy classes, hidden connectivity ranges, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked ambient gluing admission, subobject exposure, overlap exposure, simplicial route exposure, homology-window readback, VanKampen and Freudenthal handoffs, transport, replay, provenance, and local naming for BEDC.Derived.BlakersMasseyUp.

Chapter 8864

A Concrete Naming Certificate for $\mathsf{RHBoundaryKindSeparation}^{\uparrow}$

The $\mathsf{RHBoundaryKindSeparation}^{\uparrow}$ packet realizes the three-boundary separation of chapter 9240 as finite NameCert data. It sits after the complex carrier of chapter 39, the real-name seal of chapter 38, the zeta-zero witness surface of chapter 73, and the finite prime-window gluing route of chapter 8765. The packet keeps the geometric critical-line surface, certified zero predicate, and RH rigidity boundary in separate rows before any consumer may ask about a total zero decider.

Definition 8864.1 (RH boundary-kind separation carrier)**.** *An* $\mathsf{RHBoundaryKindSeparation}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (G, Z, R, D, F, H, C, P, N)$$

with the following displayed rows:

1. *G is the geometric critical-line row, storing the mirror-fixed surface and its* $\mathsf{Real}^{\uparrow}$ *readback.*
2. *Z is the certified zeta-zero predicate row, read through the displayed* $\mathsf{ZetaZeros}^{\uparrow}$ *witness surface and the inspected* $\mathsf{Complex}^{\uparrow}$ *point.*
3. *R is the RH rigidity row, recording only the conditional route from certified critical-strip zero evidence to a critical-line witness.*
4. *D is the decider-boundary row, recording whether a total zero-decider row is explicitly displayed; absence of this row blocks any total-decision read.*
5. *F is the finite prime-window gluing row, exposing prime-window data only as a sibling dependency of the certified zero route, not as a replacement for G, Z, R, D.*
6. *H records componentwise* hsame *transport for the geometric row, zero-predicate row, rigidity row, decider-boundary row, gluing row, replay, provenance, and local naming.*
7. *C records displayed* Cont *replay from an RH-facing boundary request through G, Z, R, D, F, H, P, N.*
8. *P is the* Pkg *provenance over* $\mathsf{RHBoundaryKindSeparation}^{\uparrow}$, $\mathsf{Complex}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{ZetaZeros}^{\uparrow}$, $\mathsf{Prime}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
9. *N is the local* $\mathsf{NameCert}_{\mathsf{RHBoundaryKindSeparation}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $G, Z, R, D, F, H, C, P, N$. It has no coordinate for an RH proof, an RH refutation, a hidden total zero decider, a quotient zero set, host complex equality, or a collapse of geometric, predicate, and rigidity data into one row.

Theorem 8864.2 (RH boundary-kind separation NameCert obligations)**.** *For every accepted* $\mathsf{RHBoundaryKindSeparation}^{\uparrow}$ *carrier*

$$B = (G, Z, R, D, F, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{RHBoundaryKindSeparation}^{\uparrow}}$ *surface consists exactly of carrier admission for the geometric critical-line row, certified zero-predicate row, RH rigidity row, displayed decider-boundary row, finite prime-window gluing row, componentwise transport, displayed replay, provenance, and local naming. A consumer may use the packet only after it keeps* G*,* Z*, and* R *as distinct rows and treats* D *as the sole place where a total zero decider could be displayed.*

Proof. Project the carrier of Definition 8864.1. The rows G, Z, R, D, F are listed separately before the structural rows H, C, P, N.

The geometric row G is read from the mirror-fixed surface and real readback. The zero-predicate row Z is read from certified zeta-zero evidence at a complex point. The rigidity row R consumes zero and strip evidence conditionally; it does not decide whether such evidence exists.

The decider-boundary row D is the only coordinate in which a total zero decider can be displayed. Since the classifier has no hidden coordinate outside $G, Z, R, D, F, H, C, P, N$, omitting D blocks a total-decision read. □

Theorem 8864.3 (RH boundary-kind decider nonescape)**.** *Any accepted* $\mathsf{RHBoundaryKindSeparation}^{\uparrow}$ *packet has no row for a total zero decider unless the decider-boundary row* D *explicitly displays one. In particular, the geometric critical-line row* G*, certified zero-predicate row* Z*, rigidity row* R*, and finite prime-window gluing row* F *cannot be reclassified as a total decision procedure.*

Proof. Inspect the carrier inventory. The rows G, Z, R, F record a fixed surface, a supplied zero predicate, a conditional rigidity route, and finite prime-window gluing data.

None of those rows has the shape of a total decision procedure over all complex histories. The row D is the only row assigned to the zero-decider boundary.

Transport through H and replay through C preserve the same row inventory. Provenance and local naming through P, N do not add a missing decider coordinate. Therefore a total zero-decider read is accepted only when it is displayed in D. □

Theorem 8864.4 (RH boundary-kind sibling separation)**.** *The* $\mathsf{RHBoundaryKindSeparation}^{\uparrow}$ *carrier is not bijective to the sibling packets for real names, complex names, zeta-zero witnesses, or finite prime-window gluing. It jointly binds geometric critical-line, certified zero-predicate, rigidity, decider-boundary, and gluing rows, while each listed sibling supplies only one component surface or one dependency route.*

Proof. Compare row inventories. The real and complex siblings supply the scalar and point carriers used by G and Z, but they do not contain a zeta-zero predicate or RH rigidity row.

The zeta-zero sibling supplies certified zero evidence, but it does not by itself display the mirror-fixed geometric surface, the rigidity boundary, or the decider-boundary row.

The finite prime-window gluing sibling supplies the gluing route consumed by F. It does not carry the three-way boundary ledger G, Z, R, D.

Thus no listed sibling has the same accepted carrier surface as $B = (G, Z, R, D, F, H, C, P, N)$, and no bijection can preserve the local NameCert rows component by component. □

Falsifiable prediction: Any accepted RHBoundaryKindSeparationUp packet has no row for a total zero decider unless the zero-decider row is explicitly displayed.

Independence witness: real, complex, zeta, finite_prime_window_gluing: the packet is not bijective to these siblings because it carries boundary-kind separation rows linking all of them while none of the listed siblings carries the three-way separation ledger.

Closure status for $\mathsf{NameCert}_{\mathsf{RHBoundaryKindSeparation}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RHBoundaryKindSeparation}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8864.1, Definition 8864.2, Definition 8864.3, and Definition 8864.4 seed the finite three-boundary ledger separating geometric critical-line, certified zero-predicate, RH rigidity, decider-boundary, and finite prime-window gluing rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RHBoundaryKindSeparation}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not prove RH, refute RH, decide all zeta zeros, enumerate all zeros, collapse the critical-line surface into the zero predicate, supply Lean verification, or provide bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, geometric-row exactness, certified zero-predicate routing, rigidity-row separation, decider-boundary nonescape, finite prime-window gluing handoff, transport, replay, provenance, local naming, and the future Nontrivial and FieldFaithful taste gates for BEDC.Derived.RHBoundaryKindSeparationUp.

Constructive story: An $\mathsf{RHBoundaryKindSeparation}^{\uparrow}$ packet is generated from geometric critical-line rows, certified zeta-zero predicate rows, RH rigidity rows, decider-boundary rows, finite prime-window gluing rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 8865

A Concrete Naming Certificate for $\mathsf{PrecompactSpace}^{\uparrow}$

Following Bishop–Bridges constructive analysis and Kelley-style finite-net readings of precompactness, the $\mathsf{PrecompactSpace}^{\uparrow}$ packet records the finite route by which a metric space supplies total-bounded data to completion-facing consumers. It sits over the metric carrier of chapter 57, the finite-net surface of chapter 127, and the compact-metric consumer boundary of chapter 129. The packet is a displayed NameCert interface for finite ε-net handoff; it is not an open-cover compactness theorem, a selected dense subset, a quotient completion, or a host choice principle.

Definition 8865.1 (PrecompactSpace carrier)**.** *A* $\mathsf{PrecompactSpace}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$P = (M, T, K, S, Q, R, N, H, C, G)$$

with the following displayed rows:

1. *M is the* $\mathsf{Met}^{\uparrow}$ *carrier row, including the accepted point histories, point classifier, and metric-distance witness surface;*
2. *T is the* $\mathsf{TotallyBounded}^{\uparrow}$ *finite-net row, assigning each positive tolerance request to a closed finite net surface;*
3. *K is the* $\mathsf{CompactMetric}^{\uparrow}$ *consumer boundary row, recording the completion-facing interface that may later combine total boundedness with complete-metric data;*
4. *S is the* $\mathsf{StreamName}^{\uparrow}$ *observation schedule for the finite windows consumed by completion-facing reads;*
5. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *regular rational readback attached to the same stream windows;*
6. *R is the* $\mathsf{Real}^{\uparrow}$ *tolerance and distance-readback seal used by dyadic or rational comparison consumers;*
7. *N records the closed finite net data: center histories,* $\mathsf{ProbeBundle}$ *membership rows, displayed distance witnesses, and radius comparison ledgers;*
8. *H records componentwise* hsame *transport for M, T, K, S, Q, R, N and for every center, stream window, readback, distance, and radius row exposed by them;*
9. *C records the displayed* Cont *replay route from a tolerance request through the finite net rows and then to any completion-facing consumer;*

10. *G is the* Pkg *provenance and local* $\mathsf{NameCert}_{\mathsf{PrecompactSpace}^{\uparrow}}$ *row naming* $\mathsf{PrecompactSpace}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{TotallyBounded}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

The classifier on such packets is componentwise transport through H together with the route replay in C. No coordinate stores an open cover, a choice-selected dense sequence, a completed quotient point, or an ambient compactness witness.

Theorem 8865.2 (PrecompactSpace NameCert obligations)**.** *For an accepted* $\mathsf{PrecompactSpace}^{\uparrow}$ *carrier $P = (M, T, K, S, Q, R, N, H, C, G)$, the local* $\mathsf{NameCert}_{\mathsf{PrecompactSpace}^{\uparrow}}$ *surface consists exactly of carrier admission, metric source exposure, total-bounded finite-net exposure, compact-metric consumer boundary exposure, stream-window scheduling, regular rational readback, real tolerance sealing, closed finite-net ledger visibility, componentwise transport, displayed replay, package provenance, and local naming. These obligations make precompactness available as finite NameCert data over $M, T, K, S, Q, R, N, H, C, G$, without adding open-cover compactness, choice-selected dense subsets, quotient completions, selected limit points, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Carrier admission is Definition 8865.1. The accepted packet exposes only the rows $M, T, K, S, Q, R, N, H, C$, and the finite subrows named by those coordinates.

The metric and total-bounded obligations are read before any completion-facing consumer is reached. The row M supplies the point histories, classifier, and distance witnesses, while T and N expose the finite net centers, ProbeBundle membership rows, distance witnesses, and radius comparison ledgers.

The consumer boundary is then routed through K, S, Q, R, H, C, G. These rows say which compact-metric, stream, regular-readback, real-tolerance, transport, replay, provenance, and local naming data may be inspected. Since no open-cover, dense-choice, quotient-completion, selected-limit, or ambient-completeness coordinate is present, no such principle can be projected from the local certificate. □

Theorem 8865.3 (PrecompactSpace total-bounded handoff)**.** *Every completion-facing consumer of an accepted* $\mathsf{PrecompactSpace}^{\uparrow}$ *packet must read total-boundedness through the displayed finite-net rows T and N before using the compact-metric boundary row K. In particular, a consumer may pass from a tolerance request to the stream and regular-readback rows S, Q, R only along the replay route C and the componentwise transport ledger H; it cannot replace the finite net by an open-cover argument, a choice-selected dense subset, a host compactness theorem, or a quotient completion.*

Proof. Open the carrier $P = (M, T, K, S, Q, R, N, H, C, G)$. The only total-bounded data in the packet is the displayed finite-net surface in T together with the closed net ledger N.

Use the NameCert obligations above. They order the read so that a tolerance request reaches the metric source M, the total-bounded finite-net row T, and the net ledger N before any compact-metric consumer boundary in K can be used.

Finally transport and replay are explicit. The rows H and C preserve the same center histories, membership constructors, distance witnesses, radius comparisons, stream windows, regular readbacks, and real tolerance seals when the consumer moves toward completion-facing data. Thus the handoff remains a finite NameCert route rather than an appeal to open-cover compactness, selected dense subsets, host choice, or quotient completion. □

Closure status for $\mathsf{NameCert}_{\mathsf{PrecompactSpace}^{\uparrow}}$.
Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{PrecompactSpace}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8865.1, Definition 8865.2, and Definition 8865.3 seed the finite-net handoff from MetricSpace and TotallyBounded rows to CompactMetric-facing consumers.

Formal verification: FormalStatus(NameCert$_{\mathsf{PrecompactSpace}\uparrow}$, formalTarget)

Bridge status: none

Not claimed: This chapter does not claim open-cover compactness, choice-selected dense subsets, quotient completions, selected limit points, ambient Real completeness, or Lean verification.

Upgrade path: Obligation closure requires checked carrier admission, finite-net exactness, total-bounded handoff, transport stability, replay stability, and local naming for BEDC.Derived.PrecompactSpaceUp.

Constructive story: A PrecompactSpace$^{\uparrow}$ packet is generated from a MetricSpace carrier, TotallyBounded finite-net row, CompactMetric consumer boundary, StreamName windows, RegSeqRat readback, Real tolerance seal, closed finite net ledger, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 8866

A Concrete Naming Certificate for $\mathsf{BirkhoffProjectiveMetric}^{\uparrow}$

Following Birkhoff's projective metric on cones and standard positive-operator treatments, the $\mathsf{BirkhoffProjectiveMetric}^{\uparrow}$ packet records the finite cone-ratio surface by which two positive cone elements are compared before a contraction theorem consumes the result. It sits over the positive-cone carrier of chapter 2297, the metric carrier of chapter 57, the real-name readback of chapter 38, and the contraction consumer of chapter 7755. The packet names a finite projective-distance ledger; it is not a quotient of cone rays, an ambient topological cone, a supremum-infimum oracle, or a fixed-point theorem.

Definition 8866.1 (Birkhoff projective metric carrier)**.** *A* $\mathsf{BirkhoffProjectiveMetric}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (K, x, y, U, L, \rho, d, M, G, H, C, P, N)$$

with the following displayed rows:

1. *K is the* $\mathsf{PositiveCone}^{\uparrow}$ *source row, fixing the cone surface and the scalar-order comparison used by every ratio read.*
2. *x and y are two displayed positive cone elements in the same K row.*
3. *U is the finite upper-ratio ledger, listing the displayed scalar witnesses for $x \leq u\,y$ that the packet is allowed to inspect.*
4. *L is the finite lower-ratio ledger, listing the displayed scalar witnesses for $\ell\,y \leq x$ that the packet is allowed to inspect.*
5. *ρ is the* $\mathsf{Real}^{\uparrow}$ *scalar readback row for the accepted upper and lower ratio bounds.*
6. *d is the* $\mathsf{Met}^{\uparrow}$ *projective-distance row, storing only the displayed logarithmic ratio readback produced from U, L, ρ.*
7. *M is the metric-surface compatibility row, requiring the distance read to be symmetric on the displayed pair and zero only through the local projective-identification ledger.*
8. *G is the* $\mathsf{BirkhoffContraction}^{\uparrow}$ *consumer handoff row, exposing K, x, y, U, L, ρ, d as the finite Hilbert-projective metric surface later used by contraction budgets.*
9. *H records componentwise* hsame *transport for the cone source, two positive elements, ratio ledgers, scalar readbacks, projective-distance row, metric compatibility, consumer handoff, replay, provenance, and local naming.*

10. *C records displayed* Cont *replay from a projective-distance request through* $K, x, y, U, L, \rho, d, M, G, H, P, N$.
11. *P is the* Pkg *provenance over* $\mathsf{BirkhoffProjectiveMetric}^{\uparrow}$, $\mathsf{PositiveCone}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{BirkhoffContraction}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*
12. *N is the local* $\mathsf{NameCert}_{\mathsf{BirkhoffProjectiveMetric}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $K, x, y, U, L, \rho, d, M, G, H, C, P, N$. It has no coordinate for an unstated cone quotient, hidden supremum or infimum, ambient norm, fixed point, eigenvector, non-displayed operator, or host real equality outside the finite ratio ledgers.

Theorem 8866.2 (Birkhoff projective metric NameCert obligations)**.** *For every accepted* $\mathsf{BirkhoffProjectiveMetric}^{\uparrow}$ *carrier*

$$B = (K, x, y, U, L, \rho, d, M, G, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{BirkhoffProjectiveMetric}^{\uparrow}}$ *surface consists exactly of carrier admission for the* $\mathsf{PositiveCone}^{\uparrow}$ *source row, the two displayed positive elements, finite upper- and lower-ratio ledgers,* $\mathsf{Real}^{\uparrow}$ *scalar readbacks, the* $\mathsf{Met}^{\uparrow}$ *projective-distance row, the metric-compatibility row, the* $\mathsf{BirkhoffContraction}^{\uparrow}$ *consumer handoff, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming.*

Every downstream projective-metric read must first display the common cone source and both ratio ledgers. The read may then consume ρ and d as finite scalar and metric rows, but it cannot replace them with a completed quotient of rays, a hidden extremal ratio, a host topological cone, or a contraction conclusion.

Proof. Project the carrier of Definition 8866.1. The rows K, x, y fix a single positive-cone source and two elements in that source before any ratio comparison can be read.

The rows U and L are finite ledgers. They display only the upper witnesses $x \leq u\, y$ and lower witnesses $\ell\, y \leq x$ that the packet records, so no hidden supremum, infimum, or ambient order oracle is available.

The scalar row ρ and metric row d are downstream of those ledgers. The compatibility row M keeps the projective-distance read inside the displayed metric surface, and G exposes exactly the same data to the $\mathsf{BirkhoffContraction}^{\uparrow}$ consumer.

Transport through H, replay through C, provenance through P, and local naming through N preserve the same finite row inventory. Since the classifier has no coordinate outside $K, x, y, U, L, \rho, d, M, G, H, C, P$, every accepted NameCert obligation is one of the listed rows. □

Theorem 8866.3 (Birkhoff projective metric ratio nonescape)**.** *An accepted* $\mathsf{BirkhoffProjectiveMetric}^{\uparrow}$ *packet exports no projective distance unless the common* $\mathsf{PositiveCone}^{\uparrow}$ *source row, both positive elements, finite upper-ratio ledger, finite lower-ratio ledger,* $\mathsf{Real}^{\uparrow}$ *scalar readback, and* $\mathsf{Met}^{\uparrow}$ *projective-distance row are all displayed in the same carrier.*

Proof. Inspect the carrier inventory. The distance row d is admitted only after the source row K, element rows x, y, ratio ledgers U, L, and scalar readback row ρ have been displayed.

The replay row C follows the same order, and the handoff row G exposes the distance to $\mathsf{BirkhoffContraction}^{\uparrow}$ only with the source, elements, ledgers, and readback still attached.

Thus no public read can detach d from the finite ratio evidence that produced it. Quotient-ray language, hidden extremal ratios, and host completeness claims remain outside the packet. □

Falsifiable prediction: Any accepted BirkhoffProjectiveMetricUp distance read is refuted if it omits the common positive-cone source, either displayed positive element, either finite ratio ledger, the RealUp readback, or the MetricUp projective-distance row.

Independence witness: positive-cone, metric, real, birkhoff-contraction: none alone is bijective with $\mathsf{BirkhoffProjectiveMetric}^{\uparrow}$ because the packet jointly records two positive cone elements, finite upper and lower ratio ledgers, scalar readbacks, projective-distance rows, contraction handoff, transport, replay, provenance, and local NameCert rows.

Closure status for $\mathsf{NameCert}_{\mathsf{BirkhoffProjectiveMetric}^{\uparrow}}$.

Constructive story: A $\mathsf{BirkhoffProjectiveMetric}^{\uparrow}$ packet is generated from a PositiveConeUp source row, two displayed positive cone elements, finite upper- and lower-ratio ledgers, RealUp scalar readbacks, a MetricUp projective-distance row, a BirkhoffContractionUp consumer handoff, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BirkhoffProjectiveMetric}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8866.1, Definition 8866.2, and Definition 8866.3 seed the finite cone-ratio projective metric surface over PositiveConeUp, MetricUp, RealUp, BirkhoffContractionUp, BHist, hsame, Cont, Pkg, and NameCert rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BirkhoffProjectiveMetric}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not construct a quotient of cone rays, prove contraction, select an eigenvector or fixed point, supply hidden extremal ratios, invoke host cone topology, close Lean verification, or provide bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, common-cone discipline, upper- and lower-ratio ledger exactness, scalar readback, projective-distance routing, contraction handoff, transport, replay, provenance, and local naming for BEDC.Derived.BirkhoffProjectiveMetricUp.

Chapter 8867

A Concrete Naming Certificate for $\mathsf{BishopLocatedIntervalRefinementChain}^{\uparrow}$

Following Bishop and Bridges on located intervals, regular Cauchy names, and constructive real completion, the $\mathsf{BishopLocatedIntervalRefinementChain}^{\uparrow}$ packet records a finite chain of located interval refinements before a Real or Completion consumer may read a terminal real-name seal. It sits between the located-interval source of chapter 394, the real-interval endpoint surface of chapter 4111, the dyadic tolerance descent of chapter 291, the finite observation windows of chapter 126, the regular rational readback of chapter 301, and the terminal real-name seal of chapter 38. The certificate gives the L10 Real and Completion route a displayed refinement-chain object; it does not assert compactness, trichotomy, selected representatives, countable choice, quotient equality of names, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 8867.1 (Bishop located interval refinement-chain carrier)**.** *A* $\mathsf{BishopLocatedIntervalRefinementChain}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$R = (L, I, D, W, Q, S, H, C, P, N)$$

with the following displayed rows:

1. *L is the* $\mathsf{LocatedInterval}^{\uparrow}$ *source row naming the initial located interval and its apartness-facing boundary data.*
2. *I is the* $\mathsf{RealInterval}^{\uparrow}$ *endpoint and enclosure row, displaying lower and upper real-interval endpoints together with the enclosure relation consumed by the chain.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance-descent row, recording a finite decreasing dyadic budget for the refinement steps.*
4. *W is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row inspected at each displayed tolerance stage.*
5. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row attached to the same finite windows and dyadic tolerances.*
6. *S is the* $\mathsf{Real}^{\uparrow}$ *seal row reached only after the located interval source, endpoint-enclosure row, tolerance descent, windows, and readback have been displayed.*
7. *H records componentwise* hsame *transport for the located source, endpoint-enclosure row, dyadic descent, finite windows, regular readback, Real seal, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from a refinement request through $L, I, D, W, Q, S, H, P, N$.*

9. *P is the* Pkg *provenance over* $\mathsf{BishopLocatedIntervalRefinementChain}^{\uparrow}$, $\mathsf{LocatedInterval}^{\uparrow}$, $\mathsf{RealInterval}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{BishopLocatedIntervalRefinementChain}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $L, I, D, W, Q, S, H, C, P, N$. It has no coordinate for interval compactness, trichotomy of reals, a selected representative of a completion class, countable choice, quotient equality of interval names, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 8867.2 (Bishop located interval refinement-chain NameCert obligations)**.** *For every accepted* $\mathsf{BishopLocatedIntervalRefinementChain}^{\uparrow}$ *carrier*

$$R = (L, I, D, W, Q, S, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{BishopLocatedIntervalRefinementChain}^{\uparrow}}$ *surface consists exactly of carrier admission for the located interval source, RealInterval endpoint and enclosure row, DyadicRatCore tolerance descent, StreamName finite windows, RegSeqRat readback, RealUp seal, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming.*

Proof. Project the carrier of Definition 8867.1. The tuple displays the located source L, the endpoint-enclosure row I, the tolerance descent D, the finite windows W, the regular readback Q, and the terminal seal S before any structural row is consumed.

The structural rows H, C, P, N preserve, replay, source, and name only those displayed rows. They do not add a hidden interval compactness theorem, a selected completion representative, or an ambient completeness principle.

Thus the local NameCert surface is exhausted by the ten displayed rows, and every accepted consumer must read the refinement chain through that finite packet. □

Theorem 8867.3 (Bishop located interval refinement-chain sibling route)**.** *The* BishopLocatedIntervalRefinementCh *carrier is not bijective to the located interval, real interval, dyadic rational core, stream-name, regular rational readback, or real-name sibling packets. It binds all six sibling surfaces into one ordered refinement-chain packet whose endpoint, tolerance, window, readback, and seal rows are consumed together.*

Proof. Compare row inventories. The located interval sibling supplies L, but it does not include the endpoint-enclosure row, dyadic tolerance descent, finite window schedule, regular readback, or terminal Real seal.

The real interval and dyadic rational siblings supply I and D respectively. Neither one records the StreamName windows, RegSeqRat readback, Real seal, and structural rows as a single chain.

The stream-name, regular-rational, and real-name siblings supply W, Q, S as downstream readings. They do not contain the located source and endpoint-enclosure data that make those readings a refinement chain. Therefore no listed sibling preserves the accepted packet $R = (L, I, D, W, Q, S, H, C, P, N)$ component by component. □

Theorem 8867.4 (Bishop located interval refinement-chain Real-seal boundary)**.** *Every* $\mathsf{Real}^{\uparrow}$*-facing read from an accepted* $\mathsf{BishopLocatedIntervalRefinementChain}^{\uparrow}$ *packet reaches the seal row S only through the displayed route*

$$L, I, D, W, Q, S, H, C, P, N.$$

The read does not select a representative, decide trichotomy, infer compactness, or import ambient completeness of $\mathsf{Real}^{\uparrow}$.

Proof. Use the NameCert obligations of Definition 8867.2. They force the located source, endpoint-enclosure row, dyadic tolerance descent, finite windows, and regular readback to be present before the seal row is public.

The sibling-route theorem Definition 8867.3 prevents a consumer from replacing this packet by any one sibling surface. Transport and replay keep the same displayed rows.

The classifier of Definition 8867.1 has no coordinate for selected representatives, trichotomy, compactness, countable choice, quotient equality, or ambient completeness. Hence the Real-facing read is confined to the finite refinement-chain route. □

Falsifiable prediction: Any accepted $\mathsf{BishopLocatedIntervalRefinementChain}^{\uparrow}$ consumer that reaches a $\mathsf{Real}^{\uparrow}$ seal without displaying the located interval source, RealInterval endpoint-enclosure row, DyadicRatCore tolerance descent, StreamName finite windows, RegSeqRat readback, transport, replay, provenance, and local naming refutes the carrier surface.

Independence witness: locatedinterval, realinterval, dyadicratcore, streamname, regseqrat, real: no listed sibling is bijective to $\mathsf{BishopLocatedIntervalRefinementChain}^{\uparrow}$, because each sibling supplies one source, endpoint, tolerance, window, readback, or seal surface while this packet stores their ordered refinement-chain dependency in one NameCert row.

Closure status for $\mathsf{NameCert}_{\mathsf{BishopLocatedIntervalRefinementChain}^{\uparrow}}$.

Constructive story: A $\mathsf{BishopLocatedIntervalRefinementChain}^{\uparrow}$ packet is generated from a LocatedInterval source row, a RealInterval endpoint-enclosure row, a DyadicRatCore tolerance descent, StreamName finite windows, RegSeqRat readback, a terminal RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BishopLocatedIntervalRefinementChain}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8867.1, Definition 8867.2, Definition 8867.3, and Definition 8867.4 seed the finite refinement-chain packet over located interval source, endpoint enclosure, dyadic tolerance descent, finite windows, regular readback, terminal sealing, transport, replay, provenance, and local naming.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BishopLocatedIntervalRefinementChain}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close compactness, trichotomy, countable choice, selected representatives, quotient equality of interval names, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, sibling-route separation, Real-seal boundary, transport, replay, provenance, and local naming for BEDC.Derived.BishopLocatedIntervalRefinementChainUp.

Chapter 8868

A Concrete Naming Certificate for RHCriticalStripWindowCertificate$^{\uparrow}$

The RHCriticalStripWindowCertificate$^{\uparrow}$ packet realizes a finite critical-strip window route from chapter 9240 as NameCert data. It sits beside the three-boundary separation of chapter 8864, the zeta-zero witness surface of chapter 73, the complex carrier of chapter 39, the real-name seal of chapter 38, and the finite prime-window gluing route of chapter 8765. The packet exposes a finite critical-strip window and certified-zero row while refusing to turn that window into an exact zero decider or a global RH rigidity proof.

Definition 8868.1 (RH critical-strip window certificate carrier)**.** *An* RHCriticalStripWindowCertificate$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$W = (B, M, Z, E, R, G, H, C, P, N)$$

with the following displayed rows:

1. *B is the finite critical-strip window row, storing the inspected complex histories and their critical-strip bounds.*
2. *M is the mirror fixed-surface row, recording the functional-equation mirror surface available on the same finite window.*
3. *Z is the certified-zero exposure row, naming supplied zeta-zero packets inside the displayed window.*
4. *E is the exact-decider refusal row, recording that the carrier does not provide $\prod_s$ Decidable(ZetaZero(s)).*
5. *R is the rigidity refusal row, recording that the carrier does not provide the global RH route from every critical-strip zero to an* OnCritLine *witness.*
6. *G is the finite prime-window gluing row available only as a dependency of the displayed certified-zero exposure, not as a substitute for B, M, Z, E, R.*
7. *H records componentwise* hsame *transport for the strip window, mirror row, certified-zero row, refusal rows, gluing row, replay, provenance, and local naming.*
8. *C records displayed* Cont *replay from an RH-facing finite-window request through $B, M, Z, E, R, G, H, P, N$.*
9. *P is the* Pkg *provenance over* RHCriticalStripWindowCertificate$^{\uparrow}$*,* RHBoundaryKindSeparation$^{\uparrow}$*,* ZetaZeros$^{\uparrow}$*,* Complex$^{\uparrow}$*,* Real$^{\uparrow}$*,* FinitePrimeWindowGluing$^{\uparrow}$*,* BHist*,* hsame*,* Cont*, and* NameCert*.*

10. N is the local $\mathsf{NameCert}_{\mathsf{RHCriticalStripWindowCertificate}^{\uparrow}}$ *row.*
The classifier compares accepted packets only through $B, M, Z, E, R, G, H, C, P, N$. It has no coordinate for an exact zero decider, an RH proof, a zero enumeration theorem, a quotient zero set, a hidden critical-line classifier, or global rigidity outside the displayed finite window.

Theorem 8868.2 (RH critical-strip window certificate NameCert obligations)**.** *For every accepted* $\mathsf{RHCriticalStripWindowCertificate}^{\uparrow}$ *carrier*

$$W = (B, M, Z, E, R, G, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{RHCriticalStripWindowCertificate}^{\uparrow}}$ *surface consists exactly of carrier admission for the finite critical-strip window, mirror fixed-surface row, certified-zero exposure row, exact-decider refusal row, rigidity refusal row, finite prime-window gluing row, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming.*

Proof. Project the carrier of Definition 8868.1. The rows B, M, Z, E, R, G are displayed before transport, replay, provenance, and local naming are read.

The certified-zero row Z is window-local: it exposes supplied zero packets only inside B. The mirror row M records the fixed-surface geometry available on that same finite surface.

The refusal rows E and R are part of the carrier inventory. Since no other row has the type of a total zero decider or global RH rigidity route, transport through H and replay through C cannot manufacture either object. □

Theorem 8868.3 (RH critical-strip window certificate boundary separation)**.** *An accepted* RHCriticalStripWindowC *packet separates finite critical-strip inspection from exact zero decision and global RH rigidity. A consumer may read certified zero exposure inside B, but it may not infer a total zero decider or a proof that every critical-strip zero lies on the mirror fixed surface.*

Proof. Use the NameCert obligations of Definition 8868.2. They keep the finite strip window, mirror row, certified-zero exposure, exact-decider refusal, and rigidity refusal as separate rows.

The exact-decider refusal row E blocks a read of $\prod_s \mathsf{Decidable}(\mathsf{ZetaZero}(s))$. The rigidity refusal row R blocks a read of the global route from every certified critical-strip zero to an $\mathsf{OnCritLine}$ witness.

The finite prime-window gluing row G is only a sibling dependency for the displayed window. It does not change the carrier inventory, so the accepted packet remains a finite certificate rather than an exact decider or global RH proof. □

Falsifiable prediction: Any accepted $\mathsf{RHCriticalStripWindowCertificate}^{\uparrow}$ consumer that reads an exact zeta-zero decider or a global RH rigidity proof from the finite window rows B, M, Z, G, H, C, P, N without displaying the refusal rows E, R refutes the carrier surface.

Independence witness: rh-boundary-kind-separation, zeta-zeros, complex, finite-prime-window-gluing, rh-free-zero-initiality: no listed sibling is bijective to $\mathsf{RHCriticalStripWindowCertificate}^{\uparrow}$, because this packet binds a finite critical-strip window, mirror fixed-surface row, certified-zero exposure, exact-decider refusal, and rigidity refusal in one local NameCert surface.

Closure status for $\mathsf{NameCert}_{\mathsf{RHCriticalStripWindowCertificate}^{\uparrow}}$.

Constructive story: An $\mathsf{RHCriticalStripWindowCertificate}^{\uparrow}$ packet is generated from a finite critical-strip window row, mirror fixed-surface row, certified-zero exposure row, exact-decider refusal row, rigidity refusal row, finite prime-window gluing row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RHCriticalStripWindowCertificate}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8868.1, Definition 8868.2, and Definition 8868.3 seed the finite RH critical-strip window certificate while separating mirror geometry from exact zero decision and global RH rigidity.

Formal verification: FormalStatus(NameCert$_{\text{RHCriticalStripWindowCertificate}\uparrow}$, unformalized)

Bridge status: none

Not claimed: This chapter does not prove RH, refute RH, decide all zeta zeros, enumerate all zeros, select a quotient zero set, supply a hidden critical-line classifier, close Lean verification, or provide bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, window exactness, mirror fixed-surface exposure, certified-zero routing, exact-decider refusal, rigidity refusal, gluing handoff, transport, replay, provenance, and local naming for BEDC.Derived.RHCriticalStripWindowCertificateUp.

Chapter 8869

A Concrete Naming Certificate for $\mathsf{SturmLiouville}^{\uparrow}$

Following Sturm and Liouville, the $\mathsf{SturmLiouville}^{\uparrow}$ packet records the regular-endpoint spectral ODE surface as finite BEDC NameCert data. It sits over the ODE carrier of chapter 193, the Wronskian determinant boundary of chapter 6877, the Hilbert-space source of chapter 91, the spectral-data package of chapter 214, and the terminal real-name seal of chapter 38. The packet names a displayed coefficient, boundary, Wronskian, Hilbert, and spectral-row handoff; it does not import host differential operators, quotient function spaces, selected eigenfunction bases, classical completeness, or an ambient $\mathsf{Real}^{\uparrow}$ spectral theorem.

Definition 8869.1 (Sturm–Liouville carrier)**.** *A* $\mathsf{SturmLiouville}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (O, B, W, H, T, R, E, K, C, P, N)$$

with the following displayed rows:

1. *O is the* $\mathsf{Ode}^{\uparrow}$ *coefficient-and-equation row for the inspected second-order scalar equation on the displayed interval.*
2. *B is the regular-endpoint boundary row, naming the two endpoint cells, boundary forms, separated or coupled boundary clauses, and the finite compatibility checks attached to O.*
3. *W is the* $\mathsf{Wronskian}^{\uparrow}$ *row used to compare endpoint solutions and boundary-admissible solution pairs.*
4. *H is the* $\mathsf{Hilbert}^{\uparrow}$ *row carrying the inner-product and norm surface on which boundary-admissible solution rows may be compared.*
5. *T is the* $\mathsf{SpectralTheorem}^{\uparrow}$ *spectral-data row read only after the ODE, boundary, Wronskian, and Hilbert rows have been displayed.*
6. *R is the regular-endpoint resolvent packet, recording the finite Green-kernel, endpoint, and inhomogeneous-source reads that remain inside the same boundary surface.*
7. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row for eigenvalue, norm, and endpoint scalar reads.*
8. *K records componentwise* hsame *transport for the ODE, boundary, Wronskian, Hilbert, spectral, resolvent, and Real-seal rows.*
9. *C records displayed* Cont *replay from coefficient requests through boundary admission, Wronskian comparison, Hilbert comparison, spectral-data exposure, resolvent readback, and the Real seal.*

10. *P is the* Pkg *provenance over* $\mathsf{SturmLiouville}^{\uparrow}$, $\mathsf{Ode}^{\uparrow}$, $\mathsf{Wronskian}^{\uparrow}$, $\mathsf{Hilbert}^{\uparrow}$, $\mathsf{SpectralTheorem}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

11. *N is the local* $\mathsf{NameCert}_{\mathsf{SturmLiouville}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these rows. It has no coordinate for a host unbounded operator, quotient function equality, selected eigenbasis, endpoint distribution, classical compact-resolvent theorem, or ambient real completeness.

Theorem 8869.2 (Sturm–Liouville NameCert obligations)**.** *For every accepted* $\mathsf{SturmLiouville}^{\uparrow}$ *carrier*

$$S = (O, B, W, H, T, R, E, K, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{SturmLiouville}^{\uparrow}}$ *surface consists exactly of ODE coefficient admission through O, regular-endpoint boundary admission through B, Wronskian comparison through W, Hilbert comparison through H, spectral-data exposure through T, regular-endpoint resolvent readback through R, terminal real sealing through E, componentwise* hsame *transport through K, displayed* Cont *replay through C,* Pkg *provenance through P, and local naming through N.*

Proof. Project the carrier of Definition 8869.1. The ODE, boundary, Wronskian, Hilbert, spectral, resolvent, and Real-seal rows are the only mathematical rows available before the structural support is read.

The ODE and boundary rows supply the regular-endpoint source. The Wronskian row compares endpoint solutions inside the same displayed boundary surface, and the Hilbert row supplies only the carried inner-product and norm comparison data.

The spectral row is downstream of those displays. It is consumed as a $\mathsf{SpectralTheorem}^{\uparrow}$ data packet over the same Hilbert-facing source, while the resolvent row records only finite Green-kernel and source reads attached to the boundary packet.

Finally, K, C, P, N transport, replay, source, and locally name the same route. Since no carrier coordinate stores a host differential operator, quotient function equality, selected eigenbasis, endpoint distribution, compact-resolvent theorem, or ambient completeness principle, the listed rows exhaust the local NameCert surface. □

Theorem 8869.3 (Sturm–Liouville regular-endpoint handoff)**.** *Every regular-endpoint read exported by an accepted* $\mathsf{SturmLiouville}^{\uparrow}$ *packet factors through*

$$\mathsf{Ode}^{\uparrow},\ B,\ \mathsf{Wronskian}^{\uparrow},\ \mathsf{Hilbert}^{\uparrow},\ \mathsf{SpectralTheorem}^{\uparrow},\ R,\ \mathsf{Real}^{\uparrow}.$$

The endpoint clauses are read before Wronskian comparison, the Wronskian row is read before Hilbert and spectral comparison, and the terminal $\mathsf{Real}^{\uparrow}$ *seal is exposed only after the displayed spectral or resolvent row is visible.*

Proof. Start from the obligation surface of Definition 8869.2. It fixes O and B as the source of coefficient and endpoint data, so an endpoint consumer cannot begin from an unrecorded host operator.

Apply the carrier definition. The Wronskian row W is attached to the same ODE and boundary rows, and the Hilbert row H is available only as the comparison surface for those displayed solution rows.

The spectral-data row T and resolvent row R are downstream of O, B, W, H. Therefore every endpoint-facing scalar read reaches E through the displayed spectral or resolvent packet, not through a host eigenfunction argument or quotient function space. □

Theorem 8869.4 (Sturm–Liouville spectral packet nonescape)**.** *No accepted* $\mathsf{SturmLiouville}^{\uparrow}$ *spectral packet can escape the displayed rows*

$$O, B, W, H, T, R, E, K, C, P, N.$$

In particular, a consumer may read eigenvalue, orthogonality, normalization, or resolvent scalar data only through the $\mathsf{Ode}^{\uparrow}$*,* $\mathsf{Wronskian}^{\uparrow}$*,* $\mathsf{Hilbert}^{\uparrow}$*,* $\mathsf{SpectralTheorem}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*,* hsame*,* Cont*,* Pkg*, and* NameCert *route named by the carrier.*

Proof. Read the carrier and the NameCert obligations. The rows $O, B, W, H, T, R, E, K, C, P, N$ are the complete accepted packet, and each spectral read must preserve the same ODE, boundary, Wronskian, Hilbert, spectral, resolvent, and Real-seal order.

Use Definition 8869.3. It places endpoint reads before Wronskian comparison and Wronskian comparison before Hilbert and spectral consumption, so a later spectral packet cannot bypass the regular-endpoint route.

The structural rows then close the nonescape claim. Componentwise hsame transport, displayed Cont replay, Pkg provenance, and the local NameCert row keep eigenvalue, orthogonality, normalization, and resolvent scalar reads inside the finite packet, excluding host operators, quotient function spaces, selected eigenbases, and ambient completeness. □

Theorem 8869.5 (Sturm–Liouville Wronskian boundary)**.** *Every boundary-admissible solution comparison in an accepted* $\mathsf{SturmLiouville}^{\uparrow}$ *packet factors through the* $\mathsf{Wronskian}^{\uparrow}$ *row* W *over the same ODE row* O *and regular-endpoint row* B*. A consumer that compares endpoint solutions through Hilbert or spectral data without first displaying* W *is outside the local certificate.*

Proof. The carrier of Definition 8869.1 places W between the regular-endpoint source O, B and the Hilbert and spectral rows H, T. Thus boundary-admissible solution comparison has a displayed Wronskian coordinate before any Hilbert-facing read is available.

Apply Definition 8869.2. Wronskian comparison is a separate obligation row, not a consequence of host equality or a hidden classical zero theorem.

Finally use Definition 8869.4. Since every spectral or resolvent scalar read remains inside $O, B, W, H, T, R, E, K, C, P, N$, omitting W leaves the accepted certificate rather than producing another valid boundary comparison. □

Falsifiable prediction: A Sturm–Liouville spectral read that reaches Hilbert or spectral rows without first displaying ODE coefficient data, regular-endpoint boundary data, and the Wronskian comparison row refutes the local carrier.

Independence witness: ode, wronskian, hilbert, spectraltheorem, real: $\mathsf{SturmLiouville}^{\uparrow}$ is not bijective to any listed sibling because it jointly binds ODE coefficients, regular endpoint boundary data, Wronskian comparison, Hilbert comparison, spectral-data exposure, resolvent readback, Real sealing, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{SturmLiouville}^{\uparrow}}$**.**

Constructive story: A $\mathsf{SturmLiouville}^{\uparrow}$ packet is generated from an ODE coefficient row, a regular-endpoint boundary row, a Wronskian comparison row, a Hilbert comparison row, a spectral-data row, a regular-endpoint resolvent packet, a terminal Real seal, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{SturmLiouville}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8869.1, Definition 8869.2, Definition 8869.3, Definition 8869.4, and Definition 8869.5 seed the regular-endpoint spectral ODE carrier, obligation, handoff, nonescape, and Wronskian-boundary surface.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{SturmLiouville}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host unbounded operators, quotient function spaces, selected eigenfunction bases, classical compact-resolvent completeness, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, boundary-row exactness, Wronskian comparison stability, Hilbert and spectral packet routing, resolvent readback, Real-seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.SturmLiouvilleUp.

Chapter 8870

A Concrete Naming Certificate for $\mathsf{CantorBorelSet}^{\uparrow}$

Following Cantor and Kechris, the $\mathsf{CantorBorelSet}^{\uparrow}$ packet records the finite cylinder-window surface used when countable-name real routes inspect Borel-style subsets of Cantor space. It sits after the Cantor prefix carrier of chapter 1475, the cylinder basis of chapter 2153, the nested interval route of chapter 320, and the L10 real-name chain through chapter 126, chapter 301, and chapter 38. The packet names only displayed finite cylinder rows and countable-name windows; it is not a completed sigma-algebra object, quotient set equality, selected infinite branch, countable-choice schedule, or ambient $\mathsf{Real}^{\uparrow}$ completeness principle.

Definition 8870.1 (CantorBorelSet carrier)**.** *A* $\mathsf{CantorBorelSet}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (A, C, W, R, E, H, K, P, N)$$

with the following displayed rows:

1. *A is the* $\mathsf{CantorSpace}^{\uparrow}$ *address row naming the finite binary prefixes currently inspected.*
2. *C is the cylinder-window row supplied through* $\mathsf{CantorCylinderBasis}^{\uparrow}$*.*
3. *W is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row selecting the countable-name observations visible to the Borel-window request.*
4. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row obtained from the displayed windows when the request feeds a countable real-name route.*
5. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row, readable only after A, C, W, R have remained visible.*
6. *H records componentwise* hsame *transport for the Cantor address, cylinder window, stream window, regular readback, Real seal, replay, provenance, and local name.*
7. *K records displayed* Cont *replay from a cylinder-membership or countable-name request through A, C, W, R, E, H, P, N.*
8. *P is the* Pkg *provenance over* $\mathsf{CantorBorelSet}^{\uparrow}$*,* $\mathsf{CantorSpace}^{\uparrow}$*,* $\mathsf{CantorCylinderBasis}^{\uparrow}$*,* $\mathsf{NestedInterval}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*,* BHist*,* hsame*,* Cont*, and* $\mathsf{NameCert}$*.*
9. *N is the local* $\mathsf{NameCert}_{\mathsf{CantorBorelSet}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these displayed rows. It has no coordinate for a host Borel sigma-algebra, quotient equality of subsets, selected infinite branches, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 8870.2 (CantorBorelSet obligation surface)**.** *For every accepted* $\mathsf{CantorBorelSet}^{\uparrow}$ *carrier* $B = (A, C, W, R, E, H, K, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{CantorBorelSet}^{\uparrow}}$ *surface consists exactly of carrier admission for the Cantor address row, cylinder-window row,* $\mathsf{StreamName}^{\uparrow}$ *finite-window row,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row, terminal* $\mathsf{Real}^{\uparrow}$ *seal row, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. The surface contains no hidden obligation for a completed Borel sigma algebra, quotient set equality, selected branch, countable choice, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the carrier of Definition 8870.1. The accepted packet exposes $A, C, W, R, E, H, K, P, N$ as separate finite rows, so every local obligation must be read from one of those coordinates.

The cylinder data is supplied by A and C. These rows point to Cantor-space prefixes and the cylinder basis, not to a completed host set of all Borel subsets.

The countable-name route is supplied by W, R, E. A request first reads finite $\mathsf{StreamName}^{\uparrow}$ windows, then $\mathsf{RegSeqRat}^{\uparrow}$ readback, and only then the terminal $\mathsf{Real}^{\uparrow}$ seal.

Finally H, K, P, N transport, replay, package, and name the same finite rows. Since no carrier coordinate contains a sigma-algebra completion, quotient equality, selected branch, countable-choice schedule, or ambient completeness principle, the obligation surface is exactly the displayed packet. □

Theorem 8870.3 (CantorBorelSet cylinder generation)**.** *Every public cylinder read exported by an accepted* $\mathsf{CantorBorelSet}^{\uparrow}$ *carrier factors through the finite route*

$$\mathsf{CantorSpace}^{\uparrow} \longmapsto \mathsf{CantorCylinderBasis}^{\uparrow} \longmapsto \mathsf{StreamName}^{\uparrow}.$$

The route exposes the Cantor prefix row A*, the cylinder-window row* C*, and the finite stream-window row* W *before any* $\mathsf{RegSeqRat}^{\uparrow}$ *readback or* $\mathsf{Real}^{\uparrow}$ *seal is public. Thus cylinder generation remains a finite NameCert route, not a host powerset, completed sigma algebra, quotient subset equality, selected infinite branch, or countable-choice enumeration.*

Proof. Start from the Cantor address row A. It names only the finite binary prefixes currently visible in the accepted carrier.

Use the cylinder-window row C next. By construction, C is read through the cylinder basis of chapter 2153, so generation is by displayed finite cylinder windows.

Finally expose the stream window W. The $\mathsf{StreamName}^{\uparrow}$ row records exactly the bounded countable-name observations used by downstream consumers. Since R and E are downstream and no carrier coordinate names a host powerset or completed sigma algebra, the public cylinder generation route is exhausted by the displayed finite rows. □

Theorem 8870.4 (CantorBorelSet real route)**.** *Every countable-name real consumer of an accepted* $\mathsf{CantorBorelSet}^{\uparrow}$ *packet must read the route*

$$\mathsf{CantorCylinderBasis}^{\uparrow} \longmapsto \mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}$$

before using the packet as a real-facing Borel-window input. The consumer receives C, W, R, E, H, K, P, N *as displayed* BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *rows; it receives no quotient stream equality, selected representative, selected branch, host Borel set equality, countable-choice schedule, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Apply the cylinder-generation theorem Definition 8870.3. It forces the read through the Cantor address, cylinder basis, and finite StreamName window before real-facing data is available.

Next read the regular rational row R. This is the only $\mathsf{RegSeqRat}^{\uparrow}$ coordinate in the carrier, so any countable-name real consumer must pass through the displayed readback rather than a quotient stream or selected representative.

Finally consume the terminal seal E and structural rows H, K, P, N. The seal is downstream of C, W, R, and the structural rows preserve the same displayed route. Therefore the real-facing Borel-window input is exactly the finite path through cylinder, stream, regular readback, and Real rows, with no hidden host Borel equality, branch selection, countable choice, or ambient completeness. □

Closure status for $\mathsf{NameCert}_{\mathsf{CantorBorelSet}^{\uparrow}}$.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{CantorBorelSet}^{\uparrow}}$, seed)

Scope closed: Definition 8870.1, Definition 8870.2, Definition 8870.3, and Definition 8870.4 seed the finite cylinder-window route from Cantor prefixes through StreamName, RegSeqRat, and Real rows for later countable-name consumers.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{CantorBorelSet}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close completed Borel sigma algebras, quotient set equality, selected infinite branches, countable choice, ambient RealUp completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, cylinder-window exactness, countable-name window discipline, regular readback, Real sealing, transport, replay, provenance, local naming, and TasteGate field faithfulness for BEDC.Derived.CantorBorelSetUp.

Constructive story: A $\mathsf{CantorBorelSet}^{\uparrow}$ packet is generated from a CantorSpace address row, CantorCylinderBasis window row, StreamName finite-window row, RegSeqRat readback row, RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 8871

A Concrete Naming Certificate for $\mathsf{FellerSemigroup}^{\uparrow}$

Following Feller and Ethier–Kurtz on Markov transition semigroups, the $\mathsf{FellerSemigroup}^{\uparrow}$ packet records the finite route by which a displayed transition family preserves continuous observables on a compact metric state surface before any process-level or generator-facing consumer reads it. It sits after the compact state boundary of chapter 129, the continuous observable route of chapter 130, the Markov transition row of chapter 189, and the terminal real-value seal of chapter 38. The packet names a finite Markov-continuity carrier; it is not a host semigroup theorem, a selected stochastic process, a measure-space completion, quotient equality of kernels, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 8871.1 (FellerSemigroup carrier)**.** *A* $\mathsf{FellerSemigroup}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$F = (X, T, K, A, O, V, R, H, C, P, N)$$

with the following displayed rows:

1. *X is the* $\mathsf{CompactMetric}^{\uparrow}$ *state row, exposing only the finite metric and compact-window data used by transition reads.*
2. *T is the finite time-window row, listing the semigroup times and composition comparisons inspected by the packet.*
3. *K is the* $\mathsf{MarkovChain}^{\uparrow}$ *transition-kernel row, recording the displayed Markov transition data available at the times in T.*
4. *A is the algebraic semigroup ledger for identity time, displayed composition, and compatibility of the transition rows in K.*
5. *O is the finite list of* $\mathsf{ContinuousMap}^{\uparrow}$ *observable rows on the compact state surface.*
6. *V is the* $\mathsf{Real}^{\uparrow}$ *value-read row for the observable evaluations before and after transition.*
7. *R is the Markov-continuity row saying that transition reads carry the displayed observables in O to displayed continuous observable rows over the same compact state surface.*
8. *H records componentwise* hsame *transport for the state, time, transition, semigroup, observable, value, and Markov-continuity rows.*
9. *C records displayed* Cont *replay from a transition request through observable readback and Markov-continuity exposure.*

10. *P is the* Pkg *provenance over* $\mathsf{FellerSemigroup}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{MarkovChain}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{FellerSemigroup}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $X, T, K, A, O, V, R, H, C, P, N$. It has no coordinate for a host probability space, selected sample paths, measure completion, quotient equality of kernels, countable choice, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 8871.2 (FellerSemigroup NameCert obligations)**.** *For every accepted* $\mathsf{FellerSemigroup}^{\uparrow}$ *carrier $F = (X, T, K, A, O, V, R, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{FellerSemigroup}^{\uparrow}}$ *surface consists exactly of carrier admission for the compact metric state row, finite time-window row, Markov transition row, semigroup ledger, continuous observable rows, real-value readback, Markov-continuity row, componentwise transport, displayed replay, provenance, and local naming. Every semigroup-facing consumer must read the finite route*

$$\mathsf{CompactMetric}^{\uparrow},\ \mathsf{ContinuousMap}^{\uparrow},\ \mathsf{MarkovChain}^{\uparrow},\ \mathsf{Real}^{\uparrow},\ \mathsf{BHist},\ \mathsf{hsame},\ \mathsf{Cont},\ \mathsf{Pkg},\ \mathsf{NameCert}$$

through those carrier rows before any Feller-continuity conclusion is available. The exported boundary is finite NameCert data for Markov-continuity, not a host stochastic-process construction, measure-space completion, selected path law, quotient kernel equality, or ambient completeness theorem.

Proof. Project the accepted carrier of Definition 8871.1. The displayed analytic rows are X, T, K, A, O, V, R, and the structural rows are H, C, P, N.

The compact state and transition rows are read first. The row X supplies the finite compact-metric state surface, T names the inspected time windows, and K supplies only the displayed Markov transition data at those times.

The semigroup and observable rows then bind the transition route. The ledger A records identity and composition checks, while O, V, R expose continuous observable rows, their real-value reads, and the Markov-continuity handoff.

Transport, replay, provenance, and local naming preserve that same route. Since the carrier has no host probability-space, selected-path, measure-completion, quotient-kernel, choice, trichotomy, or ambient-completeness coordinate, no local NameCert obligation can export one. □

Theorem 8871.3 (FellerSemigroup Markov-continuity handoff)**.** *Every Feller-continuity read exported by an accepted* $\mathsf{FellerSemigroup}^{\uparrow}$ *packet factors through the displayed route*

$$X, T, K, A \longmapsto O, V, R \longmapsto H, C, P, N.$$

In particular, the $\mathsf{MarkovChain}^{\uparrow}$ *transition row is consumed only together with the* $\mathsf{CompactMetric}^{\uparrow}$ *state row, the* $\mathsf{ContinuousMap}^{\uparrow}$ *observable rows, and the* $\mathsf{Real}^{\uparrow}$ *value-read row. A downstream consumer cannot bypass those sibling rows by appealing to host kernel equality, a selected process realization, measure completion, countable choice, trichotomy, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start from the carrier inventory. The only transition-facing row is K, and it is indexed by the finite time-window row T over the compact state surface X.

Use the NameCert obligations of Definition 8871.2. They require any semigroup-facing consumer to expose the semigroup ledger A, observable rows O, and value-read row V before the Markov-continuity row R can be inspected.

The row R is therefore a handoff from displayed Markov transition data to displayed continuous observables. The componentwise transport H and replay C preserve the same compact state, transition, observable, and value rows, while P, N record the provenance and local certificate.

Because no excluded coordinate appears in the carrier, the handoff is exactly the finite Markov-continuity route through $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{MarkovChain}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$. □

Falsifiable prediction: Every accepted $\mathsf{FellerSemigroup}^{\uparrow}$ consumer that reaches the Markov-continuity row without first reading the CompactMetricUp state row, ContinuousMapUp observable rows, MarkovChainUp transition row, RealUp value row, transport, replay, provenance, and local NameCert row refutes the carrier surface.

Independence witness: compactmetric, continuousmap, markovchain, real: $\mathsf{FellerSemigroup}^{\uparrow}$ is not bijective to any listed sibling because it jointly binds finite time windows, Markov transition rows, semigroup composition, continuous observable rows, real-value readback, Markov-continuity handoff, transport, replay, provenance, and local naming in one packet.

Closure status for $\mathsf{NameCert}_{\mathsf{FellerSemigroup}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{FellerSemigroup}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8871.1, Definition 8871.2, and Definition 8871.3 seed the finite Markov-continuity certificate over compact state rows, continuous observable rows, Markov transition rows, Real value reads, transport, replay, provenance, and local naming.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{FellerSemigroup}^{\uparrow}}, \mathsf{formalTarget})$

Bridge status: none

Not claimed: This chapter does not close host stochastic-process construction, measure completion, selected sample paths, quotient equality of kernels, countable choice, trichotomy, ambient Real completeness, theorem-level Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, finite time-window exposure, semigroup ledger exactness, observable-row handoff, Markov-continuity exposure, transport, replay, provenance, and local naming for BEDC.Derived.FellerSemigroupUp.

Constructive story: A $\mathsf{FellerSemigroup}^{\uparrow}$ packet is generated from a CompactMetric state row, finite time-window row, MarkovChain transition row, semigroup ledger, ContinuousMap observable rows, RealUp value-read rows, Markov-continuity row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 8872

A Concrete Naming Certificate for $\mathsf{RegularCauchyBoundedTail}^{\uparrow}$

Following Bishop and Bridges on regular Cauchy real names and explicit bounded tails, the $\mathsf{RegularCauchyBoundedTail}^{\uparrow}$ packet records the finite witness by which a regular rational Cauchy schedule exposes a bounded tail before a Real or Completion consumer reads the source. It sits beside the regular rational readback of chapter 301, the finite stream-window surface of chapter 126, the dyadic tolerance ledger of chapter 291, the terminal real-name seal of chapter 38, the selected bounded-tail window of chapter 8282, and the bounded Cauchy sequence packet of chapter 1522. The chapter names a displayed L10 bounded-tail witness; it does not claim quotient stream equality, a selected limit, countable choice, trichotomy, located suprema, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 8872.1 (Regular Cauchy bounded-tail carrier)**.** *A* $\mathsf{RegularCauchyBoundedTail}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$T = (S, W, D, B, R, E, H, C, P, N)$$

with the following displayed rows:

1. *S is the* $\mathsf{StreamName}^{\uparrow}$ *schedule row, displaying the finite observation windows inspected by the tail request.*
2. *W is the selected window row consumed from* $\mathsf{CauchyBoundSelector}^{\uparrow}$*, recording the finite threshold and inspected bounded-tail windows.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, naming the dyadic radius, endpoint arithmetic, and comparison budget used by the bounded-tail read.*
4. *B is the* $\mathsf{CauchySequenceBounded}^{\uparrow}$ *boundedness row, exposing the explicit tail bound attached to the same stream and tolerance data.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *regular readback row, repacking the displayed stream windows and dyadic comparisons as regular rational Cauchy data.*
6. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row, available only after S, W, D, B, R have been displayed.*
7. *H records componentwise* hsame *transport for the schedule, selected window, dyadic ledger, boundedness row, regular readback, Real seal, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from a bounded-tail request through $S, W, D, B, R, E, H, P, N$.*

9. *P is the* Pkg *provenance over* $\mathsf{RegularCauchyBoundedTail}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{CauchyBoundSelector}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{CauchySequenceBounded}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyBoundedTail}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $S, W, D, B, R, E, H, C, P, N$. It has no coordinate for quotient stream equality, selected limits, countable choice, trichotomy, located suprema, open-cover compactness, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 8872.2 (Regular Cauchy bounded-tail NameCert obligations)**.** *For every accepted* RegularCauchyBounde *carrier*

$$T = (S, W, D, B, R, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{RegularCauchyBoundedTail}^{\uparrow}}$ *surface consists exactly of carrier admission for the StreamName schedule, CauchyBoundSelector selected window, DyadicRatCore tolerance ledger, CauchySequenceBounded explicit bound, RegSeqRat readback, RealUp seal, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming.*

Proof. Project the carrier of Definition 8872.1. The accepted tuple displays the schedule row S, selected window row W, dyadic tolerance ledger D, boundedness row B, regular readback row R, Real seal row E, and structural rows H, C, P, N.

The bounded-tail read is ordered. A consumer first opens the finite stream schedule and selected window, then reads the dyadic tolerance ledger and the boundedness row, and only then consumes the regular readback and terminal Real seal.

The structural rows preserve exactly that route. The transport and replay rows carry the displayed schedule, window, tolerance, bound, readback, and seal rows; provenance and local naming source the same packet. Since the classifier has no coordinate for quotient stream equality, selected limits, countable choice, trichotomy, located suprema, compactness, or ambient completeness, the listed rows exhaust the local NameCert surface. □

Theorem 8872.3 (Regular Cauchy bounded-tail window boundary)**.** *Every* $\mathsf{Real}^{\uparrow}$ *or completion-facing read from an accepted* $\mathsf{RegularCauchyBoundedTail}^{\uparrow}$ *packet reaches the seal row E only after the finite route*

$$S, W, D, B, R, E, H, C, P, N$$

has been displayed. The read may use the bounded-tail window and regular rational handoff as source data, but it cannot infer quotient equality of regular names, select a limit, choose tail bounds for all Cauchy predicates, decide trichotomy, form a located supremum, or import ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Apply the NameCert obligations of Definition 8872.2. They force the StreamName schedule, CauchyBoundSelector window, DyadicRatCore tolerance ledger, CauchySequenceBounded bound, and RegSeqRat readback to be public before the Real seal can be read.

The seal row E is therefore downstream of a finite displayed bounded-tail route. Transport through H and replay through C preserve the same rows, while P and N supply provenance and local naming without adding further analytic structure.

Finally inspect the excluded coordinates of the carrier. No row stores quotient equality of regular names, selected limits, a global choice function, trichotomy, located suprema, compactness, or ambient Real completeness. Thus every Real or completion-facing read remains confined to the displayed bounded-tail boundary. □

Falsifiable prediction: Every accepted $\mathsf{RegularCauchyBoundedTail}^{\uparrow}$ consumer that reads a $\mathsf{Real}^{\uparrow}$ or completion-facing bounded-tail source must display the $\mathsf{StreamName}^{\uparrow}$ schedule, $\mathsf{CauchyBoundSelector}^{\uparrow}$ selected window, $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance ledger, $\mathsf{CauchySequenceBounded}^{\uparrow}$ bound, $\mathsf{RegSeqRat}^{\uparrow}$ readback, $\mathsf{Real}^{\uparrow}$ seal, transport, replay, provenance, and local NameCert rows.

Independence witness: streamname, cauchy-bound-selector, dyadicratcore, cauchy-sequence-bounded, regseqrat, real: no listed sibling is bijective to $\mathsf{RegularCauchyBoundedTail}^{\uparrow}$, because this packet jointly binds a finite stream schedule, selected bounded-tail window, dyadic tolerance ledger, explicit boundedness row, regular rational readback, terminal Real seal, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{RegularCauchyBoundedTail}^{\uparrow}}$.

Constructive story: A $\mathsf{RegularCauchyBoundedTail}^{\uparrow}$ packet is generated from a StreamName schedule, CauchyBoundSelector selected window, DyadicRatCore tolerance ledger, CauchySequenceBounded explicit bound, RegSeqRat readback, RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RegularCauchyBoundedTail}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8872.1, Definition 8872.2, and Definition 8872.3 seed the finite regular-Cauchy bounded-tail packet over stream schedules, selected windows, dyadic tolerances, explicit bounds, regular readback, Real sealing, transport, replay, provenance, and local naming.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RegularCauchyBoundedTail}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim quotient stream equality, selected limits, countable choice, trichotomy, located suprema, open-cover compactness, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, selected-window exposure, dyadic tolerance exactness, boundedness readback, regular rational handoff, Real seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.RegularCauchyBoundedTailUp.

Chapter 8873

A Concrete Naming Certificate for CompactIntervalCantorBisection$^{\uparrow}$

Following Cantor's nested-interval bisection and the Bishop–Bridges finite-means reading of compact intervals, the CompactIntervalCantorBisection$^{\uparrow}$ packet records a closed interval search as finite dyadic interval data before any completion consumer reads a limit. It is anchored in the dyadic interval net of chapter 5966, the located interval bisection route of chapter 8867, the nested interval convergence surface of chapter 5987, the regular-rational readback of chapter 301, and the terminal real seal of chapter 38. The chapter treats Cantor bisection as a finite NameCert obligation surface over displayed intervals, not as open-cover compactness, a selected limit, countable choice, or ambient real completeness.

Definition 8873.1 (Compact interval Cantor bisection carrier)**.** *A* CompactIntervalCantorBisection$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (D, L, N, R, Q, H, C, P, M)$$

with the following displayed rows:

1. *D is the* DyadicIntervalNet$^{\uparrow}$ *row listing the finite dyadic cells used at the displayed bisection depth.*
2. *L is the* LocatedIntervalBisection$^{\uparrow}$ *row recording the left/right interval decision ledger for each inspected cell.*
3. *N is the* NestedIntervalConvergence$^{\uparrow}$ *row that retains the nested enclosure relation through the finite bisection spine.*
4. *R is the* RegSeqRat$^{\uparrow}$ *readback row for endpoint windows and shrinking-radius budgets.*
5. *Q is the terminal* Real$^{\uparrow}$ *seal row reached only after the dyadic cells, located bisection ledger, nested enclosure row, and regular-rational readback have been displayed.*
6. *H records componentwise* hsame *transport for the dyadic interval net, located bisection, nested enclosure, regular-rational readback, real seal, continuation, provenance, and local naming rows.*
7. *C records displayed* Cont *replay from a compact interval request through finite dyadic subdivision, located bisection, nested enclosure, regular-rational readback, and the real seal.*
8. *P is the* Pkg *provenance over* CompactIntervalCantorBisection$^{\uparrow}$, DyadicIntervalNet$^{\uparrow}$, LocatedIntervalBisection$^{\uparrow}$, NestedIntervalConvergence$^{\uparrow}$, RegSeqRat$^{\uparrow}$, Real$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*

9. M is the local $\mathsf{NameCert}_{\mathsf{CompactIntervalCantorBisection}^{\uparrow}}$ *row.*
The classifier compares accepted carriers only through $D, L, N, R, Q, H, C, P, M$. It has no coordinate for open-cover compactness, selected finite subcovers, countable-choice schedules, quotient equality of real names, host interval endpoints, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 8873.2 (Compact interval Cantor bisection NameCert obligations)**.** *For every accepted* $\mathsf{CompactIntervalCantorBisection}^{\uparrow}$ *carrier*

$$B = (D, L, N, R, Q, H, C, P, M),$$

the local $\mathsf{NameCert}_{\mathsf{CompactIntervalCantorBisection}^{\uparrow}}$ *surface consists exactly of carrier admission, finite dyadic interval-net exposure, located interval bisection exposure, nested interval convergence retention, regular-rational endpoint readback, terminal real sealing, componentwise transport, displayed replay, provenance, and local naming.*

Proof. Carrier admission projects the tuple $D, L, N, R, Q, H, C, P, M$. The finite dyadic interval-net row D is the only source of cells inspected by the bisection route.

The located bisection row L records the finite left/right interval decisions, and the nested enclosure row N keeps the resulting chain visible as a displayed interval spine. These rows precede every completion-facing read.

The readback row R converts endpoint windows and shrinking-radius budgets into regular rational data, and the seal row Q is downstream of that readback. Transport, replay, provenance, and local naming preserve the same route through H, C, P, M.

Since the carrier has no coordinate for open covers, selected subcovers, countable-choice schedules, quotient equality of real names, host endpoints, or ambient completeness, the listed rows exhaust the local NameCert surface. □

Theorem 8873.3 (Compact interval Cantor bisection five-row route)**.** *Every completion-facing consumer of an accepted* $\mathsf{CompactIntervalCantorBisection}^{\uparrow}$ *packet reads the five visible mathematical rows*

$$\mathsf{DyadicIntervalNet}^{\uparrow} \longmapsto \mathsf{LocatedIntervalBisection}^{\uparrow} \longmapsto \mathsf{NestedIntervalConvergence}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}$$

before inspecting transport, replay, provenance, or local naming data. The route exports no open-cover compactness theorem, selected limit, countable-choice schedule, quotient real-name equality, or ambient completeness principle.

Proof. Begin with the dyadic interval net row D. It supplies the finite cell list and dyadic endpoint arithmetic consumed by the located bisection ledger.

The located bisection row L records only displayed interval decisions. The nested convergence row N then retains the enclosure relation for the finite bisection spine without selecting a host-real limit.

The regular-rational row R reads back the endpoint windows and shrinking-radius budgets, and the real seal Q can be opened only after that readback. The structural rows H, C, P, M replay this same chain and add no excluded compactness or choice coordinate. □

Closure status for $\mathsf{NameCert}_{\mathsf{CompactIntervalCantorBisection}^{\uparrow}}$.

Constructive story: A $\mathsf{CompactIntervalCantorBisection}^{\uparrow}$ packet is generated from a finite dyadic interval net, a located bisection ledger, a nested interval convergence row, regular-rational endpoint readback, a terminal real seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CompactIntervalCantorBisection}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8873.1, Definition 8873.2, and Definition 8873.3 seed the finite Cantor-bisection route over DyadicIntervalNet, LocatedIntervalBisection, NestedIntervalConvergence, RegSeqRat, and Real rows.

Formal verification: FormalStatus(NameCert$_{\text{CompactIntervalCantorBisection}\uparrow}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim open-cover compactness, a selected limit, countable choice, quotient real-name equality, host interval endpoints, or ambient real completeness.

Upgrade path: Obligation closure requires checked carrier admission, five-row route exactness, classifier nonescape, transport, replay, provenance, and local naming for BEDC.Derived.CompactIntervalCantorBisectionUp.

Chapter 8874

A Concrete Naming Certificate for $\mathsf{RHMirrorOrbitTarget}^{\uparrow}$

The $\mathsf{RHMirrorOrbitTarget}^{\uparrow}$ packet realizes the non-fixed orbit target of chapter 9334 as finite NameCert data. It names the critical-strip candidate row, mirror involution row, orbit-zero row, fixedness boundary, apartness witness, and obstruction ledger that must be displayed before an RH route may consume a non-fixed mirror orbit. The packet is a target surface for the RH orbit layer; it does not prove RH, does not assert zero-free strips, and does not collapse weak orbit exclusion into fixed-section evidence.

It depends on the critical-strip window carrier of chapter 8868, the boundary-kind separation surface of chapter 8864, and the fixed-statement separation route of chapter 8824. Rows S, J, Z, F, A, W consume their candidate-row, fixedness-boundary, apartness, and weak-exclusion rows before any mirror-orbit target is eligible for downstream RH routing.

Definition 8874.1 (RH mirror-orbit target carrier)**.** *An* $\mathsf{RHMirrorOrbitTarget}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$O = (S, J, Z, F, A, W, H, C, P, N)$$

with the following displayed rows:

1. *S is the critical-strip candidate row read from the carrier of Definition 9334.1.*
2. *J is the mirror-involution row recording the displayed map $s \mapsto 1 - \overline{s}$ and its finite replay data.*
3. *Z is the orbit-zero row naming the two possible zero reads $Z_\zeta(s)$ and $Z_\zeta(J(s))$.*
4. *F is the fixedness boundary row, separating fixed mirror rows from non-fixed mirror rows without deciding the equality globally.*
5. *A is the apart non-fixed witness row when a positive rational separation is displayed.*
6. *W is the weak-exclusion obstruction row, recording that weak orbit exclusion supplies only a refutation route unless additional located equality transport is present.*
7. *H records componentwise* hsame *transport for candidate, mirror, orbit-zero, fixedness, apartness, obstruction, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from an orbit target request through the critical-strip candidate, mirror row, orbit-zero row, fixedness boundary, apartness witness, and obstruction ledger.*

9. *P is the* Pkg *provenance over* $\mathsf{RHMirrorOrbitTarget}^{\uparrow}$*, the RH non-fixed orbit vision layer,* BHist*,* hsame*,* Cont*, and* NameCert *rows.*
10. *N is the local* $\mathsf{NameCert}_{\mathsf{RHMirrorOrbitTarget}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $S, J, Z, F, A, W, H, C, P, N$. It has no coordinate for an RH proof, global zero-free strip, classical excluded middle over mirror fixedness, quotient equality of candidate rows, host complex analysis, or unrecorded functional-equation transport.

Theorem 8874.2 (RH mirror-orbit target NameCert obligations)**.** *For every accepted* $\mathsf{RHMirrorOrbitTarget}^{\uparrow}$ *carrier*

$$O = (S, J, Z, F, A, W, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{RHMirrorOrbitTarget}^{\uparrow}}$ *surface consists exactly of carrier admission, critical-strip candidate exposure, mirror-involution replay, orbit-zero exposure, fixedness-boundary retention, apart non-fixed witness exposure when present, weak-exclusion obstruction retention, component-wise transport, displayed replay, provenance, and local naming.*

Proof. Carrier admission projects $S, J, Z, F, A, W, H, C, P, N$. The critical-strip candidate row S and mirror row J are the only rows from which an orbit target can be read.

The orbit-zero row Z keeps the two zero reads visible as a finite disjoint target surface. The fixedness boundary row F records whether the consumer is reading a fixed row, a non-fixed row, or only a refutational boundary.

The apart row A is available only when a positive rational separation is displayed, and the obstruction row W records the gap between weak exclusion and fixed-section evidence. Transport, replay, provenance, and local naming preserve these rows without adding a hidden RH conclusion.

Since the carrier has no coordinate for an RH proof, global zero-free strip, classical decision of fixedness, quotient candidate equality, host complex-analysis oracle, or unrecorded functional-equation transport, the displayed rows exhaust the local NameCert surface. □

Theorem 8874.3 (RH mirror-orbit fixedness boundary)**.** *Every accepted* $\mathsf{RHMirrorOrbitTarget}^{\uparrow}$ *consumer that reads an orbit-zero row must keep the finite route*

$$S \longmapsto J \longmapsto Z \longmapsto F, W$$

visible before any apartness or fixed-section handoff is consumed. If the apart witness row A is absent, the packet records a weak refutation boundary only; it does not inhabit the fixed-section target.

Proof. Project the accepted carrier. The critical-strip source is S, the mirror involution is J, and orbit-zero exposure is Z.

The fixedness boundary F and obstruction row W are downstream of Z. They record whether the consumer has a fixed-row route, a non-fixed refutation route, or only a double-negation boundary.

The apartness row A is a separate positive witness row. Without it, the route has no coordinate for located equality transport, so it cannot be read as fixed-section evidence. The structural rows preserve this separation. □

Falsifiable prediction: Any accepted $\mathsf{RHMirrorOrbitTarget}^{\uparrow}$ consumer that reads an RH conclusion without displaying S, J, Z, F, W refutes the carrier; any accepted consumer that turns weak orbit exclusion into fixed-section evidence without an apartness or located-equality row refutes the fixedness boundary.

Independence witness: rh-critical-strip-window-certificate, rh-boundary-kind-separation, rh-route-closure-fixed-statement-separation: the mirror-orbit target is not bijective to any listed sibling because it jointly names the candidate row, mirror involution, orbit-zero row, fixedness boundary, apartness witness, weak-exclusion obstruction, transport, replay, provenance, and local naming.

The Lean follow-up for BEDC.Derived.RHMirrorOrbitTargetUp must provide a TasteGate surface whose non-smoke witness inspects the mirror row, orbit-zero row, fixedness boundary, apartness row, and obstruction row. A downstream positive gate must not treat weak non-fixed orbit exclusion as a fixed-section inhabitant unless a separate located-equality transport row is checked.

Closure status for $\mathsf{NameCert}_{\mathsf{RHMirrorOrbitTarget}^{\uparrow}}$.

Constructive story: An $\mathsf{RHMirrorOrbitTarget}^{\uparrow}$ packet is generated from a critical-strip candidate row, mirror-involution replay, orbit-zero exposure, fixedness boundary, apart non-fixed witness when present, weak-exclusion obstruction, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RHMirrorOrbitTarget}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8874.1, Definition 8874.2, and Definition 8874.3 seed the finite RH mirror-orbit target over critical-strip candidates, mirror involution, orbit-zero exposure, fixedness boundary, apartness, and weak-exclusion obstruction rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RHMirrorOrbitTarget}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not prove RH, zero-free strips, classical fixedness decidability, quotient candidate equality, host complex-analysis facts, or unrecorded functional-equation transport.

Upgrade path: Obligation closure requires checked carrier admission, mirror replay, orbit-zero exposure, fixedness-boundary retention, apartness handling, weak-exclusion obstruction, transport, replay, provenance, local naming, and TasteGate evidence for BEDC.Derived.RHMirrorOrbitTargetUp.

Chapter 8875

A Concrete Naming Certificate for CauchyCompletionInductionPrinciple$^{\uparrow}$

Following Bishop and Bridges, *Constructive Analysis*, the CauchyCompletionInductionPrinciple$^{\uparrow}$ packet names the finite row-by-row induction surface used by Cauchy-completion proofs before a terminal real seal is exposed. It is an L10 companion to the dense-source induction of chapter 1776, the quotient-free completion boundary of chapter 1639, the universal-property route of chapter 6041, the finite stream window of chapter 126, the regular rational readback of chapter 301, the dyadic tolerance ledger of chapter 291, and the terminal real-name seal of chapter 38. The packet is not another completion object; it is the displayed induction rule that lets Real and Completion consumers traverse those rows without receiving quotient equality, selected limits, countable choice, host real equality, or ambient completeness.

Definition 8875.1 (Cauchy completion induction principle carrier)**.** *A* CauchyCompletionInductionPrinciple$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$J = (S, R, D, B, U, E, I, H, C, P, N)$$

with the following displayed rows:

1. *S is the* StreamName$^{\uparrow}$ *finite-window schedule whose listed entries are the only sequence coordinates inspected by the induction.*
2. *R is the* RegSeqRat$^{\uparrow}$ *readback reached from the same windows.*
3. *D is the* DyadicRatCore$^{\uparrow}$ *tolerance ledger assigning each finite induction row its visible dyadic budget.*
4. *B is the* BishopRegularCauchyCompletion$^{\uparrow}$ *boundary row, recording that the induction is completion-facing without selecting a completed limit.*
5. *U is the* RealCompletionUniversalProperty$^{\uparrow}$ *handoff row, read only after S, R, D, B have been displayed.*
6. *E is the terminal* Real$^{\uparrow}$ *seal produced by the displayed handoff.*
7. *I is the finite-row induction ledger: it orders the base row, successor row, and terminal seal handoff over S, R, D, B, U, E.*
8. *H records componentwise* hsame *transport for all displayed rows.*

9. *C records displayed* Cont *replay of the same finite-row route.*
10. *P is the* Pkg *provenance over* $\mathsf{CauchyCompletionInductionPrinciple}^{\uparrow}$, $\mathsf{BishopCompletionInduction}^{\uparrow}$, $\mathsf{BishopRegularCauchyCompletion}^{\uparrow}$, $\mathsf{RealCompletionUniversalProperty}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{CauchyCompletionInductionPrinciple}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through $S, R, D, B, U, E, I, H, C, P, N$. It contains no coordinate for quotient stream equality, selected representatives, countable choice, host real equality, ambient completeness, Lean verification, or bridge checking.

Theorem 8875.2 (Cauchy completion induction principle NameCert obligations)**.** *For every accepted* $\mathsf{CauchyCompletionInductionPrinciple}^{\uparrow}$ *carrier $J = (S, R, D, B, U, E, I, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{CauchyCompletionInductionPrinciple}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the eleven displayed rows;*
2. *finite-window visibility, requiring every induction premise to read only entries listed by S;*
3. *regular readback and tolerance compatibility, requiring R and D to answer the same displayed window requests;*
4. *completion-boundary routing, requiring B to expose the quotient-free* $\mathsf{BishopRegularCauchyCompletion}^{\uparrow}$ *boundary before any universal-property handoff is read;*
5. *universal-property handoff exactness, requiring U and E to be read downstream of S, R, D, B;*
6. *finite-row induction exactness, requiring I to store only the base, successor, and terminal handoff rows over the displayed route;*
7. *componentwise transport, displayed replay, provenance, and local naming through H, C, P, N.*

No obligation row for quotient completion, selected limits, countable choice, host real equality, ambient completeness, Lean verification, or bridge checking is exported by the packet.

Proof. Project the carrier of Definition 8875.1. Its visible rows are exactly the finite windows, regular readback, dyadic budget, completion boundary, universal handoff, terminal seal, induction ledger, transport, replay, provenance, and local naming rows.

The first three obligations are forced by the source route. An induction premise has no sequence coordinate outside S, and the readback row R is compatible with the tolerance ledger D only along the same displayed finite windows.

The completion-facing handoff is downstream. The boundary row B records that the route is a Bishop regular Cauchy completion route without a selected limit, while U and E are visible only after S, R, D, B have been displayed.

The induction ledger is local. It stores the base row, successor row, and terminal handoff row over the same displayed route, and H, C, P, N transport, replay, source, and name that route without adding another analytic coordinate.

Since all excluded objects are absent from the carrier, the listed obligations exhaust the local NameCert surface. □

Theorem 8875.3 (Cauchy completion finite-row induction)**.** *Let $J = (S, R, D, B, U, E, I, H, C, P, N)$ be an accepted* $\mathsf{CauchyCompletionInductionPrinciple}^{\uparrow}$ *carrier. Every completion-facing induction step exported by J factors through the displayed finite route*

$$S \longmapsto R \longmapsto D \longmapsto B \longmapsto U \longmapsto E \longmapsto I \longmapsto H, C, P, N.$$

The base row and each successor row of the induction may inspect only the finite $\mathsf{StreamName}^{\uparrow}$ *entries in* S*, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback* R*, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *budget* D*, the quotient-free* BishopRegularCauchyComplet *boundary* B*, the* $\mathsf{RealCompletionUniversalProperty}^{\uparrow}$ *handoff* U*, and the terminal* $\mathsf{Real}^{\uparrow}$ *seal* E*. No induction step may export quotient equality, a selected limit, countable choice, host real equality, ambient completeness, Lean verification, or bridge checking.*

Proof. Begin with an accepted carrier and project the finite-window row. The induction ledger I has no source outside S, so the base and successor rows can inspect only the listed StreamName entries.

Readback and tolerance control then fix the middle route. The row R is the displayed regular rational readback from those windows, and D is the dyadic budget attached to the same finite observations.

The completion handoff is reached only after the quotient-free boundary row is visible. The row B supplies the Bishop regular Cauchy completion boundary, while U and E record the universal-property handoff and terminal Real seal downstream of S, R, D, B.

Finally read I, H, C, P, N. The induction ledger stores the base, successor, and terminal handoff rows over the same displayed route, and the structural rows transport, replay, source, and name that route. Because no excluded object appears in the carrier, no induction step can export any of the forbidden completion or verification data. □

Theorem 8875.4 (Cauchy completion induction principle consumer boundary)**.** *Every Real or Completion consumer of an accepted* $\mathsf{CauchyCompletionInductionPrinciple}^{\uparrow}$ *packet receives only the finite-row induction route named by* $S, R, D, B, U, E, I, H, C, P, N$*. In particular, the consumer may reuse the dense-source discipline of* $\mathsf{BishopCompletionInduction}^{\uparrow}$*, the quotient-free boundary of* $\mathsf{BishopRegularCauchyCompletion}^{\uparrow}$*, and the handoff surface of* $\mathsf{RealCompletionUniversalProperty}^{\uparrow}$*, but only through the displayed rows of the packet. It receives no separate completion object, quotient stream equality, selected representative, countable-choice schedule, host equality service, ambient* $\mathsf{Real}^{\uparrow}$ *completeness theorem, Lean verification, or bridge checking.*

Proof. Project the accepted packet. The rows S, R, D, B, U, E, I give the only analytic and induction data, while H, C, P, N give only transport, replay, provenance, and local naming.

The sibling packets enter as named rows, not as external services. The dense-source discipline is cited by the provenance row P, the regular Cauchy completion boundary is stored in B, and the universal-property handoff is stored in U after the finite route has been displayed.

Thus a consumer cannot bypass the carrier to obtain another completion object or another equality service. It reads exactly the finite-row induction route and no excluded quotient, choice, host-equality, ambient-completeness, Lean, or bridge datum. □

Falsifiable prediction: Every $\mathsf{CauchyCompletionInductionPrinciple}^{\uparrow}$ consumer read factors through one StreamName finite-window schedule, one RegSeqRat readback, one DyadicRatCore tolerance ledger, one BishopRegularCauchyCompletion boundary row, one RealCompletionUniversalProperty handoff, one terminal RealUp seal, one finite-row induction ledger, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming.

Independence witness: bishop-completion-induction, bishop-regular-cauchy-completion, real-completion-universal-property, streamname, regseqrat, dyadicratcore, real: $\mathsf{CauchyCompletionInductionPrinciple}^{\uparrow}$ is not bijective to any listed sibling because it isolates the base-successor-terminal induction ledger over the completion-facing Cauchy route rather than naming the dense-source principle, the completion boundary, the universal handoff, or the terminal seal alone.

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyCompletionInductionPrinciple}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CauchyCompletionInductionPrinciple}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8875.1, Definition 8875.2, and Definition 8875.3 seed the finite-row induction route through StreamName windows, RegSeqRat readback, DyadicRatCore tolerances, Bishop regular Cauchy completion boundary, Real completion universal-property handoff, terminal Real seal, transport, replay, provenance, and local naming.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CauchyCompletionInductionPrinciple}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient completion equality, selected limits, countable choice, host real equality, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Scoped closure requires binding consumer nonescape, row induction exactness, and universal-property handoff exactness to BEDC.Derived.CauchyCompletionInductionPrincipleUp.

Constructive story: A $\mathsf{CauchyCompletionInductionPrinciple}^{\uparrow}$ packet is generated from finite StreamName windows, RegSeqRat readback, DyadicRatCore tolerance data, a BishopRegularCauchyCompletion boundary row, a RealCompletionUniversalProperty handoff, a terminal RealUp seal, a base-successor-terminal induction ledger, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Chapter 8876

A Concrete Naming Certificate for $\mathsf{FareyIntervalRefinement}^{\uparrow}$

Following Hardy–Wright on Farey sequences and Stern–Brocot intervals, the $\mathsf{FareyIntervalRefinement}^{\uparrow}$ packet records a finite rational interval-refinement route between adjacent Farey boundary rows and the real-facing readback surface. It consumes the Farey-neighbor certificate of chapter 1759, the Stern–Brocot branch route of chapter 1704, the dyadic tolerance core of chapter 291, the finite observation windows of chapter 126, the regular rational readback of chapter 301, the rational approximation handoff of chapter 1668, and the terminal real-name seal of chapter 38. The packet names a non-quotient finite refinement witness; it is not real completeness, a selected infinite branch, trichotomy, quotient equality, or a host density theorem.

Definition 8876.1 (Farey interval-refinement carrier)**.** *A* $\mathsf{FareyIntervalRefinement}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$I = (F, S, D, W, R, A, E, H, C, P, N)$$

with the following displayed rows:

1. *F is the* $\mathsf{FareySequence}^{\uparrow}$ *row naming the adjacent rational boundary pair and its denominator budget.*
2. *S is the* $\mathsf{SternBrocot}^{\uparrow}$ *row naming the same interval by a finite branch word and mediant path.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger for endpoint conversion, interval width, and requested precision.*
4. *W is the* $\mathsf{StreamName}^{\uparrow}$ *family of finite windows opened before a real-facing consumer reads the retained interval.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row assembled from the displayed windows and dyadic tolerances.*
6. *A is the* $\mathsf{RealRationalApproximation}^{\uparrow}$ *handoff row recording the rational interval as a finite approximation window.*
7. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row available only after F, S, D, W, R, A have been exposed.*
8. *H stores componentwise* hsame *transport for the Farey row, Stern–Brocot row, dyadic tolerance ledger, stream windows, regular readback, approximation handoff, real seal, provenance, and local name.*
9. *C stores displayed* Cont *replay from F, S, D through W, R, A, E and then through the structural rows.*

10. *P is the* Pkg *provenance over* $\mathsf{FareyIntervalRefinement}^{\uparrow}$, $\mathsf{FareySequence}^{\uparrow}$, $\mathsf{SternBrocot}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{RealRationalApproximation}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{FareyIntervalRefinement}^{\uparrow}}$ *row.*

The carrier has no coordinate for quotient real equality, a selected infinite Stern–Brocot branch, trichotomy, countable choice, host order completeness, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 8876.2 (Farey interval-refinement NameCert obligations)**.** *For every accepted* $\mathsf{FareyIntervalRefinement}^{\uparrow}$ *carrier*

$$I = (F, S, D, W, R, A, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{FareyIntervalRefinement}^{\uparrow}}$ *surface consists exactly of Farey adjacency admission, Stern–Brocot branch agreement for the same rational interval, DyadicRatCore tolerance control, StreamName finite-window exposure, RegSeqRat readback, RealRationalApproximation handoff, RealUp seal boundary, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming.*

Proof. Carrier admission is projection from Definition 8876.1. The packet displays the Farey boundary pair, the Stern–Brocot branch row, dyadic endpoint tolerances, finite windows, readback, approximation handoff, real seal, and structural rows.

The interval agreement obligation is finite. The Farey row F supplies adjacent rational boundaries at the displayed denominator budget, while the Stern–Brocot row S supplies the finite mediant path for the same interval. Their compatibility is read before any downstream approximation row is available.

The real-facing obligations are downstream of that agreement. The dyadic tolerance ledger D controls endpoint conversion and interval width; the windows W expose the inspected prefixes; the readback R and approximation handoff A route the same finite interval to the seal row E.

Finally H, C, P, N transport, replay, source, and name exactly those rows. Since the carrier contains no quotient representative, selected infinite branch, trichotomy witness, choice principle, host completeness theorem, or ambient Real completeness coordinate, the listed rows exhaust the local NameCert surface. □

Theorem 8876.3 (Farey interval-refinement real readback)**.** *Every* $\mathsf{Real}^{\uparrow}$ *consumer of an accepted* $\mathsf{FareyIntervalRefinement}^{\uparrow}$ *packet must read the finite route*

$$\mathsf{FareySequence}^{\uparrow},\ \mathsf{SternBrocot}^{\uparrow},\ \mathsf{DyadicRatCore}^{\uparrow},\ \mathsf{StreamName}^{\uparrow},\ \mathsf{RegSeqRat}^{\uparrow},\ \mathsf{RealRationalApproximation}^{\uparrow},\ \mathsf{Real}^{\uparrow}$$

through the displayed rows $F, S, D, W, R, A, E, H, C, P, N$. The packet can therefore serve Real and completion-facing consumers as a non-quotient rational interval-refinement witness, but it exports no proof of $\mathsf{Real}^{\uparrow}$ *completeness, no selected limiting real, and no quotient equality of real names.*

Proof. Begin with an accepted packet and project its displayed rows. The Farey row F and Stern–Brocot row S fix the same rational interval before any dyadic or real-facing row is consulted.

Next read the dyadic and stream route. The tolerance ledger D records the finite endpoint and width budget, and W records the finite windows opened under that budget. The regular readback R is assembled only from those displayed windows and tolerances.

The rational approximation handoff A is downstream of F, S, D, W, R. Only after that handoff has been displayed may the terminal row E be read as a $\mathsf{Real}^{\uparrow}$ seal.

Rows H, C, P, N preserve the same route under transport, replay, provenance, and local naming. Thus every Real-facing consumer receives a finite interval-refinement witness and cannot extract a selected limit, quotient representative, trichotomy witness, countable-choice selector, host completeness theorem, or ambient $\mathsf{Real}^{\uparrow}$ completeness claim. □

Closure status for $\mathsf{NameCert}_{\mathsf{FareyIntervalRefinement}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{FareyIntervalRefinement}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8876.1, Definition 8876.2, and Definition 8876.3 seed the finite rational interval-refinement route from FareySequence and SternBrocot rows through DyadicRatCore tolerances, StreamName windows, RegSeqRat readback, RealRationalApproximation handoff, RealUp seal, transport, replay, provenance, and local naming.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{FareyIntervalRefinement}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim RealUp completeness, quotient real equality, selected infinite branches, selected limiting reals, trichotomy, countable choice, host order completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, Farey and SternBrocot interval agreement, dyadic tolerance control, StreamName exposure, RegSeqRat readback, RealRationalApproximation handoff, RealUp seal boundary, transport, replay, provenance, and local naming for BEDC.Derived.FareyIntervalRefinementUp.

Constructive story: A $\mathsf{FareyIntervalRefinement}^{\uparrow}$ packet is generated from a FareySequence adjacent-boundary row, a SternBrocot finite branch row for the same interval, DyadicRatCore endpoint tolerances, StreamName finite windows, RegSeqRat readback, RealRationalApproximation handoff, RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 8877

A Concrete Naming Certificate for $\mathsf{DyadicRealEmbeddingFaithful}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{DyadicRealEmbeddingFaithful}^{\uparrow}$ packet records the finite route by which a displayed $\mathsf{DyadicRatCore}^{\uparrow}$ row enters the $\mathsf{Real}^{\uparrow}$ completion seal and remains readable at the $\mathsf{RealClassifier}^{\uparrow}$ boundary. It sits after the dyadic source ledger of chapter 291, the constant finite-window schedule of chapter 126, the regular rational readback of chapter 301, the terminal real seal of chapter 38, and the public classifier surface of chapter 1620. The certificate is a faithfulness surface for displayed dyadic sources, not a host embedding theorem, quotient stream equality, selected representative, trichotomy, countable choice, or ambient completeness principle.

Definition 8877.1 (Dyadic real embedding faithfulness carrier)**.** *A* $\mathsf{DyadicRealEmbeddingFaithful}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$F = (D, S, R, L, Q, C, H, K, P, N)$$

with the following displayed rows:

1. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *source row, including the dyadic numerator, scale, comparison ledger, and tolerance budget under inspection.*
2. *S is the* $\mathsf{StreamName}^{\uparrow}$ *constant-window row that presents the dyadic source to completion-facing reads.*
3. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row obtained from the constant window and the displayed dyadic tolerance ledger.*
4. *L is the* $\mathsf{Real}^{\uparrow}$ *seal row reached only after D, S, R have been displayed.*
5. *Q is the* $\mathsf{RealClassifier}^{\uparrow}$ *boundary row that compares two embedded dyadic sources through one common classifier window.*
6. *C records the classifier conclusion visible at that boundary: equality of accepted classifier reads preserves equality of the displayed dyadic source surface.*
7. *H stores componentwise* hsame *transport for the dyadic source, constant window, regular readback, real seal, classifier row, conclusion row, replay, provenance, and local name.*
8. *K stores displayed* Cont *replay from the dyadic source through the constant window, regular readback, real seal, classifier boundary, and dyadic-source conclusion.*

9. *P records* Pkg *provenance over* $\mathsf{DyadicRealEmbeddingFaithful}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{RealClassifier}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{DyadicRealEmbeddingFaithful}^{\uparrow}}$ *row.*

The carrier has no coordinate for a host-level injection function, quotient stream equality, selected real representative, trichotomy, countable choice, or ambient completeness of $\mathsf{Real}^{\uparrow}$.

Theorem 8877.2 (Dyadic real embedding faithfulness NameCert obligations)**.** *For every accepted* $\mathsf{DyadicRealEmbeddingFaithful}^{\uparrow}$ *carrier* $F = (D, S, R, L, Q, C, H, K, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{DyadicRealEmbeddingFaithful}^{\uparrow}}$ *surface consists exactly of six rows:*

1. *carrier admission for the dyadic source, constant window, regular readback, Real seal, classifier row, conclusion row, transport, replay, provenance, and local name;*
2. *dyadic source exposure, requiring every consumer to read the displayed* $\mathsf{DyadicRatCore}^{\uparrow}$ *ledger D before it reaches the completion seal;*
3. *constant-window scheduling, requiring the* $\mathsf{StreamName}^{\uparrow}$ *row S to be the only window through which the dyadic source is presented;*
4. *regular readback handoff, requiring the* $\mathsf{RegSeqRat}^{\uparrow}$ *row R to mediate the route from D, S to the* $\mathsf{Real}^{\uparrow}$ *seal L;*
5. *classifier faithfulness, requiring the* $\mathsf{RealClassifier}^{\uparrow}$ *row Q and conclusion row C to preserve the displayed dyadic source equality surface under equality of accepted classifier reads;*
6. *non-escape, requiring H, K, P, N to transport, replay, source, and locally name only the displayed finite packet.*

No NameCert obligation is stored outside these rows.

Proof. Project the carrier of Definition 8877.1. Its analytic rows are exactly the dyadic source D, constant window S, regular readback R, Real seal L, classifier row Q, and conclusion row C.

The source, window, and readback obligations are forced by the ordered route. A completion-facing consumer first reads D, then opens only the constant $\mathsf{StreamName}^{\uparrow}$ window S, and then consumes the $\mathsf{RegSeqRat}^{\uparrow}$ readback R before reaching L.

The classifier obligation is local to Q and C. Equality at the accepted $\mathsf{RealClassifier}^{\uparrow}$ boundary is permitted to report only the dyadic source equality surface already displayed by D, S, R, L.

The structural rows H, K, P, N transport, replay, package, and name that same finite packet. Since the carrier omits host injection data, quotient stream equality, selected representatives, trichotomy, countable choice, and ambient completeness, no further obligation is available. □

Theorem 8877.3 (Dyadic real embedding faithfulness sibling anchors)**.** *Every accepted* $\mathsf{DyadicRealEmbeddingFaithf}$ *carrier is anchored in the ordered sibling chain*

$$\mathsf{DyadicRatCore}^{\uparrow} \longrightarrow \mathsf{StreamName}^{\uparrow} \longrightarrow \mathsf{RegSeqRat}^{\uparrow} \longrightarrow \mathsf{Real}^{\uparrow} \longrightarrow \mathsf{RealClassifier}^{\uparrow}.$$

The $\mathsf{DyadicRatCore}^{\uparrow}$ *row supplies the source ledger,* $\mathsf{StreamName}^{\uparrow}$ *supplies the constant finite window,* $\mathsf{RegSeqRat}^{\uparrow}$ *supplies the regular readback,* $\mathsf{Real}^{\uparrow}$ *supplies the terminal seal, and* $\mathsf{RealClassifier}^{\uparrow}$ *supplies the common classifier boundary. No accepted read may bypass one of these rows by appealing to host real equality or quotient stream equality.*

Proof. Start from an accepted carrier $F = (D, S, R, L, Q, C, H, K, P, N)$. The tuple names exactly one source row, one window row, one readback row, one seal row, and one classifier row.

The dyadic source is therefore read as D, not as an unstated rational representative. The constant-window route is S, and the regular rational readback is R.

The terminal completion boundary is the $\mathsf{Real}^{\uparrow}$ seal L. The only public equality-facing consumer after that seal is the $\mathsf{RealClassifier}^{\uparrow}$ row Q, whose conclusion row C reports the displayed dyadic source equality surface.

Because H, K, P, N only transport, replay, source, and name the same packet, the listed sibling chain exhausts the accepted route. □

Theorem 8877.4 (Dyadic real embedding faithfulness public certificate)**.** *Let*

$$F = (D, S, R, L, Q, C, H, K, P, N)$$

and

$$F' = (D', S', R', L', Q', C', H', K', P', N')$$

be accepted $\mathsf{DyadicRealEmbeddingFaithful}^{\uparrow}$ *carriers. Suppose Q and Q' are accepted* $\mathsf{RealClassifier}^{\uparrow}$ *boundary rows using the same common classifier window and the same dyadic tolerance ledger, and suppose equality at that boundary identifies the two public classifier decision surfaces. Then the public certificate may identify only the displayed dyadic source equality surface carried by D and D', transported through the constant windows S, S', the regular readbacks R, R', and the Real seals L, L'.*

Proof. Apply the sibling-anchor theorem Definition 8877.3 to both carriers. Both accepted routes must pass through the dyadic source, constant window, regular readback, Real seal, and RealClassifier boundary rows.

Use the common classifier window and dyadic tolerance ledger hypotheses. They ensure that the public classifier decision surfaces are read through the same finite inspection data rather than through separate representatives or host real values.

Now read the conclusion rows C and C'. Their only permitted content is preservation of the displayed dyadic source equality surface under equality of accepted classifier reads.

Finally inspect the structural rows. Since H, K, P, N and H', K', P', N' do not add quotient streams, selected representatives, trichotomy, countable choice, or ambient completeness, the public certificate cannot report anything beyond equality of the displayed dyadic source surfaces. □

Theorem 8877.5 (Dyadic real embedding faithfulness scope)**.** *The* $\mathsf{DyadicRealEmbeddingFaithful}^{\uparrow}$ *certificate closes only the finite NameCert surface that says: constant* $\mathsf{StreamName}^{\uparrow}$ *lifts of* $\mathsf{DyadicRatCore}^{\uparrow}$ *rows, read back through* $\mathsf{RegSeqRat}^{\uparrow}$ *and sealed as* $\mathsf{Real}^{\uparrow}$*, preserve the displayed dyadic source equality surface when compared through a common* $\mathsf{RealClassifier}^{\uparrow}$ *window and dyadic tolerance ledger. It does not close a global injection theorem for a host function into* $\mathsf{Real}^{\uparrow}$*, quotient stream equality, selected canonical representatives, trichotomy, countable choice, or ambient completeness.*

Proof. The positive scope is exactly the route of Definition 8877.1. The certificate displays $D, S, R, L, Q, C, H, K, P, N$ and no other analytic coordinate.

The NameCert obligations of Definition 8877.2 require source exposure, constant-window scheduling, regular readback handoff, classifier faithfulness, and structural non-escape.

The public certificate theorem Definition 8877.4 then identifies what equality at the common classifier boundary may preserve: only the displayed dyadic source equality surface.

The excluded principles are absent from the carrier and from every obligation row, so they remain outside the chapter scope. □

Closure status for $\mathsf{NameCert}_{\mathsf{DyadicRealEmbeddingFaithful}^{\uparrow}}$.

Constructive story: A $\mathsf{DyadicRealEmbeddingFaithful}^{\uparrow}$ packet is generated from a DyadicRatCore source ledger, a constant StreamName window, a RegSeqRat readback, a RealUp seal, a RealClassifier common-window boundary, a dyadic-source conclusion row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{DyadicRealEmbeddingFaithful}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8877.1, Definition 8877.2, Definition 8877.3, Definition 8877.4, and Definition 8877.5 seed the finite dyadic-to-real faithfulness surface through DyadicRatCore, StreamName, RegSeqRat, RealUp, and RealClassifier rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{DyadicRealEmbeddingFaithful}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close Lean verification, bridge checking, a host injection theorem, quotient stream equality, selected canonical representatives, trichotomy, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Upgrade path: Obligation closure requires checked carrier admission, constant-window scheduling, RegSeqRat readback, Real seal handoff, and RealClassifier dyadic-source faithfulness for BEDC.Derived.DyadicRealEmbeddingFaithfulUp.

Chapter 8878

A Concrete Naming Certificate for $\mathsf{BishopMeanValueInequality}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{BishopMeanValueInequality}^{\uparrow}$ packet records the constructive finite-window route by which derivative rows and a displayed norm bound produce an endpoint displacement bound. It sits beside the $\mathsf{FrechetDerivative}^{\uparrow}$ certificate of chapter 3634, the directional derivative surfaces of chapter 6344 and chapter 7621, the linear action row of chapter 48, the norm row of chapter 89, the regular rational readback of chapter 301, and the terminal real seal of chapter 38. The packet is a finite BEDC proof surface for a mean-value inequality; it is not a host mean-value theorem, a selected derivative point, an extremum principle, compactness, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 8878.1 (Bishop mean-value inequality carrier)**.** *A* $\mathsf{BishopMeanValueInequality}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M = (I, D, B, \Delta, Q, R, H, C, P, N)$$

with the following displayed rows:

1. *I is the finite segment-window row, listing the two endpoint rows, the inspected partition windows, and the segment domain on which the comparison is read.*
2. *D is the derivative-row ledger, exposing only the* $\mathsf{FrechetDerivative}^{\uparrow}$*,* $\mathsf{GateauxDerivative}^{\uparrow}$*, and* $\mathsf{HadamardDirectionalDerivative}^{\uparrow}$ *reads used inside the displayed windows.*
3. *B is the norm-bound row, pairing each derivative read with a* $\mathsf{LinMap}^{\uparrow}$ *action row and a* $\mathsf{Norm}^{\uparrow}$ *bound row.*
4. *Δ is the endpoint-displacement row, naming the source endpoint difference and the target displacement to be bounded.*
5. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the finite slope budgets, partition lengths, and endpoint-distance observations.*
6. *R is the terminal* $\mathsf{Real}^{\uparrow}$ *seal for the displayed inequality after I, D, B, Δ, Q have been read.*
7. *H records componentwise* hsame *transport for segment windows, derivative rows, norm bounds, endpoint displacement, readback, seal, replay, provenance, and local naming.*
8. *C records displayed* Cont *replay from each finite-window derivative read through the norm-bound row to the endpoint displacement comparison.*

9. *P is the* Pkg *provenance over* $\mathsf{BishopMeanValueInequality}^{\uparrow}$, $\mathsf{FrechetDerivative}^{\uparrow}$, $\mathsf{GateauxDerivative}^{\uparrow}$, $\mathsf{HadamardDirectionalDerivative}^{\uparrow}$, $\mathsf{LinMap}^{\uparrow}$, $\mathsf{Norm}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

10. *N is the local* $\mathsf{NameCert}_{\mathsf{BishopMeanValueInequality}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $I, D, B, \Delta, Q, R, H, C, P, N$. It has no coordinate for a host mean-value theorem, a selected derivative point, an extremum argument, compactness of a segment, countable choice, quotient real equality, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 8878.2 (Bishop mean-value inequality NameCert obligations)**.** *For every accepted* $\mathsf{BishopMeanValueInequality}^{\uparrow}$ *carrier $M = (I, D, B, \Delta, Q, R, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{BishopMeanValueInequality}^{\uparrow}}$ *surface consists exactly of carrier admission for finite segment windows, derivative-row exposure through D, norm-bound accountability through B, endpoint-displacement exposure through Δ, regular rational readback through Q, Real sealing through R, componentwise* hsame *transport through H, displayed* Cont *replay through C, provenance through P, local naming through N, and nonescape excluding host mean-value selection, compactness, countable choice, quotient equality, and ambient completeness.*

Proof. Carrier admission is projection from Definition 8878.1. The rows I, D, B, Δ, Q, R expose the finite segment windows, derivative reads, norm bounds, endpoint displacement, regular rational readback, and terminal Real seal.

The derivative rows are read only as displayed data. The $\mathsf{FrechetDerivative}^{\uparrow}$, $\mathsf{GateauxDerivative}^{\uparrow}$, and $\mathsf{HadamardDirectionalDerivative}^{\uparrow}$ entries in D are paired with the $\mathsf{LinMap}^{\uparrow}$ and $\mathsf{Norm}^{\uparrow}$ rows in B, so the packet records bounded local linear behavior without selecting a host derivative point.

The structural rows then preserve the same finite route. Componentwise transport is supplied by H, replay by C, provenance by P, and local naming by N. Since the carrier lists no selected point, extremum principle, compact segment theorem, countable-choice schedule, quotient equality, or ambient completeness row, those objects are not NameCert obligations for $\mathsf{BishopMeanValueInequality}^{\uparrow}$. □

Theorem 8878.3 (Bishop mean-value inequality finite slope bound)**.** *Every accepted* $\mathsf{BishopMeanValueInequality}^{\uparrow}$ *carrier routes the endpoint displacement comparison through the displayed finite-window inequality*

$$I, D, B, \Delta, Q \longmapsto R, H, C, P, N.$$

A consumer may read the resulting bound only after the segment-window row, derivative-row ledger, norm-bound row, endpoint-displacement row, and $\mathsf{RegSeqRat}^{\uparrow}$ *readback row have all been displayed. The route is a BEDC finite slope-bound surface, not a host mean-value theorem, selected derivative witness, compactness argument, countable-choice construction, quotient real equality, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness principle.*

Proof. Start with the carrier inventory of Definition 8878.1. The only endpoint comparison coordinate is Δ, and it is downstream of the segment-window row I and the derivative ledger D.

Use the NameCert obligations of Definition 8878.2. They force every slope-bound read to expose the derivative rows and the norm-bound row B before the regular rational readback Q and Real seal R are available.

The displayed inequality route is therefore finite. The packet accumulates the inspected slope budgets through Q, seals the comparison through R, and transports, replays, sources, and names the same route through H, C, P, N. Because no carrier row names a selected derivative point or compactness principle, the endpoint displacement bound remains a finite-window BEDC proof surface. □

Falsifiable prediction: Every accepted $\mathsf{BishopMeanValueInequality}^{\uparrow}$ consumer that reaches an endpoint displacement bound without displaying the rows $I, D, B, \Delta, Q, R, H, C, P, N$ refutes the carrier surface.

Independence witness: frechetderivative, gateauxderivative, hadamarddirectionalderivative, linearmap, norm, regseqrat, real: none is bijective to $\mathsf{BishopMeanValueInequality}^{\uparrow}$ because this packet jointly carries finite segment windows, derivative rows, norm-bound rows, endpoint displacement, readback, sealing, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{BishopMeanValueInequality}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BishopMeanValueInequality}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8878.1, Definition 8878.2, and Definition 8878.3 seed the finite slope-bound certificate over segment windows, derivative rows, norm bounds, endpoint displacement, RegSeqRat readback, Real sealing, transport, replay, provenance, and local naming.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BishopMeanValueInequality}^{\uparrow}}, \mathsf{formalTarget})$

Bridge status: none

Not claimed: This chapter does not close a host mean-value theorem, selected derivative point, extremum principle, compactness, countable choice, quotient real equality, ambient Real completeness, theorem-level Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, derivative-row exposure, norm-bound accountability, endpoint-displacement exposure, readback, sealing, transport, replay, provenance, and local naming for BEDC.Derived.BishopMeanValueInequalityUp.

Constructive story: A $\mathsf{BishopMeanValueInequality}^{\uparrow}$ packet is generated from finite segment windows, derivative rows, norm-bound rows, endpoint displacement, RegSeqRat readback, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 8879

A Concrete Naming Certificate for $\mathsf{LocatedUniformQuotient}^{\uparrow}$

Following Bourbaki and Kelley-style uniform-space quotient constructions, the $\mathsf{LocatedUniformQuotient}^{\uparrow}$ packet records the finite BEDC surface where a displayed equivalence relation on a located uniform source descends the uniformity only through saturated entourage evidence. It sits after the uniform-space carrier of chapter 339, the Real-uniform source of chapter 1624, and the metric witness discipline of chapter 57. The packet is a constructive quotient-uniformity object: it names source rows, relation rows, saturation rows, representative-change transport, replay, provenance, and local naming without forming host quotient types, selecting representatives, or importing ambient completeness.

Definition 8879.1 (Located uniform quotient carrier)**.** *A* $\mathsf{LocatedUniformQuotient}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Q = (X, R, S, W, T, H, C, P, N)$$

with the following displayed rows:

1. *X is the source uniform carrier, read through* $\mathsf{UniformSpace}^{\uparrow}$ *and, when the source is metric or Real-facing, through the sibling rows of* $\mathsf{Met}^{\uparrow}$ *and* $\mathsf{RealUniformStructure}^{\uparrow}$*.*
2. *R is the displayed equivalence relation on the source carrier; it is stored as finite relation data and not as a host quotient type.*
3. *S is the saturated entourage row: each quotient-facing entourage request is accepted only after a source entourage of X has been shown stable under R on both coordinates.*
4. *W is the representative-change witness, recording that changing either displayed representative along R preserves the accepted saturated entourage request.*
5. *T is the transport row that carries accepted saturated-entourage reads through componentwise source-uniform, relation, and representative-change data.*
6. *H records componentwise* hsame *transport for X, R, S, W, T, C, P, N.*
7. *C records displayed* Cont *replay of the same quotient-uniformity route.*
8. *P is the* Pkg *provenance over* $\mathsf{LocatedUniformQuotient}^{\uparrow}$*,* $\mathsf{UniformSpace}^{\uparrow}$*,* $\mathsf{RealUniformStructure}^{\uparrow}$*,* $\mathsf{Met}^{\uparrow}$*,* BHist*,* hsame*,* Cont*, and* $\mathsf{NameCert}$*.*
9. *N is the local* $\mathsf{NameCert}_{\mathsf{LocatedUniformQuotient}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through $X, R, S, W, T, H, C, P, N$. It has no coordinate for host quotient types, selected representatives, quotient-set equality, hidden choice of section, ambient completeness, Lean verification, or bridge checking.

Theorem 8879.2 (Located uniform quotient NameCert obligations)**.** *For every accepted* $\mathsf{LocatedUniformQuotient}^{\uparrow}$ *carrier $Q = (X, R, S, W, T, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{LocatedUniformQuotient}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *source-uniform admission through X;*
2. *displayed equivalence-relation admission through R;*
3. *saturated-entourage admission through S, requiring every quotient-facing entourage request to come from a source entourage stable under R on both coordinates;*
4. *representative-change exactness through W, requiring each permitted representative change to preserve the same saturated-entourage read;*
5. *transport, replay, provenance, and local naming through T, H, C, P, N.*

No NameCert obligation is stored in a host quotient type, a selected representative, a quotient equality principle, a hidden section, ambient completeness, Lean verification, or bridge checking.

Proof. Project the carrier of Definition 8879.1. The accepted packet exposes exactly the source uniform row, the displayed relation row, the saturated entourage row, the representative-change witness, and the structural rows.

The source and relation obligations are immediate projections. A quotient-facing request has no data except the source uniform carrier X and the displayed equivalence relation R.

The saturated-entourage obligation is the only route from source uniformity to quotient uniformity. The row S records that the source entourage is stable under R in both coordinates before any quotient-facing consumer can read it.

Representative change is then local to W. It preserves the same saturated-entourage read and does not choose a canonical representative.

Finally T, H, C, P, N transport, replay, source, and name the displayed route. Since none of the excluded objects is a row of the carrier, the listed obligations exhaust the local NameCert surface. □

Theorem 8879.3 (Saturated-entourage descent)**.** *Let $Q = (X, R, S, W, T, H, C, P, N)$ be an accepted* $\mathsf{LocatedUniformQuotient}^{\uparrow}$ *carrier. Every quotient-facing entourage read exported by Q descends from a displayed source-uniform entourage of X whose saturation is witnessed by S and whose representative changes are witnessed by W. The descent exports no host quotient type, selected representative, quotient-set equality, hidden section, ambient completeness, Lean verification, or bridge checking.*

Proof. Start with an accepted quotient-facing entourage read. Carrier admission gives access only to $X, R, S, W, T, H, C, P, N$.

The source of the read is therefore the source uniform row X. The relation row R supplies the only comparison data between representatives.

The row S supplies descent: it states that the source entourage is saturated with respect to R on both coordinates. Hence the quotient-facing read is not a new entourage generated by a host quotient object; it is the displayed saturated source entourage.

The row W verifies that changing representatives along R leaves the same saturated read available. The remaining structural rows preserve and name that route, so none of the excluded quotient or completeness data can be exported. □

Theorem 8879.4 (Representative-change transport)**.** *For every accepted* $\mathsf{LocatedUniformQuotient}^{\uparrow}$ *carrier* $Q = (X, R, S, W, T, H, C, P, N)$*, any two accepted reads that differ only by displayed* R*-equivalent representatives are transported by the same rows* W, T, H, C, P, N*. The transported read remains attached to the original source uniform carrier* X*, the relation row* R*, and the saturated-entourage row* S*, and it does not create a selected representative, a quotient type, an equality service on quotient classes, ambient completeness, Lean verification, or bridge checking.*

Proof. Take two accepted reads differing only by displayed R-equivalent representatives. Projection of the carrier shows that both reads share the same source uniform row X, relation row R, and saturated-entourage row S.

Representative change is handled by W. This row witnesses that the same saturated-entourage request remains accepted after changing either representative along R.

The transport row T and the structural rows H, C, P, N then carry the accepted read through componentwise transport, displayed replay, provenance, and local naming. These rows preserve the displayed source and saturation data; they do not add a representative selector or quotient-class equality coordinate.

Thus representative-change transport stays inside the finite carrier surface and cannot export any of the excluded host quotient, selection, completeness, Lean, or bridge data. □

Falsifiable prediction: Every accepted $\mathsf{LocatedUniformQuotient}^{\uparrow}$ consumer read that claims quotient-uniformity data must expose one source uniform carrier row, one displayed equivalence-relation row, one saturated-entourage row, one representative-change witness row, transport, componentwise hsame, displayed Cont replay, Pkg provenance, and local naming.

Independence witness: uniformspace, real-uniform-structure, metric: $\mathsf{LocatedUniformQuotient}^{\uparrow}$ is not bijective to any listed sibling because it binds a displayed equivalence relation and saturated-entourage descent surface over a source uniform carrier, while those siblings name the source uniform, Real-uniform, or metric rows alone.

Closure status for $\mathsf{NameCert}_{\mathsf{LocatedUniformQuotient}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{LocatedUniformQuotient}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8879.1, Definition 8879.2, Definition 8879.3, and Definition 8879.4 seed the finite quotient-uniformity route through a source uniform carrier, displayed equivalence relation, saturated entourage row, representative-change witness, transport, replay, provenance, and local naming.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{LocatedUniformQuotient}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host quotient types, selected representatives, quotient-set equality, hidden sections, ambient completeness, Lean verification, or bridge checking.

Upgrade path: Scoped closure requires checked carrier admission, saturated-entourage descent, representative-change transport, nonescape, replay, provenance, and local naming for BEDC.Derived.LocatedUniformQuotientUp.

Constructive story: A $\mathsf{LocatedUniformQuotient}^{\uparrow}$ packet is generated from a source UniformSpace row, a displayed equivalence-relation row, a saturated-entourage row, a representative-change witness, transport, componentwise hsame, Cont replay, Pkg provenance, and a local NameCert row.

Chapter 8880

A Concrete Naming Certificate for QuarticSpectralCommonCarrier$^{\uparrow}$

Following standard recurrence theory, companion matrices, and affine spectral curves, the QuarticSpectralCommonC packet records the fixed quartic spectral object of section 9413.9 as finite NameCert data. It sits beside the polynomial carrier of chapter 50, the matrix carrier of chapter 49, the elliptic curve carrier of chapter 175, the real-polynomial carrier of chapter 1728, and the complex-number carrier of chapter 39. The certificate binds the recurrence source, companion matrix, spectral polynomial, affine curve, elliptic normalization, and projection ledger as one finite carrier surface; it is not an ambient algebraic-geometry theorem, a host spectral theorem, or an analytic continuation principle.

Definition 8880.1 (Quartic spectral common carrier)**.** *A* QuarticSpectralCommonCarrier$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Q = (R, M, P, A, E, L, H, C, G, N)$$

with the following displayed rows:

1. *R is the recurrence-source row, storing the numerator $N(t, y)$, denominator $D(t, y)$, coefficient readback, and order-four recurrence schedule of Definition 9413.86.*
2. *M is the companion-matrix row, storing the displayed 4×4 transfer matrix and its characteristic-polynomial readout.*
3. *P is the spectral-polynomial row, storing the quartic $\Pi(\lambda, y)$ as both the reciprocal denominator face and the matrix characteristic face.*
4. *A is the affine spectral-curve row, storing the finite equation $\Pi(\lambda, y) = 0$ and the projection coordinates (λ, y).*
5. *E is the elliptic-normalization row, storing the balanced-quartic normalization route to the displayed Weierstrass model.*
6. *L is the projection ledger, storing the generating-function, recurrence, companion-matrix, spectral-polynomial, affine-curve, elliptic-normalization, real-projection, and complex-coordinate reads.*
7. *H stores componentwise* hsame *transport for the recurrence, matrix, polynomial, curve, normalization, ledger, replay, provenance, and local naming rows.*
8. *C stores displayed* Cont *replay for each projection in L.*

9. *G stores* Pkg *provenance over* $\mathsf{QuarticSpectralCommonCarrier}^{\uparrow}$, $\mathsf{Poly}^{\uparrow}$, $\mathsf{Mat}^{\uparrow}$, $\mathsf{EllipticCurve}^{\uparrow}$, $\mathsf{RealPolynomial}^{\uparrow}$, $\mathsf{Complex}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{QuarticSpectralCommonCarrier}^{\uparrow}}$ *row.*

The carrier has no coordinate for an arbitrary quartic family, external eigenvalue selection, analytic continuation, global branch choice, or a proof of the Riemann hypothesis.

Definition 8880.2 (Quartic spectral carrier NameCert obligations)**.** *For an accepted* QuarticSpectralCommonCarrie *carrier $Q = (R, M, P, A, E, L, H, C, G, N)$, the local* $\mathsf{NameCert}_{\mathsf{QuarticSpectralCommonCarrier}^{\uparrow}}$ *surface consists exactly of six finite obligation rows:*

1. *carrier admission for the recurrence source, companion matrix, spectral polynomial, affine curve, elliptic normalization, projection ledger, transport, replay, provenance, and local naming data;*
2. *recurrence-matrix compatibility, requiring the recurrence row R and matrix row M to expose the same order-four transfer law;*
3. *matrix-polynomial compatibility, requiring M and P to expose the same characteristic face $\Pi(\lambda, y)$;*
4. *polynomial-curve compatibility, requiring P and A to expose the same affine equation;*
5. *normalization compatibility, requiring E to be read only as the finite elliptic-normalization route of the displayed quartic curve;*
6. *projection non-escape, requiring L, H, C, G, N to transport, replay, source, and name only the displayed finite packet.*

No obligation row stores a host spectral theorem, arbitrary branch selection, analytic continuation, or global zeta-zero claim.

Theorem 8880.3 (Quartic spectral projection ledger)**.** *Every accepted* $\mathsf{QuarticSpectralCommonCarrier}^{\uparrow}$ *packet exports a projection ledger whose public reads are exactly the recurrence source, the companion matrix, the spectral polynomial, the affine spectral curve, the elliptic-normalization route, the real-polynomial face, and the complex coordinate face displayed in R, M, P, A, E, L. The export cannot replace those rows by an external polynomial family, a free matrix spectrum, an unbounded branch selector, analytic continuation, or a global zeta-zero statement.*

Proof. Project the accepted carrier of Definition 8880.1. The recurrence row R, companion row M, spectral-polynomial row P, affine-curve row A, elliptic-normalization row E, and ledger row L are the only mathematical rows exposed before the structural data are read.

Use the NameCert obligations of Definition 8880.2. They bind R to M through the order-four transfer law, M to P through the characteristic face, P to A through the affine equation, and A to E through the displayed normalization route.

Finally read the structural rows H, C, G, N. Componentwise transport, displayed replay, provenance, and local naming preserve the same finite carrier. Since the carrier omits arbitrary polynomial families, free spectra, branch selectors, analytic continuation, and global zeta-zero data, the public projection ledger is exactly the displayed quartic spectral surface. □

Closure status for $\mathsf{NameCert}_{\mathsf{QuarticSpectralCommonCarrier}^{\uparrow}}$.

Constructive story: A $\mathsf{QuarticSpectralCommonCarrier}^{\uparrow}$ packet is generated from a recurrence-source row, companion-matrix row, spectral-polynomial row, affine-curve row, elliptic-normalization row, projection ledger, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{QuarticSpectralCommonCarrier}^{\uparrow}}$, seed)

Scope closed: Definition 8880.1, Definition 8880.2, and Definition 8880.3 seed the finite quartic spectral common-carrier surface over recurrence, matrix, polynomial, affine-curve, elliptic-normalization, real-polynomial, and complex-coordinate rows.

Formal verification: FormalStatus(NameCert$_{\mathsf{QuarticSpectralCommonCarrier}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close Lean verification, bridge checking, an arbitrary quartic-family theorem, analytic continuation, global branch selection, external spectral theory, or a global zeta-zero statement.

Upgrade path: Obligation closure requires checked carrier admission, recurrence-matrix compatibility, matrix-polynomial compatibility, polynomial-curve compatibility, normalization routing, and projection non-escape for BEDC.Derived.QuarticSpectralCommonCar

Chapter 8881

A Concrete Naming Certificate for LocalHalfSplitCertificate$^{\uparrow}$

The LocalHalfSplitCertificate$^{\uparrow}$ packet realizes the local two-branch half-split certificate of section 9413.60 as finite NameCert data. It sits beside the complex carrier of chapter 39, the zeta zero type-factorization carrier of chapter 8772, the zeta-zero carrier of chapter 73, the zeta-basic carrier of chapter 71, and the quartic spectral common-carrier packet of chapter 8880. The certificate stores a local zero island, half-split coordinate, real-defect ledger, phase-residual row, and refusal boundary; it is not a global zeta theorem, a Lee–Yang theorem, an analytic continuation proof, or a proof of the Riemann hypothesis.

Definition 8881.1 (Local half-split certificate carrier)**.** *A* LocalHalfSplitCertificate$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (Z, D, A, B, R, S, F, P, H, C, G, N)$$

with the following displayed rows:

1. *Z is the local zero-island row, storing the critical-strip point, local disk, dominant two-branch window, and zero-relevant boundary.*
2. *D is the dominance row for the two visible branches.*
3. *A and B are the two complex branch rows read through* Complex$^{\uparrow}$*.*
4. *R is the Rouché tail-control row for the remainder term.*
5. *S is the half-split row, storing the equal-length coordinate and the real-defect split formula.*
6. *F is the phase-residual row, storing the opposite-phase congruence and height-facing residual data after the equal-length row has been read.*
7. *P is the no-hidden-real-correction row, refusing a cofinal correction that cancels a nonzero real defect outside the displayed local island.*
8. *H stores componentwise* hsame *transport for the zero island, dominance, branch, tail, split, phase, refusal, replay, provenance, and local naming rows.*
9. *C stores displayed* Cont *replay for the local certificate route.*
10. *G stores* Pkg *provenance over* LocalHalfSplitCertificate$^{\uparrow}$*,* Complex$^{\uparrow}$*,* ZetaZeroTypeFactorization$^{\uparrow}$*,* ZetaZeros$^{\uparrow}$*,* ZetaBasic$^{\uparrow}$*,* QuarticSpectralCommonCarrier$^{\uparrow}$*,* BHist*,* hsame*,* Cont*, and* NameCert*.*

11. *N is the local* $\mathsf{NameCert}_{\mathsf{LocalHalfSplitCertificate}^{\uparrow}}$ *row.*

The carrier has no coordinate for a global zero enumeration, analytic continuation, functional equation proof, Lee–Yang stability theorem, or RH conclusion.

Theorem 8881.2 (Local half-split certificate NameCert obligations)**.** *For every accepted* $\mathsf{LocalHalfSplitCertificate}^{\uparrow}$ *carrier $L = (Z, D, A, B, R, S, F, P, H, C, G, N)$, the local* $\mathsf{NameCert}_{\mathsf{LocalHalfSplitCertificate}^{\uparrow}}$ *surface consists exactly of seven finite obligation rows:*

1. *carrier admission for the local zero island, dominance, branch, tail, half-split, phase-residual, refusal, transport, replay, provenance, and local naming rows;*
2. *branch dominance, requiring D to expose the two active local branches before any zero certificate is exported;*
3. *complex branch readback, requiring A and B to be read through the displayed* $\mathsf{Complex}^{\uparrow}$ *branch rows;*
4. *tail control, requiring R to keep the local zero count inside the same island;*
5. *half-split exactness, requiring S to expose the equal-length coordinate and real-defect split formula;*
6. *phase-residual exposure, requiring F to remain present whenever the packet exports a half-split zero certificate;*
7. *non-escape, requiring P, H, C, G, N to refuse hidden real corrections and to transport, replay, source, and name only the displayed finite packet.*

Proof. Project the accepted carrier of Definition 8881.1. Its zero-facing rows are exactly Z, D, A, B, R, S, F, P, and its structural rows are exactly H, C, G, N.

The branch obligations force a consumer to read dominance and the two complex branches before the half-split row is available. The tail-control row then keeps the read inside the same local island.

The half-split row supplies equal length and the real-defect split formula. The phase-residual row remains a separate displayed row, so the certificate records the remaining zero-location data rather than hiding it in the real coordinate.

Finally the refusal and structural rows prevent a hidden real correction, unrelated zeta-zero carrier, global analytic principle, or RH conclusion from entering the packet. □

Theorem 8881.3 (Local half-split public certificate)**.** *Every accepted* $\mathsf{LocalHalfSplitCertificate}^{\uparrow}$ *packet exports a half-split zero certificate only through the displayed route*

$$Z \longmapsto D \longmapsto A, B \longmapsto R \longmapsto S \longmapsto F \longmapsto P \longmapsto H, C, G, N.$$

If the phase-residual row F is absent, the packet cannot export a half-split zero certificate.

Proof. Start with carrier admission. The local zero-island row Z, dominance row D, branch rows A, B, tail-control row R, half-split row S, phase-residual row F, and refusal row P are all explicit coordinates of the accepted packet.

Apply the NameCert obligations of Definition 8881.2. They require dominance before branch readback, branch readback before tail control, tail control before half-split exactness, and phase-residual exposure before export.

Thus removing F removes one of the required rows in the certificate route. The structural rows H, C, G, N can transport and replay only rows that are present, so the packet cannot export the half-split zero certificate without the phase-residual row. □

Falsifiable prediction: If the phase-residual row is absent, the packet cannot export a half-split zero certificate.

Independence witness: complex, zeta-zero-type-factorization, zeta-zeros, zeta-basic, quartic-spectral-common-carrier: each sibling supplies a source row or finite template, but none carries the combined local zero-island, two-branch dominance, Rouché tail-control, half-split exactness, phase-residual, and no-hidden-real-correction surface in one NameCert packet.

The Lean follow-up for BEDC.Derived.LocalHalfSplitCertificateUp.TasteGate must provide Nontrivial LocalHalfSpli and FieldFaithful LocalHalfSplitCertificate$^{\uparrow}$ instances with displayed projections for the zero-island, dominance, branch, tail-control, half-split, phase-residual, and refusal rows.

Closure status for $\mathsf{NameCert}_{\mathsf{LocalHalfSplitCertificate}\uparrow}$.

Constructive story: A LocalHalfSplitCertificate$^{\uparrow}$ packet is generated from a local zero-island row, dominance row, two Complex branch rows, Rouche tail-control row, half-split row, phase-residual row, no-hidden-real-correction row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{LocalHalfSplitCertificate}\uparrow}, \mathsf{seed})$

Scope closed: Definition 8881.1, Definition 8881.2, and Definition 8881.3 seed the finite local half-split certificate surface over two-branch dominance, complex branch readback, tail control, real-defect splitting, phase residuals, and no-hidden-real-correction refusal.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{LocalHalfSplitCertificate}\uparrow}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close Lean verification, bridge checking, analytic continuation, Lee–Yang stability, global zero enumeration, a zeta functional-equation proof, or RH.

Upgrade path: Obligation closure requires checked carrier admission, branch dominance, complex branch readback, tail control, half-split exactness, phase-residual exposure, and refusal non-escape for BEDC.Derived.LocalHalfSplitCertificateUp.

Chapter 8882

A Concrete Naming Certificate for $\mathsf{CantorFan}^{\uparrow}$

Following classical continuum theory, the $\mathsf{CantorFan}^{\uparrow}$ packet names the finite-prefix compact metric fan obtained by joining Cantor-space branch data to a single apex through dyadic height rows. It consumes the Cantor-space source of chapter 1475, the compact-metric and metric-space surfaces of chapter 129 and chapter 4230, the continuous-map interface of chapter 130, the dyadic tolerance ledger of chapter 291, the finite stream windows of chapter 126, and the regular rational readback of chapter 301. The chapter reconstructs the traditional fan as NameCert data over finite branch prefixes and dyadic heights; it does not use quotient equality of branches, host compactness, selected paths, or ambient real completeness.

Definition 8882.1 (Cantor fan carrier)**.** *A* $\mathsf{CantorFan}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$F = (K, M, C, \Delta, W, R, D, A, E, H, Q, P, N)$$

with the following displayed rows:

1. *K is the* $\mathsf{CantorSpace}^{\uparrow}$ *row naming the binary branch-prefix source.*
2. *M is the* $\mathsf{CompactMetric}^{\uparrow}$ *row naming the compact metric presentation visible to finite-net consumers.*
3. *C is the* $\mathsf{Met}^{\uparrow}$ *row whose distance observations are read only through displayed dyadic bounds.*
4. *Δ is the* $\mathsf{ContinuousMap}^{\uparrow}$ *row carrying the apex-to-branch and branch-height continuity witnesses.*
5. *W is the* $\mathsf{StreamName}^{\uparrow}$ *window family opened on branch prefixes and height prefixes.*
6. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the displayed branch-height regular Cauchy data.*
7. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger for prefix agreement, height comparison, and apex collapse.*
8. *A is the finite apex row identifying the zero-height endpoint shared by all displayed branches.*
9. *E is the edge classifier row distinguishing an apex read from a positive-height branch read.*
10. *H stores componentwise* hsame *transport for all displayed rows.*
11. *Q stores displayed* Cont *replay from Cantor prefixes and dyadic heights through the metric and compact rows.*

12. *P is the* Pkg *provenance over* $\mathsf{CantorFan}^{\uparrow}$, $\mathsf{CantorSpace}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

13. *N is the local* $\mathsf{NameCert}_{\mathsf{CantorFan}^{\uparrow}}$ *row.*

The carrier exports no quotient class of branches, selected infinite path, host continuum theorem, open-cover compactness proof, or ambient complete real line.

Theorem 8882.2 (Cantor fan NameCert)**.** *For every accepted* $\mathsf{CantorFan}^{\uparrow}$ *carrier*

$$F = (K, M, C, \Delta, W, R, D, A, E, H, Q, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{CantorFan}^{\uparrow}}$ *surface consists exactly of Cantor-space prefix admission, compact-metric finite-net exposure, metric distance exposure, continuous apex-and-height transport, StreamName finite-window exposure, RegSeqRat readback, DyadicRatCore tolerance control, apex classification, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming.*

The classifier is stable under any componentwise transport that preserves the displayed Cantor prefixes, dyadic height ledger, stream windows, regular readback, metric row, compact row, continuous-map row, and apex classifier. A consumer therefore receives the fan only as the finite ledger $K, M, C, \Delta, W, R, D, A, E, H, Q, P, N$.

Proof. Carrier exposure is projection from Definition 8882.1. The row K supplies the finite Cantor-prefix source, while D, W, R supply the dyadic height and prefix windows through which a consumer can inspect a branch-height point.

The classifier separates two displayed cases. In the apex case, A is read with the zero-height dyadic row and all branch prefixes collapse only through the same displayed tolerance ledger. In the positive-height case, E keeps the branch-prefix row visible together with the metric and compact rows C, M.

Continuity and compactness are consumed as finite NameCert rows, not as host principles. The row Δ records the apex and branch-height continuity handoff, and M records the compact-metric finite-net surface exposed to downstream consumers.

Finally H, Q, P, N transport, replay, source, and name that same finite packet. Since the carrier has no coordinate for quotient branch equality, selected paths, open-cover compactness, or ambient completeness, the listed rows exhaust the $\mathsf{CantorFan}^{\uparrow}$ NameCert surface. □

Closure status for $\mathsf{NameCert}_{\mathsf{CantorFan}^{\uparrow}}$**.**

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{CantorFan}^{\uparrow}}$, seed)

Scope closed: Definition 8882.1 and Definition 8882.2 seed the finite Cantor-prefix, compact-metric, metric, continuous-map, dyadic-height, StreamName, RegSeqRat, apex-classifier, transport, replay, provenance, and local naming surface.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{CantorFan}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim quotient equality of Cantor branches, selected infinite paths, host continuum compactness, open-cover compactness, ambient completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, classifier stability, compact-metric finite-net exposure, continuous apex transport, dyadic height control, stream-window readback, and local naming for BEDC.Derived.CantorFanUp.

Constructive story: A $\mathsf{CantorFan}^{\uparrow}$ packet is generated from CantorSpace prefixes, CompactMetric and MetricSpace rows, a ContinuousMap apex-height route, DyadicRatCore tolerances, StreamName windows, RegSeqRat readback, apex classification, componentwise transport, displayed replay, provenance, and a local NameCert row.

Chapter 8883

A Concrete Naming Certificate for $\mathsf{UniformTailAscoli}^{\uparrow}$

Following Arzela–Ascoli in its compact-metric constructive form, the $\mathsf{UniformTailAscoli}^{\uparrow}$ packet records finite uniform-tail data for an equicontinuous family on compact finite nets. It consumes the compact-uniform-continuity route of chapter 9237, the compact-metric source of chapter 129, the metric-space and continuous-map surfaces of chapter 4230 and chapter 130, the finite-net equicontinuity certificate of chapter 2362, and the L10 readback rows $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ from chapter 291, chapter 126, chapter 301, and chapter 38. The packet is a finite NameCert surface for uniform tails and diagonal subfamilies, not a choice-selected subsequence theorem or a host compact-open theorem.

Definition 8883.1 (Uniform-tail Ascoli carrier)**.** *A* $\mathsf{UniformTailAscoli}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$A = (K, M, C, F, E, U, T, W, R, D, S, L, H, Q, P, N)$$

with the following displayed rows:

1. *K is the compact finite-net source row.*
2. *M is the* $\mathsf{Met}^{\uparrow}$ *row for the source and target distance observations.*
3. *C is the* $\mathsf{CompactMetric}^{\uparrow}$ *row that makes the finite-net read available.*
4. *F is the* $\mathsf{ContinuousMap}^{\uparrow}$ *family row.*
5. *E is the finite-net equicontinuity row.*
6. *U is the shared uniform-modulus row read from K, M, C, F, E.*
7. *T is the uniform-tail row recording the finite stage after which the family is uniformly Cauchy on the displayed net.*
8. *W is the* $\mathsf{StreamName}^{\uparrow}$ *window schedule used for the diagonal read.*
9. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row assembled from the displayed tails.*
10. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger controlling all tail and net comparisons.*
11. *S is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached by the readback.*
12. *L is the diagonal-subfamily ledger, finite at every displayed window.*

13. *H stores componentwise* hsame *transport for the listed rows.*
14. *Q stores displayed* Cont *replay from compact finite nets and equicontinuity rows to uniform tails and Real seals.*
15. *P is the* Pkg *provenance over* $\mathsf{UniformTailAscoli}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, FiniteNetEquicontinuit DyadicRatCore$^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
16. *N is the local* $\mathsf{NameCert}_{\mathsf{UniformTailAscoli}^{\uparrow}}$ *row.*

The carrier exports no choice-selected infinite subsequence, host compact-open topology, quotient equality of functions, or ambient completeness theorem.

Theorem 8883.2 (Uniform-tail Ascoli NameCert)**.** *For every accepted* $\mathsf{UniformTailAscoli}^{\uparrow}$ *carrier*

$$A = (K, M, C, F, E, U, T, W, R, D, S, L, H, Q, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{UniformTailAscoli}^{\uparrow}}$ *surface consists exactly of compact finite-net admission, metric and compact-metric exposure, continuous-map family exposure, finite-net equicontinuity, shared uniform-modulus extraction, uniform-tail control, StreamName diagonal windows, RegSeqRat readback, DyadicRatCore tolerance control, RealUp seal boundary, diagonal-subfamily ledger rows, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming.*

The uniform-tail classifier is stable under any transport that preserves the compact net, equicontinuity row, shared modulus, tail stage, diagonal windows, regular readback, dyadic ledger, Real seal, and diagonal-subfamily ledger. Thus every consumer receives a finite Ascoli packet rather than a selected infinite subsequence.

Proof. Project the carrier of Definition 8883.1. The source rows K, M, C, F, E expose the compact finite net, metric observations, continuous family, and equicontinuity surface before any tail row is read.

Read the modulus and tail rows next. The shared modulus U is computed from the displayed compact-net and equicontinuity data, and the uniform-tail row T records a finite stage for the dyadic tolerance ledger D.

The diagonal part is windowed. The row L records only finite diagonal-subfamily data at each displayed $\mathsf{StreamName}^{\uparrow}$ window W, and R reads those windows as regular rational data before the terminal $\mathsf{Real}^{\uparrow}$ seal S is exposed.

Finally H, Q, P, N preserve the same finite route under transport, replay, provenance, and local naming. Since the carrier has no coordinate for a choice-selected infinite subsequence, quotient equality of maps, compact-open host topology, or ambient completeness, the stated rows exhaust the NameCert surface. □

Closure status for $\mathsf{NameCert}_{\mathsf{UniformTailAscoli}^{\uparrow}}$.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{UniformTailAscoli}^{\uparrow}}$, seed)

Scope closed: Definition 8883.1 and Definition 8883.2 seed the finite compact-net, equicontinuity, uniform-modulus, uniform-tail, diagonal-window, RegSeqRat, DyadicRatCore, Real-seal, transport, replay, provenance, and local naming route.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{UniformTailAscoli}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim a choice-selected infinite subsequence, host compact-open topology, quotient equality of functions, ambient completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, compact finite-net exposure, equicontinuity-to-uniform-modulus extraction, uniform-tail control, diagonal-window readback, Real seal boundary, transport, replay, provenance, and local naming for BEDC.Derived.UniformTailAscoliUp.

Constructive story: A UniformTailAscoli$^{\uparrow}$ packet is generated from compact finite nets, metric and compact-metric rows, continuous-map family rows, finite-net equicontinuity, a shared uniform modulus, a finite uniform-tail stage, StreamName diagonal windows, RegSeqRat readback, DyadicRatCore tolerances, a RealUp seal, a diagonal-subfamily ledger, componentwise transport, displayed replay, provenance, and a local NameCert row.

Chapter 8884

A Concrete Naming Certificate for $\mathsf{RegularCauchyMedian}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{RegularCauchyMedian}^{\uparrow}$ packet records the median of three regular Cauchy real-facing names by finite comparison windows. It reads the regular rational rows of chapter 301, the finite schedules of chapter 126, the dyadic comparison budgets of chapter 291, the sibling minimum and maximum routes of chapter 1528 and chapter 1502, and the terminal real-name seal of chapter 38. The packet names the middle window by displayed finite data; it does not import trichotomy, quotient real equality, selected representatives, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 8884.1 (Regular Cauchy median carrier)**.** *A* $\mathsf{RegularCauchyMedian}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M = (A, B, C, W_A, W_B, W_C, D, m_{AB}, j_{AB}, u, v, R, E, H, K, P, N)$$

with the following displayed rows:

1. A, B, C *are the three source* $\mathsf{RegSeqRat}^{\uparrow}$ *regular rational Cauchy name rows.*
2. W_A, W_B, W_C *are the* $\mathsf{StreamName}^{\uparrow}$ *schedules used to inspect the three source names on the same finite precision request.*
3. D *is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *comparison-budget row, recording the endpoint tolerances, overlap slack, and dyadic cells consumed by the displayed pairwise comparisons.*
4. m_{AB} *is the* $\mathsf{RegularCauchyMin}^{\uparrow}$ *sibling route for the lower row of* A *and* B *over the inspected windows.*
5. j_{AB} *is the* $\mathsf{RegularCauchyMax}^{\uparrow}$ *sibling route for the upper row of* A *and* B *over the same inspected windows.*
6. u *is the* $\mathsf{RegularCauchyMax}^{\uparrow}$ *row for the displayed maximum of* m_{AB} *and* C*.*
7. v *is the* $\mathsf{RegularCauchyMin}^{\uparrow}$ *row for the displayed minimum of* u *and* j_{AB}*; it is the median row.*
8. R *is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row exported by* v*.*
9. E *is the terminal* $\mathsf{Real}^{\uparrow}$ *seal reached only after the readback row* R *has been exposed.*
10. H *records componentwise* hsame *transport for the three source rows, schedules, dyadic budget, sibling min and max rows, median row, readback, seal, replay, provenance, and local naming.*

11. *K records displayed* Cont *replay from a median request through* $W_A, W_B, W_C, D, m_{AB}, j_{AB}, u, v, R, E, H, P, N$.
12. *P is the* Pkg *provenance over* $\mathsf{RegularCauchyMedian}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegularCauchyMin}^{\uparrow}$, $\mathsf{RegularCauchyMax}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
13. *N is the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyMedian}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these rows. It has no coordinate for host trichotomy, quotient stream equality, selected limits, countable-choice schedules, ambient $\mathsf{Real}^{\uparrow}$ *completeness, or an unbounded comparison procedure.*

Theorem 8884.2 (Regular Cauchy median NameCert obligations)**.** *For every accepted* $\mathsf{RegularCauchyMedian}^{\uparrow}$ *carrier*

$$M = (A, B, C, W_A, W_B, W_C, D, m_{AB}, j_{AB}, u, v, R, E, H, K, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{RegularCauchyMedian}^{\uparrow}}$ *surface consists exactly of three-source* $\mathsf{RegSeqRat}^{\uparrow}$ *admission, synchronized* $\mathsf{StreamName}^{\uparrow}$ *window exposure,* $\mathsf{DyadicRatCore}^{\uparrow}$ *comparison-budget accounting, the displayed* $\mathsf{RegularCauchyMin}^{\uparrow}$ *and* $\mathsf{RegularCauchyMax}^{\uparrow}$ *sibling routes, median readback, terminal* $\mathsf{Real}^{\uparrow}$ *sealing, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, local naming, and non-escape from those rows.*

Proof. Carrier admission is projection from Definition 8884.1. The source rows are A, B, C, the finite observation schedules are W_A, W_B, W_C, and the common comparison budget is D.

The operation rows are the sibling routes already named in the carrier. The rows m_{AB} and j_{AB} expose the lower and upper pairwise bounds for A and B; the row u then places C against the lower bound, and the row v places the result against the upper bound. Thus the median read is assembled from min and max rows over the same finite windows.

The readback and seal rows add no comparison principle. The row R is downstream of v, and the terminal seal E is downstream of R.

Finally H, K, P, N transport, replay, source, and name this displayed route. Since the carrier contains no other coordinate, the local NameCert exports no host trichotomy, quotient stream equality, selected representative, countable-choice schedule, ambient completeness, or unbounded comparison datum. □

Theorem 8884.3 (Regular Cauchy median finite-window route)**.** *Every* $\mathsf{RegSeqRat}^{\uparrow}$ *or* $\mathsf{Real}^{\uparrow}$ *consumer of an accepted* $\mathsf{RegularCauchyMedian}^{\uparrow}$ *carrier reaches the median row only through the finite route*

$$(A, B, C, W_A, W_B, W_C, D) \longrightarrow (m_{AB}, j_{AB}) \longrightarrow (u, v) \longrightarrow R \longrightarrow E.$$

The route is a displayed finite-window median operation over regular Cauchy names. It is not a trichotomy on completed reals, not a quotient-real equality principle, not a selected limit, and not an ambient completeness argument.

Proof. Start with a consumer of the accepted carrier. By Definition 8884.2, it must first expose the three regular rational sources, the three finite stream schedules, and the common dyadic comparison budget.

Next read the sibling operation rows. The first pair of rows, m_{AB} and j_{AB}, is supplied by the finite $\mathsf{RegularCauchyMin}^{\uparrow}$ and $\mathsf{RegularCauchyMax}^{\uparrow}$ chapters over A and B. The second pair, u and v, uses the same sibling routes to compare C with the displayed lower and upper rows.

The median row is therefore v, and the readback row R is downstream of that displayed operation packet. The terminal $\mathsf{Real}^{\uparrow}$ seal E is reached only after R has been exposed.

Transport through H and replay through K preserve exactly the same finite route. The provenance and local naming rows source the route but do not add a host comparison, quotient stream, selected representative, countable choice, or completeness coordinate. □

Closure status for $\mathsf{NameCert}_{\mathsf{RegularCauchyMedian}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RegularCauchyMedian}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8884.1, Definition 8884.2, and Definition 8884.3 seed the finite median route for three regular Cauchy names through RegSeqRat, StreamName, DyadicRatCore, RegularCauchyMin, RegularCauchyMax, and Real rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RegularCauchyMedian}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close Lean theorem verification, bridge checking, trichotomy, quotient real equality, selected representatives, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, or unbounded comparison schedules.

Upgrade path: Obligation closure requires checked carrier admission, synchronized-window exposure, dyadic budget accounting, min and max sibling-route compatibility, median readback stability, Real seal handoff, transport, replay, provenance, local naming, and non-escape proofs for BEDC.Derived.RegularCauchyMedianUp.

Constructive story: A $\mathsf{RegularCauchyMedian}^{\uparrow}$ packet is generated from three RegSeqRat source rows, three StreamName schedules, a DyadicRatCore comparison budget, RegularCauchyMin and RegularCauchyMax sibling routes, a median readback row, a RealUp seal row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 8885

A Concrete Naming Certificate for $\mathsf{BishopRegularCauchyTailGluing}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{BishopRegularCauchyTailGluing}^{\uparrow}$ packet names the finite tail-gluing step used when regular rational Cauchy data are spliced after a shared prefix and then read as the same real-name route. It sits on the dyadic tolerance ledger of chapter 291, the finite stream windows of chapter 126, the regular rational readback of chapter 301, and the terminal real-name seal of chapter 38. The chapter records a finite NameCert route for tail agreement and gluing stability; it does not assert quotient stream equality, selected representatives, countable choice, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 8885.1 (Bishop regular-Cauchy tail-gluing carrier)**.** *A* $\mathsf{BishopRegularCauchyTailGluing}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$G = (S, D, R, T, E, W, H, C, P, N)$$

with the following displayed rows:

1. *S is the* $\mathsf{StreamName}^{\uparrow}$ *row, listing the finite prefix and tail windows inspected by the gluing request.*
2. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, recording the dyadic radius, endpoint arithmetic, and comparison budget used at the splice.*
3. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the two regular rational tails.*
4. *T is the tail-gluing row: it records the common prefix, the tail threshold, and the proof that all inspected post-threshold windows agree within the displayed dyadic budget.*
5. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal, available only after S, D, R, T have been displayed.*
6. *W is the finite window-stability row, recording that later consumers may enlarge the inspected window only by reusing the same threshold and dyadic ledger.*
7. *H records componentwise* hsame *transport for the stream, dyadic, regular-readback, tail-gluing, seal, stability, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay of the same finite gluing route.*
9. *P is the* Pkg *provenance over* $\mathsf{BishopRegularCauchyTailGluing}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

10. N is the local $\mathsf{NameCert}_{\mathsf{BishopRegularCauchyTailGluing}^{\uparrow}}$ *row.*
The classifier compares accepted packets only through $S, D, R, T, E, W, H, C, P, N$. It contains no coordinate for quotient equality of streams, selected real representatives, countable choice, trichotomy, located suprema, host real equality, or ambient completeness.

Theorem 8885.2 (Bishop regular-Cauchy tail-gluing NameCert obligations)**.** *For every accepted* $\mathsf{BishopRegularCauchyTailGluing}^{\uparrow}$ *carrier $G = (S, D, R, T, E, W, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{BishopRegularCauchyTailGlu}}$ *surface consists exactly of carrier admission for the StreamName schedule, DyadicRatCore tolerance ledger, RegSeqRat readback, tail-threshold gluing row, RealUp seal, finite window-stability row, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming.*

Proof. Project the carrier of Definition 8885.1. The analytic rows are exactly the finite stream schedule S, dyadic tolerance ledger D, regular rational readback R, tail-gluing row T, terminal seal E, and window-stability row W.

The gluing row is downstream of finite data. It can compare tails only after the inspected prefix, threshold, dyadic budget, and regular readback have been displayed, so it has no hidden equality service for all streams.

The structural rows preserve the same route. Transport H, replay C, provenance P, and local naming N certify the displayed packet without adding quotient equality, selected representatives, choice, trichotomy, host equality, or ambient completeness. □

Theorem 8885.3 (Bishop regular-Cauchy tail-gluing window stability)**.** *Let $G = (S, D, R, T, E, W, H, C, P, N)$ be an accepted* $\mathsf{BishopRegularCauchyTailGluing}^{\uparrow}$ *carrier. Every Real or Completion consumer that enlarges the inspected post-threshold window must reuse the same finite route*

$$S, D, R, T, E, W, H, C, P, N.$$

The enlarged read may inspect more StreamName entries only through the displayed tail threshold and DyadicRatCore ledger; it cannot replace the glued tail by quotient equality, a selected representative, countable choice, trichotomy, host real equality, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Begin with the NameCert obligations of Definition 8885.2. They force every consumer to expose $S, D, R, T, E, W, H, C, P, N$ before reading the tail-gluing surface.

The stability row W records the only permitted enlargement. It extends the inspected StreamName window while keeping the same threshold, dyadic budget, and regular readback rows, so the post-threshold comparison remains tied to the displayed finite packet.

Finally inspect the excluded carrier coordinates. Since no quotient equality, selected representative, choice schedule, trichotomy, host equality, or ambient completeness row exists, an enlarged consumer read remains the same finite tail-gluing route rather than a new real-equality principle. □

Falsifiable prediction: Every accepted $\mathsf{BishopRegularCauchyTailGluing}^{\uparrow}$ consumer read displays StreamName prefix and tail windows, a DyadicRatCore tolerance ledger, RegSeqRat readback, a tail-threshold gluing row, a RealUp seal, a window-stability row, componentwise hsame transport, Cont replay, Pkg provenance, and local NameCert naming.

Independence witness: dyadicratcore, streamname, regseqrat, real: $\mathsf{BishopRegularCauchyTailGluing}^{\uparrow}$ is not bijective to any listed sibling because it jointly records a finite prefix, a tail threshold, dyadic splice tolerances, regular rational readback, terminal Real sealing, window stability, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{BishopRegularCauchyTailGluing}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BishopRegularCauchyTailGluing}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8885.1, Definition 8885.2, and Definition 8885.3 seed the finite regular-Cauchy tail-gluing route over stream windows, dyadic tolerances, regular rational readback, tail thresholds, Real sealing, window stability, transport, replay, provenance, and local naming.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BishopRegularCauchyTailGluing}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient stream equality, selected representatives, countable choice, trichotomy, host real equality, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, dyadic tolerance exactness, regular readback compatibility, tail-threshold gluing, window stability, Real seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.BishopRegularCauchyTailGluingUp.

Constructive story: A $\mathsf{BishopRegularCauchyTailGluing}^{\uparrow}$ packet is generated from StreamName prefix and tail windows, DyadicRatCore tolerance data, RegSeqRat readback, a tail-threshold gluing row, a RealUp seal, a window-stability row, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Chapter 8886

A Concrete Naming Certificate for $\mathsf{DyadicCompletionFunctor}^{\uparrow}$

Following Bishop–Bridges constructive completion practice, the $\mathsf{DyadicCompletionFunctor}^{\uparrow}$ packet records the finite map-level route that sends displayed dyadic rational data into the regular Cauchy real-name boundary. It sits after the dyadic tolerance source of chapter 291, the finite stream-window surface of chapter 126, the regular rational readback of chapter 301, the terminal real-name seal of chapter 38, and the extension ledger of chapter 397. The packet names a functorial completion surface for displayed maps; it is not a quotient completion, a selected limit, countable choice, host real equality, or an ambient completeness principle for $\mathsf{Real}^{\uparrow}$.

Definition 8886.1 (Dyadic completion functor carrier)**.** *A* $\mathsf{DyadicCompletionFunctor}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$F = (D, S, R, E, U, M, H, C, P, N)$$

with the following displayed rows:

1. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *source row, exposing dyadic numerators, scales, tolerance comparisons, and finite refinement data.*
2. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row through which each dyadic source and map request is inspected.*
3. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *regular rational readback row reached after D and S have been displayed.*
4. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row for the completed source and target names.*
5. *U is the* $\mathsf{CompletionUniversalProperty}^{\uparrow}$ *extension row, read only after the dyadic, stream, regular-rational, and Real-seal rows have been projected.*
6. *M is the map ledger, recording identity preservation and composition preservation for displayed dyadic maps through the same D, S, R, E, U route.*
7. *H records componentwise* hsame *transport for dyadic data, stream windows, regular rational readback, Real seals, universal-property rows, map ledgers, replay, provenance, and local naming.*
8. *C records displayed* Cont *replay from a dyadic map request through D, S, R, E, U, M, H.*
9. *P is the* Pkg *provenance over* $\mathsf{DyadicCompletionFunctor}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{CompletionUniversalProperty}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{DyadicCompletionFunctor}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $D, S, R, E, U, M, H, C, P, N$. It has no coordinate for quotient stream equality, selected representatives, countable-choice schedules, host-level function equality, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.DyadicCompletionFunctorUp.DyadicCompletionFunctorTasteGate single carrier alignment`

Theorem 8886.2 (Dyadic completion functor NameCert obligations)**.** *For every accepted* $\mathsf{DyadicCompletionFunctor}$ *carrier*

$$F = (D, S, R, E, U, M, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{DyadicCompletionFunctor}^{\uparrow}}$ *surface consists exactly of dyadic source admission through D, finite window inspection through S, regular rational readback through R, terminal Real sealing through E, universal-property extension through U, identity and composition preservation through M, componentwise transport through H, displayed replay through C, provenance through P, and local naming through N. Every map-level completion consumer must read*

$$\mathsf{DyadicRatCore}^{\uparrow} \longmapsto \mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow} \longmapsto \mathsf{CompletionUniversalProperty}^{\uparrow}$$

before treating the completed map as public.

Proof. Project the carrier of Definition 8886.1. The source and observation rows are D and S, so a map consumer first sees dyadic tolerance data and finite stream windows.

Read R and E next. The regular rational row is the only readback route from the finite windows, and the Real seal is downstream of that readback rather than a selected host limit.

The universal-property row U and map ledger M then record the functorial part. Identity and composition are preserved as finite ledger reads over the same dyadic, stream, regular, and Real-seal route; no host function equality or quotient completion is introduced.

Finally H, C, P, N transport, replay, source, and name the displayed packet. Since the carrier has no coordinates for quotient streams, selected representatives, countable choice, host equality, or ambient completeness, the listed rows exhaust the local NameCert obligations. □

Theorem 8886.3 (Dyadic completion functor map route)**.** *Every completed-map read exported by an accepted* $\mathsf{DyadicCompletionFunctor}^{\uparrow}$ *packet factors through the finite route*

$$\mathsf{DyadicRatCore}^{\uparrow},\ \mathsf{StreamName}^{\uparrow},\ \mathsf{RegSeqRat}^{\uparrow},\ \mathsf{Real}^{\uparrow},\ \mathsf{CompletionUniversalProperty}^{\uparrow},\ \mathsf{BHist},\ \mathsf{hsame},\ \mathsf{Cont},\ \mathsf{Pkg},\ \mathsf{Name}$$

The functorial read preserves displayed identities and displayed compositions through the map ledger M and never bypasses the dyadic tolerance ledger, finite stream windows, regular rational readback, Real seal, or universal-property extension row.

Proof. Apply Definition 8886.2. It places D, S, R, E, U before the map ledger M, so every completed-map read is already tied to the displayed dyadic-to-Real completion route.

The identity and composition clauses are ledger clauses inside M. They compare the completed map reads only after the same dyadic, stream, regular-rational, Real-seal, and universal-property rows have been exposed.

Transport and replay through H and C preserve those rows componentwise, while P and N source and name the same finite packet. Therefore the public map route cannot be replaced by quotient completion equality, selected representatives, countable choice, host function equality, or ambient completeness. □

Falsifiable prediction: An accepted $\mathsf{DyadicCompletionFunctor}^{\uparrow}$ consumer that reaches a completed map without displaying $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{CompletionUniversalProperty}^{\uparrow}$, transport, replay, provenance, and local NameCert rows refutes the carrier surface.

Independence witness: dyadicratcore, streamname, regseqrat, real, completionuniversalproperty: $\mathsf{DyadicCompletionFunctor}^{\uparrow}$ is not bijective to any listed sibling because it binds the dyadic source, finite window, regular readback, Real seal, universal-property extension, identity ledger, composition ledger, transport, replay, provenance, and local naming as one map-level completion packet.

Closure status for $\mathsf{NameCert}_{\mathsf{DyadicCompletionFunctor}^{\uparrow}}$.

Constructive story: A $\mathsf{DyadicCompletionFunctor}^{\uparrow}$ packet is generated from a DyadicRatCore source row, StreamName finite windows, RegSeqRat readback, a RealUp seal, a CompletionUniversalProperty extension row, identity and composition ledgers, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{DyadicCompletionFunctor}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8886.1, Definition 8886.2, and Definition 8886.3 seed the finite map-level completion route from dyadic data to Real-facing completion consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{DyadicCompletionFunctor}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient completion equality, selected representatives, countable choice, host function equality, ambient RealUp completeness, theorem checking, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, dyadic source exposure, finite window inspection, regular rational readback, Real seal nonescape, universal-property extension, identity preservation, composition preservation, transport, replay, provenance, and local naming for BEDC.Derived.DyadicCompletionFunctorUp.

Chapter 8887

A Concrete Naming Certificate for $\mathsf{EulerMaclaurinFiniteSum}^{\uparrow}$

Following Euler and Maclaurin, and in the Bishop–Bridges constructive reading of finite summation formulae, the $\mathsf{EulerMaclaurinFiniteSum}^{\uparrow}$ packet records only the finite summation budget needed to read a bounded Euler–Maclaurin correction as BEDC data. It refines the broader summation-remainder route of chapter 2059, keeps the terminal value on the $\mathsf{Real}^{\uparrow}$ seal of chapter 38, reads rational approximants through chapter 301, and sends every tolerance request through the $\mathsf{DyadicRatCore}^{\uparrow}$ surface of chapter 291. The chapter names a finite summation-window object; it does not assert a host asymptotic expansion, an infinite series theorem, an integral theorem, a chosen limiting process, quotient equality, countable choice, trichotomy, or ambient real completeness.

Definition 8887.1 (Euler–Maclaurin finite-sum carrier)**.** *An* $\mathsf{EulerMaclaurinFiniteSum}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$F = (W, L, U, B, D, Q, R, Z, H, C, P, N)$$

with the following displayed rows:

1. *W is the finite summation-window row. It contains the lower and upper indices, the inspected term rows, and the finite partial-sum observations allowed to enter the budget.*
2. *L and U are endpoint rows for the boundary evaluations, including the* $\mathsf{Real}^{\uparrow}$ *names read at the lower and upper edges of the window.*
3. *B is the Bernoulli-correction row. It records the finite correction order, the coefficient rows requested at that order, and the boundary slots to which those coefficients are applied.*
4. *D is the derivative-window row. It lists only the derivative observations and interval windows used by the finite correction and remainder rows.*
5. *Q is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *remainder-budget row, carrying the positive tolerance, split budget, and refinement data for the displayed finite window.*
6. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the summation window, endpoint rows, Bernoulli-correction row, derivative-window row, and dyadic remainder budget.*
7. *Z is the terminal* $\mathsf{Real}^{\uparrow}$ *seal reached after W, L, U, B, D, Q, R have been displayed.*

8. *H records componentwise* hsame *transport for the summation window, endpoint rows, Bernoulli-correction row, derivative-window row, dyadic budget, regular rational readback, terminal seal, replay row, provenance row, and local naming row.*

9. *C records displayed* Cont *replay through*

$$W, L, U, B, D, Q, R \longmapsto Z \longmapsto H, P, N.$$

10. *P is the* Pkg *provenance over* $\mathsf{EulerMaclaurinFiniteSum}^{\uparrow}$, $\mathsf{EulerMaclaurin}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

11. *N is the local* $\mathsf{NameCert}_{\mathsf{EulerMaclaurinFiniteSum}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $W, L, U, B, D, Q, R, Z, H, C, P, N$. It has no coordinate for an unbounded series, a host integral, a hidden asymptotic remainder, a selected limit, quotient equality, countable choice, trichotomy, ambient $\mathsf{Real}^{\uparrow}$ *completeness, Lean verification, or bridge checking.*

Theorem 8887.2 (Euler–Maclaurin finite-sum NameCert obligations)**.** *For every accepted* EulerMaclaurinFiniteSun *carrier*

$$F = (W, L, U, B, D, Q, R, Z, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{EulerMaclaurinFiniteSum}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *finite-window admission, requiring the indices, inspected term rows, and partial-sum observations in W to be displayed before any correction row is read;*

2. *endpoint readiness, requiring both endpoint rows L, U to be opened before boundary corrections or terminal seals are named;*

3. *Bernoulli-correction readiness, requiring the finite coefficient ledger B to expose its order and boundary slots before it contributes to the budget;*

4. *derivative-window readiness, requiring D to list the derivative observations and interval windows used by the correction and remainder rows;*

5. *dyadic remainder budgeting, requiring every final error request to factor through the positivity, split-budget, and refinement data in Q;*

6. *regular rational readback, requiring R to expose rational approximants for W, L, U, B, D, Q before the terminal* $\mathsf{Real}^{\uparrow}$ *seal Z is opened;*

7. *classifier transport, requiring H and C to preserve the same W, L, U, B, D, Q, R, Z inventory under* hsame *and displayed* Cont *replay;*

8. *provenance and local naming, requiring P, N to source and name only the finite packet above, with no host asymptotic expansion, unbounded summation, host integral, selected limit, quotient equality, countable choice, trichotomy, ambient real completeness, Lean verification, or bridge checking.*

No NameCert obligation is stored outside these rows.

Proof. Carrier admission is projection from Definition 8887.1. The accepted packet displays $W, L, U, B, D, Q, R, Z, H, C, P, N$, so every obligation must be read from one of those rows.

The finite-window and endpoint obligations come first. A consumer cannot reach the correction row until the summation bounds and inspected term rows in W are visible, and it cannot form boundary corrections until both endpoint rows L, U have been opened.

The correction and derivative obligations are rowwise. The Bernoulli-correction row B supplies only the finite coefficient ledger requested by the order of the packet, while D supplies the derivative observations and interval windows used by that same finite order.

The remainder obligation is forced by Q. Positivity, split-budget data, and refinements are displayed there before the regular rational readback R can name approximants for the whole budget and before the terminal real seal Z can be opened.

Finally, H and C replay the same inventory under transport, and P, N source and name only that replayed packet. Since the carrier has no additional coordinate, none of the excluded host-analytic or choice-based data can be read from an accepted packet. □

Theorem 8887.3 (Euler–Maclaurin finite-sum budget handoff)**.** *Every downstream quadrature, summation, or real-series consumer of an accepted* $\mathsf{EulerMaclaurinFiniteSum}^{\uparrow}$ *packet must read the finite summation window* W*, endpoint rows* L, U*, Bernoulli-correction row* B*, derivative-window row* D*, dyadic remainder budget* Q*,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback* R*, terminal* $\mathsf{Real}^{\uparrow}$ *seal* Z*, componentwise* hsame *transport* H*, displayed* Cont *replay* C*,* Pkg *provenance* P*, and local* NameCert *row* N *before treating the packet as an Euler–Maclaurin budget. The handoff is therefore a finite BEDC budget route, not an invocation of the broader Euler–Maclaurin theorem as a host asymptotic principle.*

Proof. Let $F = (W, L, U, B, D, Q, R, Z, H, C, P, N)$ be accepted. By Definition 8887.1, these are exactly the rows available to any consumer.

The consumer first opens W for the finite summation interval and inspected terms, then opens L, U for endpoint data. It may then read B and D for the finite correction and derivative windows requested by the packet.

The error route passes through Q and then through R, so every tolerance and rational approximation is tied to the displayed dyadic budget and regular readback. Only after this route is visible may the terminal seal Z be consumed.

The structural rows H, C, P, N transport, replay, source, and name the same packet. Thus the handoff exports exactly the finite budget surface and gives later consumers no route to a host asymptotic theorem. □

Closure status for $\mathsf{NameCert}_{\mathsf{EulerMaclaurinFiniteSum}^{\uparrow}}$.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{EulerMaclaurinFiniteSum}^{\uparrow}}$, seed)

Scope closed: Definition 8887.1, Definition 8887.2, and Definition 8887.3 seed the finite summation-window, endpoint, Bernoulli-correction, derivative-window, dyadic remainder, RegSeqRat readback, Real seal, hsame transport, Cont replay, Pkg provenance, and local NameCert surface.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{EulerMaclaurinFiniteSum}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close a host asymptotic expansion, unbounded summation theorem, host integral theorem, selected limiting process, quotient equality, countable choice, trichotomy, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, finite-window exposure, endpoint readiness, Bernoulli-correction readiness, derivative-window readiness, dyadic remainder budgeting, RegSeqRat readback, Real seal handoff, classifier transport, and non-escape for BEDC.Derived.EulerMaclaurinFiniteSumUp.

Constructive story: An $\mathsf{EulerMaclaurinFiniteSum}^{\uparrow}$ packet is generated from a finite summation-window row, endpoint RealUp rows, Bernoulli-correction row, derivative-window row, DyadicRatCore remainder budget, RegSeqRat readback, terminal RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert row.

Chapter 8888

A Concrete Naming Certificate for $\mathsf{FiniteRadiusContraction}^{\uparrow}$

Following Banach and Picard, the $\mathsf{FiniteRadiusContraction}^{\uparrow}$ packet records the local contraction-budget data needed to run a displayed Picard window inside a fixed metric radius. It sits over the metric source of chapter 57, the regular rational readback of chapter 301, the stream-window route of chapter 126, and the terminal real-name seal of chapter 38. The packet names only a finite local budget: it does not assert a global fixed-point theorem, a complete ambient space, a selected limit outside the displayed window, quotient equality of real names, countable choice, or a host contraction principle.

Definition 8888.1 (Finite-radius contraction carrier)**.** *A* $\mathsf{FiniteRadiusContraction}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$F = (M, r, q, W, B, S, Q, R, H, C, P, N)$$

with the following displayed rows:

1. *M is the* $\mathsf{Met}^{\uparrow}$ *source row naming the carried metric and the finite distance reads used by the local argument.*
2. *r is the positive radius row for the local ball being inspected.*
3. *q is the contraction-constant row, displayed as a rational bound with $0 \leq q < 1$ in the packet's rational readback.*
4. *W is the Picard window row, listing the finitely many iterates and distance requests opened from the chosen seed.*
5. *B is the Cauchy-tail budget row, recording the finite geometric tail estimates consumed inside the radius r.*
6. *S is the* $\mathsf{StreamName}^{\uparrow}$ *row naming the displayed iterate stream window.*
7. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the rational error bounds attached to W and B.*
8. *R is the* $\mathsf{Real}^{\uparrow}$ *seal row available only after the stream and regular-rational rows have been displayed.*
9. *H records componentwise* hsame *transport for the metric source, radius, contraction constant, Picard window, Cauchy-tail budget, StreamName, RegSeqRat, Real seal, replay, provenance, and local naming rows.*

10. *C records displayed* Cont *replay from the metric and radius rows through the Picard window, tail budget, StreamName, RegSeqRat, and Real seal rows.*
11. *P is the* Pkg *provenance over* $\mathsf{FiniteRadiusContraction}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
12. *N is the local* $\mathsf{NameCert}_{\mathsf{FiniteRadiusContraction}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $M, r, q, W, B, S, Q, R, H, C, P, N$. It has no coordinate for a global fixed point, a complete ambient metric space, a selected host limit, quotient equality of real names, countable choice, or an unbounded Picard iteration.

Theorem 8888.2 (Finite-radius contraction NameCert obligations)**.** *For every accepted* $\mathsf{FiniteRadiusContraction}^{\uparrow}$ *carrier*

$$F = (M, r, q, W, B, S, Q, R, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{FiniteRadiusContraction}^{\uparrow}}$ *surface consists exactly of metric-source exposure through M, radius exposure through r, contraction-constant exposure through q, Picard-window exposure through W, Cauchy-tail budget exposure through B, StreamName exposure through S, RegSeqRat readback through Q, Real seal delivery through R, componentwise transport through H, displayed replay through C, package provenance through P, and local naming through N.*

Proof. Project the accepted carrier. Its analytic rows are exactly the metric source, radius, contraction constant, Picard window, tail budget, stream window, rational readback, and Real seal.

The local contraction data are read before any Picard consumer can act. The row M supplies only displayed metric distances, r fixes the ball in which the argument is allowed to run, and q supplies the finite rational contraction bound.

The iterative route is then confined to W, B, S, Q, R. The Picard window W lists only finitely many iterates, the budget row B records only the displayed geometric tail estimates, the stream row S names the visible window, the regular rational row Q reads the finite error bounds, and the Real row R seals only that displayed readback.

Finally H, C, P, N transport, replay, source, and name the same finite packet. Since no excluded global object is a coordinate of the carrier, the listed rows exhaust the local NameCert surface. □

Theorem 8888.3 (Finite-radius contraction Picard budget)**.** *Every Picard consumer of an accepted* $\mathsf{FiniteRadiusContraction}^{\uparrow}$ *packet must read the finite route*

$$M, r, q, W, B, S, Q, R, H, C, P, N$$

before using a contraction estimate. The route supplies a local radius, a displayed contraction constant, a finite Picard window, and a Cauchy-tail budget for the visible iterates; it supplies no global fixed point, no ambient completeness theorem, no selected limit outside the window, no quotient equality of real names, and no countable-choice schedule.

Proof. Begin with the NameCert obligations of Definition 8888.2. They place the metric source, radius, contraction constant, window, and tail-budget rows before any Real-facing read.

Read the Picard route inside the fixed radius. The displayed constant q is consumed only together with the ball row r and the finite window row W, so a consumer cannot extend the estimate to an unbounded iteration or to a different metric source.

The tail estimate remains finite. The budget row B records the geometric tail data visible to the packet, while S, Q, R turn that window into StreamName, RegSeqRat, and Real-facing rows without selecting a host limit.

Transport, replay, provenance, and local naming preserve this same route. Thus the packet exports exactly a local Picard budget, and any global fixed-point conclusion must be supplied by a separate downstream certificate. □

Falsifiable prediction: Every accepted $\mathsf{FiniteRadiusContraction}^{\uparrow}$ Picard read exposes the metric source, radius row, contraction constant, finite Picard window, Cauchy-tail budget, StreamName row, RegSeqRat readback, Real seal, transport, replay, provenance, and local NameCert row before using the contraction estimate.

Independence witness: metric, streamname, regseqrat, real: $\mathsf{FiniteRadiusContraction}^{\uparrow}$ is not bijective to any listed sibling because it jointly binds a local radius, contraction constant, Picard window, Cauchy-tail budget, stream readback, regular rational readback, Real seal, transport, replay, provenance, and local naming in one packet.

Closure status for $\mathsf{NameCert}_{\mathsf{FiniteRadiusContraction}^{\uparrow}}$.

Constructive story: A $\mathsf{FiniteRadiusContraction}^{\uparrow}$ packet is generated from a Metric source row, local radius row, contraction-constant row, finite Picard window, Cauchy-tail budget, StreamName row, RegSeqRat readback, RealUp seal row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{FiniteRadiusContraction}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8888.1, Definition 8888.2, and Definition 8888.3 seed the finite local contraction-budget route for Picard-window and Cauchy-tail consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{FiniteRadiusContraction}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close a global fixed-point theorem, ambient metric completeness, selected host limits, quotient equality of real names, countable choice, unbounded Picard iteration, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, metric-source exposure, radius exactness, contraction-constant exactness, Picard-window exposure, Cauchy-tail budget exactness, StreamName and RegSeqRat readback, Real seal delivery, transport, replay, provenance, and local naming for BEDC.Derived.FiniteRadiusContractionUp.

Chapter 8889

UniformRegularCompletionScale NameCert Construction

Following Bourbaki's uniform-space completion interface and Bishop-style regular Cauchy completion, the $\mathsf{UniformRegularCompletionScale}^{\uparrow}$ packet records a finite tolerance-scale route from uniform entourages to regular rational names. It sits after the dyadic tolerance core of chapter 291, the finite stream-window surface of chapter 126, the regular rational readback of chapter 301, and the terminal real-name seal of chapter 38. The packet names the scale used by completion-facing consumers without quotienting Cauchy filters, selecting representatives, importing ambient completeness, or deciding equality of completed points.

Definition 8889.1 (Uniform regular completion scale)**.** *A* $\mathsf{UniformRegularCompletionScale}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$U = (E, D, W, R, T, S, H, C, P, N)$$

with the following displayed rows:

1. *E is the finite uniform-entourage request ledger, indexed by the precision cells actually inspected by a consumer.*
2. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row, carrying dyadic radii, slack conversions, and monotone refinement data for the inspected cells.*
3. *W is the* $\mathsf{StreamName}^{\uparrow}$ *pointwise certification row, exposing finite observations at the requested tolerance scale.*
4. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *tail-stability row, reading the same observations as a regular rational Cauchy name.*
5. *T is the scale-coherence ledger, requiring finer dyadic requests to replay through compatible stream windows and regular rational tails.*
6. *S is the terminal* $\mathsf{Real}^{\uparrow}$ *sealing row reached only after D, W, R, T have been displayed.*
7. *H records componentwise* hsame *transport for the uniform request ledger, dyadic tolerance row, stream windows, regular rational tail, scale-coherence ledger, terminal seal, replay, provenance, and local naming.*
8. *C records displayed* Cont *replay of the ordered route E, D, W, R, T, S.*
9. *P is the* Pkg *provenance over* $\mathsf{UniformRegularCompletionScale}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.

10. N is the local $\mathsf{NameCert}_{\mathsf{UniformRegularCompletionScale}^{\uparrow}}$ *row.*
The classifier compares accepted packets only through these rows. It has no coordinate for quotient completion, selected Cauchy representative, ambient uniform space equality, countable choice, trichotomy, or completeness of $\mathsf{Real}^{\uparrow}$.

Theorem 8889.2 (Uniform regular completion scale NameCert obligations)**.** *For every accepted* $\mathsf{UniformRegularCompletionScale}^{\uparrow}$ *carrier*

$$U = (E, D, W, R, T, S, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{UniformRegularCompletionScale}^{\uparrow}}$ *obligations are exactly carrier admission for the displayed ten-row packet, dyadic tolerance-scale admission through D, pointwise stream certification through W, regular rational tail stability through R, coherence of finer requests through T, terminal* $\mathsf{Real}^{\uparrow}$ *sealing through S, and transport, replay, provenance, and local naming through H, C, P, N. These obligations export a uniform regular completion scale only as finite BEDC data and do not assert quotient equality of completed points, a selected representative, countable choice, trichotomy, or ambient completeness.*

Proof. Carrier admission is projection from Definition 8889.1. The uniform request ledger, dyadic tolerance row, pointwise stream windows, regular rational tail, scale-coherence ledger, terminal seal, transport, replay, provenance, and local name are explicit coordinates of U.

The tolerance route is dyadic. The row D supplies the inspected radii and slack conversions, while W reads only the finite stream observations licensed by those cells. Thus pointwise certification is a $\mathsf{StreamName}^{\uparrow}$ read attached to a $\mathsf{DyadicRatCore}^{\uparrow}$ scale, not a selected infinite representative.

Tail stability is then read through R and T. The $\mathsf{RegSeqRat}^{\uparrow}$ row supplies the regular rational Cauchy handoff, and the scale-coherence ledger forces finer requests to replay through compatible windows and tails before any terminal seal is available.

Finally S exposes the $\mathsf{Real}^{\uparrow}$ boundary only after the ordered route E, D, W, R, T has been displayed. The structural rows H, C, P, N transport and replay that same route, so the NameCert surface has no path to quotient completion, selected limits, countable choice, trichotomy, or ambient real completeness. □

Closure status for $\mathsf{NameCert}_{\mathsf{UniformRegularCompletionScale}^{\uparrow}}$.

Constructive story: A $\mathsf{UniformRegularCompletionScale}^{\uparrow}$ packet is generated from a finite uniform-entourage request ledger, a DyadicRatCore tolerance row, StreamName pointwise certification, RegSeqRat tail stability, a scale-coherence ledger, a terminal RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert data.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{UniformRegularCompletionScale}^{\uparrow}}$, seed)

Scope closed: Definition 8889.1 and Definition 8889.2 seed the finite uniform regular completion scale over $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, Pkg, and NameCert rows.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{UniformRegularCompletionScale}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim quotient completion, selected Cauchy representatives, host uniform-space equality, countable choice, trichotomy, Lean verification, bridge checking, or ambient completeness of $\mathsf{Real}^{\uparrow}$.

Upgrade path: Obligation closure requires checked dyadic tolerance-scale admission, StreamName pointwise certification, RegSeqRat tail stability, scale-coherence replay, RealUp sealing, transport stability, and non-escape for BEDC.Derived.UniformRegularCom

Chapter 8890

ZeckendorfPrimeEdge NameCert Construction

Following Zeckendorf's finite Fibonacci-word normal form and the standard irreducible-edge language of finite directed combinatorics, the $\mathsf{ZeckendorfPrimeEdge}^{\uparrow}$ packet records an atomic recursive prime edge as NameCert data. It sits beside the normal-window surface of chapter 278, the carry route of chapter 558, the carry-classifier boundary of chapter 567, the phase-shell window of chapter 8811, and the classifier-channel ledger of chapter 6765. The packet turns the atomic recursive prime-edge vision into a finite carrier over displayed operations, not into a theorem about ordinary integer primes.

Definition 8890.1 (Zeckendorf prime-edge carrier)**.** *A* $\mathsf{ZeckendorfPrimeEdge}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$P = (B_0, B_1, O, \alpha, E, N_D, I, Q, L, H, C, R, N)$$

with the following displayed rows:

1. B_0 *is the source Zeckendorf window row, read through the finite no-adjacent-*11 *classifier.*
2. B_1 *is the target Zeckendorf window row, read through the same finite classifier after the displayed operation fires.*
3. O *is the recursive-operation carrier row: it exposes an operation identity, composition, equivalence, and action on displayed window records.*
4. α *is the atomic operation row acting from* B_0 *toward* B_1*.*
5. E *is the edge row witnessing that* $\alpha(B_0)$ *classifies as* B_1*.*
6. N_D *is the nondegeneracy row, keeping* B_0 *and* B_1 *classifier-distinct before the edge is consumed.*
7. I *is the irreducibility row: every displayed factorization of* α *has a unit factor.*
8. Q *is the prime-divisibility row for the chosen operation divisibility classifier.*
9. L *is the finite ledger exposing source, target, operation, edge, nondegeneracy, irreducibility, and primeness rows.*
10. H *records componentwise* hsame *transport for all displayed rows.*
11. C *records displayed* Cont *replay from source window through operation action, edge readback, and prime-edge ledger.*

12. *R is the* Pkg *provenance over* ZeckendorfPrimeEdge$^{\uparrow}$, ZeckendorfNormal$^{\uparrow}$, ZCarry$^{\uparrow}$, ZeckendorfCarryClassifier$^{\uparrow}$, ZeckendorfPhaseShell$^{\uparrow}$, ClassifierChannelShiftLedger$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
13. *N is the local* NameCert$_{\text{ZeckendorfPrimeEdge}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these rows. It has no coordinate for ordinary integer primality, hidden factorization search, quotient equality of histories, selected normalizer, or a global rewrite system.

Lean4 ✓ `BEDC.Derived.ZeckendorfPrimeEdgeUp.TasteGate.ZeckendorfPrimeEdgeTasteGate single carrier alignment`

Theorem 8890.2 (Zeckendorf prime-edge NameCert obligations)**.** *For every accepted* ZeckendorfPrimeEdge$^{\uparrow}$ *carrier*

$$P = (B_0, B_1, O, \alpha, E, N_D, I, Q, L, H, C, R, N),$$

the local NameCert$_{\text{ZeckendorfPrimeEdge}^{\uparrow}}$ *obligations are exactly carrier admission for the displayed thirteen-row packet, source and target Zeckendorf-window admission, recursive-operation admission, edge exactness, nondegeneracy, irreducibility, operation-prime divisibility, ledger exactness, componentwise transport, continuation replay, provenance, and local naming. These rows realize the atomic recursive prime-edge carrier as finite NameCert data and do not assert ordinary integer primality, quotient history equality, a selected normal form representative, or a global confluence theorem.*

Proof. Carrier admission is projection from Definition 8890.1. The source window, target window, recursive-operation carrier, atomic operation, edge row, nondegeneracy row, irreducibility row, prime-divisibility row, ledger, transport, replay, provenance, and local name are all explicit coordinates of P.

The source and target obligations read the Zeckendorf siblings. The no-adjacent-11 classifier and carry-classifier boundary supply the finite window discipline, while the phase-shell and channel-shift ledgers explain which visible window and classifier-channel rows are being consumed.

Recursive-operation admission is row-local. The carrier reads identity, composition, operation equivalence, and action from O, then reads α as a displayed operation rather than as a hidden evaluator.

Edge exactness, nondegeneracy, irreducibility, and primeness are then read from E, N_D, I, Q. The irreducibility row handles factorization by requiring a unit side in every displayed decomposition of α, and the prime row is relative to operation divisibility, not ordinary integer primality.

Finally L, H, C, R, N expose the finite ledger, transport the same rows, replay the same route, record provenance, and name the packet. Since the carrier has no quotient-history, selected-normalizer, hidden search, or global confluence coordinate, the listed rows exhaust the NameCert obligations. □

Closure status for NameCert$_{\text{ZeckendorfPrimeEdge}^{\uparrow}}$.

Constructive story: A ZeckendorfPrimeEdge$^{\uparrow}$ packet is generated from source and target Zeckendorf window rows, a recursive-operation carrier, an atomic operation, edge exactness, nondegeneracy, irreducibility, operation-prime divisibility, a finite ledger, componentwise hsame transport, Cont replay, Pkg provenance, and local NameCert data.

Theory closure: TheoryGate(NameCert$_{\text{ZeckendorfPrimeEdge}^{\uparrow}}$, seed)

Scope closed: Definition 8890.1 and Definition 8890.2 seed the finite atomic recursive prime-edge surface over Zeckendorf normal windows, carry/classifier rows, phase-shell rows, classifier-channel ledger rows, recursive operations, BHist, hsame, Cont, Pkg, and NameCert.

Formal verification: FormalStatus(NameCert$_{\text{ZeckendorfPrimeEdge}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim ordinary integer primality, quotient history equality, selected normal representatives, global carry confluence, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked source/target window admission, recursive-operation admission, edge exactness, nondegeneracy, irreducibility, operation-prime divisibility, ledger exactness, transport stability, and non-escape for BEDC.Derived.ZeckendorfPrimeEdgeUp.

Chapter 8891

A Concrete Naming Certificate for $\mathsf{FiniteIntervalSignSplit}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{FiniteIntervalSignSplit}^{\uparrow}$ packet records the finite sign-split data used by constructive bisection before any limiting root object is named. It refines the sign-change bracket surface of chapter 3359 and the contraction-facing interval route of chapter 5867 into a single NameCert carrier for endpoint Real seals, located signs, dyadic midpoint budgets, retained subintervals, StreamName windows, RegSeqRat readback, componentwise transport, displayed replay, provenance, and local naming. The packet is a finite handoff object; it is not classical intermediate value, real trichotomy, quotient equality, countable choice, a selected infinite branch, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 8891.1 (Finite interval sign-split carrier)**.** *A* $\mathsf{FiniteIntervalSignSplit}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (a, b, L, U, D, M, T, W, R, E, H, C, P, N)$$

with the following displayed rows:

1. *a and b are endpoint* $\mathsf{Real}^{\uparrow}$ *seal rows read only through finite regular-rational windows.*
2. *L and U are located sign witnesses at the endpoint windows, with opposed sign evidence displayed at the requested precision.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *interval ledger storing endpoint dyadics, width comparisons, tolerance radii, and midpoint requests.*
4. *M is the midpoint/budget row, recording the finite bisection query and the dyadic budget consumed by the inspected midpoint.*
5. *T is the retained subinterval row, naming the left or right half whose endpoint signs still form an opposed located pair.*
6. *W is the* $\mathsf{StreamName}^{\uparrow}$ *window row for the inspected endpoint and midpoint data.*
7. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback assembled from the retained subinterval windows and the same dyadic ledger.*
8. *E is the terminal pair of* $\mathsf{Real}^{\uparrow}$ *seals reached only after $a, b, L, U, D, M, T, W, R$ have been displayed.*
9. *H records componentwise* hsame *transport for endpoint, sign, dyadic, midpoint, retained-subinterval, window, readback, seal, replay, provenance, and local naming rows.*

10. *C records displayed* Cont *replay from the sign-split request through* $a, b, L, U, D, M, T, W, R, E, H, P, N$.
11. *P is the* Pkg *provenance over* $\mathsf{FiniteIntervalSignSplit}^{\uparrow}$, $\mathsf{RealBolzano}^{\uparrow}$, $\mathsf{BishopIntervalContraction}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
12. *N is the local* $\mathsf{NameCert}_{\mathsf{FiniteIntervalSignSplit}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these rows. It has no coordinate for real trichotomy, a selected zero, quotient real equality, countable choice, an infinite bisection branch, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 8891.2 (Finite interval sign-split NameCert obligations)**.** *For every accepted* $\mathsf{FiniteIntervalSignSplit}^{\uparrow}$ *carrier*

$$S = (a, b, L, U, D, M, T, W, R, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{FiniteIntervalSignSplit}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for endpoint Real seals, located sign witnesses, dyadic interval data, midpoint budget, retained subinterval, StreamName windows, RegSeqRat readback, terminal Real seals, transport, replay, provenance, and local naming;*
2. *endpoint sign exposure, requiring L, U to be read from a, b as displayed located apartness data before any midpoint is inspected;*
3. *dyadic midpoint exactness, requiring D, M to record the same finite width, midpoint, tolerance, and budget rows used by the split;*
4. *retained-subinterval stability, requiring T to keep one opposed located sign pair and to stay inside the displayed endpoint interval;*
5. *window and readback routing, requiring W, R, E to be assembled from the retained subinterval and dyadic budget rows rather than from a selected root;*
6. *componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local* NameCert *naming through H, C, P, N for the same rows;*
7. *refusal of classical intermediate value, real trichotomy, quotient equality, selected roots, countable choice, infinite branches, and ambient* $\mathsf{Real}^{\uparrow}$ *completeness as certificate data.*

No finite sign-split obligation is stored outside $a, b, L, U, D, M, T, W, R, E, H, C, P, N$.

Proof. Project the carrier of Definition 8891.1. The endpoint rows a, b and the located sign witnesses L, U are the only sources of sign data, and both are read at displayed finite precision.

The split itself is dyadic. The ledger D and midpoint row M record the width, midpoint, tolerance, and budget data before the retained subinterval T is admitted.

The completion-facing rows are downstream of the retained subinterval. The window row W and readback row R are assembled from T, D, M, and the terminal Real seals E are read only after that finite route is present.

Finally H, C, P, N transport, replay, source, and name the same packet rows. Since the carrier contains no excluded order, quotient, choice, branch, root-selection, or completeness coordinate, the listed rows exhaust the local NameCert surface. □

Theorem 8891.3 (Finite interval sign-split bisection handoff)**.** *Every bisection-facing consumer of an accepted* $\mathsf{FiniteIntervalSignSplit}^{\uparrow}$ *packet must read the finite route*

$$a, b, L, U, D, M \longmapsto T, W, R, E \longmapsto H, C, P, N$$

before it can treat a retained half-interval as sign-change evidence. The handoff supplies endpoint Real seals, located sign witnesses, dyadic midpoint and budget rows, a retained subinterval, finite StreamName windows, RegSeqRat readback, componentwise transport, displayed continuation replay, provenance, and local naming. It supplies no unrestricted intermediate-value theorem, selected root, real trichotomy, quotient real equality, countable choice, infinite branch, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start with the NameCert obligations of Definition 8891.2. They force endpoint sign exposure through a, b, L, U and dyadic midpoint exactness through D, M before a retained subinterval can be consumed.

Apply the RealBolzano sign-change bisection route of Definition 3359.6. The retained half may be exported only as opposed located sign data inside a displayed bracket, not as a selected root or unrestricted intermediate-value result.

The StreamName and RegSeqRat rows then carry the retained half to completion-facing consumers. This is the same finite kind of Cauchy handoff isolated by Definition 5867.3, with W, R, E downstream of the dyadic and sign rows.

The structural rows H, C, P, N preserve that route for later consumers. Since none of the cited rows contains real trichotomy, quotient real equality, countable choice, an infinite branch, selected roots, or ambient Real completeness, the handoff remains the finite bisection surface stated above. □

Falsifiable prediction: An accepted $\mathsf{FiniteIntervalSignSplit}^{\uparrow}$ consumer that reaches a retained subinterval, $\mathsf{RegSeqRat}^{\uparrow}$ readback, or terminal $\mathsf{Real}^{\uparrow}$ seal without reading $a, b, L, U, D, M, T, W, R, E, H, C, P, N$ refutes the carrier surface.

Independence witness: real-bolzano, bishop-interval-contraction, dyadicratcore, streamname, regseqrat, real: no listed sibling supplies exactly the joint packet containing endpoint Real seals, located sign witnesses, dyadic midpoint budgets, a retained subinterval, finite windows, regular-rational readback, terminal Real seals, transport, replay, provenance, and local NameCert row.

Closure status for $\mathsf{NameCert}_{\mathsf{FiniteIntervalSignSplit}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{FiniteIntervalSignSplit}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8891.1, Definition 8891.2, and Definition 8891.3 seed the constructive finite sign-split route from endpoint Real seals and located sign witnesses to retained subinterval, RegSeqRat readback, and terminal Real-seal consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{FiniteIntervalSignSplit}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim classical intermediate value, real trichotomy, quotient real equality, selected roots, countable choice, infinite branches, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, endpoint sign exposure, dyadic midpoint exactness, retained-subinterval stability, window readback routing, transport, replay, provenance, and local naming for BEDC.Derived.FiniteIntervalSignSplitUp.

Constructive story: A $\mathsf{FiniteIntervalSignSplit}^{\uparrow}$ packet is generated from endpoint Real seals, located sign witnesses, dyadic midpoint and budget rows, a retained subinterval row, StreamName finite windows, RegSeqRat readback, terminal Real seals, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 8892

A Concrete Naming Certificate for $\mathsf{RegularRealFamilyDiagonal}^{\uparrow}$

Bishop and Bridges constructive analysis treats diagonal arguments over regular real families through explicit finite observations, moduli, and null-tail comparisons rather than selected representatives of completed real names. The $\mathsf{RegularRealFamilyDiagonal}^{\uparrow}$ packet records that family-diagonal route as finite NameCert data. It sits over the finite stream interface of chapter 126, the regular rational readback of chapter 301, the dyadic tolerance ledger of chapter 291, the zero-tail comparison service of chapter 380, the terminal real-name seal of chapter 38, and the completion-facing boundary of chapter 360. The packet names a finite diagonal family carrier for Real and Completion consumers; it is not quotient stream equality, a selected limit, countable choice, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 8892.1 (Regular real family diagonal carrier)**.** *A* $\mathsf{RegularRealFamilyDiagonal}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$F = (S, R, D, Z, E, H, C, P, N)$$

with the following displayed rows:

1. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window family, listing the source-family coordinates and observation windows inspected by the diagonal request.*
2. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row obtained from the displayed family windows rather than from a selected stream representative.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row, recording the diagonal precision request, local dyadic slack, and comparison budget used by the readback.*
4. *Z is the* $\mathsf{NullSequence}^{\uparrow}$ *zero-tail row, displaying that the diagonal difference route is eventually absorbed by the named tolerance windows.*
5. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row exposed only after S, R, D, Z have been displayed.*
6. *H records componentwise* hsame *transport for the stream-family, regular readback, dyadic tolerance, zero-tail, Real seal, replay, provenance, and naming rows.*
7. *C records displayed* Cont *replay from a diagonal-family request through S, R, D, Z, E, H, P, N.*
8. *P is the* Pkg *provenance over* $\mathsf{RegularRealFamilyDiagonal}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{NullSequence}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

9. N is the local $\mathsf{NameCert}_{\mathsf{RegularRealFamilyDiagonal}^{\uparrow}}$ *row.*

The carrier predicate asserts exactly that these rows form one displayed regular-real family diagonal history. It has no coordinate for quotient streams, selected limits, countable choice, trichotomy, host real equality, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 8892.2 (Regular real family diagonal NameCert obligations)**.** *For every accepted* RegularRealFamilyDiago *carrier $F = (S, R, D, Z, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{RegularRealFamilyDiagonal}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the displayed stream-family windows, regular rational readback, dyadic tolerance ledger, zero-tail comparison, terminal Real seal, transport, replay, provenance, and local naming rows;*
2. *window-family exactness, requiring S to expose only the finite source-family observations inspected by the diagonal request;*
3. *regular-readback handoff, requiring R to be read from the displayed windows and not from an unrecorded representative of the source family;*
4. *dyadic tolerance exactness, requiring D to bind the diagonal precision request to the readback and zero-tail rows;*
5. *null-tail handoff, requiring Z to be displayed before the Real seal E is consumed by any equality-facing or completion-facing reader;*
6. *ledger exhaustion, requiring H, C, P, N to transport, replay, source, and name no quotient stream, selected limit, countable-choice schedule, trichotomy branch, host equality, ambient Real-completeness theorem, Lean verification, or checked bridge.*

No regular-real family diagonal obligation is stored outside these rows.

Proof. Carrier admission is projection from Definition 8892.1. The accepted packet exposes exactly the finite stream-family windows, regular readback, dyadic tolerance row, zero-tail row, terminal seal, and structural rows.

Window-family exactness is read from S. A diagonal request names which family coordinates and finite windows are inspected before any regular readback can be consumed.

The regular-readback and dyadic clauses are supplied by R and D. The readback row receives the displayed family windows, while the dyadic row records the precision and slack budget used by the diagonal comparison.

The null-tail handoff is the row Z. It must be displayed before the terminal Real seal E, so an equality-facing or completion-facing consumer receives the zero-tail evidence as part of the same finite route.

Finally H, C, P, N preserve the route by componentwise transport, replay, provenance, and local naming. Since the carrier has no coordinate for the excluded quotient, selector, choice, trichotomy, host-equality, or completeness objects, the listed rows exhaust the local NameCert surface. □

Theorem 8892.3 (Regular real family diagonal seal route)**.** *Every* $\mathsf{Real}^{\uparrow}$*-facing or* $\mathsf{RealCauchyCompletion}^{\uparrow}$*-facing consumer of an accepted* $\mathsf{RegularRealFamilyDiagonal}^{\uparrow}$ *carrier must read the displayed route*

$$S, R, D, Z, E, H, C, P, N$$

before using the diagonal family as a real-name or completion-name input. The consumer therefore receives the finite StreamName family, RegSeqRat readback, DyadicRatCore tolerance, NullSequence zero-tail comparison, Real seal, transport, replay, provenance, and local naming rows as

prior data. It cannot replace that route by quotient streams, selected limits, countable choice, trichotomy, host equality, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the carrier of Definition 8892.1. The only Real-facing endpoint is E, and the carrier places E after the finite family windows, regular readback, dyadic tolerance ledger, and null-tail row.

Apply Definition 8892.2. The window-family, readback, dyadic, and null-tail obligation rows force every consumer to read S, R, D, Z before the terminal Real seal can be used.

The completion-facing handoff is downstream of the same seal. A $\mathsf{RealCauchyCompletion}^{\uparrow}$ consumer may read the diagonal family only as the already named route $S, R, D, Z, E, H, C, P, N$; it receives no independent completion coordinate from the carrier.

The structural rows preserve this route and add no quotient stream, selected limit, countable-choice schedule, trichotomy branch, host equality, or ambient completeness theorem. Hence the displayed route is exhaustive for both Real-facing and completion-facing consumers. □

Closure status for $\mathsf{NameCert}_{\mathsf{RegularRealFamilyDiagonal}^{\uparrow}}$.

Constructive story: A $\mathsf{RegularRealFamilyDiagonal}^{\uparrow}$ packet is generated from finite StreamName family windows, a RegSeqRat readback, a DyadicRatCore tolerance ledger, a NullSequence zero-tail comparison, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RegularRealFamilyDiagonal}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8892.1, Definition 8892.2, and Definition 8892.3 seed the finite diagonal-family route through StreamName, RegSeqRat, DyadicRatCore, NullSequence, Real, and RealCauchyCompletion consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RegularRealFamilyDiagonal}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient streams, selected limits, countable choice, trichotomy, ambient RealUp completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, window-family exactness, regular-readback handoff, dyadic tolerance exactness, null-tail handoff, Real seal ordering, transport, replay, provenance, and local naming for BEDC.Derived.RegularRealFamilyDiagonalUp.

Chapter 8893

A Concrete Naming Certificate for $\mathsf{BishopLocatedRealApartnessModulus}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{BishopLocatedRealApartnessModulus}^{\uparrow}$ packet records the finite located-real apartness schedule that turns a displayed separation request into dyadic brackets and a readable modulus row. It sits over the located-real source of chapter 1933, the terminal real-name seal of chapter 38, the regular rational readback of chapter 301, the dyadic tolerance ledger of chapter 291, and the located-apartness comparison row of chapter 6450. The packet names only finite bracket and modulus data; it does not assert trichotomy, quotient real equality, selected real representatives, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 8893.1 (Bishop located-real apartness modulus carrier)**.** *A* $\mathsf{BishopLocatedRealApartnessModulus}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$A = (L, E, R, D, B, M, H, C, P, N)$$

with the following displayed rows:

1. *L is the* $\mathsf{LocatedReal}^{\uparrow}$ *source row naming the located real datum whose apartness request is being read.*
2. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row available only after the located source and its finite readbacks have been displayed.*
3. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the regular rational windows inspected by the apartness request.*
4. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row carrying dyadic radii, half-radius comparisons, endpoint brackets, and bracket-refinement requests.*
5. *B is the located-bracket transport row, requiring each apartness request to pass through the same displayed brackets before a modulus can be consumed.*
6. *M is the apartness-modulus extraction row: it records the finite precision schedule that turns a positive dyadic separation witness into the requested apartness margin.*
7. *H records componentwise* hsame *transport for the located source, Real seal, regular-rational readback, dyadic tolerance ledger, bracket transport, modulus extraction, replay, provenance, and local naming rows.*

8. *C records displayed* Cont *replay along the same located-real, regular-rational, dyadic, bracket, and modulus route.*
9. *P is the* Pkg *provenance over* BishopLocatedRealApartnessModulus$^{\uparrow}$, LocatedReal$^{\uparrow}$, Real$^{\uparrow}$, RegSeqRat$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, LocatedRealApartness$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* NameCert$_{\text{BishopLocatedRealApartnessModulus}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $L, E, R, D, B, M, H, C, P, N$. It has no coordinate for trichotomy, quotient real equality, selected real representatives, hidden limit choice, countable choice, or ambient Real$^{\uparrow}$ *completeness.*

Theorem 8893.2 (Bishop located-real apartness modulus obligations)**.** *For every accepted* BishopLocatedRealApart *carrier*

$$A = (L, E, R, D, B, M, H, C, P, N),$$

the local NameCert$_{\text{BishopLocatedRealApartnessModulus}^{\uparrow}}$ *surface consists exactly of five rows:*

1. *carrier admission through the displayed rows $L, E, R, D, B, M, H, C, P, N$;*
2. *classifier stability, requiring comparison only through the same located-real, real-seal, regular-rational, dyadic, bracket, modulus, and structural rows;*
3. *located bracket transport through B, so each apartness read consumes the same finite bracket route before reaching* LocatedRealApartness$^{\uparrow}$ *consumers;*
4. *apartness modulus extraction through M, turning a displayed positive dyadic separation witness into the finite precision schedule requested by the consumer;*
5. *ledger exactness through D, H, C, P, N, preserving the dyadic tolerance row, componentwise transport, replay, provenance, and local naming without adding a host real equality service.*

No obligation supplies trichotomy, quotient real equality, selected representatives, hidden limit choice, countable choice, or ambient Real$^{\uparrow}$ *completeness.*

Lean4 (statement) `BEDC.Derived.BishopLocatedRealApartnessModulusUp`

Proof. Project the carrier of Definition 8893.1. Its visible rows are exactly the located source, Real seal, regular-rational readback, dyadic tolerance ledger, bracket transport, modulus extraction, and structural naming rows.

The classifier-stability clause is immediate from that projection. Since the carrier has no coordinate outside $L, E, R, D, B, M, H, C, P, N$, an accepted comparison can inspect only those rows.

The located-bracket and apartness-modulus clauses are the two value-facing obligations. The row B forces each apartness request to pass through displayed brackets, and the row M extracts the finite precision schedule from the positive dyadic separation witness recorded through D.

Finally H, C, P, N preserve the same finite route under transport, replay, provenance, and local naming. Because none of the excluded principles is a row of the packet, the listed five rows exhaust the local NameCert surface. □

Falsifiable prediction: Every accepted BishopLocatedRealApartnessModulus$^{\uparrow}$ apartness read exposes the located-real source, Real seal, RegSeqRat readback, DyadicRatCore tolerance ledger, bracket transport, modulus extraction, hsame transport, Cont replay, provenance, and local NameCert row before using a positive separation margin.

Independence witness: located-real, real, regseqrat, dyadicratcore, located-real-apartness: BishopLocatedRealAp is not bijective to any listed sibling because it jointly binds a located source, real seal, regular-rational readback, dyadic tolerance ledger, bracket transport, modulus extraction, transport, replay, provenance, and local naming in one packet.

Closure status for $\mathsf{NameCert}_{\mathsf{BishopLocatedRealApartnessModulus}^{\uparrow}}$.

Constructive story: A $\mathsf{BishopLocatedRealApartnessModulus}^{\uparrow}$ packet is generated from a LocatedReal source row, RealUp seal row, RegSeqRat readback, DyadicRatCore tolerance ledger, located-bracket transport row, apartness-modulus extraction row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BishopLocatedRealApartnessModulus}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8893.1 and Definition 8893.2 seed the finite located-real apartness-modulus route through brackets, dyadic tolerances, regular-rational readback, and local naming.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BishopLocatedRealApartnessModulus}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close trichotomy, quotient real equality, selected real representatives, hidden limit choice, countable choice, ambient Real completeness, theorem checking, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, classifier stability, located bracket transport, apartness modulus extraction, ledger exactness, transport, replay, provenance, and local naming for BEDC.Derived.BishopLocatedRealApartnes

Chapter 8894

RieszInterpolationRealUp NameCert Construction

Following Riesz's interpolation property for ordered groups and vector lattices, the $\mathsf{RieszInterpolationReal}^{\uparrow}$ packet records a finite interpolation witness for two displayed lower real names and two displayed upper real names inside the constructive Real algebraic-order surface. It sits between the terminal real-name seal of chapter 38, the Real algebraic-order boundary of chapter 766, and the dyadic tolerance core of chapter 291. The packet names the dyadic comparison route that witnesses one interpolant w with $a_0, a_1 \leq w \leq b_0, b_1$; it does not assert trichotomy, quotient real equality, selected representatives, order completion, choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 8894.1 (RieszInterpolationReal carrier)**.** *A* $\mathsf{RieszInterpolationReal}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$I = (R, A, D, L, U, W, H, C, P, N)$$

with the following displayed rows:

1. *R is the* $\mathsf{Real}^{\uparrow}$ *seal row naming the four endpoint real names and the candidate interpolant real name.*
2. *A is the* $\mathsf{RealAlgOrder}^{\uparrow}$ *operation-and-order row exposing the constructive nonnegative-difference comparisons used by the packet.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *comparison ledger recording the finite dyadic radii, slack rows, and lower-upper comparison budget.*
4. *L is the lower-pair row, displaying the two lower endpoints a_0, a_1 and their dyadic comparison requests against the upper endpoints.*
5. *U is the upper-pair row, displaying the two upper endpoints b_0, b_1 and the finite evidence that each lower endpoint is below each upper endpoint through A and D.*
6. *W is the interpolation-witness row, naming a displayed real name w together with the four comparison reads $a_0 \leq w$, $a_1 \leq w$, $w \leq b_0$, and $w \leq b_1$ through the same RealAlgOrder and dyadic ledger rows.*
7. *H records componentwise* hsame *transport for the Real seal, RealAlgOrder row, dyadic ledger, lower pair, upper pair, witness row, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from a real-order interpolation request through R, A, D, L, U, W, H back to the same finite comparison surface.*

9. *P is the* Pkg *provenance over* $\mathsf{RieszInterpolationReal}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{RealAlgOrder}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{RieszInterpolationReal}^{\uparrow}}$ *row binding the interpolation packet.*

The classifier compares accepted packets only through $R, A, D, L, U, W, H, C, P, N$. It has no coordinate for host real order, trichotomy, quotient representatives, a selected order-completion element, countable choice, or ambient completeness of $\mathsf{Real}^{\uparrow}$.

Theorem 8894.2 (RieszInterpolationReal dyadic witness)**.** *For every accepted* $\mathsf{RieszInterpolationReal}^{\uparrow}$ *carrier*

$$I = (R, A, D, L, U, W, H, C, P, N),$$

every real-order interpolation consumer must read the finite route

$$R, A, D, L, U \longrightarrow W \longrightarrow H, C, P, N$$

before using the interpolant. The route supplies the four endpoint real seals, the RealAlgOrder comparison row, the shared dyadic comparison ledger, the lower-pair row, the upper-pair row, and the displayed witness row; it supplies no trichotomy branch, quotient equality of real names, selected representative, order-completion principle, countable-choice schedule, or ambient $\mathsf{Real}^{\uparrow}$ *completeness theorem.*

Proof. Project the accepted carrier of Definition 8894.1. Its analytic rows are exactly the Real seal row R, the RealAlgOrder row A, the dyadic comparison ledger D, the lower-pair row L, the upper-pair row U, and the interpolation witness row W.

The comparison premises are finite. The lower and upper rows are accepted only through the displayed RealAlgOrder comparisons and the dyadic ledger, so the request cannot switch to a host order relation or to a quotient equality of real names.

The witness row is read after those premises. Its four comparisons reuse the same A and D rows, and the structural rows H, C, P, N transport, replay, source, and name this same packet. Since none of the excluded order-completion or choice principles appears as a carrier coordinate, the listed route exhausts the consumer-facing witness surface. □

Theorem 8894.3 (RieszInterpolationReal ledger stability)**.** *Let $I = (R, A, D, L, U, W, H, C, P, N)$ be an accepted* $\mathsf{RieszInterpolationReal}^{\uparrow}$ *carrier. If a downstream* $\mathsf{RealAlgOrder}^{\uparrow}$ *consumer refines the dyadic tolerance rows inside the same ledger D while preserving the displayed lower-pair, upper-pair, and witness comparisons, then the accepted interpolation read still factors through*

$$R, A, D, L, U, W, H, C, P, N.$$

The refinement may narrow the comparison radii, but it cannot add a new host real-order coordinate, a trichotomy selector, quotient real equality, countable choice, a selected completion point, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start with the dyadic witness route of Definition 8894.2. It identifies the only rows available to any real-order interpolation consumer.

A refinement inside D changes only the displayed dyadic radius and slack entries carried by the same ledger. The lower-pair row L, upper-pair row U, and witness row W remain tied to the same Real seal R and RealAlgOrder row A.

Transport and replay are already recorded by H and C, while P and N keep the provenance and local naming fixed. Therefore the refined read is still the same finite NameCert route, with no additional analytic or choice-dependent coordinate. □

Falsifiable prediction: Every accepted $\mathsf{RieszInterpolationReal}^{\uparrow}$ witness read exposes the Real seal row, RealAlgOrder comparison row, dyadic comparison ledger, lower-pair row, upper-pair row, witness row, componentwise transport, displayed replay, provenance, and local NameCert row before using the interpolant.

Independence witness: real, real-alg-order, dyadicratcore: $\mathsf{RieszInterpolationReal}^{\uparrow}$ is not bijective to any listed sibling because it jointly binds four real endpoints, one witness real name, a RealAlgOrder comparison surface, a dyadic comparison ledger, lower and upper pair rows, transport, replay, provenance, and local naming in one packet.

Closure status for $\mathsf{NameCert}_{\mathsf{RieszInterpolationReal}^{\uparrow}}$.

Constructive story: A $\mathsf{RieszInterpolationReal}^{\uparrow}$ packet is generated from Real endpoint and witness seals, a RealAlgOrder comparison row, a DyadicRatCore comparison ledger, displayed lower and upper pairs, an interpolation witness row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RieszInterpolationReal}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8894.1, Definition 8894.2, and Definition 8894.3 seed the finite real-order interpolation witness route over displayed $\mathsf{Real}^{\uparrow}$, $\mathsf{RealAlgOrder}^{\uparrow}$, and $\mathsf{DyadicRatCore}^{\uparrow}$ rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RieszInterpolationReal}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close trichotomy, quotient real equality, selected representatives, order completion, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, Real seal exposure, RealAlgOrder comparison exactness, dyadic ledger stability, lower-pair and upper-pair display, witness display, transport, replay, provenance, and local naming for BEDC.Derived.RieszInterpolationRealUp.

Chapter 8895

A Concrete Naming Certificate for DyadicCoverModulus$^{\uparrow}$

Following Bishop and Bridges finite-cover arguments, the DyadicCoverModulus$^{\uparrow}$ packet records the mesh-control data used when a regular-Cauchy limit route must pass through finitely many dyadic cells. It concretizes the regular-Cauchy vision of section 9238.1 by naming the finite cover modulus that sits between the dyadic tolerance ledger of chapter 291, the regular-rational readback of chapter 301, the terminal real-name seal of chapter 38, the finite epsilon-net surface of chapter 1767, and the dyadic interval-net cells of chapter 5966. The packet exports only finite mesh coverage and modulus bookkeeping; it does not assert compactness of a host space, selected limits, quotient equality of real names, countable choice, or ambient Real$^{\uparrow}$ completeness.

Definition 8895.1 (Dyadic cover modulus carrier)**.** *A* DyadicCoverModulus$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (D, I, E, R, L, W, H, C, P, N)$$

with the following displayed rows:

1. *D is the* DyadicRatCore$^{\uparrow}$ *tolerance ledger, carrying dyadic radii, mesh widths, half-radius comparisons, and finite refinement requests.*
2. *I is the* DyadicIntervalNet$^{\uparrow}$ *cell row naming the finite dyadic interval cells inspected by the cover request.*
3. *E is the* FiniteEpsilonNet$^{\uparrow}$ *row that records the finite net points or cells at the requested tolerance.*
4. *R is the* RegSeqRat$^{\uparrow}$ *readback row whose regular-Cauchy windows are controlled by the displayed mesh.*
5. *L is the terminal* Real$^{\uparrow}$ *seal row, available only after the dyadic mesh and regular-rational readback have been exposed.*
6. *W is the cover-modulus row: for each requested dyadic tolerance it records the finite mesh level and cover cells sufficient for the regular-Cauchy read.*
7. *H records componentwise* hsame *transport for $D, I, E, R, L, W, C, P, N$.*
8. *C records displayed* Cont *replay of the same dyadic-cover route.*
9. *P is the* Pkg *provenance over* DyadicCoverModulus$^{\uparrow}$*,* DyadicRatCore$^{\uparrow}$*,* DyadicIntervalNet$^{\uparrow}$*,* FiniteEpsilonNet$^{\uparrow}$*,* RegSeqRat$^{\uparrow}$*,* Real$^{\uparrow}$*,* BHist*,* hsame*,* Cont*, and* NameCert*.*

10. N is the local $\mathsf{NameCert}_{\mathsf{DyadicCoverModulus}^{\uparrow}}$ *row.*
The classifier compares accepted carriers only through $D, I, E, R, L, W, H, C, P, N$. It has no coordinate for host compactness, selected limiting covers, quotient real equality, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 8895.2 (Dyadic cover modulus obligations)**.** *For every accepted* $\mathsf{DyadicCoverModulus}^{\uparrow}$ *carrier*

$$K = (D, I, E, R, L, W, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{DyadicCoverModulus}^{\uparrow}}$ *surface consists exactly of dyadic tolerance admission through D, dyadic interval-cell exposure through I, finite epsilon-net exposure through E, regular-rational readback through R, Real seal delivery through L, finite cover-modulus exactness through W, componentwise transport through H, displayed replay through C, provenance through P, and local naming through N.*

Proof. Project the carrier of Definition 8895.1. Its rows are exactly the dyadic tolerance ledger, interval-net cells, finite epsilon-net surface, regular-rational readback, Real seal, cover-modulus row, and structural naming rows.

The dyadic mesh is read before any regular-Cauchy consumer reaches the Real seal. The rows D, I, E expose the requested tolerance, the finite interval cells, and the finite net data.

The cover modulus is then the row W. It binds each tolerance request to a mesh level and a finite list of cover cells before R and L can be consumed.

Finally H, C, P, N transport, replay, source, and name the same finite route. Since none of the excluded host objects is a carrier coordinate, the listed rows exhaust the local NameCert surface. □

Theorem 8895.3 (Regular-Cauchy finite mesh control)**.** *Every regular-Cauchy limit consumer reading an accepted* $\mathsf{DyadicCoverModulus}^{\uparrow}$ *packet must pass through the finite route*

$$\mathsf{DyadicRatCore}^{\uparrow},\ \mathsf{DyadicIntervalNet}^{\uparrow},\ \mathsf{FiniteEpsilonNet}^{\uparrow},\ \mathsf{RegSeqRat}^{\uparrow},\ \mathsf{Real}^{\uparrow}$$

together with the cover-modulus, transport, replay, provenance, and local naming rows. The route supplies finite mesh control for the regular-Cauchy limit read and supplies no host compactness theorem, selected limit, quotient equality of real names, countable-choice schedule, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Use the NameCert obligations of Definition 8895.2. They force the dyadic tolerance ledger, interval-net row, finite epsilon-net row, and cover-modulus row to be exposed before the regular-rational readback or terminal Real seal is available.

The regular-Cauchy consumer therefore reads mesh control as finite data. A requested tolerance first opens D, then chooses the displayed cell level in I and finite cover in E, and only then reaches R and L.

The structural rows H, C, P, N preserve that route without adding a compactness theorem or a selected limiting object. Thus the packet realizes finite mesh control for the regular-Cauchy limit route and nothing stronger. □

Falsifiable prediction: Every accepted $\mathsf{DyadicCoverModulus}^{\uparrow}$ regular-Cauchy read exposes the DyadicRatCore tolerance ledger, DyadicIntervalNet cells, FiniteEpsilonNet row, cover-modulus row, RegSeqRat readback, Real seal, transport, replay, provenance, and local NameCert row before using finite mesh control.

Independence witness: dyadicratcore, dyadic-interval-net, finite-epsilon-net, regseqrat, real: $\mathsf{DyadicCoverModulus}^{\uparrow}$ is not bijective to any listed sibling because it jointly binds dyadic tolerances, interval cells, finite net data, a cover-modulus schedule, regular-rational readback, Real sealing, transport, replay, provenance, and local naming in one packet.

Closure status for $\mathsf{NameCert}_{\mathsf{DyadicCoverModulus}^{\uparrow}}$.

Constructive story: A $\mathsf{DyadicCoverModulus}^{\uparrow}$ packet is generated from a DyadicRatCore tolerance ledger, DyadicIntervalNet cell row, FiniteEpsilonNet row, RegSeqRat readback, RealUp seal, cover-modulus row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{DyadicCoverModulus}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8895.1, Definition 8895.2, and Definition 8895.3 seed the finite dyadic mesh-control route for regular-Cauchy limit consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{DyadicCoverModulus}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host compactness, selected limiting covers, selected real limits, quotient equality of real names, countable choice, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, dyadic tolerance admission, interval-net exposure, finite epsilon-net exposure, cover-modulus exactness, RegSeqRat readback, Real seal delivery, transport, replay, provenance, and local naming for BEDC.Derived.DyadicCoverModulusUp.

Chapter 8896

Diffeological Space NameCert Construction

Following Souriau and Iglesias-Zemmour, the $\mathsf{DiffeologicalSpace}^{\uparrow}$ packet reconstructs a diffeological-space interface as finite plot-observation data. The carrier records point rows, plot rows, domain-window rows, locality and gluing checks, pullback stability, transport, replay, provenance, and local naming; it gives topology and manifold consumers a visible smooth-space neighbour without quotienting all plots into a global smooth object.

The packet sits between the open-set reading of chapter 88, the chart-facing manifold surface of chapter 96, the stream-name interface of chapter 126, and the BHist and $\mathsf{NameCert}$ surfaces used throughout the concrete-instance ledger. It does not claim quotient smooth spaces, selected atlases, global colimits, or full manifold reconstruction.

Definition 8896.1 (Diffeological-space carrier)**.** *A* $\mathsf{DiffeologicalSpace}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$D = (X, P, U, L, G, S, T, R, Q, N)$$

with the following displayed rows:

1. *X is the point row, listing the observed points whose plot memberships are named by the packet.*
2. *P is the finite plot row, storing selected parameterized observations into X.*
3. *U is the domain-window row, recording the open-domain fragments on which the displayed plots are inspected.*
4. *L is the locality row, stating that plot admission is checked on the named domain windows.*
5. *G is the gluing row, recording compatible finite local plots before a glued plot is read.*
6. *S is the pullback-stability row, showing that a displayed smooth reparameterization keeps the read inside the same plot surface.*
7. *T records componentwise transports for point, plot, domain, locality, gluing, and pullback rows.*
8. *R is the replay ledger that exposes only X, P, U, L, G, S, T to downstream consumers.*
9. *Q is the* Pkg *provenance over* $\mathsf{DiffeologicalSpace}^{\uparrow}$*,* $\mathsf{Topology}^{\uparrow}$*,* $\mathsf{Manifold}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* BHist*, and* $\mathsf{NameCert}$*.*
10. *N is the local* $\mathsf{NameCert}_{\mathsf{DiffeologicalSpace}^{\uparrow}}$ *row.*

The carrier has no coordinate for quotient smooth-space construction, global colimits, selected atlases, full manifold reconstruction, or host smoothness semantics.

Theorem 8896.2 (Diffeological-space NameCert obligations)**.** *For an accepted* $\mathsf{DiffeologicalSpace}^{\uparrow}$ *carrier*

$$D = (X, P, U, L, G, S, T, R, Q, N),$$

the local $\mathsf{NameCert}_{\mathsf{DiffeologicalSpace}^{\uparrow}}$ *surface consists exactly of point-row admission, finite plot-row admission, domain-window visibility, locality checking, gluing checking, pullback stability, componentwise transport, replay exactness, provenance, and local naming. Every topology, manifold, or stream-name consumer of the packet must read the same rows before using a plot observation.*

Proof. Project the carrier in Definition 8896.1. The rows X, P, U give the observed points, the selected plots, and the domain windows on which those plots are inspected.

Next read the diffeological closure data. The locality row L keeps plot admission local to the displayed windows, the gluing row G records finite compatible local plots, and the pullback row S keeps smooth reparameterization inside the observed plot surface.

Transport and replay are then structural. The row T preserves each displayed coordinate componentwise, while R exposes only the finite plot-observation inventory to downstream reads.

Finally, provenance and naming are Q and N. Since no quotient smooth space, selected atlas, global colimit, full manifold reconstruction, or host smoothness object appears as a carrier coordinate, the listed rows exhaust the local NameCert obligations. □

Theorem 8896.3 (Diffeological-space plot-observation nonescape)**.** *Every public read exported from an accepted* $\mathsf{DiffeologicalSpace}^{\uparrow}$ *packet factors through* $X, P, U, L, G, S, T, R, Q, N$*. The read may be consumed by* $\mathsf{Topology}^{\uparrow}$*,* $\mathsf{Manifold}^{\uparrow}$*, and* $\mathsf{StreamName}^{\uparrow}$ *only as finite plot-observation data; it is not a quotient smooth space, a selected atlas, a global colimit, or a proof of full manifold reconstruction.*

Proof. Use the NameCert-obligation inventory of Definition 8896.2. It requires every accepted read to expose the point, plot, domain-window, locality, gluing, pullback, transport, replay, provenance, and naming rows.

The topology, manifold, and stream-name consumers therefore receive a finite observation interface. The packet can say which displayed plot rows are available and how they survive locality, gluing, and pullback checks.

No refused global object is present in the carrier. Hence quotient smooth spaces, selected atlases, global colimits, host smoothness semantics, and full manifold reconstruction cannot be extracted from the $\mathsf{DiffeologicalSpace}^{\uparrow}$ packet. □

Closure status for $\mathsf{NameCert}_{\mathsf{DiffeologicalSpace}^{\uparrow}}$**.**

Constructive story: A $\mathsf{DiffeologicalSpace}^{\uparrow}$ packet is generated from finite point, plot, domain-window, locality, gluing, pullback, transport, replay, provenance, and naming rows.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{DiffeologicalSpace}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8896.1, Definition 8896.2, and Definition 8896.3 bind the finite plot-observation seed surface.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{DiffeologicalSpace}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not construct quotient smooth spaces, selected atlases, global colimits, host smoothness semantics, or full manifold reconstruction.

Upgrade path: Obligation closure requires checked carrier admission, locality and gluing rows, pullback stability, replay exactness, provenance, and local naming for the same finite packet.

Chapter 8897

A Concrete Naming Certificate for LocatedDedekindCutCauchyBracket$^{\uparrow}$

Following Bishop and Bridges, the LocatedDedekindCutCauchyBracket$^{\uparrow}$ packet records the finite bridge by which a displayed regular Cauchy real name supplies lower and upper located Dedekind-cut brackets. It sits after the dyadic arithmetic source of chapter 291, the finite observation windows of chapter 126, the regular rational readback of chapter 301, the terminal real-name seal of chapter 38, and the cut surfaces of chapter 7256 and chapter 8086. The packet names a bracket display for downstream cut consumers; it is not a construction of Real$^{\uparrow}$ from Dedekind cuts, quotient equality of real names, trichotomy, countable choice, or ambient Real$^{\uparrow}$ completeness.

Definition 8897.1 (Located Dedekind cut Cauchy bracket carrier)**.** *A* LocatedDedekindCutCauchyBracket$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (D, W, R, E, L, U, H, C, P, N)$$

with the following displayed rows:

1. *D is the* DyadicRatCore$^{\uparrow}$ *window and tolerance ledger used to compare rational probes with the regular Cauchy source.*
2. *W is the* StreamName$^{\uparrow}$ *finite observation row that lists the inspected Cauchy windows.*
3. *R is the* RegSeqRat$^{\uparrow}$ *regular rational readback row accepted from the same windows and dyadic ledger.*
4. *E is the terminal* Real$^{\uparrow}$ *seal row for the named regular Cauchy real.*
5. *L is the lower located cut bracket row, consumed through* LocatedLowerCut$^{\uparrow}$ *and the lower side of* LocatedDedekindCut$^{\uparrow}$*.*
6. *U is the upper located cut bracket row, displaying the complementary upper tests attached to the same dyadic windows.*
7. *H records componentwise* hsame *transport for the dyadic ledger, stream windows, regular readback, Real seal, lower bracket, upper bracket, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from a cut-bracket request back through D, W, R, E, L, U, H.*
9. *P is the* Pkg *provenance over* LocatedDedekindCutCauchyBracket$^{\uparrow}$*,* DyadicRatCore$^{\uparrow}$*,* StreamName$^{\uparrow}$*,* RegSeqRat$^{\uparrow}$*,* Real$^{\uparrow}$*,* LocatedDedekindCut$^{\uparrow}$*,* LocatedLowerCut$^{\uparrow}$*,* BHist*,* hsame*,* Cont*, and* NameCert*.*

10. N is the local $\mathsf{NameCert}_{\mathsf{LocatedDedekindCutCauchyBracket}^{\uparrow}}$ *row.*
The classifier compares accepted packets only through $D, W, R, E, L, U, H, C, P, N$. It has no coordinate for constructing a Dedekind real quotient, identifying $\mathsf{Real}^{\uparrow}$ *with cut equality, choosing representatives, deciding trichotomy, or importing ambient completeness.*

Theorem 8897.2 (Located Dedekind cut Cauchy bracket)**.** *Every accepted regular Cauchy real name displayed by*

$$\mathsf{DyadicRatCore}^{\uparrow} \longmapsto \mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}$$

yields a $\mathsf{LocatedDedekindCutCauchyBracket}^{\uparrow}$ *packet whose lower row is a located lower cut bracket and whose upper row is the matching upper bracket over the same dyadic window data. The packet supplies displayed lower and upper located cut brackets for* $\mathsf{LocatedDedekindCut}^{\uparrow}$ *consumers, while making no claim that* $\mathsf{Real}^{\uparrow}$ *is constructed from Dedekind cuts and no claim of quotient equality between the regular Cauchy name and a Dedekind-cut real.*

Proof. Project the accepted regular Cauchy route. The dyadic ledger D, finite windows W, and regular rational readback R are displayed before the terminal $\mathsf{Real}^{\uparrow}$ seal E is available.

Build the lower bracket from the same data. A rational probe below the inspected Cauchy window is recorded in L through the $\mathsf{LocatedLowerCut}^{\uparrow}$ surface, and the locatedness row is attached to the same dyadic tolerance ledger rather than to a host order oracle.

Build the upper bracket in parallel. The upper tests in U use the same D, W, R, E route, so lower and upper bracket reads share one regular Cauchy source and one finite window schedule.

Finally attach transport, replay, provenance, and local naming through H, C, P, N. Since no carrier coordinate stores a Dedekind-real construction, quotient equality, trichotomy, countable choice, or ambient completeness, the accepted packet exports only the displayed lower and upper bracket rows. □

Theorem 8897.3 (Located Dedekind cut Cauchy bracket order refinement)**.** *For every accepted* $\mathsf{LocatedDedekindCutCauchyBracket}^{\uparrow}$ *carrier*

$$B = (D, W, R, E, L, U, H, C, P, N),$$

the lower and upper located cut rows exposed to an order-refinement consumer are read through the same $\mathsf{RegSeqRat}^{\uparrow}$ *readback and the same terminal* $\mathsf{Real}^{\uparrow}$ *seal. Thus any accepted comparison or refinement of the bracket route must pass through the* $\mathsf{DyadicRatCore}^{\uparrow}$ *arithmetic source D, finite* $\mathsf{StreamName}^{\uparrow}$ *windows W, the regular readback R, the lower row L, the upper row U, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and the local* $\mathsf{NameCert}_{\mathsf{LocatedDedekindCutCauchyBracket}^{\uparrow}}$ *row. The packet supplies no trichotomy row, no Dedekind-to-Cauchy reconstruction, and no quotient identification of cut equality with* $\mathsf{Real}^{\uparrow}$ *equality.*

Proof. Project the packet rows of Definition 8897.1. The lower bracket row L and upper bracket row U are stored next to the same dyadic ledger D, finite windows W, regular readback R, and real seal E.

Use the main bracket theorem, Definition 8897.2. It identifies both cut-facing rows as downstream of one displayed regular Cauchy route

$$\mathsf{DyadicRatCore}^{\uparrow} \longmapsto \mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}.$$

An order-refinement consumer can therefore compare only the lower and upper bracket rows already attached to that route. Transport through H, replay through C, provenance through P,

and local naming through N preserve the same displayed packet and add no classifier coordinate beyond D, W, R, E, L, U.

Since the carrier has no row for trichotomy, no Dedekind-to-Cauchy reconstruction, and no quotient identification between cut equality and $\mathsf{Real}^{\uparrow}$ equality, the refinement remains confined to the displayed lower and upper located cut rows. □

Falsifiable prediction: An accepted $\mathsf{LocatedDedekindCutCauchyBracket}^{\uparrow}$ consumer that reads a lower or upper cut bracket without displaying $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, transport, replay, provenance, and local $\mathsf{NameCert}$ rows refutes the carrier surface.

Independence witness: dyadicratcore, streamname, regseqrat, real, located-dedekind-cut, located-lower-cut: $\mathsf{LocatedDedekindCutCauchyBracket}^{\uparrow}$ is not bijective to any listed sibling because it jointly binds one regular Cauchy real route, one lower located cut bracket, one upper bracket, transport, replay, provenance, and local naming in a single finite bridge packet.

Closure status for $\mathsf{NameCert}_{\mathsf{LocatedDedekindCutCauchyBracket}^{\uparrow}}$.

Constructive story: A $\mathsf{LocatedDedekindCutCauchyBracket}^{\uparrow}$ packet is generated from DyadicRatCore tolerance data, StreamName finite windows, RegSeqRat readback, a RealUp seal, lower and upper located cut bracket rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{LocatedDedekindCutCauchyBracket}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8897.1 and Definition 8897.2 seed the finite bracket route from regular Cauchy real data to located lower and upper cut rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{LocatedDedekindCutCauchyBracket}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close Dedekind construction of RealUp, quotient equality, trichotomy, countable choice, ambient RealUp completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, dyadic tolerance exposure, finite window inspection, regular rational readback, Real seal nonescape, lower bracket locatedness, upper bracket locatedness, transport, replay, provenance, and local naming for BEDC.Derived.LocatedDedekindCutCauchyBracketUp.

Chapter 8898

A Concrete Naming Certificate for $\mathsf{FiniteDataAssembly}^{\uparrow}$

The $\mathsf{FiniteDataAssembly}^{\uparrow}$ packet realizes the finite data interface spine of chapter 9353 as a single NameCert assembly over the existing Boolean, option, sum, product, and list chapters. It consumes $\mathsf{Bool}^{\uparrow}$ from chapter 32, $\mathsf{Option}^{\uparrow}$ from chapter 33, $\mathsf{Sum}^{\uparrow}$ from chapter 35, $\mathsf{Prod}^{\uparrow}$ from chapter 34, and $\mathsf{List}^{\uparrow}$ from chapter 36. The packet names the finite constructor, eliminator, stability, and ledger rows shared by those interfaces; it is not a new kernel input, a host finite-set universe, quotient equality, or a choice principle.

Definition 8898.1 (Finite data assembly carrier)**.** *A* $\mathsf{FiniteDataAssembly}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$F = (B, O, S, Pd, L, K, E, T, C, Q, N)$$

with the following displayed rows:

1. *B is the* $\mathsf{Bool}^{\uparrow}$ *row exposing the two endpoint constructors and Boolean case analysis.*
2. *O is the* $\mathsf{Option}^{\uparrow}$ *row exposing absent and present branches.*
3. *S is the* $\mathsf{Sum}^{\uparrow}$ *row exposing left and right tagged injections.*
4. *Pd is the* $\mathsf{Prod}^{\uparrow}$ *row exposing paired component projections.*
5. *L is the* $\mathsf{List}^{\uparrow}$ *row exposing empty and cons constructors together with finite induction.*
6. *K is the shared constructor ledger, recording how the five interfaces build admitted histories from displayed rows.*
7. *E is the shared eliminator ledger, recording the allowed case-analysis, projection, and finite-induction reads.*
8. *T records classifier stability and componentwise* hsame *transport for all five finite-data interfaces.*
9. *C records displayed* Cont *replay from a finite-data request back through B, O, S, Pd, L, K, E, T.*
10. *Q is the* Pkg *provenance over* $\mathsf{FiniteDataAssembly}^{\uparrow}$, $\mathsf{Bool}^{\uparrow}$, $\mathsf{Option}^{\uparrow}$, $\mathsf{Sum}^{\uparrow}$, $\mathsf{Prod}^{\uparrow}$, $\mathsf{List}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{FiniteDataAssembly}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $B, O, S, Pd, L, K, E, T, C, Q, N$. It has no coordinate for a host finite-set universe, unbounded case split, quotient equality, choice-selected branch, or extra kernel primitive.

Theorem 8898.2 (Finite data assembly seed obligation)**.** *Every public finite-data read that uses the Bool, Option, Sum, Prod, and List interface layer factors through an accepted* $\mathsf{FiniteDataAssembly}^{\uparrow}$ *packet. The packet displays the five sibling rows*

$$\mathsf{Bool}^{\uparrow},\ \mathsf{Option}^{\uparrow},\ \mathsf{Sum}^{\uparrow},\ \mathsf{Prod}^{\uparrow},\ \mathsf{List}^{\uparrow}$$

together with shared constructor, eliminator, classifier-stability, transport, replay, provenance, and local naming rows before any finite-data consumer may use the interface layer as a single public surface.

Proof. Project the sibling rows. Boolean reads consume B, option reads consume O, sum reads consume S, product reads consume Pd, and list reads consume L; none of these rows is replaced by host finite data.

Read the shared constructor and eliminator ledgers. The constructor ledger K records how admitted histories are built, while the eliminator ledger E records the allowed case-analysis, projection, and finite-induction paths for the same displayed rows.

Apply classifier stability and transport through T. The five interfaces remain comparable only by their displayed classifiers and componentwise hsame routes.

Finally attach replay, provenance, and local naming through C, Q, N. The resulting assembly is a finite NameCert packet over existing sibling interfaces, so it supplies no host finite-set universe, quotient equality, unbounded branch selector, choice principle, or additional kernel input. □

Falsifiable prediction: An accepted $\mathsf{FiniteDataAssembly}^{\uparrow}$ consumer that uses the finite data layer without displaying Bool, Option, Sum, Prod, List, constructor, eliminator, stability, replay, provenance, and local NameCert rows refutes the assembly surface.

Independence witness: bool, option, sum, prod, list: $\mathsf{FiniteDataAssembly}^{\uparrow}$ is not bijective to any listed sibling because it jointly binds five finite-data interfaces, one constructor ledger, one eliminator ledger, shared stability, transport, replay, provenance, and local naming in a single assembly packet.

Closure status for $\mathsf{NameCert}_{\mathsf{FiniteDataAssembly}^{\uparrow}}$.

Constructive story: A $\mathsf{FiniteDataAssembly}^{\uparrow}$ packet is generated from Bool, Option, Sum, Prod, and List rows, shared constructor and eliminator ledgers, classifier stability, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{FiniteDataAssembly}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8898.1 and Definition 8898.2 seed the finite assembly NameCert route for the Bool/Option/Sum/Prod/List interface spine.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{FiniteDataAssembly}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close a host finite-set universe, quotient equality, unbounded branch selection, choice, extra kernel primitives, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, sibling row exposure, constructor ledger exactness, eliminator ledger exactness, classifier stability, transport, replay, provenance, and local naming for BEDC.Derived.FiniteDataAssemblyUp.

Chapter 8899

A Concrete Naming Certificate for $\mathsf{FiniteInterfaceSpine}^{\uparrow}$

The $\mathsf{FiniteInterfaceSpine}^{\uparrow}$ packet realizes the finite data layer of chapter 9353 as one L6 NameCert interface over the existing $\mathsf{Bool}^{\uparrow}$, $\mathsf{Option}^{\uparrow}$, $\mathsf{Sum}^{\uparrow}$, $\mathsf{Prod}^{\uparrow}$, and $\mathsf{List}^{\uparrow}$ rows. It reconstructs the ordinary finite-data toolkit as displayed BEDC certificate data rather than as kernel input: truth tags, nullable alternatives, disjoint branch tags, ordered pairs, and finite lists are all read through histories, history sameness, continuation replay, package provenance, gap discipline, and local naming. The packet sits after chapter 32, chapter 33, chapter 35, chapter 34, and chapter 36; it exports no host datatype primitive, unrestricted recursion scheme, quotient equality of finite objects, or hidden kernel constructor.

Definition 8899.1 (Finite interface spine carrier)**.** *A* $\mathsf{FiniteInterfaceSpine}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$F = (B, O, S, P, L, H, C, Q, N)$$

with the following displayed rows:

1. *B is the* $\mathsf{Bool}^{\uparrow}$ *endpoint row, naming the two visible truth tags.*
2. *O is the* $\mathsf{Option}^{\uparrow}$ *nullable row, naming absence and displayed presence over the admitted carrier.*
3. *S is the* $\mathsf{Sum}^{\uparrow}$ *branch row, naming left and right injections with their branch tags.*
4. *P is the* $\mathsf{Prod}^{\uparrow}$ *pair row, naming first and second projections as displayed components.*
5. *L is the* $\mathsf{List}^{\uparrow}$ *finite sequence row, naming nil, cons, length, and component readback ledgers.*
6. *H records componentwise* hsame *transport for all five finite-data rows and the structural rows.*
7. *C records displayed* Cont *replay from finite-data requests through B, O, S, P, L.*
8. *Q is the* Pkg *provenance over* $\mathsf{FiniteInterfaceSpine}^{\uparrow}$*,* $\mathsf{Bool}^{\uparrow}$*,* $\mathsf{Option}^{\uparrow}$*,* $\mathsf{Sum}^{\uparrow}$*,* $\mathsf{Prod}^{\uparrow}$*,* $\mathsf{List}^{\uparrow}$*,* BHist*,* hsame*,* Cont*, and* $\mathsf{NameCert}$*.*
9. *N is the local* $\mathsf{NameCert}_{\mathsf{FiniteInterfaceSpine}^{\uparrow}}$ *row.*

The carrier is an interface spine only. It has no coordinate for a host finite-type universe, an external eliminator, quotient equality of displayed finite objects, or a new BEDC kernel constructor.

Theorem 8899.2 (Finite interface spine NameCert obligations)**.** *For every accepted* $\mathsf{FiniteInterfaceSpine}^{\uparrow}$ *carrier $F = (B, O, S, P, L, H, C, Q, N)$, the local* $\mathsf{NameCert}_{\mathsf{FiniteInterfaceSpine}^{\uparrow}}$ *surface consists exactly*

of carrier admission for the displayed five finite-data rows, constructor exposure for the Boolean, option, sum, product, and list interfaces, componentwise hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming.*

Proof. Project the carrier of Definition 8899.1. The rows B, O, S, P, L are the only finite-data rows available to an accepted packet.

Each constructor surface is inherited from its displayed sibling row. Boolean reads use the endpoint row B; option reads use the absent-or-present row O; sum reads use the branch row S; product reads use the projection row P; and list reads use the nil, cons, length, and component ledgers in L.

The structural rows H, C, Q, N transport, replay, source, and name only those displayed rows. Since the carrier has no host finite-type universe, external eliminator, quotient equality, or kernel constructor coordinate, the listed rows exhaust the local NameCert obligations. □

Theorem 8899.3 (Finite interface spine L6 handoff)**.** *Every L6 consumer of* $\mathsf{Bool}^{\uparrow}$, $\mathsf{Option}^{\uparrow}$, $\mathsf{Sum}^{\uparrow}$, $\mathsf{Prod}^{\uparrow}$, *or* $\mathsf{List}^{\uparrow}$ *through a* $\mathsf{FiniteInterfaceSpine}^{\uparrow}$ *packet must display the finite route*

$$\mathsf{Bool}^{\uparrow}, \mathsf{Option}^{\uparrow}, \mathsf{Sum}^{\uparrow}, \mathsf{Prod}^{\uparrow}, \mathsf{List}^{\uparrow}, \mathsf{BHist}, \mathsf{hsame}, \mathsf{Cont}, \mathsf{Pkg}, \mathsf{NameCert} \longmapsto \mathsf{FiniteInterfaceSpine}^{\uparrow}.$$

The handoff exports the common finite-data interface packet and no host datatype primitive, hidden recursion principle, quotient equality, or kernel extension.

Proof. Start with the obligation surface of Definition 8899.2. It forces every consumer to read the five sibling finite-data rows before any common interface name is public.

The replay row C orders the route through the displayed Boolean, option, sum, product, and list certificates. The transport row H keeps the same five-row packet stable under hsame, while Q and N attach provenance and local naming.

Thus the L6 handoff is exactly the displayed finite-data packet. No additional coordinate can supply a host datatype primitive, hidden recursion principle, quotient equality, or kernel extension. □

Falsifiable prediction: Every accepted $\mathsf{FiniteInterfaceSpine}^{\uparrow}$ consumer displays BoolUp, OptionUp, SumUp, ProdUp, ListUp, hsame transport, Cont replay, Pkg provenance, and local NameCert rows before reading the common L6 finite-data interface.

Independence witness: bool, option, sum, prod, list: $\mathsf{FiniteInterfaceSpine}^{\uparrow}$ is not bijective to any listed sibling because it binds the five finite-data rows into one common L6 interface packet with shared transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{FiniteInterfaceSpine}^{\uparrow}}$.

Constructive story: A $\mathsf{FiniteInterfaceSpine}^{\uparrow}$ packet is generated from BoolUp endpoints, OptionUp nullable rows, SumUp branch tags, ProdUp projection rows, ListUp finite-sequence ledgers, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{FiniteInterfaceSpine}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8899.1, Definition 8899.2, and Definition 8899.3 seed the common L6 finite-data interface over BoolUp, OptionUp, SumUp, ProdUp, and ListUp rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{FiniteInterfaceSpine}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close Lean verification, bridge checking, unrestricted recursion, quotient equality of finite objects, host datatype primitives, or a new BEDC kernel constructor.

Upgrade path: Obligation closure requires checked carrier admission, constructor exposure, L6 handoff, transport, replay, provenance, and local naming for BEDC.Derived.FiniteInterfaceSpineUp.

Chapter 8900

A Concrete Naming Certificate for GrothendieckInequality$^{\uparrow}$

Following Grothendieck's inequality and Pisier's Banach-space formulation, the GrothendieckInequality$^{\uparrow}$ packet records the finite BEDC surface by which a displayed bilinear matrix estimate is routed through Banach, tensor, norm, real, and bounded-operator rows. It sits over the Banach source of chapter 90, the algebraic tensor surface of chapter 87, the bounded-operator interface of chapter 1644, the norm row of chapter 89, and the terminal scalar seal of chapter 38. The packet names a displayed inequality ledger only; it does not import the analytic proof of Grothendieck's theorem, a host supremum over all sign choices, selected optimizers, quotient tensor norms, or a global Banach-space completion principle.

Definition 8900.1 (Grothendieck inequality carrier)**.** *A* GrothendieckInequality$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$G = (E, F, T, O, A, B, K, H, C, P, N)$$

with the following visible rows:

1. *E and F are displayed* Banach$^{\uparrow}$ *source rows with their* Norm$^{\uparrow}$ *scalar-bound interfaces.*
2. *T is the* TensorProduct$^{\uparrow}$ *row naming the finite tensor table on which the bilinear estimate is read.*
3. *O is the* BoundedLinearOperator$^{\uparrow}$ *handoff row for the associated operator or bilinear form.*
4. *A is the finite coefficient ledger, listing the matrix entries, sign or vector probes, and their displayed norm bounds.*
5. *B is the scalar inequality ledger over* Real$^{\uparrow}$*, recording the two compared finite bounds and the displayed constant row K.*
6. *K is the Grothendieck-constant boundary row; it is a named scalar bound read through* Real$^{\uparrow}$*, not a selected optimal constant.*
7. *H records componentwise* hsame *transport for source rows, tensor rows, operator rows, coefficient ledgers, scalar inequality rows, constant rows, replay data, provenance, and local naming.*
8. *C records displayed* Cont *replay from a bilinear-estimate request through E, F, T, O, A, B, K.*
9. *P is the* Pkg *provenance over* GrothendieckInequality$^{\uparrow}$*,* Banach$^{\uparrow}$*,* TensorProduct$^{\uparrow}$*,* BoundedLinearOperator$^{\uparrow}$*,* Norm$^{\uparrow}$*,* Real$^{\uparrow}$*,* BHist*,* hsame*,* Cont*, and* NameCert*.*

10. N is the local $\mathsf{NameCert}_{\mathsf{GrothendieckInequality}^{\uparrow}}$ *row.*
The carrier exports only this finite inequality ledger. It has no coordinate for an ambient proof of the classical theorem, a universal supremum, a selected optimizer, quotient tensor-norm equality, or an unrestricted Banach completion.

Theorem 8900.2 (Grothendieck inequality NameCert obligations)**.** *For every accepted* $\mathsf{GrothendieckInequality}^{\uparrow}$ *carrier* $G = (E, F, T, O, A, B, K, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{GrothendieckInequality}^{\uparrow}}$ *surface consists exactly of Banach source exposure, tensor-table exposure, bounded-operator handoff, finite coefficient-ledger admission, scalar inequality readback through* $\mathsf{Norm}^{\uparrow}$ *and* $\mathsf{Real}^{\uparrow}$*, Grothendieck-constant boundary exposure, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming.*

Proof. Project the carrier of Definition 8900.1. The source rows E, F, tensor row T, bounded-operator row O, coefficient ledger A, scalar inequality ledger B, and constant boundary K are the only analytic-facing rows available.

The inequality read is finite. It compares the displayed matrix or bilinear table in A with scalar bounds read through the source norm rows and the terminal $\mathsf{Real}^{\uparrow}$ ledger B, K.

Finally H, C, P, N transport, replay, source, and name the same packet. Since no carrier coordinate stores a host theorem proof, universal supremum, selected optimizer, quotient tensor norm, or unrestricted completion, the listed rows exhaust the local NameCert surface. □

Theorem 8900.3 (Grothendieck inequality tensor-norm handoff)**.** *Every tensor-norm or operator-ideal consumer of an accepted* $\mathsf{GrothendieckInequality}^{\uparrow}$ *packet must read the finite route*

$$\mathsf{Banach}^{\uparrow}, \mathsf{TensorProduct}^{\uparrow}, \mathsf{BoundedLinearOperator}^{\uparrow}, \mathsf{Norm}^{\uparrow}, \mathsf{Real}^{\uparrow} \longmapsto E, F, T, O, A, B, K, H, C, P, N.$$

The handoff supplies the displayed coefficient ledger, scalar inequality ledger, and constant boundary as reusable finite data; it does not supply a completed tensor norm, an optimal-factorization theorem, quotient equality of operators, or host-level compactness.

Proof. Start with the obligation surface of Definition 8900.2. It forces the consumer to expose Banach endpoints, tensor data, bounded-operator handoff, coefficient entries, scalar bounds, and the constant boundary before the inequality row is public.

The tensor-norm consumer reads only the route through T, A, B, K. The bounded-operator consumer reads only the route through O, A, B, K. In both cases the norm and scalar comparisons remain displayed rows, not ambient supremum calculations.

Transport, replay, provenance, and naming then keep the same route attached to H, C, P, N. Because the packet lacks coordinates for completion, optimal factorization, quotient operator equality, and host compactness, the handoff exports only the finite inequality ledger. □

Falsifiable prediction: Every accepted $\mathsf{GrothendieckInequality}^{\uparrow}$ consumer displays Banach endpoints, TensorProductUp data, BoundedLinearOperatorUp handoff, NormUp scalar rows, RealUp bound rows, hsame transport, Cont replay, Pkg provenance, and local NameCert rows before using the inequality ledger.

Independence witness: banach, tensorproduct, boundedlinearoperator, norm, real: $\mathsf{GrothendieckInequality}^{\uparrow}$ is not bijective to any listed sibling because it binds coefficient tables, bilinear or operator handoff, scalar inequality ledgers, Grothendieck-constant boundary, transport, replay, provenance, and local naming into one finite estimate packet.

Closure status for $\mathsf{NameCert}_{\mathsf{GrothendieckInequality}^{\uparrow}}$.

Constructive story: A GrothendieckInequality$^{\uparrow}$ packet is generated from Banach endpoint rows, TensorProductUp finite tensor tables, BoundedLinearOperatorUp handoff rows, coefficient ledgers, NormUp and RealUp scalar inequality rows, a Grothendieck-constant boundary, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\text{GrothendieckInequality}^{\uparrow}}$, seed)

Scope closed: Definition 8900.1, Definition 8900.2, and Definition 8900.3 seed the finite Grothendieck inequality ledger over Banach, tensor-product, bounded-operator, norm, and real rows.

Formal verification: FormalStatus(NameCert$_{\text{GrothendieckInequality}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close Lean verification, bridge checking, the analytic proof of Grothendieck's theorem, optimal constants, quotient tensor norms, selected optimizers, or unrestricted Banach completion.

Upgrade path: Obligation closure requires checked carrier admission, tensor-table exposure, bounded-operator handoff, scalar inequality readback, constant-boundary exposure, transport, replay, provenance, and local naming for BEDC.Derived.GrothendieckInequalityUp.

Chapter 8901

A Concrete Naming Certificate for $\mathsf{ParticularPointTopology}^{\uparrow}$

Following Alexandrov and standard finite-topology examples, the $\mathsf{ParticularPointTopology}^{\uparrow}$ packet records the included-point topology on a finite displayed carrier as BEDC NameCert data. It sits after the topology carrier of chapter 88, the two-point truth classifier of chapter 1860, and the separation boundary of chapter 3338. The packet names a distinguished point, the open-set classifier that accepts exactly the empty set and the displayed subsets containing that point, and the finite boundary where specialization may fail.

Definition 8901.1 (Particular point topology carrier)**.** *A* $\mathsf{ParticularPointTopology}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$X = (p, O, S, T, H, C, P, N)$$

with the following displayed rows:

1. *p is the distinguished point row on the finite carrier.*
2. *O is the open classifier row, accepting the empty displayed subset and every displayed subset whose membership row contains p.*
3. *S is the Sierpinski truth handoff row that reads membership in a particular-point open as a two-point truth observation.*
4. *T is the T_0-boundary row, recording which displayed point pairs are separated by the particular-point classifier and which pairs remain specialization-indistinguishable.*
5. *H records componentwise* hsame *transport for the distinguished point, open classifier, Sierpinski handoff, separation boundary, provenance, and naming rows.*
6. *C records displayed* Cont *replay through topology, Sierpinski truth, and T_0-reflection consumers.*
7. *P is the* Pkg *provenance over* $\mathsf{ParticularPointTopology}^{\uparrow}$, $\mathsf{Topology}^{\uparrow}$, $\mathsf{SierpinskiSpace}^{\uparrow}$, $\mathsf{TZeroReflection}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
8. *N is the local* $\mathsf{NameCert}_{\mathsf{ParticularPointTopology}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through p, O, S, T, H, C, P, N. It has no coordinate for host powersets, arbitrary union closure, quotient equality of opens, selected specialization classes, or completed separation reflection.

Theorem 8901.2 (Particular point topology NameCert obligations)**.** *For every accepted* $\mathsf{ParticularPointTopology}^{\uparrow}$ *carrier*

$$X = (p, O, S, T, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{ParticularPointTopology}^{\uparrow}}$ *surface consists exactly of distinguished-point admission, open-classifier exposure through* O*, Sierpinski truth handoff through* S*,* T_0*-boundary exposure through* T*, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming.*

Proof. Project the carrier of Definition 8901.1. The distinguished point row, open classifier row, Sierpinski handoff, separation boundary, transport, replay, provenance, and local name are all visible coordinates of one finite packet.

The topology-facing obligation reads O only as a displayed classifier over finite subsets. The accepted open rows are the empty subset row and the rows that contain p, so no host powerset or arbitrary-union theorem is imported.

The truth and separation obligations are then read through S and T. Transport, replay, provenance, and local naming preserve the same finite rows and do not add quotient equality of opens or completed reflection data. □

Theorem 8901.3 (Particular point topology Sierpinski handoff)**.** *Every accepted* $\mathsf{ParticularPointTopology}^{\uparrow}$ *open-membership read factors through the Sierpinski truth row* S *before a topology consumer may use it as a classifier. The handoff reads the sibling* $\mathsf{SierpinskiSpace}^{\uparrow}$ *surface of chapter 1860 and returns only displayed truth data for the finite open row* O*.*

Proof. Start from the open classifier row O. A displayed subset is accepted as open either because it is the empty row or because its membership row contains the distinguished point p.

The row S repacks that membership test as a Sierpinski truth observation. Since S is a carrier row, the handoff is finite and visible rather than a host characteristic-function theorem.

Transport and replay through H, C keep the read attached to the same finite classifier. Thus topology consumers receive only the displayed truth handoff and cannot infer host powerset extensionality or arbitrary open-set equality. □

Theorem 8901.4 (Particular point topology T0 boundary)**.** *Every* T_0*-facing read of an accepted* $\mathsf{ParticularPointTopology}^{\uparrow}$ *packet must expose the boundary row* T *before it reaches chapter 3338. The row records the finite point pairs separated by opens containing* p *and the pairs that remain indistinguishable by the displayed classifier.*

Proof. Project the rows p, O, T from the carrier. Separation information is not stored as a global theorem about all opens; it is the displayed finite ledger T attached to the particular-point classifier.

The topology and Sierpinski rows supply the inspected opens and truth observations. The T_0-boundary row records which point pairs those displayed observations separate.

Finally H, C, P, N transport, replay, source, and name only that ledger. A T_0 consumer may use the boundary row as input to reflection, but the packet does not export completed reflection, quotient specialization classes, or ambient topological separation. □

Closure status for $\mathsf{NameCert}_{\mathsf{ParticularPointTopology}^{\uparrow}}$**.**

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{ParticularPointTopology}^{\uparrow}}$, seed)

Scope closed: Definition 8901.1, Definition 8901.2, Definition 8901.3, and Definition 8901.4 seed the finite distinguished-point topology, truth-handoff, and separation-boundary surface.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{ParticularPointTopology}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close host powerset topology, arbitrary union closure, quotient equality of opens, selected specialization classes, completed T_0 reflection, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, open-classifier exactness, Sierpinski handoff, T_0 boundary replay, transport, provenance, and local naming for BEDC.Derived.ParticularPointTopologyUp.

Constructive story: A ParticularPointTopology$^{\uparrow}$ packet is generated from a distinguished point row, finite open classifier row, Sierpinski truth handoff, T_0 boundary row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 8902

A Concrete Naming Certificate for $\mathsf{CompactUniformModulusNerve}^{\uparrow}$

Following Heine–Cantor and Bishop compactness machinery, the $\mathsf{CompactUniformModulusNerve}^{\uparrow}$ packet records the finite nerve route by which compact finite covers, local continuity moduli, rational lower-bound folds, and a $\mathsf{UniformModulus}^{\uparrow}$ handoff are read as one NameCert object. It realizes the finite-cover branch of chapter 9237 and sits beside the finite cover nerve of chapter 7597, the compact metric source of chapter 129, the continuous-map surface of chapter 130, the rational comparison row of chapter 37, and the downstream uniform-modulus consumer of chapter 369.

Definition 8902.1 (Compact uniform modulus nerve carrier)**.** *A* $\mathsf{CompactUniformModulusNerve}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M = (K, F, L, R, B, U, H, C, P, N)$$

with the following displayed rows:

1. *K is the* $\mathsf{CompactMetric}^{\uparrow}$ *finite-cover source row, displaying the inspected* $\mathsf{ProbeBundle}$ *centers and cover-radius histories.*
2. *F is the finite nerve row, recording cover membership, overlap compatibility, and the accepted finite faces used by the modulus extraction.*
3. *L is the local-modulus row read from the* $\mathsf{ContinuousMap}^{\uparrow}$ *surface, assigning displayed source neighborhoods to displayed target tolerances.*
4. *R is the* $\mathsf{Rat}^{\uparrow}$ *lower-bound comparison row for the cover radii and local modulus radii.*
5. *B is the finite rational-fold row that computes the uniform positive lower-bound ledger.*
6. *U is the* $\mathsf{UniformModulus}^{\uparrow}$ *handoff row consumed after K, F, L, R, B have been displayed.*
7. *H records componentwise* hsame *transport for cover, nerve, local-modulus, rational-fold, handoff, provenance, and naming rows.*
8. *C records displayed* Cont *replay through finite covers, nerve faces, local moduli, rational folds, and uniform-modulus handoff.*
9. *P is the* Pkg *provenance over* $\mathsf{CompactUniformModulusNerve}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{FiniteCoverNerve}^{\uparrow}$, $\mathsf{Rat}^{\uparrow}$, $\mathsf{UniformModulus}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{CompactUniformModulusNerve}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $K, F, L, R, B, U, H, C, P, N$. It has no coordinate for arbitrary open-cover compactness, selected subcovers, host function equality, countable choice, quotient equality of covers, or ambient real completeness.

Theorem 8902.2 (Compact uniform modulus nerve NameCert obligations)**.** *For every accepted* $\mathsf{CompactUniformModulusNerve}^{\uparrow}$ *carrier*

$$M = (K, F, L, R, B, U, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{CompactUniformModulusNerve}^{\uparrow}}$ *surface consists exactly of compact finite-cover exposure through K, finite nerve exposure through F, local-modulus exposure through L, rational comparison through R, finite lower-bound folding through B, uniform-modulus handoff through U, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming.*

Proof. Project the carrier of Definition 8902.1. The compact-cover, nerve, local-modulus, rational-fold, uniform-modulus, transport, replay, provenance, and naming rows are the complete inventory of the packet.

The cover and nerve obligations are read through K, F. These rows expose finite ProbeBundle data and accepted faces, not an arbitrary open cover or selected subcover.

The modulus obligations are read through L, R, B, U. Local continuity data is displayed before the rational lower-bound fold, and the uniform-modulus handoff is downstream of that fold.

Finally H, C, P, N preserve and name only these rows. No host function equality, countable choice principle, quotient cover equality, or ambient completeness theorem is exported. □

Theorem 8902.3 (Compact uniform modulus nerve vision handoff)**.** *The compact finite-cover, local-modulus,* $\mathsf{Rat}^{\uparrow}$ *lower-bound fold, and* $\mathsf{UniformModulus}^{\uparrow}$ *handoff route of chapter 9237 is realized by an accepted* $\mathsf{CompactUniformModulusNerve}^{\uparrow}$ *carrier as the finite row sequence*

$$K, F, L, R, B \longmapsto U, H, C, P, N.$$

The handoff is a concrete NameCert packet and not an external Heine–Cantor theorem.

Proof. Read the vision chapter through its finite-cover branch. The compact ProbeBundle and cover-radius histories land in K, and the finite nerve membership and overlap checks land in F.

The local continuity witnesses land in L. Their radii are compared through R and folded by B before any uniform-modulus row is exposed.

The row U is therefore downstream of finite cover, nerve, local-modulus, and rational-fold data. Transport, replay, provenance, and local naming keep the handoff inside the same packet, so the construction does not invoke an external compactness theorem or selector. □

Theorem 8902.4 (Compact uniform modulus nerve no-choice boundary)**.** *Every accepted* CompactUniformModulus *read keeps the finite nerve and rational lower-bound fold visible before the* $\mathsf{UniformModulus}^{\uparrow}$ *handoff. Consequently the packet exports no arbitrary open-cover compactness principle, selected subcover, countable choice functional, quotient equality of covers, host function equality, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness claim.*

Proof. Start from the carrier rows $K, F, L, R, B, U, H, C, P, N$. The only route to U passes through the finite cover row, nerve row, local-modulus row, rational comparison row, and finite fold row.

The sibling finite cover nerve chapter supplies a displayed cover-nerve route, while the compact metric, continuous-map, rational, and uniform-modulus chapters supply the rows consumed by the packet. None of these rows is a choice functional or host equality principle.

Since transport and replay preserve only the displayed carrier coordinates, a consumer cannot bypass F, R, B to obtain a modulus from an external compactness theorem. The refused choice, quotient, host-function, and completeness claims remain outside the packet. □

Closure status for $\mathsf{NameCert}_{\mathsf{CompactUniformModulusNerve}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CompactUniformModulusNerve}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8902.1, Definition 8902.2, Definition 8902.3, and Definition 8902.4 seed the finite cover-nerve, local-modulus, rational-fold, and uniform-modulus handoff surface.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CompactUniformModulusNerve}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close arbitrary open-cover compactness, selected subcovers, countable choice, quotient cover equality, host function equality, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, finite nerve exactness, local-modulus replay, rational-fold stability, uniform-modulus handoff, and no-choice boundary proofs for BEDC.Derived.CompactUniformModulusNerveUp.

Constructive story: A $\mathsf{CompactUniformModulusNerve}^{\uparrow}$ packet is generated from CompactMetric finite-cover rows, finite nerve rows, ContinuousMap local-modulus rows, Rat lower-bound comparison rows, rational-fold rows, UniformModulus handoff rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 8903

A Concrete Naming Certificate for $\mathsf{Hypercover}^{\uparrow}$

Following Grothendieck and Verdier on hypercovers, the $\mathsf{Hypercover}^{\uparrow}$ packet records the finite BEDC surface by which a displayed Grothendieck topology is refined into a simplicial cover diagram and then consumed by sheaf-descent data. It sits after the site carrier of chapter 6718, the cover-to-simplicial inventory of chapter 6755, the sheaf-facing refinement route of chapter 7336, and the cocycle-effectivity surface of chapter 8142. The packet names levelwise cover rows, matching-object comparison rows, Cech truncation rows, descent handoff rows, transport, replay, provenance, and local naming; it is not a host simplicial presheaf, a selected coskeleton, a model-structure fibrancy theorem, a quotient stack, or global choice of refinements.

Definition 8903.1 (Hypercover carrier)**.** *A* $\mathsf{Hypercover}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$H = (J, U, M, C, S, D, T, R, P, N)$$

with the following displayed rows:

1. *J is the* $\mathsf{GrothendieckTopology}^{\uparrow}$ *site row, carrying the covering-sieve, pullback-stability, and transitivity data over which all levels are read.*
2. *U is the levelwise cover row, listing the displayed cover data for each finite simplicial level used by the packet.*
3. *M is the matching-object comparison row, recording the finite boundary request that each level must cover before the next level is public.*
4. *C is the* $\mathsf{CechNerve}^{\uparrow}$ *truncation row, identifying the ordinary cover nerve recovered at the initial levels.*
5. *S is the* $\mathsf{Sheafification}^{\uparrow}$ *compatibility row, requiring locality and gluing reads to remain attached to the same site and levelwise cover data.*
6. *D is the* $\mathsf{DescentData}^{\uparrow}$ *handoff row, exposing cocycle and effectivity requests only after the levelwise and matching rows have been displayed.*
7. *T records componentwise* hsame *transport for the site, levelwise cover, matching-object, Cech, sheafification, descent, replay, provenance, and local naming rows.*
8. *R records displayed* Cont *replay from a sheaf-descent request through J, U, M, C, S, D, T.*

9. *P is the* Pkg *provenance over* $\mathsf{Hypercover}^{\uparrow}$, $\mathsf{GrothendieckTopology}^{\uparrow}$, $\mathsf{CechNerve}^{\uparrow}$, $\mathsf{Sheafification}^{\uparrow}$, $\mathsf{DescentData}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

10. *N is the local* $\mathsf{NameCert}_{\mathsf{Hypercover}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $J, U, M, C, S, D, T, R, P, N$. It has no coordinate for host simplicial presheaves, selected coskeleta, model structures, quotient stacks, global refinement choice, ambient sheaf equality, or bridge credentials.

Lean4 ✓ `BEDC.Derived.HypercoverUp.HypercoverTasteGate single carrier alignment`

Theorem 8903.2 (Hypercover NameCert obligations)**.** *For every accepted* $\mathsf{Hypercover}^{\uparrow}$ *carrier $H = (J, U, M, C, S, D, T, R, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{Hypercover}^{\uparrow}}$ *surface consists exactly of site exposure through J, levelwise cover admission through U, matching-object comparison through M, Cech truncation through C, sheafification compatibility through S, descent handoff through D, componentwise transport through T, displayed replay through R, provenance through P, and local naming through N.*

Lean4 ✓ `BEDC.Derived.HypercoverUp.HypercoverNameCertObligations`

Proof. Project the carrier of Definition 8903.1. The site, levelwise cover, matching-object, Cech, sheafification, and descent rows are exactly J, U, M, C, S, D.

The site row is read first. It supplies the covering-sieve and pullback-stability data that make every finite levelwise cover meaningful inside the same $\mathsf{GrothendieckTopology}^{\uparrow}$ packet.

The levelwise and matching rows then control the simplicial cover request. The row U displays the cover data at each finite level, while M records the boundary or matching comparison that must be covered before a higher-level read is exported.

Finally T, R, P, N transport, replay, source, and name the same finite packet. Since the carrier contains no coordinate for a host simplicial presheaf, selected coskeleton, model structure, quotient stack, global refinement choice, ambient sheaf equality, or bridge credential, the listed rows exhaust the local NameCert obligations. □

Lean4 ✓ `BEDC.Derived.HypercoverUp.HypercoverCarrier namecert obligations`

Theorem 8903.3 (Hypercover Cech nerve route)**.** *Every accepted* $\mathsf{Hypercover}^{\uparrow}$ *packet exposes its* $\mathsf{CechNerve}^{\uparrow}$ *row before any sheaf-descent consumer may read a higher matching level. The route from an ordinary covering family to a hypercover factors through J, U, M, C, T, R, P, N, so the initial Cech data remain visible while the packet adds levelwise matching coverage.*

Proof. Start with the carrier of Definition 8903.1. The Cech truncation row C is a displayed coordinate, not a derived host object.

Read the ordinary cover surface through chapter 6755. Its cover-member, intersection-witness, nerve-face, stability, replay, provenance, and local naming rows supply the initial finite simplicial data consumed by C.

Now expose U and M. They extend the initial Cech route level by level, but every matching comparison still reads the same site row J and the same Cech truncation row C before a higher-level cover is public.

The rows T, R, P, N preserve this route componentwise. Therefore the hypercover packet refines the Cech nerve surface without exporting selected intersection points, host realizations, quotient simplicial equality, or ambient homology data. □

Lean4 ✓ `BEDC.Derived.HypercoverUp.HypercoverCechNerveRoute`

Theorem 8903.4 (Hypercover sheaf descent handoff)**.** *Every sheaf-facing read of an accepted* $\mathsf{Hypercover}^{\uparrow}$ *carrier must expose the* $\mathsf{GrothendieckTopology}^{\uparrow}$ *site row, the* $\mathsf{Sheafification}^{\uparrow}$ *compatibility row, and the* $\mathsf{DescentData}^{\uparrow}$ *handoff row before consuming descent information. The exported route is*

$$\mathsf{GrothendieckTopology}^{\uparrow} \longmapsto \mathsf{CechNerve}^{\uparrow} \longmapsto \mathsf{Sheafification}^{\uparrow} \longmapsto \mathsf{DescentData}^{\uparrow}$$

together with $J, U, M, C, S, D, T, R, P, N$*.*

Proof. Apply the NameCert obligation surface of Definition 8903.2. It places J, U, M, C, S, D before replay, provenance, and local naming.

The sheafification row S reads locality and gluing only over the displayed site and levelwise cover rows. Thus a sheaf consumer cannot bypass J, U, M, C to obtain an external reflector or quotient of compatible families.

The descent row D is downstream of S. It exposes cocycle and effectivity requests after the levelwise matching route is visible, so descent data remain a finite handoff rather than a host quotient stack or selected global gluing.

Finally T, R, P, N preserve the same route. The displayed chain through $\mathsf{GrothendieckTopology}^{\uparrow}$, $\mathsf{CechNerve}^{\uparrow}$, $\mathsf{Sheafification}^{\uparrow}$, and $\mathsf{DescentData}^{\uparrow}$ is therefore the whole sheaf-descent handoff carried by $\mathsf{Hypercover}^{\uparrow}$. □

Lean4 ✓ `BEDC.Derived.HypercoverUp.HypercoverCarrier sheaf descent handoff`

Theorem 8903.5 (Hypercover covering-family nonescape)**.** *No accepted* $\mathsf{Hypercover}^{\uparrow}$ *read can export a covering family without also displaying the source site row* J*, the levelwise cover row* U*, the matching-object row* M*, the Cech row* C*, the sheafification row* S*, the descent row* D*, transport* T*, replay* R*, provenance* P*, and local naming* N*. In particular, hypercover consumers obtain no selected refinement schedule, host simplicial presheaf, coskeleton operator, quotient stack, ambient sheaf equality, or global cover choice from the packet.*

Lean4 ✓ `BEDC.Derived.HypercoverUp.HypercoverCarrier covering family nonescape`

Proof. Project the carrier and read the classifier coordinates. Covering-family information appears only in J, U, M, C, S, D and is preserved only by T, R, P, N.

Suppose a consumer reaches a displayed covering family. The site row J provides the ambient coverage discipline, U provides the finite levelwise cover, and M records the matching comparison that justifies the level. The Cech row C keeps the initial cover nerve visible.

For sheaf or descent reads, S and D must also be exposed. They route locality, gluing, cocycle, and effectivity through the same finite levelwise data rather than through a selected external construction.

Since the excluded objects are not carrier coordinates, componentwise transport, replay, provenance, and local naming cannot create them. Thus every covering-family read remains inside the displayed hypercover packet. □

Falsifiable prediction: An accepted $\mathsf{Hypercover}^{\uparrow}$ consumer that reads descent along a hypercover without displaying the Grothendieck topology, Cech nerve, sheafification, descent-data, transport, replay, provenance, and local NameCert rows refutes the carrier surface.

Independence witness: grothendieck topology, cech nerve, sheafification, descent data: $\mathsf{Hypercover}^{\uparrow}$ is not bijective to any listed sibling because it binds levelwise cover rows and matching-object comparisons between the site, Cech truncation, sheafification compatibility, descent handoff, transport, replay, provenance, and local naming rows.

Closure status for $\mathsf{NameCert}_{\mathsf{Hypercover}^{\uparrow}}$.

Constructive story: A $\mathsf{Hypercover}^{\uparrow}$ packet is generated from a GrothendieckTopologyUp site row, levelwise cover rows, matching-object comparison rows, a CechNerveUp truncation row, a SheafificationUp compatibility row, a DescentDataUp handoff row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{Hypercover}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8903.1, Definition 8903.2, Definition 8903.3, Definition 8903.4, and Definition 8903.5 seed the finite hypercover route from site coverage through Cech truncation to sheaf-descent consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{Hypercover}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host simplicial presheaves, selected coskeleta, model-structure fibrancy, quotient stacks, selected refinement schedules, global cover choice, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, levelwise cover exposure, matching-object comparison, Cech nerve routing, sheafification compatibility, descent handoff, transport, replay, provenance, and local naming for BEDC.Derived.HypercoverUp.

Chapter 8904

A Concrete Naming Certificate for $\mathsf{Preuniformity}^{\uparrow}$

Following Bourbaki and Kelley on uniform structures and preuniform spaces, the $\mathsf{Preuniformity}^{\uparrow}$ packet records the finite entourage-base surface that sits between topology, metric data, and uniform completion. It is read beside the uniform-space certificate of chapter 339, the metric carrier of chapter 57, the topology carrier of chapter 88, the finite observation discipline of chapter 126, and the terminal real-name seal of chapter 38. The packet names a non-symmetric uniformity-like carrier before a separated or symmetric uniform-space object is available.

Falsifiable prediction: Every accepted $\mathsf{Preuniformity}^{\uparrow}$ packet displays source, entourage, stability, base, transport, replay, provenance, and local naming rows before a UniformSpaceUp or UniformCompletionUp consumer may read it.

Independence witness: topology, metric, uniformspace, streamname, real: no listed sibling is bijective to $\mathsf{Preuniformity}^{\uparrow}$. Topology records open-neighbourhood data without an entourage base; metric supplies symmetric distance rows; UniformSpaceUp already enforces the uniform-space surface; StreamNameUp records finite schedules; RealUp seals scalar names. The preuniform packet preserves the directed entourage route separately.

Definition 8904.1 (Preuniformity carrier)**.** *A* $\mathsf{Preuniformity}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$U = (S, E, B, T, H, C, P, N)$$

with the following displayed rows:

1. *S is the source-row carrier whose points, observations, or names are being compared;*
2. *E is a finite entourage ledger, recording displayed binary-neighbourhood rows without imposing symmetry;*
3. *B is the finite filter-base ledger, recording upward closure and finite-intersection refinements for displayed entourage rows;*
4. *T is the topology-readback row, recording the neighbourhoods induced by the displayed entourage base;*
5. *H records componentwise* hsame *transport for S, E, B, T and the local naming row;*
6. *C records displayed* Cont *replay through source admission, entourage lookup, base refinement, topology readback, provenance, and local naming;*

7. *P is the* Pkg *provenance over* $\mathsf{Preuniformity}^{\uparrow}$, $\mathsf{UniformSpace}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{Topology}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* NameCert *rows;*

8. *N is the local* $\mathsf{NameCert}_{\mathsf{Preuniformity}^{\uparrow}}$ *row.*

The carrier exports no symmetry axiom, separatedness theorem, quotient completion, selected Cauchy limit, host entourage filter, countable-choice base, or ambient $\mathsf{Real}^{\uparrow}$ *completeness principle.*

Lean4 ✓ `BEDC.Derived.PreuniformityUp.PreuniformityTasteGate single carrier alignment`

Theorem 8904.2 (Preuniformity entourage stability)**.** *For every accepted* $\mathsf{Preuniformity}^{\uparrow}$ *carrier* $U = (S, E, B, T, H, C, P, N)$*, an entourage read is stable only through the displayed ledger E, the base-refinement ledger B, and componentwise transport H. A downstream* $\mathsf{UniformSpace}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{Topology}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, *or* $\mathsf{Real}^{\uparrow}$ *consumer may preserve the same directed row, but it may not replace it by a symmetric metric ball, a separated uniformity, a quotient completion row, or a selected completed point.*

Proof. Project the accepted carrier. The only binary-neighbourhood data in the packet is the displayed entourage ledger E, and the only refinement data is the base ledger B.

Transport through H preserves rows componentwise. It therefore preserves the source, entourage, base, topology readback, and naming rows already present in U without adding symmetry, separatedness, or completion data.

The sibling consumers may cite the preserved directed row only as a preuniform row. Since the carrier has no coordinate for metric symmetry, quotient completion, selected limits, host filters, countable choice, or ambient Real completeness, no such datum can be exported by the entourage read. □

Lean4 ✓ `BEDC.Derived.PreuniformityUp.PreuniformityCarrier entourage stability`

Theorem 8904.3 (Preuniformity filter-base route)**.** *For every accepted* $\mathsf{Preuniformity}^{\uparrow}$ *carrier* $U = (S, E, B, T, H, C, P, N)$*, the filter-base row B is read after the entourage ledger E and before topology readback T. The row records finite upward and intersection refinements for displayed entourages only; it does not assert a completed host filter, a symmetric uniformity, or a UniformCompletionUp limit object.*

Proof. Read the carrier rows in order. The entourage ledger E supplies the displayed binary-neighbourhood rows, and B records the finite refinements allowed for those rows.

The topology row T is downstream of the same finite base. It may expose neighbourhood data through chapter 88, but it cannot turn the preuniform base into a host filter or a completed uniform space.

The continuation row C and provenance row P replay and source the same finite route. They do not add symmetry, separatedness, quotient completion, selected limits, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness. □

Lean4 ✓ `BEDC.Derived.PreuniformityUp.PreuniformityCarrier filter base route`

Theorem 8904.4 (Preuniformity NameCert obligations)**.** *For the carrier of Definition 8904.1, the local* $\mathsf{NameCert}_{\mathsf{Preuniformity}^{\uparrow}}$ *surface consists exactly of carrier admission for* $U = (S, E, B, T, H, C, P, N)$*, source exposure through S, directed entourage exposure through E, finite filter-base exposure through B, topology readback through T, componentwise* hsame *transport through H, displayed* Cont *replay through C,* Pkg *provenance through P, and local naming through N.*

Proof. Carrier admission exposes the finite tuple S, E, B, T, H, C, P, N. The source row, entourage ledger, base ledger, topology readback, transport, replay, provenance, and local naming row are all visible coordinates of one packet.

Apply the entourage-stability theorem and the filter-base route theorem. Together they keep binary-neighbourhood reads directed, place base refinements between entourage lookup and topology readback, and prevent a consumer from replacing the preuniform carrier by a symmetric uniformity or completion object.

The listed rows therefore exhaust the local NameCert obligations. There is no additional coordinate from which to read separatedness, metric symmetry, quotient completion, selected limits, host filters, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness. □

Lean4 ✓ `BEDC.Derived.PreuniformityUp.PreuniformityNameCertObligations`

Closure status for $\mathsf{NameCert}_{\mathsf{Preuniformity}^{\uparrow}}$.

Constructive story: A $\mathsf{Preuniformity}^{\uparrow}$ packet is generated from a source row, a directed entourage ledger, a finite filter-base ledger, topology readback, componentwise hsame transport, displayed Cont replay, package provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{Preuniformity}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8904.1, Definition 8904.2, Definition 8904.3, and Definition 8904.4 seed the directed entourage-base route between topology, metric data, and uniform completion.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{Preuniformity}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close Lean verification, bridge checking, uniform-space symmetry, separatedness, quotient completion, selected Cauchy limits, countable choice, host filters, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Upgrade path: Obligation closure requires checked carrier admission, directed entourage stability, finite filter-base routing, topology readback, provenance, and local naming for BEDC.Derived.PreuniformityUp.

Chapter 8905

A Concrete Naming Certificate for $\mathsf{SchreierSims}^{\uparrow}$

Following Sims' stabilizer-chain method and the computational group theory treatments of Seress, the $\mathsf{SchreierSims}^{\uparrow}$ packet records a finite permutation-group certificate as BEDC NameCert data. It consumes the permutation source of chapter 116, the group source of chapter 41, the orbit and stabilizer rows of chapter 6559, and the finite action rows of chapter 3662. The packet names a displayed stabilizer chain, transversal ledger, Schreier generator rows, sift trace, transport, replay, provenance, and local naming; it does not implement a host permutation-group algorithm or claim a complete constructive base-change strategy.

Definition 8905.1 (Schreier-Sims carrier)**.** *A* $\mathsf{SchreierSims}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (P, G, O, R, B, T, W, F, H, C, Q, N)$$

with the following displayed rows:

1. *P is the consumed* $\mathsf{Permutation}^{\uparrow}$ *source row, exposing the finite moved-set and graph data used by the action.*
2. *G is the consumed* $\mathsf{Group}^{\uparrow}$ *source row, exposing multiplication, unit, inverse, and finite support rows for the generated permutation group.*
3. *O is the consumed* $\mathsf{OrbitStabilizer}^{\uparrow}$ *row, used to read each orbit and stabilizer boundary before a chain level is accepted.*
4. *R is the consumed* $\mathsf{FiniteGroupRepresentation}^{\uparrow}$ *action row, used only as the finite action interface through which permutation rows act on the displayed base points.*
5. *B is the finite base row, listing the inspected base points and the order in which stabilizer levels are read.*
6. *T is the transversal ledger, recording for each displayed orbit level the chosen finite transversal rows and their source in P, G, O, R.*
7. *W is the Schreier-generator row, recording the finite generator words obtained from the displayed transversal rows and group generators.*
8. *F is the sift-trace row, recording the finite reduction route of a displayed permutation through the stabilizer chain.*

9. *H is componentwise* hsame *transport for P, G, O, R, B, T, W, F.*
10. *C is displayed* Cont *replay of the stabilizer-chain read from permutation, group, orbit-stabilizer, and representation rows into the local certificate.*
11. *Q is the* Pkg *provenance over* Permutation$^{\uparrow}$, Group$^{\uparrow}$, OrbitStabilizer$^{\uparrow}$, FiniteGroupRepresentation$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
12. *N is the local* NameCert$_{\text{SchreierSims}^{\uparrow}}$ *row.*

No coordinate stores a host permutation-group procedure, ambient coset table, quotient action category, selected global base-change oracle, or proof that a particular implementation terminates.

Lean4 (statement) `BEDC.Derived.SchreierSimsUp`

Theorem 8905.2 (Schreier-Sims NameCert obligations)**.** *For every accepted* SchreierSims$^{\uparrow}$ *carrier*

$$S = (P, G, O, R, B, T, W, F, H, C, Q, N),$$

the local NameCert$_{\text{SchreierSims}^{\uparrow}}$ *surface consists exactly of carrier admission for the displayed permutation source, group source, orbit-stabilizer rows, finite action row, base row, transversal ledger, Schreier-generator row, sift-trace row, componentwise transport, displayed replay, package provenance, and local naming. Each obligation is read from the displayed finite rows before any consumer may treat the packet as a stabilizer-chain certificate.*

Proof. Project the carrier of Definition 8905.1. The first four rows expose the consumed permutation, group, orbit-stabilizer, and finite-action sources; the next four rows expose the base, transversals, Schreier generators, and sift trace.

The local naming obligations are then componentwise. The transversal ledger must cite the displayed orbit-stabilizer row, the generator ledger must cite the same transversal and group rows, and the sift trace must move through the displayed stabilizer levels in base order.

Finally H, C, Q, N transport, replay, source, and name only those finite rows. Since the packet has no host algorithm, quotient action category, or global base-change coordinate, the NameCert surface is exactly the displayed stabilizer-chain data. □

Theorem 8905.3 (Schreier-Sims stabilizer-chain handoff)**.** *Every* SchreierSims$^{\uparrow}$ *consumer that reads a stabilizer chain must first expose the base row B, the orbit-stabilizer row O, the transversal ledger T, the Schreier-generator row W, and the sift-trace row F over the consumed* Permutation$^{\uparrow}$, Group$^{\uparrow}$, *and* FiniteGroupRepresentation$^{\uparrow}$ *sources. The handoff is a finite BEDC certificate for the displayed chain; it is not a host membership algorithm, a coset-enumeration primitive, or a complete permutation-group computation engine.*

Proof. Begin with the base row B. It fixes the level order in which stabilizers can be read, so a consumer cannot inspect a later sift endpoint before the earlier orbit and stabilizer rows are displayed.

Next use the orbit-stabilizer and action sources O and R. They provide the finite orbit and stabilizer boundaries used by the transversal ledger T, with the permutation and group rows P, G still visible.

Then read the Schreier-generator row W and sift-trace row F. These rows record the finite generator and reduction data for the displayed chain, while H, C, Q, N preserve and name the same packet. Thus the exported handoff is exactly a finite stabilizer-chain certificate. □

Closure status for $\mathsf{NameCert}_{\mathsf{SchreierSims}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{SchreierSims}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8905.1, Definition 8905.2, and Definition 8905.3 seed the finite permutation-group stabilizer-chain carrier over displayed permutation, group, orbit-stabilizer, finite-action, base, transversal, Schreier-generator, and sift-trace rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{SchreierSims}^{\uparrow}}, \mathsf{unformalized})$

Lean target: `BEDC.Derived.SchreierSimsUp`

Bridge status: none

Not claimed: This chapter does not close host permutation-group algorithms, complete coset enumeration, global base-change selection, implementation termination, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, transversal exactness, Schreier-generator stability, sift-trace replay, stabilizer-chain handoff, transport, provenance, and local naming for the same finite packet.

Constructive story: A $\mathsf{SchreierSims}^{\uparrow}$ packet is generated from displayed PermutationUp, GroupUp, OrbitStabilizerUp, and FiniteGroupRepresentationUp source rows, a finite base row, transversal ledger, Schreier-generator row, sift-trace row, componentwise transport, displayed replay, provenance, and local naming.

Chapter 8906

A Concrete Naming Certificate for $\mathsf{FineUniformity}^{\uparrow}$

Following Bourbaki and Kelley, the $\mathsf{FineUniformity}^{\uparrow}$ packet records the fine uniformity carried by a completely regular topology as finite BEDC naming data. It sits between the topology source of chapter 88, the real-valued separation surface of chapter 5161, the uniform-space carrier of chapter 339, the relative-open route of chapter 5993, and the terminal real-name seal of chapter 38. The packet names the displayed entourage base generated by real-valued continuous probes; it is not a selected filter, a host powerset, a choice principle for entourages, a metrization theorem, or a completion claim.

Definition 8906.1 (Fine uniformity carrier)**.** *A* $\mathsf{FineUniformity}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$F = (T, C, U, S, R, E, H, K, P, N)$$

with the following displayed rows:

1. *T is the ambient* $\mathsf{Topology}^{\uparrow}$ *row, exposing the open-index classifier, neighbourhood reads, finite-intersection rows, and arbitrary-union rows used by the packet.*
2. *C is the* $\mathsf{CompletelyRegularSpace}^{\uparrow}$ *row, supplying the real-valued point-versus-closed-set separation route over the same topology source.*
3. *U is the* $\mathsf{UniformSpace}^{\uparrow}$ *row whose entourages are read only through the displayed fine-uniformity base.*
4. *S is the* $\mathsf{SubspaceTopology}^{\uparrow}$ *compatibility row, recording that relative opens admitted by a displayed subspace read the same topology source before any restricted uniformity request.*
5. *R is the* $\mathsf{Real}^{\uparrow}$*-valued continuous-probe row. Each accepted probe is a displayed* $\mathsf{ContinuousMap}^{\uparrow}$ *read into* $\mathsf{Real}^{\uparrow}$ *whose inverse uniform window contributes an entourage-base entry.*
6. *E is the finite entourage-base ledger generated from the displayed real-valued probes and their finite intersection reads.*
7. *H records componentwise* hsame *transport for $T, C, U, S, R, E, K, P, N$ and for the displayed probe-window and entourage-base rows.*
8. *K records displayed* Cont *replay from a fine-uniformity request through topology, complete-regularity, uniform-space, subspace, real-probe, entourage-base, transport, provenance, and naming rows.*

9. *P is the* Pkg *provenance over* $\mathsf{FineUniformity}^{\uparrow}$, $\mathsf{Topology}^{\uparrow}$, $\mathsf{CompletelyRegularSpace}^{\uparrow}$, $\mathsf{UniformSpace}^{\uparrow}$, $\mathsf{SubspaceTopology}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*
10. *N is the local* $\mathsf{NameCert}_{\mathsf{FineUniformity}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $T, C, U, S, R, E, H, K, P, N$. It has no coordinate for a host powerset of $X \times X$, a selected entourage filter, a choice of all real-valued functions, a metric generator, a completion object, or ambient real completeness.

Theorem 8906.2 (Fine uniformity NameCert obligations)**.** *For every accepted* $\mathsf{FineUniformity}^{\uparrow}$ *carrier*

$$F = (T, C, U, S, R, E, H, K, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{FineUniformity}^{\uparrow}}$ *surface consists exactly of topology-source admission, complete-regularity source admission, uniform-space handoff, subspace-topology compatibility,* $\mathsf{Real}^{\uparrow}$*-valued continuous-probe exposure, finite entourage-base exposure, componentwise* hsame *transport, displayed* Cont *replay, provenance, and local naming. Every fine-uniformity consumer must read the route*

$$T, C, U, S, R, E, H, K, P, N$$

before using an entourage as public.

Proof. Project the carrier of Definition 8906.1. The accepted packet displays the topology source, completely regular source, uniform-space row, subspace compatibility row, real-valued probe row, finite entourage-base ledger, and structural rows.

The real-valued probes are read before the entourage base. The row C supplies the point-versus-closed-set separation route, while R records only displayed $\mathsf{Real}^{\uparrow}$-valued $\mathsf{ContinuousMap}^{\uparrow}$ probes over the same topology source.

The entourage-base row E is finite and generated from the displayed probe windows. A consumer may inspect an entourage entry or a finite-intersection read already stored in E, but it cannot replace that row by a host powerset, a selected filter, or a choice of all probes.

Finally H, K, P, N transport, replay, source, and locally name the same finite route. Hence the listed rows exhaust the local NameCert surface, and no metric generator, completion object, selected filter, host powerset, or ambient real-completeness principle can enter the packet. □

Theorem 8906.3 (Fine uniformity compatible-topology handoff)**.** *Let $F = (T, C, U, S, R, E, H, K, P, N)$ be an accepted* $\mathsf{FineUniformity}^{\uparrow}$ *carrier. Any* $\mathsf{Topology}^{\uparrow}$, $\mathsf{SubspaceTopology}^{\uparrow}$, *or* $\mathsf{UniformSpace}^{\uparrow}$ *consumer that reads the topology induced by the fine uniformity must first expose the displayed topology source T, complete-regularity route C, real-valued probe row R, finite entourage-base ledger E, and structural rows H, K, P, N.*

Consequently the topology handoff is the finite route

$$\mathsf{Topology}^{\uparrow}, \mathsf{CompletelyRegularSpace}^{\uparrow}, \mathsf{Real}^{\uparrow}, \mathsf{ContinuousMap}^{\uparrow} \longmapsto \mathsf{UniformSpace}^{\uparrow}, \mathsf{SubspaceTopology}^{\uparrow} \longmapsto H, K, P, N,$$

not a host powerset topology, a selected entourage filter, a metric presentation, a completion theorem, or a choice principle for probes.

Proof. Start with the carrier definition. The topology source T and complete-regularity row C are the only entries that expose the open and real-valued separation vocabulary used by the packet.

Read the real-valued probe row R and the finite entourage-base ledger E. These rows display how the fine-uniformity windows are generated before the $\mathsf{UniformSpace}^{\uparrow}$ handoff is consumed, so the induced topology cannot be read from an untracked filter or host powerset.

For subspaces, the row S keeps the same topology source visible before restriction. Thus a $\mathsf{SubspaceTopology}^{\uparrow}$ consumer receives a relative-open route tied to T and E, not an independent restricted uniformity object.

Finally H, K, P, N transport, replay, source, and name only the displayed rows. The handoff therefore exports compatible topology data through the finite certificate route while refusing selected filters, host powersets, metric presentations, completion claims, and choice over probes. □

Closure status for $\mathsf{NameCert}_{\mathsf{FineUniformity}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{FineUniformity}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8906.1, Definition 8906.2, and Definition 8906.3 seed the fine-uniformity NameCert surface over topology, complete-regularity, uniform-space, subspace-topology, real-valued probe, entourage-base, transport, replay, provenance, and local naming rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{FineUniformity}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close Lean verification, bridge checking, selected filters, host powersets, choice over all probes, metrization, completion, or ambient real completeness.

Upgrade path: Obligation closure requires checked carrier admission, real-valued probe exactness, finite entourage-base stability, compatible-topology handoff, subspace restriction compatibility, transport, replay, provenance, and local naming for BEDC.Derived.FineUniformityUp.

Constructive story: A $\mathsf{FineUniformity}^{\uparrow}$ packet is generated from an ambient TopologyUp row, a CompletelyRegularSpaceUp row, a UniformSpaceUp row, a SubspaceTopologyUp compatibility row, RealUp-valued ContinuousMapUp probe rows, a finite entourage-base ledger, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 8907

A Concrete Naming Certificate for $\mathsf{LocallyBoundedFunction}^{\uparrow}$

Following Bishop–Bridges constructive analysis and Kelley's local-boundedness usage in general topology, the $\mathsf{LocallyBoundedFunction}^{\uparrow}$ packet records the finite surface by which a displayed function read is bounded on one local source window before any Real or Completion consumer may use it. It sits beside the continuous-map carrier of chapter 130, the finite window discipline of chapter 126, the regular rational readback route of chapter 301, the dyadic tolerance ledger of chapter 291, the terminal real-name seal of chapter 38, and the bounded-family comparison surface of chapter 3522. The packet names local boundedness by finite rows only; it does not assert compactness, ambient completeness, quotient equality of functions, countable choice, selected global bounds, or bridge checking.

Definition 8907.1 (Locally bounded function carrier)**.** *A* $\mathsf{LocallyBoundedFunction}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (K, F, V, B, W, R, D, A, H, C, P, N)$$

with the following displayed rows:

1. *K is the local source-window row, naming the finite neighborhood or bounded source portion on which the read is inspected.*
2. *F is the* $\mathsf{ContinuousMap}^{\uparrow}$ *row whose graph or evaluation interface supplies the function read on K.*
3. *V is the* $\mathsf{Real}^{\uparrow}$ *value-read row exposed by the function on the displayed source window.*
4. *B is the finite bound row, recording the displayed local upper budget against which the value read is compared.*
5. *W is the* $\mathsf{StreamName}^{\uparrow}$ *window row opened for the source inspection, value read, and bound request.*
6. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the rational observations used by V and B.*
7. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row, carrying the dyadic scale, slack, and comparison budget for the local bound.*
8. *A is the terminal* $\mathsf{Real}^{\uparrow}$ *seal reached only after K, F, V, B, W, R, D have been displayed.*

9. *H records componentwise* hsame *transport for the local source window, continuous-map read, value row, finite bound, StreamName, RegSeqRat, DyadicRatCore, Real seal, replay, provenance, and naming rows.*

10. *C records displayed* Cont *replay through*

$$K \longrightarrow F \longrightarrow V \longrightarrow B \longrightarrow W \longrightarrow R \longrightarrow D \longrightarrow A.$$

11. *P is the* Pkg *provenance over* $\mathsf{LocallyBoundedFunction}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{BoundedFunctionFamily}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

12. *N is the local* $\mathsf{NameCert}_{\mathsf{LocallyBoundedFunction}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $K, F, V, B, W, R, D, A, H, C, P, N$. It has no coordinate for an ambient function space, a selected global bound, quotient equality of functions, countable choice, ambient $\mathsf{Real}^{\uparrow}$ *completeness, or bridge checking.*

Theorem 8907.2 (Locally bounded function NameCert obligations)**.** *For every accepted* $\mathsf{LocallyBoundedFunction}^{\uparrow}$ *carrier*

$$L = (K, F, V, B, W, R, D, A, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{LocallyBoundedFunction}^{\uparrow}}$ *surface consists exactly of carrier admission for the local source window, ContinuousMap read, Real value row, finite bound, StreamName window, RegSeqRat readback, DyadicRatCore tolerance, terminal Real seal, transport, replay, provenance, and local naming rows; local-source exactness requiring K before any bound is inspected; value-bound exactness requiring V and B to be compared through R and D; and structural stability requiring H, C, P, N to preserve the displayed route.*

Lean4 ✓ `BEDC.Derived.LocallyBoundedFunctionUp.LocallyBoundedFunctionCarrier namecert obligations`

Proof. Project the carrier of Definition 8907.1. The rows $K, F, V, B, W, R, D, A, H, C, P, N$ are the only rows available to an accepted packet, so carrier admission is exactly the displayed finite list.

The local-source obligation is supplied by K and F. A consumer first opens the local source window and then reads the ContinuousMap row on that window, so the local bound is not interpreted as a host-global function-space assertion.

The value-bound obligation is supplied by V, B, R, D. The Real value and finite bound are exposed through regular rational readback and dyadic tolerance comparison before the terminal Real seal can be reached.

Finally, H, C, P, N transport, replay, source, and name the same route. Since the carrier has no rows for ambient completeness, host function-space equality, selected global bounds, quotient equality, countable choice, or bridge checking, the listed obligations exhaust the local NameCert surface. □

Theorem 8907.3 (Locally bounded function finite-window bound route)**.** *Every Real-facing or L10 completion-facing consumer of an accepted* $\mathsf{LocallyBoundedFunction}^{\uparrow}$ *packet reaches a local bound only through the finite route*

$$K \longrightarrow F \longrightarrow V \longrightarrow B \longrightarrow W \longrightarrow R \longrightarrow D \longrightarrow A$$

with componentwise transport, replay, provenance, and naming supplied by H, C, P, N. The route may be consumed by compact-continuity, equicontinuity, and bounded-family chapters that need local finite bounds, but it does not export ambient completeness, host function spaces, selected global bounds, quotient equality, countable choice, or bridge checking.

Proof. Use the carrier projection of Definition 8907.1. The source window K and ContinuousMap row F are displayed before any value or bound is read.

Apply Definition 8907.2. Its value-bound exactness clause forces the Real value row V and the finite bound row B to pass through the StreamName, RegSeqRat, and DyadicRatCore rows W, R, D before the terminal Real seal A is public.

The structural rows H, C, P, N do not add analytic content. They preserve and name the same finite route, so any compact-continuity, equicontinuity, or bounded-family consumer receives only the displayed local bound route and no ambient completeness theorem, host function-space equality, selected global bound, quotient equality, countable-choice schedule, or bridge credential. □

Lean4 ✓ `BEDC.Derived.LocallyBoundedFunctionUp.LocallyBoundedFunctionFiniteWindowBoundRoute`

Closure status for $\mathsf{NameCert}_{\mathsf{LocallyBoundedFunction}^{\uparrow}}$.

Constructive story: A $\mathsf{LocallyBoundedFunction}^{\uparrow}$ packet is generated from a local source-window row, ContinuousMap row, Real value read, finite bound row, StreamName window, RegSeqRat readback, DyadicRatCore tolerance ledger, terminal Real seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{LocallyBoundedFunction}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8907.1, Definition 8907.2, and Definition 8907.3 seed the finite local-boundedness route for Real-facing and completion-facing function consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{LocallyBoundedFunction}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close ambient completeness, host function spaces, selected global bounds, quotient equality, countable choice, or bridge checking.

Upgrade path: A formal route can encode the displayed carrier and prove the finite NameCert obligation surface and finite-window bound route for BEDC.Derived.LocallyBoundedFunctionUp.

Chapter 8908

A Concrete Naming Certificate for $\mathsf{RegularCauchyTailFunctional}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{RegularCauchyTailFunctional}^{\uparrow}$ packet records the finite functional that reads regular Cauchy tail data through displayed windows and dyadic tolerance rows before a Real-facing consumer reaches a seal. It sits over the regular rational source of chapter 301, the stream-window surface of chapter 126, the dyadic tolerance ledger of chapter 291, the terminal real-name seal of chapter 38, and the finite choice boundary of chapter 1354. The packet names a tail-functional read only; it does not assert completeness, quotient names, selected limits, countable choice, or a global choice of tails.

Definition 8908.1 (Regular Cauchy tail-functional carrier)**.** *A* $\mathsf{RegularCauchyTailFunctional}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$F = (S, W, D, T, R, H, C, P, N)$$

with the following displayed rows:

1. *S is the* $\mathsf{RegSeqRat}^{\uparrow}$ *source row whose regular rational tail is inspected.*
2. *W is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row through which tail requests are exposed.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger attached to the inspected window.*
4. *T is the tail-functional row, recording the finite read from a tolerance request to a displayed tail window.*
5. *R is the* $\mathsf{Real}^{\uparrow}$ *seal row, available only after S, W, D, T have been displayed.*
6. *H records componentwise* hsame *transport for the analytic rows and the structural rows.*
7. *C records displayed* Cont *replay from regular rational source data through the window, tolerance ledger, tail functional, seal, transport, provenance, and local naming.*
8. *P is the* Pkg *provenance over* $\mathsf{RegularCauchyTailFunctional}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{CanonicalTailChoice}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
9. *N is the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyTailFunctional}^{\uparrow}}$ *row.*

The carrier has no coordinate for quotient Cauchy classes, a selected limit, a host sequence equality test, countable choice, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 8908.2 (Regular Cauchy tail-functional NameCert obligations)**.** *For every accepted* $\mathsf{RegularCauchyTailFunctional}^{\uparrow}$ *carrier*

$$F = (S, W, D, T, R, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{RegularCauchyTailFunctional}^{\uparrow}}$ *surface consists exactly of carrier admission for the regular rational source, finite stream window, dyadic tolerance ledger, tail-functional row, terminal Real seal, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming.*

Proof. Project the carrier of Definition 8908.1. Its rows list the regular rational source S, stream window W, dyadic tolerance ledger D, tail-functional row T, seal row R, and structural support H, C, P, N.

The tail read is ordered by the carrier. A consumer must expose S, W, D before the tail-functional row can be read, and the seal row R is downstream from that finite tail read.

The structural rows do not add analytic content. Transport, replay, provenance, and local naming keep the same packet visible, so the listed rows exhaust the local NameCert surface. □

Theorem 8908.3 (Regular Cauchy tail-functional window stability)**.** *Let* $F = (S, W, D, T, R, H, C, P, N)$ *and* $F' = (S', W', D', T', R', H', C', P', N')$ *be accepted* $\mathsf{RegularCauchyTailFunctional}^{\uparrow}$ *carriers. If the source, window, and dyadic rows are transported componentwise by the displayed* hsame *data in* H *and* H'*, then the tail-functional rows* T *and* T' *remain on the same local* $\mathsf{NameCert}_{\mathsf{RegularCauchyTailFunctional}^{\uparrow}}$ *surface before either packet reaches its* $\mathsf{Real}^{\uparrow}$ *seal.*

Proof. Read the transported source rows first. Componentwise hsame identifies the regular rational sources and their finite stream windows before the tail-functional row is consumed.

The dyadic tolerance ledgers are transported along the same displayed route. Hence the tail-functional rows compare finite requests inside the same window-and-tolerance surface rather than through a host equality test.

The seal rows and structural rows are downstream. Since R, H, C, P, N and R', H', C', P', N' only seal, transport, replay, source, and name the transported packet, window stability is exactly stability of the displayed finite rows. □

Theorem 8908.4 (Regular Cauchy tail-functional Real-seal nonescape)**.** *No accepted* $\mathsf{RegularCauchyTailFunctional}^{\uparrow}$ *packet exports quotient Cauchy names, selected limits, host sequence equality, countable choice, trichotomy, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness. A Real-facing consumer reaches the seal row* R *only through the displayed route*

$$S, W, D, T, R, H, C, P, N.$$

Proof. Inspect the carrier. The only analytic rows are the regular rational source, finite window, dyadic tolerance ledger, tail-functional row, and Real seal.

Apply the NameCert obligations of Definition 8908.2. They force the consumer through S, W, D, T before R is available.

The excluded principles are not coordinates of the packet. The transport, replay, provenance, and local naming rows preserve the finite route, so any read of a quotient name, selected limit, host equality, choice row, trichotomy row, or completeness principle leaves the accepted surface. □

Falsifiable prediction: Every accepted $\mathsf{RegularCauchyTailFunctional}^{\uparrow}$ consumer displays the regular rational source, stream window, dyadic tolerance ledger, tail-functional row, Real seal, transport, replay, provenance, and local NameCert rows before reading a Real-facing tail result.

Independence witness: regseqrat, streamname, dyadicratcore, real, canonicaltailchoice: no listed sibling is bijective to $\mathsf{RegularCauchyTailFunctional}^{\uparrow}$ because this packet jointly binds a regular rational source, finite stream window, dyadic tolerance ledger, tail-functional read, Real seal, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{RegularCauchyTailFunctional}^{\uparrow}}$.

Constructive story: A $\mathsf{RegularCauchyTailFunctional}^{\uparrow}$ packet is generated from a regular rational source, a finite stream window, a dyadic tolerance ledger, a tail-functional row, a Real seal, componentwise transport, displayed continuation replay, provenance, and local naming.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RegularCauchyTailFunctional}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8908.1, Definition 8908.2, Definition 8908.3, and Definition 8908.4 seed the finite tail-functional packet over regular rational source rows, stream windows, dyadic tolerances, Real sealing, transport, replay, provenance, and local naming.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RegularCauchyTailFunctional}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient Cauchy names, selected limits, host sequence equality, countable choice, trichotomy, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, tail-functional exactness, window stability, Real-seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.RegularCauchyTailFunctionalUp.

Chapter 8909

A Concrete Naming Certificate for $\mathsf{FiniteMembershipClassifier}^{\uparrow}$

The $\mathsf{FiniteMembershipClassifier}^{\uparrow}$ packet realizes the order–set–type interface of chapter 9356 as finite membership-classifier data over displayed source, member, witness, stability, ledger, transport, replay, provenance, and local naming rows. It sits beside the finite interface spine of chapter 8899, the public finite-data rows of chapter 36, chapter 33, and chapter 32, and the set/type interface intent of $\mathsf{SetLike}^{\uparrow}$ and $\mathsf{TypeLike}^{\uparrow}$. The packet names finite membership inspection only; it does not introduce ambient subset semantics, a host finite-type universe, quotient equality, unrestricted comprehension, or excluded-middle membership.

Definition 8909.1 (Finite membership classifier carrier)**.** *A* $\mathsf{FiniteMembershipClassifier}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M = (S, A, F, Q, L, H, C, P, N)$$

with the following displayed rows:

1. *S is the source row naming the finite displayed collection being inspected.*
2. *A is the member row naming the candidate displayed element.*
3. *F is the finite witness row, exposing the bounded inspection window and the finite evidence considered by the classifier.*
4. *Q is the classifier row, recording the membership read as finite certificate data rather than as ambient elementhood.*
5. *L is the stability and ledger row, recording source stability, member stability, witness stability, and the consumed comparison evidence.*
6. *H records componentwise* hsame *transport for the source, member, witness, classifier, ledger, replay, provenance, and local naming rows.*
7. *C records displayed* Cont *replay from a membership request through S, A, F, Q, L, H, P, N.*
8. *P is the* Pkg *provenance over* $\mathsf{FiniteMembershipClassifier}^{\uparrow}$, $\mathsf{FiniteInterfaceSpine}^{\uparrow}$, $\mathsf{List}^{\uparrow}$, $\mathsf{Option}^{\uparrow}$, $\mathsf{Bool}^{\uparrow}$, $\mathsf{SetLike}^{\uparrow}$, $\mathsf{TypeLike}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
9. *N is the local* $\mathsf{NameCert}_{\mathsf{FiniteMembershipClassifier}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these rows. It has no coordinate for ambient subset semantics, an unrestricted type universe, quotient equality of members, hidden comprehension, or excluded-middle membership.

Theorem 8909.2 (Finite membership classifier NameCert obligations)**.** *For every accepted* FiniteMembershipClassif *carrier*

$$M = (S, A, F, Q, L, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{FiniteMembershipClassifier}^{\uparrow}}$ *surface consists exactly of carrier admission for the source row, member row, finite witness row, classifier row, stability and ledger row, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming.*

Proof. Project the carrier of Definition 8909.1. The source, member, witness, classifier, and ledger rows are the only membership-facing rows available to an accepted packet.

The finite witness row F bounds the inspection before Q records the classifier read. The ledger row L records which source, member, witness, and stability data have been consumed.

The rows H, C, P, N transport, replay, source, and name the same finite packet. Since no ambient subset, host type universe, quotient member equality, hidden comprehension, or excluded-middle row occurs in the carrier, the listed rows exhaust the local NameCert surface. □

Theorem 8909.3 (Finite membership classifier stability)**.** *Let* $M = (S, A, F, Q, L, H, C, P, N)$ *and* $M' = (S', A', F', Q', L', H', C', P', N')$ *be accepted* $\mathsf{FiniteMembershipClassifier}^{\uparrow}$ *carriers. If the source, member, finite witness, and ledger rows are transported componentwise by the displayed* hsame *data in* H *and* H'*, then the classifier rows* Q *and* Q' *remain on the same finite membership surface. The transported read exports no ambient subset relation, quotient member equality, hidden comprehension, or excluded-middle membership principle.*

Proof. Start with the source and member rows. Componentwise hsame transport identifies the displayed collection and candidate element before the classifier row is read.

Transport the finite witness rows next. The classifier rows are read after the same bounded evidence is displayed, and the ledger rows record the same consumed comparison data.

The replay, provenance, and local naming rows keep the transported packet inside the same surface. Therefore classifier stability is a property of the displayed finite rows, not an ambient membership principle. □

Theorem 8909.4 (Finite membership classifier interface handoff)**.** *Every order–set–type interface consumer that reads a* $\mathsf{FiniteMembershipClassifier}^{\uparrow}$ *packet must consume the route*

$$S, A, F, Q, L, H, C, P, N$$

before treating membership as public classifier data. The handoff realizes finite source, member, witness, stability, ledger, transport, replay, provenance, and NameCert rows, and supplies no host finite-type universe, unrestricted comprehension, quotient equality, or hidden decidability principle.

Proof. Apply the NameCert obligations of Definition 8909.2. They force the source, member, witness, classifier, and ledger rows to be displayed before the interface consumer can read membership.

The stability theorem Definition 8909.3 shows that transported reads remain on the same finite membership surface. Thus a consumer can move membership data across displayed sameness only by preserving the packet rows.

The carrier lacks coordinates for the excluded objects. Hence the order–set–type handoff is exactly the finite classifier route listed above. □

Falsifiable prediction: Every accepted $\mathsf{FiniteMembershipClassifier}^{\uparrow}$ consumer displays source, member, finite witness, classifier, stability ledger, transport, replay, provenance, and local NameCert rows before reading membership as order–set–type interface data.

Independence witness: finite-interface-spine, list, option, bool, setlike, typelike: no listed sibling is bijective to $\mathsf{FiniteMembershipClassifier}^{\uparrow}$ because this packet jointly binds finite source, member, witness, classifier, stability, ledger, transport, replay, provenance, and local naming rows.

Closure status for $\mathsf{NameCert}_{\mathsf{FiniteMembershipClassifier}^{\uparrow}}$.

Constructive story: A $\mathsf{FiniteMembershipClassifier}^{\uparrow}$ packet is generated from a displayed finite source, a displayed member, a finite witness row, a membership classifier row, a stability and ledger row, componentwise transport, displayed continuation replay, provenance, and local naming.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{FiniteMembershipClassifier}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8909.1, Definition 8909.2, Definition 8909.3, and Definition 8909.4 seed the finite membership-classifier packet over source, member, witness, classifier, stability, ledger, transport, replay, provenance, and local naming rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{FiniteMembershipClassifier}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close ambient subset semantics, a host finite-type universe, quotient member equality, unrestricted comprehension, excluded-middle membership, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, finite witness exactness, classifier stability, interface handoff, transport, replay, provenance, and local naming for BEDC.Derived.FiniteMembershipClassifierUp.

Chapter 8910

A Concrete Naming Certificate for $\mathsf{CaratheodoryKernelConvergence}^{\uparrow}$

Following Caratheodory, Koebe, and Ahlfors on kernel convergence of simply connected planar domains, the $\mathsf{CaratheodoryKernelConvergence}^{\uparrow}$ packet records the finite NameCert route by which pointed domain windows, compact-kernel exhaustions, holomorphic chart reads, normal-family compactness, and Riemann-map normalization are read as one carrier. It sits between the normal-family packet of chapter 2186, the Riemann mapping packet of chapter 6805, the holomorphic chart surface of chapter 68, the unit-disk source of chapter 377, and the compact-open topology surface of chapter 4138. The packet names the displayed kernel route without importing prime ends, quotient equality of functions, host domain convergence, or a selected boundary correspondence.

Definition 8910.1 (Caratheodory kernel convergence carrier)**.** *A* $\mathsf{CaratheodoryKernelConvergence}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (D, E, H, N, R, T, C, P, L)$$

with the following displayed rows.

1. *D is the pointed planar-domain window, recording the visible base point, the inspected planar open rows, and the admitted source windows for the kernel read.*
2. *E is the compact-kernel exhaustion row, recording the finite compact windows whose eventual containment witnesses the kernel interior and whose escape rows witness points outside the kernel.*
3. *H is the holomorphic chart-read row, exposing the finite* $\mathsf{Holomorphic}^{\uparrow}$ *chart observations used to compare maps on the displayed compact windows.*
4. *N is the normal-family compactness handoff, read through* $\mathsf{NormalFamily}^{\uparrow}$ *and the compact-window discipline of* $\mathsf{CompactOpenTopology}^{\uparrow}$ *before any subsequential holomorphic limit is public.*
5. *R is the Riemann-map route, recording the normalized* $\mathsf{UnitDisk}^{\uparrow}$ *source, base-point normalization, derivative-orientation row, and* $\mathsf{RiemannMapping}^{\uparrow}$ *handoff used by simply connected kernel consumers.*
6. *T records componentwise* hsame *transport for the pointed window, compact-kernel exhaustion, holomorphic chart reads, normal-family handoff, Riemann-map route, replay, provenance, and local naming rows.*

7. *C records displayed* Cont *replay from a kernel-convergence request through D, E, H, N, R, T.*

8. *P is the* Pkg *provenance over* $\mathsf{CaratheodoryKernelConvergence}^{\uparrow}$, $\mathsf{NormalFamily}^{\uparrow}$, $\mathsf{RiemannMapping}^{\uparrow}$, $\mathsf{Holomorphic}^{\uparrow}$, $\mathsf{UnitDisk}^{\uparrow}$, $\mathsf{CompactOpenTopology}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

9. *L is the local* $\mathsf{NameCert}_{\mathsf{CaratheodoryKernelConvergence}^{\uparrow}}$ *row.*

The carrier has no coordinate for prime ends, quotient function equality, host domain convergence, selected boundary correspondence, ambient compactness beyond the displayed normal-family handoff, or an unrestricted domain topology.

Lean4 ✓ `BEDC.Derived.CaratheodoryKernelConvergenceUp.CaratheodoryKernelConvergenceTasteGate`
`single carrier alignment`

Theorem 8910.2 (Caratheodory kernel convergence NameCert obligations)**.** *For every accepted* $\mathsf{CaratheodoryKernelConvergence}^{\uparrow}$ *carrier $K = (D, E, H, N, R, T, C, P, L)$, the local* $\mathsf{NameCert}_{\mathsf{CaratheodoryKernelConvergenc}}$ *surface consists exactly of carrier admission for the pointed planar-domain window, compact-kernel exhaustion visibility, holomorphic chart-read visibility, normal-family compactness handoff, Riemann-map route visibility, componentwise transport, continuation replay, provenance, and local naming. A kernel-convergence consumer must read these rows before using the packet as a Caratheodory kernel route.*

Proof. Project the carrier of Definition 8910.1. The pointed window D, compact exhaustion E, holomorphic chart row H, normal-family handoff N, and Riemann-map route R are visible coordinates of the same finite packet.

The compact-kernel row E supplies both interior containment windows and exterior escape rows. The holomorphic row H is read only on those displayed compact windows, so chart convergence is a compact-open read rather than host function equality.

The normal-family handoff N and Riemann-map route R remain downstream. They expose the compactness and normalized disk-map rows needed by consumers, but they do not add prime ends, boundary selectors, quotient equality of maps, or host domain convergence.

Finally T, C, P, L transport, replay, source, and name exactly these rows. Hence the listed rows exhaust the local NameCert obligations for the kernel packet. □

Theorem 8910.3 (Caratheodory kernel convergence normal-family handoff)**.** *Every accepted* CaratheodoryKernelCo *read that reaches a Riemann-map consumer first exposes the pointed planar-domain window D, compact-kernel exhaustion E, holomorphic chart reads H, and the* $\mathsf{NormalFamily}^{\uparrow}$ *compactness handoff N through* $\mathsf{CompactOpenTopology}^{\uparrow}$*. Only then may the normalized* $\mathsf{UnitDisk}^{\uparrow}$ *source and* $\mathsf{RiemannMapping}^{\uparrow}$ *route R be consumed. The handoff supplies no prime-end compactification, quotient function equality, host domain convergence, selected boundary correspondence, or ambient compactness principle.*

Proof. Start with the NameCert obligations of Definition 8910.2. They force every accepted kernel read to expose the pointed domain window, compact exhaustion, holomorphic chart reads, normal-family handoff, and Riemann-map route as rows of one packet.

The normal-family row is read before the Riemann-map route. It consumes the compact-open windows from chapter 4138 and the holomorphic chart reads from chapter 68, then hands a compactness boundary to chapter 2186.

The Riemann-map row is therefore downstream of the same finite handoff. Its normalized $\mathsf{UnitDisk}^{\uparrow}$ source and $\mathsf{RiemannMapping}^{\uparrow}$ data may be used only after the compact-kernel and normal-family rows are visible.

Since the carrier contains no prime-end coordinate, quotient equality of functions, host domain convergence row, boundary selector, or ambient compactness principle, the handoff is exactly the displayed normal-family route into Riemann mapping. □

Falsifiable prediction: Every accepted $\mathsf{CaratheodoryKernelConvergence}^{\uparrow}$ read displays one pointed planar-domain window, one compact-kernel exhaustion, one holomorphic chart-read row, one NormalFamily compactness handoff, one RiemannMapping route, hsame transport, Cont replay, Pkg provenance, and local NameCert row before a kernel-convergence or Riemann-map consumer may use it.

Independence witness: normalfamily, riemannmapping, holomorphic, unitdisk, compactopen-topology: none is bijective with $\mathsf{CaratheodoryKernelConvergence}^{\uparrow}$ because the packet jointly stores the pointed domain window, compact-kernel exhaustion, holomorphic chart reads, normal-family handoff, Riemann-map route, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{CaratheodoryKernelConvergence}^{\uparrow}}$.

Constructive story: A $\mathsf{CaratheodoryKernelConvergence}^{\uparrow}$ packet is generated from a pointed planar-domain window, compact-kernel exhaustion, holomorphic chart reads, NormalFamily compactness handoff, RiemannMapping route, hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CaratheodoryKernelConvergence}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8910.1, Definition 8910.2, and Definition 8910.3 seed the finite kernel-convergence route from compact-open holomorphic windows through normal-family compactness into normalized Riemann mapping.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CaratheodoryKernelConvergence}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim Lean verification, bridge checking, prime-end compactification, quotient equality of functions, host domain convergence, selected boundary correspondences, or ambient compactness beyond the displayed normal-family handoff.

Upgrade path: Obligation closure requires checked carrier admission, compact-kernel exhaustion, holomorphic chart-read visibility, normal-family handoff, Riemann-map route visibility, transport, replay, provenance, and local naming for BEDC.Derived.CaratheodoryKernelConvergenceUp.

Chapter 8911

A Concrete Naming Certificate for $\mathsf{LanczosIteration}^{\uparrow}$

Following Lanczos, the $\mathsf{LanczosIteration}^{\uparrow}$ packet records the finite three-term recurrence data used to build a Krylov basis and a tridiagonal projection from one symmetric matrix row, one inner-product row, and one seed-vector row. It sits after the Krylov carrier of chapter 8810, the matrix carrier of chapter 49, the inner-product carrier of chapter 86, and the spectral theorem surface of chapter 214. The packet names only the finite iteration certificate; it does not assert floating-point stability, Ritz-value convergence, host diagonalization, or a global equality between the tridiagonal row and the original matrix.

Definition 8911.1 (LanczosIteration carrier)**.** *A* $\mathsf{LanczosIteration}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (K, M, I, q_0, m, Q, A_{\mathrm{diag}}, B_{\mathrm{sub}}, T, R, H, C, P, N)$$

with the following displayed rows:

1. *K is the* $\mathsf{KrylovSubspace}^{\uparrow}$ *row generated by one matrix action and one displayed seed vector.*
2. *M is the* $\mathsf{Mat}^{\uparrow}$ *row for the symmetric action inspected by the iteration.*
3. *I is the* $\mathsf{InnerProduct}^{\uparrow}$ *row used to normalize vectors and test orthogonality inside the displayed Krylov span.*
4. *q_0 is the initial normalized seed row, read as the first admitted vector of the Krylov packet.*
5. *m is the finite step bound.*
6. *$Q = (q_0, \ldots, q_m)$ is the displayed vector ledger.*
7. *$A_{\mathrm{diag}} = (\alpha_0, \ldots, \alpha_m)$ is the diagonal coefficient ledger.*
8. *$B_{\mathrm{sub}} = (\beta_1, \ldots, \beta_m)$ is the subdiagonal coefficient ledger.*
9. *T is the tridiagonal matrix row with diagonal A_{diag} and symmetric subdiagonal B_{sub}.*
10. *R is the finite residual ledger recording that each next vector is generated from the previous two vectors and the same matrix action before normalization.*
11. *H records componentwise* hsame *transport for all displayed rows.*
12. *C records* Cont *replay from the seed request through the recurrence, coefficient, residual, and tridiagonal ledgers.*

13. *P is the* Pkg *provenance over* LanczosIteration$^{\uparrow}$, KrylovSubspace$^{\uparrow}$, Mat$^{\uparrow}$, InnerProduct$^{\uparrow}$, SpectralTheorem$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*
14. *N is the local* NameCert$_{\text{LanczosIteration}^{\uparrow}}$ *row.*

The carrier has no coordinate for an infinite Krylov limit, a numerical roundoff model, an eigenvalue convergence theorem, a host orthogonal projector, or a hidden spectral decomposition.

Theorem 8911.2 (LanczosIteration NameCert obligations)**.** *For every accepted* LanczosIteration$^{\uparrow}$ *carrier*

$$L = (K, M, I, q_0, m, Q, A_{\text{diag}}, B_{\text{sub}}, T, R, H, C, P, N),$$

the local NameCert$_{\text{LanczosIteration}^{\uparrow}}$ *surface is exhausted by six obligation rows:*

1. *carrier admission for the Krylov row K, matrix row M, inner-product row I, seed row q_0, step bound m, vector ledger Q, coefficient ledgers A_{diag} and B_{sub}, tridiagonal row T, residual row R, and structural rows H, C, P, N;*
2. *same-action recurrence, requiring every residual entry of R to use the same matrix row M and the previous two displayed vector rows of Q;*
3. *inner-product normalization, requiring each admitted vector and coefficient read to pass through the same* InnerProduct$^{\uparrow}$ *row I;*
4. *tridiagonal assembly, requiring T to be reconstructed only from A_{diag} and B_{sub};*
5. *Krylov compatibility, requiring every vector in Q and every residual in R to remain a displayed finite read of the Krylov packet K;*
6. *ledger exhaustion, requiring any spectral, quadrature, conjugate-gradient, or Ritz-value consumer to cite only the displayed rows before using the packet.*

No NameCert obligation for LanczosIteration$^{\uparrow}$ *is stored outside those six rows.*

Proof. Project the carrier of Definition 8911.1. The accepted packet exposes the Krylov, matrix, inner-product, seed, step, vector, coefficient, tridiagonal, residual, transport, replay, provenance, and local naming rows.

The recurrence obligation is read from R. Each residual row records a finite application of the same matrix row to the current vector, subtracts the two displayed coefficient contributions, and admits the next vector only through the same inner-product normalization surface.

The tridiagonal matrix is not an independent host object. It is assembled from A_{diag} and B_{sub}, so any read of T factors through the two finite coefficient ledgers.

Finally K, H, C, P, N provide the boundary checks. The Krylov row supplies finite iterate compatibility, the transport and replay rows preserve the displayed ledgers, and the provenance row names the spectral theorem only as downstream background rather than as a convergence claim. Therefore the six listed obligations exhaust the certificate surface. □

Theorem 8911.3 (LanczosIteration Krylov handoff)**.** *Every accepted* LanczosIteration$^{\uparrow}$ *carrier has a canonical handoff to the* KrylovSubspace$^{\uparrow}$ *packet obtained by forgetting the coefficient, tridiagonal, and residual rows and retaining the rows*

$$(K, H, C, P, N).$$

This handoff preserves the finite seed, matrix-action, span, transport, replay, provenance, and local naming reads exposed by chapter 8810; it does not add an Arnoldi basis, a spectral approximation theorem, or a host diagonalization claim.

Proof. Read K from the carrier of Definition 8911.1. By construction K is already the finite Krylov packet generated by the same seed and matrix action used by the recurrence.

Forgetting A_{diag}, B_{sub}, T, and R removes the Lanczos-specific coefficient and tridiagonal data. The rows H and C still transport and replay the remaining Krylov reads componentwise, while P and N keep the provenance and local naming boundary visible.

The handoff therefore exposes exactly the finite Krylov certificate needed by downstream consumers and no additional spectral or host-level assertion. □

Falsifiable prediction: Every accepted $\mathsf{LanczosIteration}^{\uparrow}$ read exposes one Krylov row, one Matrix row, one InnerProduct row, one normalized seed row, one finite step bound, one vector ledger, two coefficient ledgers, one tridiagonal row, one residual ledger, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row before any spectral, quadrature, conjugate-gradient, or Ritz-value consumer is served.

Independence witness: krylovsubspace, matrix, innerproduct, spectraltheorem: none alone is bijective with $\mathsf{LanczosIteration}^{\uparrow}$ because this packet alone binds finite Krylov admission, three-term recurrence data, normalization, tridiagonal assembly, residual replay, transport, provenance, and local naming as one certificate.

Closure status for $\mathsf{NameCert}_{\mathsf{LanczosIteration}^{\uparrow}}$.

Constructive story: A $\mathsf{LanczosIteration}^{\uparrow}$ packet is generated from a Krylov row, a Matrix row, an InnerProduct row, a normalized seed, a finite step bound, a vector ledger, two coefficient ledgers, a tridiagonal row, a residual ledger, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{LanczosIteration}^{\uparrow}}$, seed)

Scope closed: Definition 8911.1, Definition 8911.2, and Definition 8911.3 seed the finite Lanczos iteration certificate over Krylov, matrix, inner-product, tridiagonal, residual, transport, replay, provenance, and local naming rows.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{LanczosIteration}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close floating-point stability, loss of orthogonality, Ritz-value convergence, eigenvalue error bounds, host diagonalization, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, recurrence compatibility, inner-product normalization, tridiagonal assembly, Krylov handoff, and ledger exhaustion for BEDC.Derived.LanczosIterationUp.

Chapter 8912

A Concrete Naming Certificate for $\mathsf{BishopBridgesRegularCompletionTheorem}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{BishopBridgesRegularCompletionTheorem}^{\uparrow}$ packet records the regular-Cauchy completion theorem as finite BEDC naming data rather than as a quotient construction on streams. It reads dyadic tolerance arithmetic from chapter 291, finite observation windows from chapter 126, regular rational readback from chapter 301, the terminal real-name seal from chapter 38, and the extension-and-uniqueness route of chapter 2251. The theorem packet names a capstone handoff for regular completion consumers; it does not identify quotient streams, select limits, invoke countable choice, assert host real equality, or claim ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 8912.1 (Bishop–Bridges regular completion theorem carrier)**.** *A* BishopBridgesRegularCompletionTheor *carrier is a finite* BHist *packet*

$$T = (D, W, R, A, U, H, C, P, N)$$

with the following displayed rows:

1. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger used to compare regular Cauchy observations.*
2. *W is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row opened by the inspected completion request.*
3. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *regular rational readback row visible through D and W.*
4. *A is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row available only after the dyadic, stream, and regular-rational rows have been displayed.*
5. *U is the* $\mathsf{RegularCauchyCompletionUniversalProperty}^{\uparrow}$ *handoff row, read as an extension-and-uniqueness surface over the same finite completion data.*
6. *H records componentwise* hsame *transport for D, W, R, A, U, C, P, N.*
7. *C records displayed* Cont *replay from a completion theorem request through the dyadic, stream, regular-rational, real-seal, and universal-property rows.*
8. *P is the* Pkg *provenance over* $\mathsf{BishopBridgesRegularCompletionTheorem}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{RegularCauchyCompletionUniversalProperty}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
9. *N is the local* $\mathsf{NameCert}_{\mathsf{BishopBridgesRegularCompletionTheorem}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $D, W, R, A, U, H, C, P, N$. It has no coordinate for quotient stream equality, selected representatives, selected limits, countable choice, host real equality, or ambient completeness of $\mathsf{Real}^{\uparrow}$.

Theorem 8912.2 (Bishop–Bridges regular completion theorem NameCert obligations)**.** *For every accepted* $\mathsf{BishopBridgesRegularCompletionTheorem}^{\uparrow}$ *packet*

$$T = (D, W, R, A, U, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{BishopBridgesRegularCompletionTheorem}^{\uparrow}}$ *obligation sketch has exactly five rows:*

1. *carrier:* $D, W, R, A, U, H, C, P, N$ *must be displayed before the theorem packet is public;*
2. *classifier: accepted packets are compared only by the dyadic tolerance, stream-window, regular-rational, real-seal, universal-property, transport, replay, provenance, and local naming rows;*
3. *stability: componentwise* hsame *transport in* H *and displayed* Cont *replay in* C *preserve the same completion route;*
4. *ledger:* P *records the theorem packet as sourced from the dyadic, stream, regular-rational, real, and regular-completion universal-property siblings;*
5. *public theorem: the exported theorem handoff is the finite route through those rows, not a quotient completion, a selected limit, a choice principle, host real equality, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the carrier of Definition 8912.1. The rows D, W, R, A, U expose the dyadic tolerance ledger, finite stream windows, regular rational readback, real-name seal, and universal-property handoff before any theorem-facing consumer can inspect the packet.

The classifier and stability rows are structural. A consumer can compare packets only by the displayed coordinates, while H and C transport and replay the same ordered route without adding quotient equality or a selected representative.

Finally read the provenance and local naming rows. They bind the packet to the sibling chapters named in the opening paragraph and export only the finite theorem handoff. Since no excluded coordinate occurs in the carrier, the five listed rows exhaust the local NameCert obligation sketch. □

Theorem 8912.3 (Bishop–Bridges regular completion theorem handoff)**.** *Every completion-facing consumer of an accepted* $\mathsf{BishopBridgesRegularCompletionTheorem}^{\uparrow}$ *packet reads the route*

$\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{RegularCauchyCompletionUniversalProperty}^{\uparrow}$, BHist, hsame, Co

as the finite regular-completion theorem surface. The handoff may be consumed by Real and Completion chapters only after the dyadic tolerance, finite observation, regular rational readback, real seal, extension-and-uniqueness, transport, replay, provenance, and local naming rows have all been displayed.

Proof. Begin with the dyadic and stream rows. They determine the tolerance request and the finite windows that are visible to the theorem packet.

Next read the regular rational and real rows. The $\mathsf{RegSeqRat}^{\uparrow}$ row supplies the regular readback, and the $\mathsf{Real}^{\uparrow}$ row is reached only as the terminal seal over the same displayed data.

The universal-property row is then consumed as a finite extension-and-uniqueness ledger, through chapter 2251. Transport, replay, provenance, and local naming preserve that route for downstream consumers. No step introduces quotient stream equality, selected limits, countable choice, host real equality, or ambient $\mathsf{Real}^{\uparrow}$ completeness. □

Falsifiable prediction: Every accepted $\mathsf{BishopBridgesRegularCompletionTheorem}^{\uparrow}$ read exposes dyadic tolerance, finite StreamName windows, RegSeqRat readback, a RealUp seal, a regular-Cauchy universal-property row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert data before the theorem handoff is public.

Independence witness: dyadicratcore, streamname, regseqrat, real, regular-cauchy-completion-universal-property: none is bijective with $\mathsf{BishopBridgesRegularCompletionTheorem}^{\uparrow}$ because the theorem packet binds all five rows as one completion-facing capstone surface.

Closure status for $\mathsf{NameCert}_{\mathsf{BishopBridgesRegularCompletionTheorem}^{\uparrow}}$.

Constructive story: A $\mathsf{BishopBridgesRegularCompletionTheorem}^{\uparrow}$ packet is generated from dyadic tolerance rows, finite StreamName windows, RegSeqRat readback, a RealUp seal, a regular-Cauchy universal-property row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BishopBridgesRegularCompletionTheorem}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8912.1, Definition 8912.2, and Definition 8912.3 seed the finite regular-completion theorem route over dyadic, stream, regular rational, real-seal, universal-property, transport, replay, provenance, and local naming rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BishopBridgesRegularCompletionTheorem}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient stream equality, selected limits, countable choice, host real equality, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, classifier locality, transport stability, provenance non-escape, and theorem handoff for BEDC.Derived.BishopBridgesRegularCompletionTheoremUp.

Chapter 8913

A Concrete Naming Certificate for $\mathsf{RealCompletionCantorSieve}^{\uparrow}$

Following Bishop–Bridges constructive analysis and Cantor nested intervals, the $\mathsf{RealCompletionCantorSieve}^{\uparrow}$ packet records a finite nested-window route into the open Real and Completion phase. It consumes the dyadic arithmetic source of chapter 291, the observation stream of chapter 126, the regular rational handoff of chapter 301, the terminal real-name seal of chapter 38, and the fast Cauchy control of chapter 323. The packet names one finite Cantor-style sieve for one displayed budget; it is not a proof of full $\mathsf{Real}^{\uparrow}$ completeness, a quotient-real equality theorem, or a choice principle for infinite interval selections.

Definition 8913.1 (Real completion Cantor sieve carrier)**.** *A* $\mathsf{RealCompletionCantorSieve}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (D, W, B, O, Q, R, F, E, H, C, P, N)$$

with the following displayed rows:

1. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *arithmetic row, carrying the dyadic endpoints, midpoint operations, order checks, and radius comparisons used by the displayed windows.*
2. *W is the finite nested-window table*

$$I_0 \supseteq I_1 \supseteq \cdots \supseteq I_m,$$

   where each $I_i = [a_i, b_i]$ has dyadic endpoints and the inclusion proof is recorded as a finite row in D.
3. *B is the diameter descent budget. It records a finite schedule $\epsilon_0, \ldots, \epsilon_m$ and witnesses that the displayed diameter of I_i is bounded by ϵ_i.*
4. *O is the* $\mathsf{StreamName}^{\uparrow}$ *observation row. It lists only the stream entries inspected to decide the next nested window.*
5. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff row, translating the observed stream windows into regular rational approximation rows for the same displayed budget.*
6. *R is the* $\mathsf{Real}^{\uparrow}$ *seal row attached to the terminal window and the regular rational handoff. It exposes a real-name boundary only after D, W, B, O, Q have been read.*
7. *F is the* $\mathsf{FastCauchy}^{\uparrow}$ *control row. It records the finite modulus entries that certify the terminal window is compatible with the requested fast Cauchy tolerance.*

8. *E is the excluded-principle ledger: no ambient completeness theorem, quotient-real equality, located trichotomy, countable choice selector, or infinite nested-window choice may be read from the carrier.*
9. *H records componentwise* hsame *transport for the dyadic arithmetic, nested-window table, descent budget, stream observations, regular-rational handoff, real seal, fast Cauchy row, excluded-principle ledger, replay, provenance, and local naming rows.*
10. *C records displayed* Cont *replay of the finite route*

$$D, W, B, O \longmapsto Q, F \longmapsto R, E.$$

11. *P is the* Pkg *provenance over* $\mathsf{RealCompletionCantorSieve}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{FastCauchy}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
12. *N is the local* $\mathsf{NameCert}_{\mathsf{RealCompletionCantorSieve}^{\uparrow}}$ *row.*

The carrier predicate compares accepted packets only through $D, W, B, O, Q, R, F, E, H, C, P, N$. It has no coordinate for an infinite interval selector, a completed quotient of Cauchy names, global real completeness, or an order-trichotomy oracle.

Theorem 8913.2 (RealCompletionCantorSieveUp NameCert obligations)**.** *For every accepted* $\mathsf{RealCompletionCantorSieve}^{\uparrow}$ *carrier*

$$S = (D, W, B, O, Q, R, F, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{RealCompletionCantorSieve}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the displayed packet of Definition 8913.1;*
2. *dyadic endpoint exactness, requiring every endpoint, midpoint, comparison, and diameter computation to be read from D;*
3. *nested-window exactness, requiring W to expose only the finite chain $I_0, \ldots, I_m$ and its displayed inclusion witnesses;*
4. *descent-budget exactness, requiring B to bind each exposed diameter bound to the corresponding finite tolerance row;*
5. *observation and regularization compatibility, requiring O and Q to show that every stream observation used by the sieve has a matching* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff row;*
6. *terminal real and fast Cauchy compatibility, requiring R and F to seal only the terminal finite window and its displayed tolerance;*
7. *excluded-principle nonescape through E, requiring consumers to refuse ambient* $\mathsf{Real}^{\uparrow}$ *completeness, quotient-real equality, located trichotomy, countable choice, and infinite nested-window selection;*
8. *transport, replay, provenance, and local naming through H, C, P, N.*

No Cantor-sieve obligation is stored outside these rows.

Proof. Project the accepted carrier of Definition 8913.1. The projection exposes the dyadic arithmetic row, the finite nested-window table, the descent budget, the observation stream row, the

regular rational handoff, the terminal real seal, the fast Cauchy row, the refusal ledger, and the structural rows.

The dyadic and nested-window obligations are finite. Each endpoint and comparison is read from D, while W lists only the windows $I_0, \ldots, I_m$ and the inclusion witnesses between consecutive rows. Thus a consumer cannot replace the finite table by an infinite interval selector.

The descent budget is tied to the same table. The row B records one tolerance row for each displayed window, so every diameter claim is checked against a row already present in W and computed through D.

The observation handoff then passes through O and Q. Every inspected stream entry is named in O, and the corresponding regular rational approximation is stored in Q before the terminal real seal is visible.

The endpoint of the route is local. The rows R and F seal the final window and the requested fast Cauchy tolerance, while E blocks the host principles that are not part of the packet.

Finally H, C, P, N transport, replay, source, and name exactly the same rows. Since the carrier has no further coordinate, the listed obligations exhaust the local NameCert surface. □

Theorem 8913.3 (Finite Cantor sieve handoff)**.** *Every accepted* $\mathsf{RealCompletionCantorSieve}^{\uparrow}$ *real-name read factors through the finite route*

$$\mathsf{DyadicRatCore}^{\uparrow}, \mathsf{StreamName}^{\uparrow}, \mathsf{RegSeqRat}^{\uparrow}, \mathsf{FastCauchy}^{\uparrow}, \mathsf{Real}^{\uparrow}.$$

Concretely, the read first opens dyadic endpoint arithmetic and a finite nested-window table, then checks the diameter descent budget, then reads the inspected stream observations and regular rational handoff rows, then exposes the terminal real seal and fast Cauchy control through transport, replay, provenance, and local naming.

Proof. Start with a consumer of the terminal real row R. By carrier admission, R is downstream from D, W, B, O, Q, F, so it cannot be inspected independently of the finite sieve data.

The first part of the route is dyadic. The rows D and W expose the endpoint arithmetic and the nested finite table, while B supplies the diameter schedule attached to those same windows.

The second part is observational. The stream row O records the finite observations that selected the displayed windows, and Q repackages those observations as regular rational rows for the same budget.

The final part is the terminal seal. The fast Cauchy row F checks the requested tolerance, and H, C, P, N preserve, replay, source, and name the same route. Therefore the public read is the displayed finite handoff and not a global completeness or choice claim. □

Closure status for $\mathsf{NameCert}_{\mathsf{RealCompletionCantorSieve}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RealCompletionCantorSieve}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8913.1, Definition 8913.2, and Definition 8913.3 seed the finite Cantor-style nested-window route through DyadicRatCore, StreamName, RegSeqRat, FastCauchy, Real, transport, replay, provenance, and local naming rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RealCompletionCantorSieve}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close full $\mathsf{Real}^{\uparrow}$ completeness, quotient-real equality, located trichotomy, countable choice, infinite nested-window selection, Lean verification, or a standard bridge.

Upgrade path: Obligation closure requires checked dyadic endpoint exactness, nested-window exactness, descent-budget exactness, observation and regularization compatibility, terminal real and fast Cauchy compatibility, excluded-principle nonescape, transport, replay, provenance, and local naming for BEDC.Derived.RealCompletionCantorSieveUp.

Constructive story: A $\mathsf{RealCompletionCantorSieve}^{\uparrow}$ packet is generated from DyadicRatCore endpoint arithmetic, a finite nested-window table, a diameter descent budget, StreamName observations, RegSeqRat handoff rows, a terminal RealUp seal, FastCauchy tolerance control, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 8914

A Concrete Naming Certificate for $\mathsf{RapidCauchySubsequence}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{RapidCauchySubsequence}^{\uparrow}$ packet records the finite extraction route that turns a displayed Cauchy or bounded-sequence request into a rate-controlled subsequence handoff without countable choice. It sits after the dyadic tolerance ledger of chapter 291, the finite observation windows of chapter 126, the regular rational readback of chapter 301, the terminal real-name seal of chapter 38, and the diagonal selector route of chapter 1873. The packet supplies only a displayed subsequence extraction surface for Real and Completion consumers; it does not assert ambient sequential compactness, selected cluster points, quotient stream equality, countable choice, trichotomy, or mature $\mathsf{Real}^{\uparrow}$ completeness.

Definition 8914.1 (Rapid Cauchy subsequence carrier)**.** *A* $\mathsf{RapidCauchySubsequence}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (Q, R, I, W, D, G, E, A, L, H, C, P, N)$$

with the following displayed rows:

1. *Q is the source sequence row, recording the visible Cauchy or bounded-sequence request whose subsequence is being extracted.*
2. *R is the rapid rate row, assigning each requested precision level to a finite tail window.*
3. *I is the strictly increasing index row for the selected subsequence positions.*
4. *W is the* $\mathsf{StreamName}^{\uparrow}$ *window row read at the indices listed by I.*
5. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, storing the dyadic radii and slack comparisons used by the finite windows.*
6. *G is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row induced by W and D.*
7. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached only after the rate, index, window, tolerance, and readback rows have been displayed.*
8. *A is the* $\mathsf{CauchyDiagonalArgument}^{\uparrow}$ *handoff row, recording that the selected finite tails are read through the diagonal route rather than through an ambient subsequence choice principle.*
9. *L records the rate-extraction handoff: every precision request reaches R, I, W, D, G, E, A in that order before a downstream Real or Completion consumer can inspect the subsequence.*
10. *H records componentwise* hsame *transport for the displayed rows.*

11. *C records displayed* Cont *replay of the finite extraction route.*
12. *P is the* Pkg *provenance over* RapidCauchySubsequence$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, Real$^{\uparrow}$, CauchyDiagonalArgument$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
13. *N is the local* NameCert$_{\text{RapidCauchySubsequence}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $Q, R, I, W, D, G, E, A, L, H, C, P, N$. It has no coordinate for countable choice, selected cluster points, quotient stream equality, host subsequence equality, trichotomy, or ambient Real$^{\uparrow}$ *completeness.*

Lean4 (statement) `BEDC.Derived.RapidCauchySubsequenceUp`

Theorem 8914.2 (Rapid Cauchy subsequence NameCert obligations)**.** *For every accepted* RapidCauchySubsequenc *carrier*

$$S = (Q, R, I, W, D, G, E, A, L, H, C, P, N),$$

the local NameCert$_{\text{RapidCauchySubsequence}^{\uparrow}}$ *surface consists of carrier exposure, classifier stability, monotone index display, finite-window selection, dyadic tolerance accounting,* RegSeqRat$^{\uparrow}$ *readback, terminal* Real$^{\uparrow}$ *seal routing, diagonal handoff, rate-extraction handoff, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. No obligation is stored outside these finite rows.*

Proof. Project the carrier of Definition 8914.1. The analytic rows are the source sequence, rate schedule, increasing index list, StreamName windows, dyadic tolerance ledger, regular rational readback, Real seal, diagonal handoff, and rate-extraction handoff.

The monotone index and finite-window rows make the subsequence visible before any Real-facing seal is consumed. The dyadic ledger and RegSeqRat readback then bind the selected windows to the same tolerance route used by the L10 Real and Completion chain.

Finally replay the structural rows H, C, P, N. They transport, replay, source, and name the same finite packet, so the local NameCert obligations are exhausted by the displayed rows and do not import countable choice, quotient stream equality, host subsequence equality, trichotomy, or ambient completeness. □

Theorem 8914.3 (Rapid Cauchy subsequence rate extraction handoff)**.** *Every precision request accepted by a* RapidCauchySubsequence$^{\uparrow}$ *carrier factors through the finite route*

$$R, I, W, D, G, E, A, L, H, C, P, N.$$

The request first reads the rapid rate row R, then the increasing index row I, then the finite StreamName$^{\uparrow}$ *windows W, then the* DyadicRatCore$^{\uparrow}$ *tolerance ledger D, then the* RegSeqRat$^{\uparrow}$ *readback G, then the terminal* Real$^{\uparrow}$ *seal E, and only then the diagonal and structural handoff rows. The route supplies no selected infinite choice function, quotient stream equality, host subsequence equality, trichotomy, or ambient* Real$^{\uparrow}$ *completeness.*

Proof. Begin with the accepted carrier and inspect one precision request. The row R is the only rate entrance, so the request cannot bypass the finite schedule and read the terminal seal first.

The row I lists the selected indices and W reads only the finite windows at those indices. The dyadic ledger D supplies the tolerance radii and slack comparisons needed for those windows, and the readback row G turns the displayed windows into the regular rational surface consumed by L10 Real routes.

The seal E and diagonal row A are downstream of the same finite route. The handoff row L records this ordering for downstream Real and Completion consumers, while H, C, P, N preserve and name it. Since no carrier coordinate stores a choice function, quotient equality, host equality, trichotomy, or completeness theorem, none is exported by the handoff. □

Theorem 8914.4 (Rapid Cauchy subsequence nonchoice boundary)**.** *An accepted* $\mathsf{RapidCauchySubsequence}^{\uparrow}$ *packet may be consumed by Real and Completion routes only as the displayed finite subsequence extraction surface of Definition 8914.1. It cannot be used as a countable-choice selector, a cluster-point theorem, quotient stream equality, host subsequence equality, trichotomy, or mature* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Apply the rate extraction handoff of Definition 8914.3. Every accepted read passes through the rate, index, window, dyadic tolerance, RegSeqRat readback, Real seal, diagonal handoff, and structural rows.

Inspect the classifier in Definition 8914.1. The packet has no coordinate for a chosen infinite selector outside I, no quotient equality row, no host subsequence equality row, no trichotomy row, and no ambient completeness theorem.

Thus a downstream consumer receives only the displayed finite extraction route. Any request for the excluded objects lies outside the accepted packet. □

Falsifiable prediction: Every accepted $\mathsf{RapidCauchySubsequence}^{\uparrow}$ read displays a source sequence row, rapid rate row, monotone index row, StreamName windows, DyadicRatCore tolerances, RegSeqRat readback, RealUp seal, CauchyDiagonalArgument handoff, componentwise hsame transport, Cont replay, Pkg provenance, and local naming before any Real or Completion consumer receives subsequence data.

Independence witness: dyadicratcore, streamname, regseqrat, real, cauchy-diagonal-argument: $\mathsf{RapidCauchySubsequence}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries source sequence display, rapid rate extraction, monotone subsequence indices, finite windows, dyadic tolerance accounting, regular readback, terminal Real sealing, diagonal handoff, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{RapidCauchySubsequence}^{\uparrow}}$.

Constructive story: A $\mathsf{RapidCauchySubsequence}^{\uparrow}$ packet is generated from a source sequence row, rapid rate row, monotone index row, StreamName windows, DyadicRatCore tolerances, RegSeqRat readback, a terminal RealUp seal, CauchyDiagonalArgument handoff, rate-extraction handoff, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RapidCauchySubsequence}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8914.1, Definition 8914.2, Definition 8914.3, and Definition 8914.4 seed the finite rapid Cauchy subsequence extraction route for L10 Real and Completion consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RapidCauchySubsequence}^{\uparrow}}, \mathsf{formalTarget})$

Bridge status: none

Not claimed: This chapter does not close countable choice, selected cluster points, quotient stream equality, host subsequence equality, trichotomy, mature $\mathsf{Real}^{\uparrow}$ completeness, or bridge checking.

Upgrade path: Obligation closure requires checked carrier exposure, monotone index preservation, window selection, dyadic accounting, RegSeqRat readback, Real-seal routing, diagonal handoff, transport, replay, provenance, and local naming for BEDC.Derived.RapidCauchySubsequenceUp.

Chapter 8915

A Concrete Naming Certificate for $\mathsf{MetaCICStandardizationTheorem}^{\uparrow}$

Following Barendregt on standardization for lambda calculus, the $\mathsf{MetaCICStandardizationTheorem}^{\uparrow}$ packet records the finite route by which a residual-aware MetaCIC reduction read may be rearranged into a leftmost-facing route before any normalization or kernel-consistency conclusion is public. It sits after the lambda-calculus syntax carrier of chapter 200, the parallel-reduction packet of chapter 7468, the Church–Rosser packet of chapter 6198, and the candidate-normalization confluence handoff of chapter 5547. The packet names standardization only as displayed NameCert data; it does not assert full normalization, subject reduction, quotient syntax equality, evaluator equality, or kernel consistency.

Definition 8915.1 (MetaCIC standardization theorem carrier)**.** *A* $\mathsf{MetaCICStandardizationTheorem}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (T, R, P, C, L, J, H, Q, G, N)$$

with the following displayed rows:

1. *T is the* $\mathsf{LambdaCalc}^{\uparrow}$ *term row supplying the source syntax and binder ledger.*
2. *R is the one-step reduction route whose redex observations are still displayed.*
3. *P is the* $\mathsf{ParallelReduction}^{\uparrow}$ *residual row recording the simultaneous-contraction and residual bookkeeping surface.*
4. *C is the* $\mathsf{ChurchRosser}^{\uparrow}$ *confluence-facing row, read only as a sibling join route.*
5. *L is the leftmost schedule row naming the standardization order for the displayed reduction observations.*
6. *J is the candidate-normalization handoff row read through* $\mathsf{MetacicCandidateNormalizationConfluenceHandoff}^{\uparrow}$.
7. *H records componentwise* hsame *transport for the term, reduction, residual, confluence, leftmost schedule, handoff, replay, provenance, and naming rows.*
8. *Q records displayed* Cont *replay along the same rows.*
9. *G is the* Pkg *provenance over* $\mathsf{MetaCICStandardizationTheorem}^{\uparrow}$, $\mathsf{LambdaCalc}^{\uparrow}$, $\mathsf{ParallelReduction}^{\uparrow}$, $\mathsf{ChurchRosser}^{\uparrow}$, $\mathsf{MetacicCandidateNormalizationConfluenceHandoff}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{MetaCICStandardizationTheorem}^{\uparrow}}$ *evidence row.*

The classifier compares accepted packets only through $T, R, P, C, L, J, H, Q, G, N$. It has no coordinate for global strong normalization, unrestricted Church–Rosser, subject reduction, quotient equality of terms, host evaluator equality, or kernel consistency.

Theorem 8915.2 (MetaCIC standardization NameCert obligations)**.** *For every accepted* $\mathsf{MetaCICStandardizationT}$ *carrier* $S = (T, R, P, C, L, J, H, Q, G, N)$*, the local* $\mathsf{NameCert}_{\mathsf{MetaCICStandardizationTheorem}^{\uparrow}}$ *surface consists exactly of term-row admission, displayed reduction-route visibility, parallel residual bookkeeping, sibling Church–Rosser route exposure, leftmost schedule admission, candidate-normalization handoff exposure, componentwise transport, displayed replay, provenance, and local naming. A MetaCIC confluence or normalization consumer may read the packet only as a standardization boundary between residual data and a leftmost route; it cannot read the packet as full normalization, unrestricted confluence, subject reduction, quotient syntax equality, evaluator equality, or kernel consistency.*

Proof. Project the carrier of Definition 8915.1. The term row T, reduction route R, parallel residual row P, Church–Rosser sibling row C, leftmost schedule L, and candidate-normalization handoff J are the whole mathematical surface available to the certificate.

The standardization read first exposes T, R, P. This fixes the source syntax, the observed reduction route, and the residual bookkeeping before any leftmost schedule can be consumed.

Next it exposes C, L, J. The Church–Rosser row supplies only a sibling join route, the leftmost row names the standardization order, and the candidate-normalization handoff remains a guarded downstream boundary rather than a normalization theorem.

Finally H, Q, G, N preserve the same displayed route by transport, replay, provenance, and local naming. Since the carrier contains no coordinate for the excluded global endpoints, none of those endpoints can be exported by the local NameCert surface. □

Theorem 8915.3 (MetaCIC standardization leftmost route)**.** *Every accepted* $\mathsf{MetaCICStandardizationTheorem}^{\uparrow}$ *read that is handed to a MetaCIC confluence or candidate-normalization consumer must expose the finite route*

$$\mathsf{LambdaCalc}^{\uparrow} \longmapsto \mathsf{ParallelReduction}^{\uparrow} \longmapsto \mathsf{ChurchRosser}^{\uparrow} \longmapsto \mathsf{MetacicCandidateNormalizationConfluenceHandoff}^{\uparrow}$$

through the displayed rows $T, R, P, C, L, J, H, Q, G, N$ before any leftmost-facing endpoint is public. The leftmost route is a residual standardization handoff only; it does not claim global strong normalization, full Church–Rosser, unrestricted subject reduction, quotient syntax equality, host evaluator soundness, or kernel consistency.

Proof. Start with the obligation surface of Definition 8915.2. It forces the term row, reduction route, parallel residual bookkeeping, Church–Rosser sibling row, leftmost schedule, and candidate-normalization handoff to be displayed together.

Read the sibling dependencies in order. The lambda-calculus row supplies syntax, $\mathsf{ParallelReduction}^{\uparrow}$ supplies residual bookkeeping, $\mathsf{ChurchRosser}^{\uparrow}$ supplies the confluence-facing sibling route, and $\mathsf{MetacicCandidateNormalizationConfluenceHandoff}^{\uparrow}$ supplies the guarded downstream boundary.

The structural rows H, Q, G, N then transport, replay, source, and name the same finite path. Hence the public endpoint is only a residual standardization handoff to a leftmost route, with no coordinate for the refused global MetaCIC claims. □

Closure status for $\mathsf{NameCert}_{\mathsf{MetaCICStandardizationTheorem}^{\uparrow}}$**.**

Constructive story: A $\mathsf{MetaCICStandardizationTheorem}^{\uparrow}$ packet is generated from lambda-term syntax, displayed reduction observations, parallel residual bookkeeping, a Church–Rosser sibling route, a leftmost schedule, candidate-normalization handoff data, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert evidence.

Theory closure: TheoryGate(NameCert$_{\mathsf{MetaCICStandardizationTheorem}\uparrow}$, seed)

Scope closed: Definition 8915.1, Definition 8915.2, and Definition 8915.3 seed the finite residual standardization route from lambda syntax and parallel residual data to a guarded MetaCIC candidate-normalization handoff.

Formal verification: FormalStatus(NameCert$_{\mathsf{MetaCICStandardizationTheorem}\uparrow}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim full normalization, unrestricted Church–Rosser, subject reduction, quotient syntax equality, host evaluator equality, kernel consistency, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, residual bookkeeping, sibling Church–Rosser exposure, leftmost-schedule exactness, candidate-normalization handoff discipline, transport, replay, provenance, and local naming for BEDC.Derived.MetaCICStandardizationTheoremUp.

Chapter 8916

A Concrete Naming Certificate for $\mathsf{ApartnessOrderedField}^{\uparrow}$

Following Bishop and Bridges on constructive algebra and ordered real fields, the $\mathsf{ApartnessOrderedField}^{\uparrow}$ packet records the finite interface in which field operations, strict apartness, and order-facing comparison data are displayed before any Real consumer may read an algebraic order claim. It sits over the apartness real carrier of chapter 304, the real apartness field surface of chapter 5562, the located apartness field of chapter 7144, the algebraic order route of chapter 766, the Archimedean ordered field boundary of chapter 1419, the regular rational readback of chapter 301, and the terminal real-name seal of chapter 38. The packet names constructive ordered-field data only through displayed rows; it does not replace apartness by host inequality, trichotomy, quotient real equality, or ambient completeness.

Definition 8916.1 (Apartness ordered field carrier)**.** *An* $\mathsf{ApartnessOrderedField}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$F = (R, A, O, L, Q, E, H, C, P, N)$$

with the following displayed rows:

1. *R is the underlying* $\mathsf{Real}^{\uparrow}$ *name row whose operations are being read.*
2. *A is the* $\mathsf{ApartnessReal}^{\uparrow}$ *row naming positive apartness as data rather than as negated equality.*
3. *O is the order-facing row supplied through* $\mathsf{RealAlgOrder}^{\uparrow}$ *and* $\mathsf{ArchimedeanOrderedField}^{\uparrow}$*.*
4. *L is the located-field row inherited from* $\mathsf{LocatedApartnessField}^{\uparrow}$*.*
5. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for rational operation and comparison witnesses.*
6. *E is the Real-seal row reached only after R, A, O, L, Q remain visible.*
7. *H records componentwise* hsame *transport for the real, apartness, order, locatedness, readback, seal, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from an ordered-field consumer request through apartness, order, locatedness, rational readback, and the Real seal.*
9. *P is the* Pkg *provenance over* $\mathsf{ApartnessOrderedField}^{\uparrow}$*,* $\mathsf{ApartnessReal}^{\uparrow}$*,* $\mathsf{RealApartnessField}^{\uparrow}$*,* $\mathsf{LocatedApartnessField}$ $\mathsf{RealAlgOrder}^{\uparrow}$*,* $\mathsf{ArchimedeanOrderedField}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*,* BHist*,* hsame*,* Cont*, and* $\mathsf{NameCert}$ *rows.*
10. *N is the local* $\mathsf{NameCert}_{\mathsf{ApartnessOrderedField}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $R, A, O, L, Q, E, H, C, P, N$. It has no coordinate for trichotomy, host real equality, quotient real equality, choice-selected representatives, or an ambient completeness principle.

Lean4 (statement) `BEDC.Derived.ApartnessOrderedFieldUp`

Theorem 8916.2 (Apartness ordered field NameCert obligations)**.** *For every accepted* $\mathsf{ApartnessOrderedField}^{\uparrow}$ *carrier* $F = (R, A, O, L, Q, E, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{ApartnessOrderedField}^{\uparrow}}$ *surface consists exactly of carrier admission for the* $\mathsf{Real}^{\uparrow}$ *source row, explicit* $\mathsf{ApartnessReal}^{\uparrow}$ *apartness, algebraic order data, located apartness-field data,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback, Real sealing, componentwise* hsame *stability, displayed* Cont *replay,* Pkg *provenance, and local naming. A consumer therefore reads constructive ordered-field structure only through the finite route*

$$R, A, O, L, Q \longmapsto E, H, C, P, N.$$

Proof. Project the accepted carrier of Definition 8916.1. The rows R, A, O, L, Q display the real name, apartness relation, algebraic order, located-field evidence, and regular rational readback before the seal row is available.

The structural rows H, C, P, N preserve that displayed route under transport, replay, provenance, and local naming. Since the carrier has no row for trichotomy, host equality, quotient equality, or selected representatives, those data cannot enter the NameCert surface. □

Theorem 8916.3 (Apartness ordered field Real handoff)**.** *Every* $\mathsf{Real}^{\uparrow}$*-facing algebraic or order-facing consumer of an accepted* $\mathsf{ApartnessOrderedField}^{\uparrow}$ *carrier must first display the* $\mathsf{Real}^{\uparrow}$ *source row R, the apartness row A, the order row O, the locatedness row L, and the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row Q. The handoff may consume the seal row E only as this displayed constructive ordered-field route. It does not assert trichotomy, host real equality, quotient real equality, selected representatives, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Apply the NameCert obligations of Definition 8916.2. They force every ordered-field read through the displayed rows R, A, O, L, Q before E can be consumed.

The sibling chapters named in the carrier supply the traditional components as finite BEDC rows: apartness from chapter 304, located field data from chapter 7144, algebraic order from chapter 766, Archimedean order from chapter 1419, and rational readback from chapter 301.

Finally H, C, P, N preserve that same route. Because the carrier exports no trichotomy row, quotient equality row, selected representative, or ambient completeness row, the Real handoff remains constructive and apartness-explicit. □

Falsifiable prediction: An accepted $\mathsf{ApartnessOrderedField}^{\uparrow}$ read that produces an ordered-field conclusion while bypassing explicit apartness, locatedness, regular rational readback, transport, replay, provenance, and local naming is outside the carrier surface.

Independence witness: apartnessreal, real-apartness-field, located-apartness-field, real-alg-order, archimedeanorderedfield, regseqrat, real: no listed sibling is bijective with $\mathsf{ApartnessOrderedField}^{\uparrow}$ because this packet binds apartness, algebraic order, located field data, regular rational readback, Real sealing, transport, replay, provenance, and local naming as one constructive ordered-field interface.

Closure status for $\mathsf{NameCert}_{\mathsf{ApartnessOrderedField}^{\uparrow}}$**.**

Constructive story: An $\mathsf{ApartnessOrderedField}^{\uparrow}$ packet is generated from RealUp source data, explicit apartness, algebraic order, located apartness-field data, RegSeqRat readback, Real sealing, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\mathsf{ApartnessOrderedField}\uparrow}$, seed)

Scope closed: Definition 8916.1, Definition 8916.2, and Definition 8916.3 seed the constructive ordered-field and apartness handoff surface.

Formal verification: FormalStatus(NameCert$_{\mathsf{ApartnessOrderedField}\uparrow}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim trichotomy, host real equality, quotient real equality, selected representatives, ambient Real completeness, Lean theorem checking, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, explicit apartness preservation, order-row exactness, located-field stability, regular readback, Real-seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.ApartnessOrderedFieldUp.

Chapter 8917

A Concrete Naming Certificate for $\mathsf{RealCompletionTailLock}^{\uparrow}$

The $\mathsf{RealCompletionTailLock}^{\uparrow}$ packet realizes the Real and Completion branch of chapter 9238 as a finite tail-lock object: a completion-facing read may inspect a finite stream window, regular rational readback, dyadic tolerance ledger, and terminal Real seal only in that order. It sits over the finite observation surface of chapter 126, the regular rational readback of chapter 301, the dyadic tolerance core of chapter 291, and the terminal real-name seal of chapter 38. The packet names a lock on the visible tail route; it does not assert quotient Cauchy equality, choose a completed limit, import trichotomy, or claim ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 8917.1 (Real completion tail-lock carrier)**.** *A* $\mathsf{RealCompletionTailLock}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$T = (S, R, D, E, L, H, C, P, N)$$

with the following displayed rows:

1. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row naming the inspected tail requests.*
2. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row attached to the same finite windows.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row locking the inspected radii and endpoint budgets.*
4. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row available only after S, R, D have been displayed.*
5. *L is the tail-lock row recording that completion-facing reads preserve the same S, R, D, E route.*
6. *H records componentwise* hsame *transport for the stream, readback, dyadic, seal, lock, replay, provenance, and local naming rows.*
7. *C records displayed* Cont *replay from a completion request through the stream window, regular readback, dyadic tolerance, Real seal, and tail lock.*
8. *P is the* Pkg *provenance over* $\mathsf{RealCompletionTailLock}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$ *rows.*
9. *N is the local* $\mathsf{NameCert}_{\mathsf{RealCompletionTailLock}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $S, R, D, E, L, H, C, P, N$. It has no coordinate for quotient stream equality, selected limits, countable choice, trichotomy, or ambient Real completeness.

Lean4 (statement) `BEDC.Derived.RealCompletionTailLockUp`

Theorem 8917.2 (Real completion tail-lock NameCert obligations)**.** *For every accepted* $\mathsf{RealCompletionTailLock}^{\uparrow}$ *carrier* $T = (S, R, D, E, L, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{RealCompletionTailLock}^{\uparrow}}$ *surface consists exactly of finite* $\mathsf{StreamName}^{\uparrow}$ *window exposure,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance locking,* $\mathsf{Real}^{\uparrow}$ *sealing, tail-lock preservation, componentwise* hsame *stability, displayed* Cont *replay,* Pkg *provenance, and local naming. A completion-facing consumer therefore reads the route only through*

$$S, R, D \longmapsto E, L, H, C, P, N.$$

Proof. Project the accepted carrier of Definition 8917.1. The stream, regular-rational, and dyadic rows S, R, D are displayed before the terminal seal E and before the lock row L can be consumed.

The rows H, C, P, N preserve exactly that finite route by transport, replay, provenance, and local naming. Since no quotient stream, selected limit, countable-choice schedule, trichotomy row, or ambient completeness row appears in the carrier, the NameCert obligations are exhausted by the displayed tail-lock surface. □

Theorem 8917.3 (Real completion tail-lock L10 handoff)**.** *Every L10 Real or Completion consumer of an accepted* $\mathsf{RealCompletionTailLock}^{\uparrow}$ *carrier must read the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row* S*, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row* R*, and the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row* D *before consuming the* $\mathsf{Real}^{\uparrow}$ *seal row* E *or the lock row* L*. The handoff may transport and replay this finite route, but it cannot replace it by quotient equality of Cauchy names, a selected completed limit, countable choice, trichotomy, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start with the NameCert obligations of Definition 8917.2. They place the stream window, regular-rational readback, and dyadic tolerance rows before the Real seal and tail-lock rows.

The vision source chapter 9238 asks for completion-facing reads to remain explicit about their finite regular-Cauchy route. This carrier supplies exactly that finite route through the sibling chapters chapter 126, chapter 301, chapter 291, and chapter 38.

Finally H, C, P, N preserve the same displayed route. Since the accepted carrier contains no quotient, selected-limit, choice, trichotomy, or ambient-completeness coordinate, the L10 handoff remains a finite tail-lock handoff. □

Falsifiable prediction: An accepted $\mathsf{RealCompletionTailLock}^{\uparrow}$ read that reaches Real or Completion data without displaying StreamName, RegSeqRat, DyadicRatCore, Real seal, tail-lock, transport, replay, provenance, and local naming is outside the carrier surface.

Independence witness: streamname, regseqrat, dyadicratcore, real: no listed sibling is bijective with $\mathsf{RealCompletionTailLock}^{\uparrow}$ because this packet binds finite windows, regular rational readback, dyadic tolerance locking, Real sealing, tail-lock preservation, transport, replay, provenance, and local naming as one completion-facing route.

Closure status for $\mathsf{NameCert}_{\mathsf{RealCompletionTailLock}^{\uparrow}}$**.**

Constructive story: A $\mathsf{RealCompletionTailLock}^{\uparrow}$ packet is generated from StreamName finite windows, RegSeqRat readback, DyadicRatCore tolerances, a RealUp seal, tail-lock preservation, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{RealCompletionTailLock}^{\uparrow}}$, seed)

Scope closed: Definition 8917.1, Definition 8917.2, and Definition 8917.3 seed the finite L10 Real and Completion tail-lock route.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{RealCompletionTailLock}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim quotient Cauchy equality, selected completed limits, countable choice, trichotomy, ambient Real completeness, Lean theorem checking, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, StreamName exposure, RegSeqRat readback, DyadicRatCore tolerance locking, Real-seal nonescape, tail-lock exactness, transport, replay, provenance, and local naming for BEDC.Derived.RealCompletionTailLockUp.

Chapter 8918

A Concrete Naming Certificate for $\mathsf{RealCompletionIdempotence}^{\uparrow}$

Following Bishop and Bridges on constructive completions, the $\mathsf{RealCompletionIdempotence}^{\uparrow}$ packet records that a $\mathsf{Real}^{\uparrow}$ seal already obtained from $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, and $\mathsf{DyadicRatCore}^{\uparrow}$ data is stable under re-entering the same completion route. It sits over the dyadic tolerance ledger of chapter 291, the finite observation windows of chapter 126, the regular rational readback of chapter 301, and the terminal seal of chapter 38. The packet names a face-local Real and Completion boundary; it does not construct quotient streams, choose representatives, select limits, invoke countable choice, or assert ambient completeness for $\mathsf{Real}^{\uparrow}$.

Definition 8918.1 (Real completion idempotence carrier)**.** *A* $\mathsf{RealCompletionIdempotence}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$I = (R, S, Q, D, H, C, P, N)$$

with the following displayed rows:

1. *R is the sealed* $\mathsf{Real}^{\uparrow}$ *row already obtained from the first completion-facing route.*
2. *S is the* $\mathsf{StreamName}^{\uparrow}$ *window row that exposes the same finite observations used to read the name.*
3. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row attached to those windows.*
4. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row governing the displayed regularity comparisons.*
5. *H records componentwise* hsame *transport for the Real seal, windows, readback, tolerance ledger, replay, provenance, and local naming rows.*
6. *C records displayed* Cont *replay from any second completion request back through D, Q, S and into the already sealed R row.*
7. *P is the* Pkg *provenance over* $\mathsf{RealCompletionIdempotence}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
8. *N is the local* $\mathsf{NameCert}_{\mathsf{RealCompletionIdempotence}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through R, S, Q, D, H, C, P, N. No coordinate stores a quotient stream equality, representative selector, selected limit, countable-choice schedule, metric-completeness theorem, or ambient completeness assertion for $\mathsf{Real}^{\uparrow}$.

Theorem 8918.2 (Real completion idempotence NameCert obligations)**.** *For every accepted* $\mathsf{RealCompletionIdempotence}^{\uparrow}$ *carrier*

$$I = (R, S, Q, D, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{RealCompletionIdempotence}^{\uparrow}}$ *surface consists exactly of carrier admission, sealed* $\mathsf{Real}^{\uparrow}$ *exposure, finite* $\mathsf{StreamName}^{\uparrow}$ *window readback,* $\mathsf{RegSeqRat}^{\uparrow}$ *regular-rational readback,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance accounting, componentwise transport, displayed replay, package provenance, and local naming.*

Proof. Project the carrier of Definition 8918.1. Its visible data are the sealed Real row R, the window row S, the regular rational readback Q, the dyadic tolerance ledger D, and the structural rows H, C, P, N.

The second completion request is read by replaying the same finite route. It first exposes D, then Q, then S, and only then reaches the already sealed $\mathsf{Real}^{\uparrow}$ row R.

The remaining rows preserve the boundary. Componentwise hsame in H transports the displayed coordinates, Cont in C replays the same dependency order, and P, N record provenance and local naming. Since the carrier has no excluded coordinate, the NameCert surface exports no quotient stream equality, selected representative, selected limit, countable choice, metric completeness, or ambient Real completeness. □

Theorem 8918.3 (Real completion idempotence nonescape)**.** *Every second completion-facing read of an accepted* $\mathsf{RealCompletionIdempotence}^{\uparrow}$ *carrier reuses the same displayed face rows*

$$R, S, Q, D, H, C, P, N.$$

Consequently re-entering the completion route cannot add quotient stream equality, selected limits, countable choice, metric completeness, or an ambient $\mathsf{Real}^{\uparrow}$ *completeness claim.*

Proof. Let a second completion-facing consumer read an accepted carrier $I = (R, S, Q, D, H, C, P, N)$. Carrier projection gives no data outside these eight rows.

The replay row C directs the request through the dyadic tolerance ledger D, the regular rational readback Q, and the finite observation windows S before the terminal seal row R is inspected. Thus the second read has the same face-local route as the first read.

Transport and provenance do not enlarge the route. The componentwise hsame row H compares only the displayed coordinates, while P and N record the package and local name for the same carrier. With no quotient, choice, selected-limit, metric-completeness, or ambient-completeness coordinate present, there is no escape path from the idempotence packet to any of those claims. □

Closure status for $\mathsf{NameCert}_{\mathsf{RealCompletionIdempotence}^{\uparrow}}$**.**

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RealCompletionIdempotence}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8918.1, Definition 8918.2, and Definition 8918.3 seed the face-local idempotence carrier over Real, StreamName, RegSeqRat, DyadicRatCore, transport, replay, provenance, and local naming rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RealCompletionIdempotence}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim quotient stream equality, selected representatives, selected limits, countable choice, metric completeness, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, StreamName window reuse, RegSeqRat readback reuse, DyadicRatCore tolerance accounting, Real seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.RealCompletionIdempotenceUp.

Constructive story: A $\mathsf{RealCompletionIdempotence}^{\uparrow}$ packet is generated from an already sealed Real row, StreamName finite windows, RegSeqRat readback, DyadicRatCore tolerance accounting, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 8919

A Concrete Naming Certificate for $\mathsf{DoobMeyerDecomposition}^{\uparrow}$

Following Doob and Meyer, the $\mathsf{DoobMeyerDecomposition}^{\uparrow}$ packet records the finite BEDC surface of a submartingale split into a martingale row and an increasing compensator row. It consumes the one-sided adapted carrier of chapter 6556, the equality-direction martingale rows of chapter 190, the singleton conditional-expectation surface of chapter 188, the bounded stopped-window route of chapter 383, and the crossing ledger of chapter 1629. The chapter names only finite martingale-compensator rows and their local certificate obligations; it does not import measure completion, optional projection, predictable host σ-algebras, almost-sure quotient equality, or an ambient stochastic-process theorem.

Definition 8919.1 (Doob-Meyer decomposition carrier)**.** *A* $\mathsf{DoobMeyerDecomposition}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$D = (S, M, A, E, O, U, H, C, P, N)$$

with the following displayed rows:

1. *S is the accepted* $\mathsf{Submartingale}^{\uparrow}$ *source row whose finite one-sided conditional-expectation comparisons are to be split.*
2. *M is the* $\mathsf{Martingale}^{\uparrow}$ *row carrying the equality-direction adapted sequence read from the same displayed finite window.*
3. *A is the compensator ledger, a finite increasing row whose successor gaps record the displayed difference between the* $\mathsf{Submartingale}^{\uparrow}$ *inequality and the* $\mathsf{Martingale}^{\uparrow}$ *equality row.*
4. *E is the family of* $\mathsf{CondExp}^{\uparrow}$ *faces that reads the successor endpoint before the compensator step row is exposed.*
5. *O is the bounded* $\mathsf{OptionalStopping}^{\uparrow}$ *window used to compare stopped reads of S, M, and A.*
6. *U is the* $\mathsf{Upcrossing}^{\uparrow}$ *ledger that keeps the same finite lower-to-upper crossing window visible to decomposition consumers.*
7. *H records componentwise* hsame *transport for the submartingale, martingale, conditional-expectation, stopped-window, upcrossing, and compensator rows.*
8. *C records displayed* Cont *replay from a decomposition request through S, M, A, E, O, U.*
9. *P is the* Pkg *provenance over* $\mathsf{Submartingale}^{\uparrow}$, $\mathsf{Martingale}^{\uparrow}$, $\mathsf{CondExp}^{\uparrow}$, $\mathsf{OptionalStopping}^{\uparrow}$, $\mathsf{Upcrossing}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.

10. N is the local $\mathsf{NameCert}_{\mathsf{DoobMeyerDecomposition}^{\uparrow}}$ *row.*

The carrier compares accepted packets only through these ten rows. It has no coordinate for measure completion, optional projection, a predictable host σ-algebra, selected almost-sure versions, quotient equality of stochastic processes, or an external decomposition theorem.

Theorem 8919.2 (Doob-Meyer decomposition NameCert obligations)**.** *For every accepted* DoobMeyerDecompositi *carrier $D = (S, M, A, E, O, U, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{DoobMeyerDecomposition}^{\uparrow}}$ *surface consists exactly of carrier admission, exposure of the source* $\mathsf{Submartingale}^{\uparrow}$ *row, exposure of the* $\mathsf{Martingale}^{\uparrow}$ *row, compensator-ledger exactness for A, conditional-expectation exposure through E, bounded stopped-window routing through O, finite upcrossing control through U, componentwise* hsame *transport through H, displayed* Cont *replay through C, package provenance through P, and local naming through N.*

Every decomposition consumer must read

$$\mathsf{Submartingale}^{\uparrow},\ \mathsf{Martingale}^{\uparrow},\ \mathsf{CondExp}^{\uparrow},\ \mathsf{OptionalStopping}^{\uparrow},\ \mathsf{Upcrossing}^{\uparrow},\ \mathsf{BHist},\ \mathsf{hsame},\ \mathsf{Cont},\ \mathsf{Pkg},\ \mathsf{NameCert}$$

through the displayed packet before a martingale-compensator conclusion is visible. The obligation surface is finite NameCert data; it is not measure completion, optional projection, predictable host measurability, almost-sure quotient equality, or an ambient Doob–Meyer theorem.

Proof. Project the accepted carrier of Definition 8919.1. The analytic rows are S, M, A, E, O, U, and the structural rows are H, C, P, N.

The source row S supplies the one-sided $\mathsf{Submartingale}^{\uparrow}$ inequality, while M supplies the equality-direction $\mathsf{Martingale}^{\uparrow}$ read on the same finite window. The conditional-expectation faces E expose the successor comparisons before any compensator step row in A can be inspected.

The bounded stopping and upcrossing rows O, U keep the finite window stable for downstream consumers. Transport, replay, provenance, and local naming preserve the same route, so no consumer can bypass the displayed packet to obtain a host optional projection or a completed ambient decomposition theorem. □

Theorem 8919.3 (Doob-Meyer compensator handoff)**.** *Every compensator read exported by an accepted* $\mathsf{DoobMeyerDecomposition}^{\uparrow}$ *packet factors through the route*

$$S, E \longmapsto M, A \longmapsto O, U, H, C, P, N.$$

The row A is visible only as the finite ledger that records the gap between the $\mathsf{Submartingale}^{\uparrow}$ *source comparisons and the* $\mathsf{Martingale}^{\uparrow}$ *equality-direction row. A downstream martingale or upcrossing consumer receives that ledger together with the bounded* $\mathsf{OptionalStopping}^{\uparrow}$ *and* $\mathsf{Upcrossing}^{\uparrow}$ *windows; it does not receive a host predictable projection, measure completion, selected almost-sure version, quotient process equality, or external compensator existence proof.*

Proof. Begin with the NameCert obligations of Definition 8919.2. They require the submartingale source, martingale row, conditional-expectation faces, compensator ledger, stopped-window row, and upcrossing row to be displayed before the local certificate can be consumed.

The compensator row is therefore not an independent host process. It is read only after the $\mathsf{CondExp}^{\uparrow}$ faces expose the one-step gap between the source $\mathsf{Submartingale}^{\uparrow}$ inequality and the $\mathsf{Martingale}^{\uparrow}$ equality row.

Finally, bounded stopping and upcrossing preserve the same finite window. Since A is carried only with O, U, H, C, P, N, every handoff remains inside the finite packet and cannot be reread as optional projection, predictable host measurability, measure completion, quotient equality, or an ambient decomposition theorem. □

Falsifiable prediction: An accepted $\mathsf{DoobMeyerDecomposition}^{\uparrow}$ consumer that reaches a compensator row without first reading the displayed $\mathsf{Submartingale}^{\uparrow}$, $\mathsf{Martingale}^{\uparrow}$, $\mathsf{CondExp}^{\uparrow}$, $\mathsf{OptionalStopping}^{\uparrow}$, $\mathsf{Upcrossing}^{\uparrow}$, BHist, hsame, Cont, Pkg, and NameCert rows refutes the carrier surface.

Independence witness: submartingale, martingale, condexp, optionalstopping, upcrossing: no listed sibling supplies the whole packet $D = (S, M, A, E, O, U, H, C, P, N)$, because the source one-sided row, equality-direction martingale row, compensator ledger, stopped-window route, crossing ledger, transport, replay, provenance, and local naming are jointly bound only here.

Closure status for $\mathsf{NameCert}_{\mathsf{DoobMeyerDecomposition}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{DoobMeyerDecomposition}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8919.1, Definition 8919.2, and Definition 8919.3 seed the finite martingale-compensator certificate over submartingale, martingale, conditional-expectation, bounded stopping, upcrossing, transport, replay, provenance, and local naming rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{DoobMeyerDecomposition}^{\uparrow}}, \mathsf{formalTarget})$

Bridge status: none

Not claimed: This chapter does not close measure completion, optional projection, predictable host sigma-algebras, selected almost-sure versions, quotient equality of stochastic processes, theorem-level Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, source submartingale exposure, martingale row exposure, compensator-ledger exactness, conditional-expectation exposure, stopped-window routing, finite upcrossing control, transport, replay, provenance, and local naming for BEDC.Derived.DoobMeyerDecompositionUp.

Constructive story: A $\mathsf{DoobMeyerDecomposition}^{\uparrow}$ packet is generated from a SubmartingaleUp source row, MartingaleUp equality row, finite compensator ledger, CondExpUp faces, OptionalStoppingUp bounded window, UpcrossingUp ledger, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 8920

A Concrete Naming Certificate for $\mathsf{DomainCompletion}^{\uparrow}$

Following Scott and the domain-theoretic completion tradition, the $\mathsf{DomainCompletion}^{\uparrow}$ packet records the finite frontier object that turns rounded-domain approximation data into a completion-facing Real handoff. It sits after the interval-domain route of chapter 1543, the Scott-domain basis of chapter 4164, the rounded-ideal completion surface of chapter 1883, the finite stream observations of chapter 126, the regular rational readback of chapter 301, and the terminal Real seal of chapter 38. The packet names a finite domain-completion route; it does not choose ideal representatives, quotient directed systems, selected limits, host order equality, countable choice, or ambient completeness.

Definition 8920.1 (Domain-completion carrier)**.** *A* $\mathsf{DomainCompletion}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$D = (I, S, R, W, Q, E, H, C, P, N)$$

with the following displayed rows:

1. *I is the* $\mathsf{IntervalDomain}^{\uparrow}$ *cell row naming the located interval approximants read by the completion frontier.*
2. *S is the* $\mathsf{ScottDomain}^{\uparrow}$ *basis row that records the inspected finite way-below comparisons.*
3. *R is the* $\mathsf{RoundedIdealCompletion}^{\uparrow}$ *row that packages the rounded directed approximation discipline.*
4. *W is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row through which completion-facing consumers observe the approximants.*
5. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row obtained from the displayed windows.*
6. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row exposed only after I, S, R, W, Q have been displayed.*
7. *H records componentwise* hsame *transport for interval cells, Scott-domain basis data, rounded ideals, stream windows, regular readbacks, Real seals, replay, provenance, and local naming.*
8. *C records displayed* Cont *replay from a completion request through $I, S, R, W, Q, E, H, P, N$.*
9. *P is the* Pkg *provenance over* $\mathsf{DomainCompletion}^{\uparrow}$, $\mathsf{IntervalDomain}^{\uparrow}$, $\mathsf{ScottDomain}^{\uparrow}$, $\mathsf{RoundedIdealCompletion}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{DomainCompletion}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $I, S, R, W, Q, E, H, C, P, N$. It has no coordinate for selected ideal representatives, quotient directed-system equality, host order equality, countable choice, or ambient completeness.

Theorem 8920.2 (Domain-completion NameCert obligations)**.** *For every accepted* $\mathsf{DomainCompletion}^{\uparrow}$ *carrier*

$$D = (I, S, R, W, Q, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{DomainCompletion}^{\uparrow}}$ *surface consists exactly of carrier admission for interval-domain cells, Scott-domain basis comparisons, rounded-ideal completion data, finite StreamName windows, RegSeqRat readback, Real sealing, componentwise transport, displayed replay, provenance, and local naming. Completion-facing reads must expose the ordered route*

$$I \to S \to R \to W \to Q \to E$$

before any Real handoff is available, and the structural rows H, C, P, N may only transport, replay, source, and name that route.

Proof. Project the carrier of Definition 8920.1. The displayed analytic rows are I, S, R, W, Q, E, and the structural rows are H, C, P, N.

Read the domain side first. The interval-domain row I supplies the located cells, the Scott-domain row S supplies the inspected finite basis comparisons, and the rounded-ideal row R records the directed approximation discipline before any completion-facing stream row is available.

The observation and Real handoff then pass through W, Q, E. The finite window row W exposes the observations admitted by the rounded route, the regular rational row Q supplies the readback, and the Real seal row E is downstream of those displayed rows.

Finally H, C, P, N preserve the same packet boundary. Since no carrier coordinate stores selected ideal representatives, quotient directed systems, host order equality, countable choice, or ambient completeness, the local NameCert obligations are exhausted by the displayed route. □

Theorem 8920.3 (Domain-completion Real handoff)**.** *Every* $\mathsf{Real}^{\uparrow}$ *or* $\mathsf{Completion}^{\uparrow}$ *consumer of an accepted* $\mathsf{DomainCompletion}^{\uparrow}$ *carrier must read the finite completion frontier*

$$\mathsf{IntervalDomain}^{\uparrow} \to \mathsf{ScottDomain}^{\uparrow} \to \mathsf{RoundedIdealCompletion}^{\uparrow} \to \mathsf{StreamName}^{\uparrow} \to \mathsf{RegSeqRat}^{\uparrow} \to \mathsf{Real}^{\uparrow}.$$

The handoff exports located interval approximation, finite Scott-basis comparison, rounded directed approximation, finite observation windows, regular rational readback, Real sealing, hsame *transport,* Cont *replay,* Pkg *provenance, and local* $\mathsf{NameCert}$ *naming. It exports no selected ideal representative, quotient directed-system equality, host order equality, countable-choice selector, or ambient completion theorem.*

Proof. Start with an accepted carrier $D = (I, S, R, W, Q, E, H, C, P, N)$. Carrier projection gives the consumer access only to those displayed rows.

The completion frontier begins with the domain rows. A consumer reads located interval approximants through I, finite Scott-basis comparisons through S, and rounded directed approximation through R before reaching any stream or Real-facing data.

The handoff then consumes W, Q, E in order. The finite observation windows in W feed the regular rational readback Q, and the terminal Real seal E is exposed only after that readback is displayed.

The structural rows add no new mathematical primitive. Componentwise transport in H, replay in C, provenance in P, and local naming in N carry the same finite route, so the excluded

representative, quotient, host-equality, choice, and ambient-completeness data have no row from which a consumer could read them. □

Falsifiable prediction: Every accepted $\mathsf{DomainCompletion}^{\uparrow}$ Real or Completion handoff displays IntervalDomain, ScottDomain, RoundedIdealCompletion, StreamName, RegSeqRat, Real seal, hsame transport, Cont replay, Pkg provenance, and local NameCert rows before the terminal seal can be consumed.

Independence witness: intervaldomain, scott-domain, rounded-ideal-completion, streamname, regseqrat, real: $\mathsf{DomainCompletion}^{\uparrow}$ is not bijective to any listed sibling because it jointly binds interval approximants, Scott-basis comparison, rounded directed approximation, finite observation windows, regular rational readback, Real sealing, transport, replay, provenance, and local naming as one completion-frontier packet.

Closure status for $\mathsf{NameCert}_{\mathsf{DomainCompletion}\uparrow}$.

Constructive story: A $\mathsf{DomainCompletion}^{\uparrow}$ packet is generated from IntervalDomain cells, ScottDomain basis data, RoundedIdealCompletion rows, StreamName finite windows, RegSeqRat readback, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{DomainCompletion}\uparrow}, \mathsf{seed})$

Scope closed: Definition 8920.1, Definition 8920.2, and Definition 8920.3 seed the finite domain-completion frontier from interval and Scott-domain approximation to the Real handoff.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{DomainCompletion}\uparrow}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim selected ideal representatives, quotient directed-system equality, host order equality, countable choice, ambient completion, Lean theorem checking, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, interval-domain approximation, Scott-domain basis comparison, rounded-ideal discipline, StreamName observation, RegSeqRat readback, Real seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.DomainCompletionUp.

Chapter 8921

A Concrete Naming Certificate for $\mathsf{CauchyNameTruncation}^{\uparrow}$

Following Bishop and Bridges on regular Cauchy names, the $\mathsf{CauchyNameTruncation}^{\uparrow}$ packet records the finite prefix and tail-budget certificate visible before a regular rational name is handed toward a Real or Completion consumer. It sits over the StreamName finite-window surface of chapter 126, the regular rational readback of chapter 301, the dyadic tolerance ledger of chapter 291, and the terminal real-name seal of chapter 38. The packet names a displayed truncation budget for one regular Cauchy read; it is not quotient stream equality, a selected limit, countable choice, open-cover compactness, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 8921.1 (CauchyNameTruncation carrier)**.** *A* $\mathsf{CauchyNameTruncation}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (S, Q, D, T, E, H, C, P, N)$$

with the following displayed rows:

1. S *is the* $\mathsf{StreamName}^{\uparrow}$ *finite prefix schedule naming the inspected source windows.*
2. Q *is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row attached to those finite windows.*
3. D *is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger recording the displayed error radii.*
4. T *is the truncation-index and tail-budget row saying which prefix is sufficient for the named tolerance.*
5. E *is the optional* $\mathsf{Real}^{\uparrow}$ *seal row, available only after* S, Q, D, T *have been displayed.*
6. H *records componentwise* hsame *transport for prefix schedule, readback, tolerance, truncation budget, optional seal, replay, provenance, and local naming.*
7. C *records displayed* Cont *replay of the same finite truncation route.*
8. P *is the* Pkg *provenance over* $\mathsf{CauchyNameTruncation}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$ *rows.*
9. N *is the local* $\mathsf{NameCert}_{\mathsf{CauchyNameTruncation}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $S, Q, D, T, E, H, C, P, N$*. It has no coordinate for quotient stream equality, selected limits, countable choice, open-cover compactness, or ambient Real completeness.*

Lean4 (statement) `BEDC.Derived.CauchyNameTruncationUp`

Theorem 8921.2 (CauchyNameTruncation NameCert obligations)**.** *For every accepted* $\mathsf{CauchyNameTruncation}^{\uparrow}$ *carrier* $K = (S, Q, D, T, E, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{CauchyNameTruncation}^{\uparrow}}$ *surface consists exactly of carrier admission, finite StreamName prefix exposure, RegSeqRat readback, DyadicRatCore tolerance accounting, truncation-index and tail-budget admission, optional RealUp sealing, componentwise transport, displayed replay, provenance, and local naming. No accepted local read may export quotient stream equality, selected limits, countable choice, open-cover compactness, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the carrier of Definition 8921.1. The rows S, Q, D, T are the finite prefix schedule, regular rational readback, dyadic tolerance ledger, and truncation budget inspected before any terminal seal is available.

The optional seal row E is downstream of that displayed route. Transport, replay, provenance, and local naming are exactly the rows H, C, P, N, so the local NameCert surface is exhausted by the nine-row packet.

The excluded outputs have no carrier coordinates. Since the packet contains no quotient row, selected-limit row, countable-choice schedule, open-cover compactness witness, or ambient-completeness certificate, an accepted local read cannot produce one. □

Theorem 8921.3 (CauchyNameTruncation tail-budget route)**.** *Every Real or Completion consumer of an accepted* $\mathsf{CauchyNameTruncation}^{\uparrow}$ *carrier must read the* $\mathsf{StreamName}^{\uparrow}$ *prefix row* S*, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row* Q*, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row* D*, and the truncation budget row* T *before consuming the optional* $\mathsf{Real}^{\uparrow}$ *seal row* E*. The route may be transported and replayed through* H *and* C*, but it cannot be replaced by quotient stream equality, a selected limit, countable choice, open-cover compactness, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Begin with the NameCert obligations of Definition 8921.2. They place S, Q, D, T before the optional seal row E, with T naming the inspected truncation index and the tail budget associated to the displayed tolerance.

The sibling chapters supply the four external rows in order: finite prefix schedules from chapter 126, regular rational readback from chapter 301, dyadic tolerance accounting from chapter 291, and the terminal seal boundary from chapter 38. Thus a downstream read sees a finite prefix and its tail budget, not a completed quotient object.

Finally, H and C preserve the displayed route under transport and replay, while P and N keep the provenance and local NameCert rows explicit. No omitted output is recovered by this preservation, because none is represented inside the accepted carrier. □

Falsifiable prediction: An accepted $\mathsf{CauchyNameTruncation}^{\uparrow}$ read that reaches Real or Completion data without displaying StreamName prefix schedule, RegSeqRat readback, DyadicRatCore tolerance ledger, truncation budget, optional seal, transport, replay, provenance, and local naming is outside the carrier surface.

Independence witness: streamname, regseqrat, dyadicratcore, real: $\mathsf{CauchyNameTruncation}^{\uparrow}$ is not bijective with any listed sibling because it binds finite prefix schedule, regular rational readback, dyadic tolerance, truncation index, optional Real seal, transport, replay, provenance, and local naming as one tail-budget packet.

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyNameTruncation}^{\uparrow}}$.

Constructive story: A CauchyNameTruncation$^{\uparrow}$ packet is generated from StreamName finite prefix schedules, RegSeqRat readback rows, DyadicRatCore tolerance ledgers, truncation-index and tail-budget rows, optional RealUp sealing, hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\text{CauchyNameTruncation}^{\uparrow}}$, seed)

Scope closed: Definition 8921.1, Definition 8921.2, and Definition 8921.3 seed the finite regular Cauchy truncation surface.

Formal verification: FormalStatus(NameCert$_{\text{CauchyNameTruncation}^{\uparrow}}$, formalTarget)

Bridge status: none

Not claimed: This chapter does not close quotient stream equality, selected limits, countable choice, open-cover compactness, ambient Real completeness, theorem checking, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, prefix exposure, regular readback, dyadic tolerance accounting, truncation-budget routing, optional Real sealing, transport, replay, provenance, and local naming for BEDC.Derived.CauchyNameTruncationUp.

Chapter 8922

A Concrete Naming Certificate for $\mathsf{CompleteSeparatedMetricReflector}^{\uparrow}$

Following Bishop–Bridges constructive completion and Kelley-style separated reflection, the CompleteSeparatedMetr packet records the standard reflector landing surface that sends a displayed metric-completion request to a complete separated metric object. It sits after the complete-metric service of chapter 128, the separated-metric classifier of chapter 1411, the metric-completion comparison route of chapter 1506, the finite stream and regular rational readback stack of chapter 126 and chapter 301, and the terminal real-name seal of chapter 38. The packet names only the finite reflector certificate; it does not assert quotient completion equality, selected limits, countable choice, host point equality, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 8922.1 (CompleteSeparatedMetricReflector carrier)**.** *A* $\mathsf{CompleteSeparatedMetricReflector}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$R = (C, S, M, W, Q, E, H, K, P, N)$$

with the following displayed rows:

1. *C is the* $\mathsf{CompleteMetric}^{\uparrow}$ *source row that exposes the limit-service surface available to completion consumers;*
2. *S is the* $\mathsf{SeparatedMetric}^{\uparrow}$ *classifier row, read only after zero-distance evidence has been displayed;*
3. *M is the* $\mathsf{MetricCompletion}^{\uparrow}$ *comparison row, carrying the metric-completion handoff and its reflector-facing comparison data;*
4. *W is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row for inspected Cauchy names and tolerance schedules;*
5. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row obtained from the displayed stream windows and rational tolerance data;*
6. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row used for zero-distance and convergence-distance reads;*
7. *H records componentwise* hsame *transport for the complete-metric, separated-classifier, metric-completion, stream-window, readback, Real-seal, provenance, and local naming rows;*
8. *K records displayed* Cont *replay from the metric-completion request through complete-metric service, stream windows, regular rational readback, Real sealing, and separated reflection;*
9. *P is the* Pkg *provenance over* $\mathsf{CompleteSeparatedMetricReflector}^{\uparrow}$, $\mathsf{CompleteMetric}^{\uparrow}$, $\mathsf{SeparatedMetric}^{\uparrow}$, $\mathsf{MetricCompletion}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert*;*

10. N is the local $\mathsf{NameCert}_{\mathsf{CompleteSeparatedMetricReflector}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these displayed rows and their structural transport and replay data.

Theorem 8922.2 (CompleteSeparatedMetricReflector NameCert obligations)**.** *For every accepted* $\mathsf{CompleteSeparatedMetricReflector}^{\uparrow}$ *carrier* $R = (C, S, M, W, Q, E, H, K, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{CompleteSeparatedMet}}$ *surface consists exactly of carrier admission for the displayed tuple, complete-metric source exposure through* C*, separated classifier exposure through* S*, metric-completion comparison through* M*, StreamName finite-window exposure through* W*, RegSeqRat readback through* Q*, Real sealing through* E*, componentwise* hsame *transport through* H*, displayed* Cont *replay through* K*, package provenance through* P*, and local naming through* N*.*

Proof. Project the carrier. Its coordinates display the complete-metric source, separated classifier, metric-completion comparison, stream windows, regular rational readback, Real seal, transport, replay, provenance, and local name.

Read the completion-facing rows first. The metric-completion row M supplies the handoff under inspection, while C supplies the complete-metric service row consumed by the reflector.

Read the finite name rows next. The stream-window row W precedes the regular rational readback Q, and the terminal Real seal E is downstream of those displayed windows and readbacks.

Finally apply the separated classifier row S and the structural rows H, K, P, N. They preserve, replay, source, and name the same finite reflector route, so no local NameCert obligation remains outside the listed rows. □

Theorem 8922.3 (CompleteSeparatedMetricReflector adjunction route)**.** *Every reflector-facing consumer of an accepted* $\mathsf{CompleteSeparatedMetricReflector}^{\uparrow}$ *packet reads the finite route*

$$\mathsf{MetricCompletion}^{\uparrow} \longmapsto \mathsf{CompleteMetric}^{\uparrow} \longmapsto \mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow} \longmapsto \mathsf{SeparatedMetric}^{\uparrow}.$$

The route is the displayed packet $R = (C, S, M, W, Q, E, H, K, P, N)$ *with* M *opening the metric-completion comparison,* C *supplying the complete-metric service,* W, Q, E *supplying the finite real-name readback, and* S *supplying the separated classifier.*

Proof. Start with the NameCert obligations of Definition 8922.2. They force every accepted reflector read to expose M, C, W, Q, E, S before the local name is consumed.

The reflector source is M followed by C. This is the finite metric-completion request together with the complete-metric service row, not a quotient completion object.

The readback stack is W, Q, E. The stream windows and regular rational readback are displayed before the Real seal, so the zero-distance or convergence-distance observation is reached only through finite name data.

The separated classifier S is terminal. Rows H, K, P, N transport, replay, source, and name this same route, so the consumer receives a reflector certificate rather than selected limits, countable choice, host point equality, or ambient Real completeness. □

Theorem 8922.4 (CompleteSeparatedMetricReflector real-seal handoff)**.** *Any* $\mathsf{Real}^{\uparrow}$*-facing read from an accepted* $\mathsf{CompleteSeparatedMetricReflector}^{\uparrow}$ *carrier must expose the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row* W *and the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row* Q *before the terminal seal* E *is public, and must expose the* $\mathsf{CompleteMetric}^{\uparrow}$ *source row* C*,* $\mathsf{MetricCompletion}^{\uparrow}$ *comparison row* M*, and* $\mathsf{SeparatedMetric}^{\uparrow}$ *classifier row* S *before the reflector handoff is public.*

Proof. Project the carrier of Definition 8922.1. The Real-facing row is E, and the only rows feeding it are the displayed stream-window and regular-readback rows W, Q.

Apply the adjunction route of Definition 8922.3. It places the metric-completion comparison and complete-metric service before the real-name readback and places the separated classifier after the Real seal.

The structural rows H, K, P, N preserve that order under transport, replay, provenance, and local naming. Therefore a Real-facing consumer cannot bypass W, Q, and a reflector-facing consumer cannot bypass M, C, S. □

Falsifiable prediction: Every accepted $\mathsf{CompleteSeparatedMetricReflector}^{\uparrow}$ consumer read factors through $\mathsf{MetricCompletion}^{\uparrow}$, $\mathsf{CompleteMetric}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{SeparatedMetric}^{\uparrow}$, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming before it can use the reflector handoff.

Independence witness: complete-metric, separated-metric, metric-completion, streamname, regseqrat, real: $\mathsf{CompleteSeparatedMetricReflector}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries the complete service, separated classifier, metric-completion comparison, finite windows, regular rational readback, Real seal, transport, replay, provenance, and local NameCert rows in one packet.

Closure status for $\mathsf{NameCert}_{\mathsf{CompleteSeparatedMetricReflector}^{\uparrow}}$.

Constructive story: A $\mathsf{CompleteSeparatedMetricReflector}^{\uparrow}$ packet is generated from a CompleteMetricUp source row, a SeparatedMetricUp classifier row, a MetricCompletionUp comparison row, StreamName windows, RegSeqRat readback, RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CompleteSeparatedMetricReflector}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8922.1, Definition 8922.2, Definition 8922.3, and Definition 8922.4 seed the finite complete separated metric reflector route over complete-metric, separated, metric-completion, stream, readback, Real-seal, transport, replay, provenance, and local naming rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CompleteSeparatedMetricReflector}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim quotient completion equality, selected limits, countable choice, host point equality, ambient RealUp completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, complete-metric source exposure, separated classifier exposure, metric-completion comparison, finite-window readback, Real-seal handoff, transport stability, replay stability, provenance non-escape, and local naming for BEDC.Derived.CompleteSeparatedMetricReflectorUp.

Chapter 8923

A Concrete Naming Certificate for $\mathsf{IntervalExchange}^{\uparrow}$

Following Keane and Veech on interval exchange transformations, the $\mathsf{IntervalExchange}^{\uparrow}$ packet records the finite interval-map surface used when a displayed partition of a real interval is rearranged by finitely many translations. It sits over the dyadic arithmetic core of chapter 291, the finite cell net of chapter 5966, the finite observation windows of chapter 126, the regular rational readback of chapter 301, and the terminal real-name seal of chapter 38. The chapter names only the finite partition, permutation, and translation ledger by which later symbolic-dynamics or interval-map certificates may inspect an interval exchange; it does not assert invariant measures, minimality, unique ergodicity, host interval functions, quotient real equality, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 8923.1 (IntervalExchange carrier)**.** *An* $\mathsf{IntervalExchange}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$E = (D, I, B, \Pi, T, W, Q, R, H, C, P, N)$$

with the following displayed rows:

1. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *row containing the located interval endpoints, dyadic cut points, endpoint comparisons, and translation budgets.*
2. *I is the* $\mathsf{DyadicIntervalNet}^{\uparrow}$ *row listing the finite source cells and target cells of the partition.*
3. *B is the boundary-incidence row recording which neighboring source cells share displayed endpoints and which target cells share displayed endpoints.*
4. *Π is the finite permutation row matching each source cell to exactly one target cell.*
5. *T is the finite translation row; for each displayed source cell it records the dyadic displacement that carries the source endpoints to the corresponding target endpoints.*
6. *W is the* $\mathsf{StreamName}^{\uparrow}$ *window row used whenever a source endpoint, target endpoint, or translated endpoint is inspected.*
7. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row turning the displayed endpoint and translation windows into regular rational comparisons.*
8. *R is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row, available only after D, I, B, Π, T, W, Q have been displayed.*
9. *H records componentwise* hsame *transport for D, I, B, Π, T, W, Q, R and the structural rows.*

10. *C records displayed* Cont *replay from partition cells through permutation, translation, StreamName windows, RegSeqRat readback, and the Real seal.*
11. *P is the* Pkg *provenance row over* $\mathsf{IntervalExchange}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{DyadicIntervalNet}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
12. *N is the local* $\mathsf{NameCert}_{\mathsf{IntervalExchange}^{\uparrow}}$ *row.*

The local classifier compares accepted carriers only through the displayed endpoint, cell, incidence, permutation, translation, window, readback, seal, transport, continuation, provenance, and local naming rows.

Theorem 8923.2 (IntervalExchange NameCert obligations)**.** *For every accepted* $\mathsf{IntervalExchange}^{\uparrow}$ *carrier $E = (D, I, B, \Pi, T, W, Q, R, H, C, P, N)$, the local NameCert surface consists exactly of carrier admission for those rows; classifier stability under common dyadic refinement of the source and target cells; interval-cell transport through I, B, Π, T; finite orbit replay by iterating only the displayed permutation and translation rows for a displayed number of steps;* $\mathsf{StreamName}^{\uparrow}$ *window exposure through W;* $\mathsf{RegSeqRat}^{\uparrow}$ *readback through Q; terminal* $\mathsf{Real}^{\uparrow}$ *sealing through R; componentwise* hsame *transport through H; displayed* Cont *replay through C;* Pkg *provenance through P; and ledger nonescape through the local certificate N.*

Proof. Carrier admission is Definition 8923.1. It fixes the finite row inventory and makes the local classifier a comparison of displayed endpoint, cell, permutation, translation, window, readback, seal, transport, replay, provenance, and naming data.

Common refinement is finite. A refined carrier replaces listed cells in I by displayed dyadic subcells whose endpoint arithmetic is still read in D, whose incidences are still read in B, and whose source-to-target matching is still read through Π, T.

Finite orbit replay is also a row operation. A displayed number of steps iterates the permutation and translation ledgers already present in Π, T, opening StreamName windows through W and rational readback through Q before the Real seal R is visible.

Finally replay H, C, P, N. Transport, continuation, provenance, and local naming preserve the same finite ledger, so the packet cannot export invariant measures, minimality, unique ergodicity, host interval functions, quotient real equality, countable choice, or ambient completeness. □

Theorem 8923.3 (IntervalExchange L10 handoff)**.** *Every downstream consumer of an accepted* $\mathsf{IntervalExchange}^{\uparrow}$ *carrier must read the* $\mathsf{DyadicIntervalNet}^{\uparrow}$ *cell row, the* $\mathsf{StreamName}^{\uparrow}$ *endpoint windows, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row, and the terminal* $\mathsf{Real}^{\uparrow}$ *seal before treating the packet as an interval map. The handoff order is*

$$\mathsf{DyadicRatCore}^{\uparrow}, \mathsf{DyadicIntervalNet}^{\uparrow} \longmapsto \mathsf{StreamName}^{\uparrow}, \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow},$$

with the permutation and translation rows displayed between the interval-net read and the terminal seal.

Proof. Project the carrier $E = (D, I, B, \Pi, T, W, Q, R, H, C, P, N)$. The dyadic endpoint arithmetic and interval-cell rows D, I, B are the only partition data visible at the start of an interval-map read.

The consumer then opens Π, T. These rows give a finite source-to-target matching and a finite translation ledger, so no host interval function or quotient real equality is used to interpret the rearrangement.

The L10 numeric route remains downstream. Endpoint observations pass through W, tolerance and regular rational comparisons pass through Q, and the Real-facing boundary is exposed only by R.

Finally replay H, C, P, N. The same finite dependency order is preserved under transport, continuation, provenance, and naming, so the handoff reaches an interval-map surface without importing invariant measures, minimality, unique ergodicity, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness. □

Falsifiable prediction: An accepted $\mathsf{IntervalExchange}^{\uparrow}$ consumer that treats the packet as an interval map before reading $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{DyadicIntervalNet}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ rows refutes the carrier surface.

Independence witness: dyadicratcore, dyadic-interval-net, streamname, regseqrat, real: no listed sibling supplies the whole interval-exchange packet $E = (D, I, B, \Pi, T, W, Q, R, H, C, P, N)$, because the sibling chapters supply arithmetic, cells, windows, readback, and seal rows while this chapter binds the finite permutation and translation ledger that turns those rows into an interval exchange surface.

Closure status for $\mathsf{NameCert}_{\mathsf{IntervalExchange}^{\uparrow}}$.

Constructive story: An $\mathsf{IntervalExchange}^{\uparrow}$ packet is generated from located dyadic endpoints, dyadic interval cells, endpoint incidence, a finite permutation row, finite translation rows, StreamName windows, RegSeqRat readback, a Real seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{IntervalExchange}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8923.1, Definition 8923.2, and Definition 8923.3 seed the finite interval-map NameCert boundary over dyadic interval partitions, permutation rows, translation rows, StreamName windows, RegSeqRat readback, and Real seals.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{IntervalExchange}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim invariant measures, minimality, unique ergodicity, host interval functions, quotient real equality, countable choice, or ambient RealUp completeness.

Upgrade path: Obligation closure requires checked carrier admission, classifier stability under common refinement, interval-cell transport, finite orbit replay, L10 handoff order, ledger nonescape, provenance, and local naming for BEDC.Derived.IntervalExchangeUp.

Chapter 8924

A Concrete Naming Certificate for $\mathsf{MetricKuratowskiEmbedding}^{\uparrow}$

Following Kuratowski and Kelley, the $\mathsf{MetricKuratowskiEmbedding}^{\uparrow}$ packet records the finite BEDC surface by which a displayed metric source is embedded into its distance-profile interface before any completion-facing consumer reads a limit object. It sits after the metric carrier of chapter 57, the separated complete-metric boundary of chapter 128, the Cauchy-net handoff of chapter 589, the finite StreamName windows of chapter 126, the regular rational readback of chapter 301, and the terminal Real seal of chapter 38. The packet names a distance-profile embedding route; it does not quotient completion names, choose limits, identify host equality, or import ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 8924.1 (Metric Kuratowski embedding carrier)**.** *A* $\mathsf{MetricKuratowskiEmbedding}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (M, D, W, Q, E, C, F, H, R, P, N)$$

with the following displayed rows:

1. *M is the* $\mathsf{Met}^{\uparrow}$ *source row, including the named point carrier and displayed metric comparison data.*
2. *D is the distance-profile row, recording finite reads of $x \mapsto d(x, a)$ against named anchor rows a from the source.*
3. *W is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row through which each distance profile is observed.*
4. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row induced by the displayed windows and dyadic tolerance data already carried by the regular-rational corridor.*
5. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row for the finite distance-profile values.*
6. *C is the* $\mathsf{CompleteMetric}^{\uparrow}$ *comparison row available when the profile is consumed by a complete-metric target.*
7. *F is the* $\mathsf{CauchyNet}^{\uparrow}$ *or* $\mathsf{CauchyFilter}^{\uparrow}$ *handoff row for completion-facing reads that enter through finite Cauchy data rather than through a selected limit.*
8. *H records componentwise* hsame *transport for source points, anchors, distance-profile rows, windows, readbacks, Real seals, complete-metric comparisons, Cauchy handoffs, replay, provenance, and local naming.*

9. *R records displayed* Cont *replay from a profile request through $M, D, W, Q, E, C, F, H, P, N$.*
10. *P is the* Pkg *provenance over* $\mathsf{MetricKuratowskiEmbedding}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{CompleteMetric}^{\uparrow}$, $\mathsf{CauchyNet}^{\uparrow}$, $\mathsf{CauchyFilter}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{MetricKuratowskiEmbedding}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $M, D, W, Q, E, C, F, H, R, P, N$. It has no coordinate for quotient completion, selected representatives, host equality of functions, ambient complete spaces, or a global Real-completeness theorem.

Theorem 8924.2 (Metric Kuratowski embedding NameCert obligations)**.** *For every accepted* $\mathsf{MetricKuratowskiEmbedding}^{\uparrow}$ *carrier*

$$K = (M, D, W, Q, E, C, F, H, R, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{MetricKuratowskiEmbedding}^{\uparrow}}$ *surface consists exactly of carrier admission for the* $\mathsf{Met}^{\uparrow}$ *source, distance-profile exposure, finite StreamName observation, RegSeqRat readback, Real sealing, CompleteMetric comparison, CauchyNet or CauchyFilter handoff, componentwise transport, displayed replay, provenance, and local naming. Every completion-facing read must expose the route*

$$\mathsf{Met}^{\uparrow} \to \mathsf{DistanceProfile} \to \mathsf{StreamName}^{\uparrow} \to \mathsf{RegSeqRat}^{\uparrow} \to \mathsf{Real}^{\uparrow}$$

and then choose either the $\mathsf{CompleteMetric}^{\uparrow}$ *comparison row or the* $\mathsf{CauchyNet}^{\uparrow}/\mathsf{CauchyFilter}^{\uparrow}$ *handoff row already displayed by the carrier.*

Proof. Project the carrier of Definition 8924.1. The source and profile rows are M and D, the observable analytic route is W, Q, E, and the completion-facing handoff rows are C and F.

Read the metric side first. The $\mathsf{Met}^{\uparrow}$ source supplies named points and metric comparisons, while D turns those comparisons into distance-profile rows against the displayed anchors.

The profile then passes through finite windows, regular rational readback, and the Real seal. The rows W, Q, E are the only value-facing route, so a consumer cannot bypass them to obtain a host function or ambient real value.

Finally C, F, H, R, P, N preserve the same finite packet for complete-metric and Cauchy consumers. Since no row stores quotient representatives, selected limits, host function equality, or ambient completeness, the NameCert obligations are exhausted by the displayed carrier. □

Theorem 8924.3 (Metric Kuratowski completion route)**.** *Every* $\mathsf{CompleteMetric}^{\uparrow}$, $\mathsf{CauchyNet}^{\uparrow}$, $\mathsf{CauchyFilter}^{\uparrow}$, *or* $\mathsf{Real}^{\uparrow}$ *consumer of an accepted* $\mathsf{MetricKuratowskiEmbedding}^{\uparrow}$ *packet must read the finite profile route through* $\mathsf{Met}^{\uparrow}$ *source rows, distance-profile rows,* $\mathsf{StreamName}^{\uparrow}$ *finite windows,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback,* $\mathsf{Real}^{\uparrow}$ *seals,* hsame *transport,* Cont *replay,* Pkg *provenance, and local* NameCert *naming. The consumer receives a displayed embedding interface for completion arguments, not quotient completion, selected limits, host equality of profiles, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start with the accepted carrier $K = (M, D, W, Q, E, C, F, H, R, P, N)$. Carrier projection gives the consumer access only to those rows.

The metric source row M and distance-profile row D fix the embedding interface. A profile value is observable only after the StreamName window W, RegSeqRat readback Q, and Real seal E have been displayed.

The completion-facing rows C and F then route the same profile either through a complete-metric comparison or through a CauchyNet/CauchyFilter handoff. These rows do not add a selected limit; they only expose the finite comparison path already named by the packet.

The structural rows H, R, P, N transport, replay, source, and name the same data. Therefore the handoff is a finite distance-profile interface and not a quotient completion or ambient completeness claim. □

Falsifiable prediction: Every accepted $\mathsf{MetricKuratowskiEmbedding}^{\uparrow}$ completion read displays Metric source rows, distance-profile rows, StreamName windows, RegSeqRat readback, Real seals, hsame transport, Cont replay, Pkg provenance, and a local NameCert row before any CompleteMetric, CauchyNet, or CauchyFilter consumer can inspect the embedding interface.

Independence witness: metric, completemetric, cauchynet, cauchyfilter, streamname, regseqrat, real: $\mathsf{MetricKuratowskiEmbedding}^{\uparrow}$ is not bijective to any listed sibling because it jointly binds a metric source, anchor-indexed distance profiles, finite observation windows, regular rational readback, Real sealing, completion handoffs, transport, replay, provenance, and local naming as one embedding packet.

Closure status for $\mathsf{NameCert}_{\mathsf{MetricKuratowskiEmbedding}^{\uparrow}}$.

Constructive story: A $\mathsf{MetricKuratowskiEmbedding}^{\uparrow}$ packet is generated from Metric source rows, distance-profile rows, StreamName finite windows, RegSeqRat readback, RealUp seals, CompleteMetric comparison rows, CauchyNet or CauchyFilter handoff rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{MetricKuratowskiEmbedding}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8924.1, Definition 8924.2, and Definition 8924.3 seed the finite distance-profile embedding interface for L10 completion consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{MetricKuratowskiEmbedding}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim quotient completion, selected limits, host equality of profile functions, ambient Real completeness, Lean theorem checking, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, distance-profile exposure, finite-window observation, RegSeqRat readback, Real sealing, completion handoff, transport, replay, provenance, and local naming for BEDC.Derived.MetricKuratowskiEmbeddingUp.

Chapter 8925

A Concrete Naming Certificate for $\mathsf{DyadicLocatedModulus}^{\uparrow}$

The $\mathsf{DyadicLocatedModulus}^{\uparrow}$ packet realizes the finite tolerance-to-window branch of the countable completion spine as BEDC NameCert data. It sits over the dyadic tolerance ledger of chapter 291, the finite observation windows of chapter 126, the regular rational readback of chapter 301, the terminal Real seal of chapter 38, the Bishop located-modulus interface of chapter 6101, and the RegSeqRat located-modulus route of chapter 3532. The packet names a dyadic finite modulus; it does not quotient streams, select limits, decide total order, or import mature $\mathsf{Real}^{\uparrow}$ completeness.

Definition 8925.1 (Dyadic located-modulus carrier)**.** *A* $\mathsf{DyadicLocatedModulus}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (D, W, R, E, B, G, H, C, P, N)$$

with the following displayed rows:

1. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, recording the dyadic precision request and slack comparison rows.*
2. *W is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row selected for that dyadic precision.*
3. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row induced by D and W.*
4. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached only after the dyadic tolerance and regular readback rows are displayed.*
5. *B is the* $\mathsf{BishopLocatedModulus}^{\uparrow}$ *interface row, naming the locatedness request that the dyadic window answers.*
6. *G is the* $\mathsf{RegSeqRatLocatedModulus}^{\uparrow}$ *handoff row, binding the regular-rational readback to the located-modulus consumer.*
7. *H records componentwise* hsame *transport for dyadic tolerance data, stream windows, regular readbacks, Real seals, located-modulus interfaces, replay, provenance, and local naming.*
8. *C records displayed* Cont *replay from a tolerance request through $D, W, R, E, B, G, H, P, N$.*
9. *P is the* Pkg *provenance over* $\mathsf{DyadicLocatedModulus}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{BishopLocatedModulus}^{\uparrow}$, $\mathsf{RegSeqRatLocatedModulus}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{DyadicLocatedModulus}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $D, W, R, E, B, G, H, C, P, N$. It has no coordinate for quotient stream equality, selected limits, trichotomy, countable choice, host real equality, or ambient completeness.

Theorem 8925.2 (Dyadic located-modulus NameCert obligations)**.** *For every accepted* $\mathsf{DyadicLocatedModulus}^{\uparrow}$ *carrier*

$$L = (D, W, R, E, B, G, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{DyadicLocatedModulus}^{\uparrow}}$ *surface consists exactly of carrier admission for dyadic tolerance rows, finite StreamName windows, RegSeqRat readback, Real sealing, Bishop located-modulus interface, RegSeqRat located-modulus handoff, componentwise transport, displayed replay, provenance, and local naming. Every countable-completion read must expose the ordered route*

$$\mathsf{DyadicRatCore}^{\uparrow} \to \mathsf{StreamName}^{\uparrow} \to \mathsf{RegSeqRat}^{\uparrow} \to \mathsf{Real}^{\uparrow}$$

before the located-modulus rows B and G can be consumed.

Proof. Project the carrier of Definition 8925.1. The dyadic tolerance row is D, the finite observation row is W, the regular readback row is R, and the Real seal row is E.

The located-modulus interface is downstream of those rows. The Bishop-facing row B names the locatedness request, while G records the RegSeqRat located-modulus handoff that answers it through the displayed regular readback.

Finally H, C, P, N transport, replay, source, and name the same finite packet. Since the carrier has no quotient stream, selected limit, trichotomy, countable-choice, host-equality, or ambient-completeness coordinate, the NameCert obligations are exhausted by the displayed rows. □

Theorem 8925.3 (Dyadic located-modulus RegSeqRat route)**.** *Every* $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{BishopLocatedModulus}^{\uparrow}$, *or* $\mathsf{RegSeqRatLocatedModulus}^{\uparrow}$ *consumer of an accepted* $\mathsf{DyadicLocatedModulus}^{\uparrow}$ *packet must read the finite route through* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerances,* $\mathsf{StreamName}^{\uparrow}$ *windows,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback,* $\mathsf{Real}^{\uparrow}$ *seals, the Bishop located-modulus interface, the RegSeqRat located-modulus handoff,* hsame *transport,* Cont *replay,* Pkg *provenance, and local* NameCert *naming. The route is a finite tolerance-to-window object for the countable completion spine, not a quotient stream or selected-limit construction.*

Proof. Start with an accepted carrier $L = (D, W, R, E, B, G, H, C, P, N)$. The tolerance request enters through D, so no consumer can obtain a located-modulus answer without first displaying the dyadic precision row.

The selected finite window W and regular readback R bind that dyadic request to the countable completion corridor. The Real seal E is downstream of the same readback and does not supply an independent completeness theorem.

The located rows B and G consume the displayed readback as a finite modulus answer. The structural rows H, C, P, N preserve and name this route, so the consumer receives only the dyadic tolerance-to-window packet. □

Falsifiable prediction: Every accepted $\mathsf{DyadicLocatedModulus}^{\uparrow}$ read displays DyadicRatCore tolerance rows, StreamName finite windows, RegSeqRat readback, RealUp seals, BishopLocatedModulus rows, RegSeqRatLocatedModulus rows, hsame transport, Cont replay, Pkg provenance, and local NameCert rows before a countable-completion consumer can inspect the located modulus.

Independence witness: dyadicratcore, streamname, regseqrat, real, bishop-located-modulus, regseqrat-located-modulus: $\mathsf{DyadicLocatedModulus}^{\uparrow}$ is not bijective to any listed sibling because

it jointly binds dyadic precision, finite window selection, regular rational readback, Real sealing, Bishop located-modulus interface, RegSeqRat located-modulus handoff, transport, replay, provenance, and local naming as one finite modulus packet.

Closure status for $\mathsf{NameCert}_{\mathsf{DyadicLocatedModulus}^{\uparrow}}$.

Constructive story: A $\mathsf{DyadicLocatedModulus}^{\uparrow}$ packet is generated from DyadicRatCore tolerance rows, StreamName finite windows, RegSeqRat readback, a RealUp seal, BishopLocatedModulus interface rows, RegSeqRatLocatedModulus handoff rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{DyadicLocatedModulus}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8925.1, Definition 8925.2, and Definition 8925.3 seed the finite dyadic located-modulus object for the countable completion spine.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{DyadicLocatedModulus}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim quotient stream equality, selected limits, trichotomy, countable choice, host real equality, ambient completeness, Lean theorem checking, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, dyadic tolerance exposure, finite-window selection, RegSeqRat readback, Real sealing, located-modulus handoff, transport, replay, provenance, and local naming for BEDC.Derived.DyadicLocatedModulusUp.

Chapter 8926

A Concrete Naming Certificate for $\mathsf{QuasiArithmeticMean}^{\uparrow}$

Following Kolmogorov and Nagumo on generalized means, the $\mathsf{QuasiArithmeticMean}^{\uparrow}$ packet records the finite carrier by which a continuous real transform, a finite list of real inputs, and a finite averaging row are inspected before a Real-valued aggregation is read. It sits after the terminal real-name surface of chapter 38, the continuous-map carrier of chapter 130, the finite input spine of chapter 36, and the finite-sum surface of chapter 1880. The packet names the Kolmogorov–Nagumo finite aggregation route; it does not import quotient equality of real functions, a selected inverse transform, infinite-series convergence, measure integration, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 8926.1 (Quasi-arithmetic mean carrier)**.** *A* $\mathsf{QuasiArithmeticMean}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Q = (F, I, V, A, R, H, C, P, N)$$

with the following displayed rows:

1. *F is the* $\mathsf{ContinuousMap}^{\uparrow}$ *transform row, naming the inspected continuous real observable used by the mean.*
2. *I is the* $\mathsf{List}^{\uparrow}$ *finite input row, recording the ordered finite family of* $\mathsf{Real}^{\uparrow}$ *names to be aggregated.*
3. *V is the transformed-value row, exposing the finite list obtained by reading F on the entries of I.*
4. *A is the finite averaging row, carried through the same finite-sum discipline as the sum surfaces of chapter 1880.*
5. *R is the terminal* $\mathsf{Real}^{\uparrow}$ *result row exposed only after F, I, V, A have been displayed.*
6. *H records componentwise* hsame *transport for the transform, input list, transformed values, finite average, result, replay, provenance, and local naming rows.*
7. *C records displayed* Cont *replay from an aggregation request through F, I, V, A, R, H.*
8. *P is the* Pkg *provenance over* $\mathsf{QuasiArithmeticMean}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{List}^{\uparrow}$, $\mathsf{DarbouxSum}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
9. *N is the local* $\mathsf{NameCert}_{\mathsf{QuasiArithmeticMean}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $F, I, V, A, R, H, C, P, N$. It has no coordinate for a host inverse-function theorem, quotient equality of real functions, infinite averaging, measure integration, countable choice, or ambient completeness.

Theorem 8926.2 (Quasi-arithmetic mean NameCert obligations)**.** *For every accepted* $\mathsf{QuasiArithmeticMean}^{\uparrow}$ *carrier*

$$Q = (F, I, V, A, R, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{QuasiArithmeticMean}^{\uparrow}}$ *surface consists exactly of carrier admission for the continuous transform row, finite input-list row, transformed-value row, finite averaging row, terminal Real result row, componentwise transport, displayed replay, package provenance, and local naming. Every aggregation consumer must read the route*

$$\mathsf{ContinuousMap}^{\uparrow} \to \mathsf{List}^{\uparrow} \to \mathsf{DarbouxSum}^{\uparrow} \to \mathsf{Real}^{\uparrow}$$

through the displayed rows F, I, V, A, R *before the output row* R *is available.*

Proof. Project the carrier of Definition 8926.1. The analytic rows are F, I, V, A, R, and the structural rows are H, C, P, N.

Read the transform and finite input first. The row F supplies the inspected continuous real observable, while I supplies only a displayed finite list of Real names. The transformed-value row V is therefore a finite readback from those two rows, not a host-level function quotient.

The aggregation step is the finite row A. It records the finite averaging surface over the transformed values before the terminal Real row R is exposed. Since the carrier has no coordinate for infinite summation, measure integration, selected inverses, countable choice, or ambient completeness, the local NameCert obligations are exhausted by the displayed route and the structural rows that preserve it. □

Theorem 8926.3 (Quasi-arithmetic mean generator handoff)**.** *Every downstream generator that consumes an accepted* $\mathsf{QuasiArithmeticMean}^{\uparrow}$ *packet receives only the rows*

$$F, I, V, A, R, H, C, P, N.$$

The handoff exposes a continuous transform row, a finite input-list row, transformed finite values, a finite average row, a terminal Real row, componentwise hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local* NameCert *naming. It exports no quotient equality of real functions, selected inverse transform, infinite-series convergence, measure-integral equality, countable-choice selector, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness theorem.*

Proof. Start with an accepted carrier $Q = (F, I, V, A, R, H, C, P, N)$. Carrier projection gives a generator access only to the displayed rows.

The generator first reads F and I, then forms the transformed finite row V. The averaging row A is downstream of those displayed rows and is the only aggregation coordinate carried by the packet.

Finally the terminal Real row R is transported and replayed through H and C, with provenance and local naming recorded by P and N. No excluded object has a carrier slot, so the generator handoff is exactly the finite route named by the packet. □

Falsifiable prediction: An accepted $\mathsf{QuasiArithmeticMean}^{\uparrow}$ consumer that reads a Real output without first displaying the ContinuousMap transform row, finite List input row, transformed-value row, finite average row, hsame transport, Cont replay, Pkg provenance, and local NameCert row refutes the carrier surface.

Independence witness: real, continuousmap, list, darboux-sum: no listed sibling is bijective with $\mathsf{QuasiArithmeticMean}^{\uparrow}$ because this packet jointly binds a continuous transform, finite real

input spine, transformed finite values, finite averaging, terminal Real output, transport, replay, provenance, and local naming as one aggregation carrier.

Closure status for $\mathsf{NameCert}_{\mathsf{QuasiArithmeticMean}^{\uparrow}}$.

Constructive story: A $\mathsf{QuasiArithmeticMean}^{\uparrow}$ packet is generated from a ContinuousMapUp transform row, a finite ListUp input row of RealUp names, transformed finite values, a finite average row, a terminal RealUp result, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{QuasiArithmeticMean}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8926.1, Definition 8926.2, and Definition 8926.3 seed the finite Kolmogorov–Nagumo aggregation route from continuous transform and finite input list to Real output.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{QuasiArithmeticMean}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim quotient equality of real functions, selected inverse transforms, infinite averaging, measure integration, countable choice, ambient Real completeness, Lean theorem checking, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, continuous-transform exposure, finite input-list exposure, transformed-value readback, finite-average discipline, Real result nonescape, transport, replay, provenance, and local naming for BEDC.Derived.QuasiArithmeticMeanUp.

Chapter 8927

A Concrete Naming Certificate for $\mathsf{DyadicRealInterval}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{DyadicRealInterval}^{\uparrow}$ packet records the finite endpoint envelope used when dyadic rational bounds are handed to Real and Completion consumers. It sits after the dyadic rational core of chapter 1658, the finite stream naming surface of chapter 126, the regular rational sequence readback of chapter 301, the terminal Real seal of chapter 38, and the closed bounded interval net route of chapter 1250. The packet is an interval-envelope certificate for displayed dyadic endpoints; it is not a quotient real interval, a selected completion point, a compactness theorem, or a proof of ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 8927.1 (DyadicRealInterval carrier)**.** *A* $\mathsf{DyadicRealInterval}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$I = (L, R, O, S, Q, E, N, H, C, P, K)$$

with the following displayed rows:

1. *L is the left* $\mathsf{DyadicRatCore}^{\uparrow}$ *endpoint row.*
2. *R is the right* $\mathsf{DyadicRatCore}^{\uparrow}$ *endpoint row.*
3. *O is the endpoint-order evidence row, recording that the displayed left endpoint is admitted before the displayed right endpoint for this interval envelope.*
4. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row used to inspect endpoint approximations and interval refinements.*
5. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row obtained from the displayed stream windows and dyadic tolerance data.*
6. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row through which endpoint and interval-envelope reads become Real-facing.*
7. *N is the* $\mathsf{ClosedBoundedIntervalNet}^{\uparrow}$ *row for finite closed bounded interval-net consumers.*
8. *H records componentwise* hsame *transport for dyadic endpoints, endpoint order, stream windows, regular rational readback, Real sealing, interval-net handoff, replay, provenance, and local naming.*
9. *C records displayed* Cont *replay from an interval-envelope query through $L, R, O, S, Q, E, N, H, P, K$.*
10. *P is the* Pkg *provenance over* $\mathsf{DyadicRealInterval}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{ClosedBoundedIntervalNet}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

11. K is the local $\mathsf{NameCert}_{\mathsf{DyadicRealInterval}^{\uparrow}}$ *row.*
The classifier compares accepted packets only through $L, R, O, S, Q, E, N, H, C, P, K$. It has no coordinate for quotient real equality, selected completion points, arbitrary located compactness, host interval topology, or ambient Real completeness.

Theorem 8927.2 (DyadicRealInterval Real seal obligations)**.** *For every accepted* $\mathsf{DyadicRealInterval}^{\uparrow}$ *carrier*

$$I = (L, R, O, S, Q, E, N, H, C, P, K),$$

the local $\mathsf{NameCert}_{\mathsf{DyadicRealInterval}^{\uparrow}}$ *surface consists exactly of left and right dyadic endpoint exposure through L, R, endpoint-order evidence through O, finite StreamName windows through S, RegSeqRat readback through Q, Real sealing through E, closed bounded interval-net handoff through N, componentwise* hsame *transport through H, displayed* Cont *replay through C, provenance through P, and local naming through K.*

Proof. Project the carrier of Definition 8927.1. Rows L, R, O are the endpoint envelope, rows S, Q, E, N are the completion-facing readback and interval-net surface, and rows H, C, P, K are the structural certificate data.

The endpoint part is read first. The two dyadic endpoint rows remain separate, and O records the displayed order evidence before any Real-facing seal can be consumed.

The completion-facing part is then read through S, Q, E, N. Stream windows precede regular rational readback, the Real seal is downstream of that readback, and the interval-net row is a finite closed bounded consumer row rather than an ambient compact interval.

Finally H, C, P, K transport, replay, source, and name the same finite packet. Since no coordinate stores quotient real equality, selected completion points, host interval topology, or ambient Real completeness, the listed rows exhaust the local NameCert surface. □

Theorem 8927.3 (DyadicRealInterval completion consumer route)**.** *Every Real or Completion consumer of an accepted* $\mathsf{DyadicRealInterval}^{\uparrow}$ *carrier must read the finite route*

$$\mathsf{DyadicRatCore}^{\uparrow} \times \mathsf{DyadicRatCore}^{\uparrow} \to \mathsf{StreamName}^{\uparrow} \to \mathsf{RegSeqRat}^{\uparrow} \to \mathsf{Real}^{\uparrow} \to \mathsf{ClosedBoundedIntervalNet}^{\uparrow}.$$

The consumer may inspect dyadic endpoint rows, endpoint-order evidence, finite stream windows, regular rational readback, Real sealing, closed bounded interval-net handoff, transport, replay, provenance, and local naming. It receives no quotient real interval, selected completion point, host interval topology, arbitrary compactness theorem, or ambient Real completeness.

Proof. Begin with the NameCert obligations of Definition 8927.2. They force every accepted consumer read to expose $L, R, O, S, Q, E, N, H, C, P, K$.

The endpoint segment is L, R, O. Both endpoint rows are dyadic rational core rows, and the order evidence is displayed as part of the same finite packet rather than inferred from an external real-order theorem.

The readback segment is S, Q, E. A completion-facing consumer reaches the Real seal only after finite StreamName windows and RegSeqRat readback have been displayed.

The interval-net segment is N, transported and replayed by H, C and sourced and named by P, K. Thus the consumer receives a finite interval-envelope route into closed bounded interval-net data, with no hidden quotient, selected point, compactness, topology, or ambient-completeness coordinate. □

Falsifiable prediction: Every accepted $\mathsf{DyadicRealInterval}^{\uparrow}$ consumer read displays two $\mathsf{DyadicRatCore}^{\uparrow}$ endpoint rows, endpoint-order evidence, $\mathsf{StreamName}^{\uparrow}$ windows, $\mathsf{RegSeqRat}^{\uparrow}$ readback, a $\mathsf{Real}^{\uparrow}$ seal, a $\mathsf{ClosedBoundedIntervalNet}^{\uparrow}$ handoff, hsame transport, Cont replay, Pkg provenance, and local NameCert naming before the interval envelope can be consumed.

Independence witness: dyadic-rat-core, streamname, regseqrat, real, closed-bounded-interval-net: $\mathsf{DyadicRealInterval}^{\uparrow}$ is not bijective to any listed sibling because it jointly binds two ordered dyadic endpoints, finite stream windows, regular rational readback, terminal Real sealing, closed bounded interval-net handoff, transport, replay, provenance, and local naming in one packet.

Closure status for $\mathsf{NameCert}_{\mathsf{DyadicRealInterval}^{\uparrow}}$.

Constructive story: A $\mathsf{DyadicRealInterval}^{\uparrow}$ packet is generated from left and right DyadicRatCore endpoint rows, endpoint-order evidence, StreamName finite windows, RegSeqRat readback, a RealUp seal, a ClosedBoundedIntervalNet handoff row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{DyadicRealInterval}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8927.1, Definition 8927.2, and Definition 8927.3 seed the finite dyadic endpoint interval-envelope route for Real and Completion consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{DyadicRealInterval}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim quotient real intervals, selected completion points, arbitrary located compactness, host interval topology, ambient RealUp completeness, Lean theorem checking, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, dyadic endpoint exposure, endpoint-order evidence, StreamName window visibility, RegSeqRat readback, Real-seal nonescape, interval-net handoff, transport, replay, provenance, and local naming for BEDC.Derived.DyadicRealIntervalUp.

Chapter 8928

A Concrete Naming Certificate for $\mathsf{LocatedUniformCompletionComparison}^{\uparrow}$

Following Bishop–Bridges constructive completion and Kelley's uniform-space terminology, the $\mathsf{LocatedUniformCompletionComparison}^{\uparrow}$ packet records the finite comparison route by which a located uniform-completion presentation is read beside a plain uniform-completion presentation before Real and Completion consumers inspect either endpoint. It sits after the located uniform-completion packet of chapter 1692, the uniform completion carrier of chapter 1473, the finite stream-name observation surface of chapter 126, the regular rational readback of chapter 301, and the terminal real-name seal of chapter 38. The packet names a displayed comparison route; it is not quotient completion equality, selected representative equality, host uniform-space equality, countable choice, or ambient completeness of $\mathsf{Real}^{\uparrow}$.

Definition 8928.1 (Located uniform completion comparison carrier)**.** *A* $\mathsf{LocatedUniformCompletionComparison}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (L, U, S, R, E, H, C, P, N)$$

with the following displayed rows:

1. *L is the* $\mathsf{LocatedUniformCompletion}^{\uparrow}$ *source row, exposing the located Cauchy-filter and completion route under comparison;*
2. *U is the* $\mathsf{UniformCompletion}^{\uparrow}$ *source row, exposing the corresponding uniform-completion route without adding a quotient comparison object;*
3. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row through which both presentations expose inspected observations;*
4. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row obtained from those displayed windows and tolerance data;*
5. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row, readable only after L, U, S, R have been displayed;*
6. *H records componentwise* hsame *transport for the two completion sources, finite windows, regular readback, Real seal, provenance, and local naming rows;*
7. *C records displayed* Cont *replay of the ordered route from the two completion sources through the finite readback and terminal seal;*
8. *P is the* Pkg *provenance over* $\mathsf{LocatedUniformCompletionComparison}^{\uparrow}$, $\mathsf{LocatedUniformCompletion}^{\uparrow}$, $\mathsf{UniformCompletion}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert*;*

9. N is the local $\mathsf{NameCert}_{\mathsf{LocatedUniformCompletionComparison}^{\uparrow}}$ *row.*
The classifier compares accepted packets only through these rows and their structural transport and replay data. It has no coordinate for quotient completion equality, selected representatives, host equality of completed objects, countable-choice schedules, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 8928.2 (Located uniform completion comparison NameCert obligations)**.** *For every accepted* $\mathsf{LocatedUniformCompletionComparison}^{\uparrow}$ *carrier* $K = (L, U, S, R, E, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{LocatedUniformCompletionComparison}^{\uparrow}}$ *surface consists exactly of carrier admission for the displayed tuple, located uniform-completion source exposure through* L*, uniform-completion source exposure through* U*, StreamName finite-window exposure through* S*, RegSeqRat readback through* R*, terminal Real sealing through* E*, componentwise* hsame *transport through* H*, displayed* Cont *replay through* C*, package provenance through* P*, and local naming through* N*.*

Proof. Project the carrier of Definition 8928.1. Its coordinates display the located completion source, the plain uniform-completion source, finite stream windows, regular rational readback, Real seal, transport, replay, provenance, and local name.

Read the two completion sources first. The row L supplies the located uniform-completion presentation, while U supplies the companion uniform-completion presentation; neither row adds quotient equality between completed objects.

Read the finite observation stack next. The row S supplies the inspected StreamName windows, R supplies the corresponding RegSeqRat readback, and E is downstream of those rows as the terminal Real seal.

Finally use H, C, P, N to transport, replay, source, and name the same route. Therefore the NameCert surface has no local obligation outside the displayed comparison packet. □

Theorem 8928.3 (Located uniform completion comparison finite route)**.** *Every Real or Completion consumer of an accepted* $\mathsf{LocatedUniformCompletionComparison}^{\uparrow}$ *packet factors through the finite displayed route*

$$\mathsf{LocatedUniformCompletion}^{\uparrow} \longmapsto \mathsf{UniformCompletion}^{\uparrow} \longmapsto \mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}.$$

The structural rows H, C, P, N *preserve that order under transport, replay, provenance, and local naming, so the comparison is a route between displayed completion presentations rather than an ambient equivalence of completions.*

Proof. Start with the obligation surface of Definition 8928.2. It forces any accepted consumer read to expose L, U, S, R, E before the local name is consumed.

The comparison source is the pair L, U. Since both rows are part of the same finite packet, a consumer may compare their displayed routes only by reading the carrier rows, not by importing host equality of completed objects.

The readback stack is S, R, E. StreamName windows are inspected before regular rational readback, and the Real seal is readable only after that finite observation stack has been displayed.

Rows H, C, P, N transport, replay, source, and name this same dependency order. Thus the consumer receives a finite comparison route and no selected representative, quotient completion equality, countable-choice schedule, or ambient completeness principle. □

Falsifiable prediction: Every accepted $\mathsf{LocatedUniformCompletionComparison}^{\uparrow}$ consumer read displays one $\mathsf{LocatedUniformCompletion}^{\uparrow}$ source row, one $\mathsf{UniformCompletion}^{\uparrow}$ source row, one $\mathsf{StreamName}^{\uparrow}$ finite-window row, one $\mathsf{RegSeqRat}^{\uparrow}$ readback row, one terminal $\mathsf{Real}^{\uparrow}$ seal, componentwise hsame

transport, displayed Cont replay, Pkg provenance, and local naming before any Real or Completion handoff is consumed.

Independence witness: located-uniform-completion, uniformcompletion, streamname, regseqrat, real: $\mathsf{LocatedUniformCompletionComparison}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries the located completion source, plain uniform-completion source, finite windows, regular readback, Real seal, transport, replay, provenance, and local NameCert rows in one packet.

Lean4 (statement) `BEDC.Derived.LocatedUniformCompletionComparisonUp`

Closure status for $\mathsf{NameCert}_{\mathsf{LocatedUniformCompletionComparison}^{\uparrow}}$.

Constructive story: A $\mathsf{LocatedUniformCompletionComparison}^{\uparrow}$ packet is generated from a LocatedUniformCompletionUp source row, a UniformCompletionUp source row, StreamName finite windows, RegSeqRat readback, a terminal RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{LocatedUniformCompletionComparison}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8928.1, Definition 8928.2, and Definition 8928.3 seed the finite comparison route through located completion, uniform completion, finite stream windows, regular rational readback, Real sealing, transport, replay, provenance, and local naming rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{LocatedUniformCompletionComparison}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim quotient completion equality, selected representatives, host equality of completed objects, countable choice, ambient RealUp completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, located completion source exposure, uniform completion source exposure, StreamName finite-window exposure, RegSeqRat readback, Real-seal handoff, transport stability, replay stability, provenance non-escape, and local naming for BEDC.Derived.LocatedUniformCompletionComparisonUp.

Chapter 8929

A Concrete Naming Certificate for $\mathsf{BishopCompactImage}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{BishopCompactImage}^{\uparrow}$ packet records the constructive continuous image of compact metric data as finite compact-source, continuous-map, uniform-modulus, image-witness, regular rational, dyadic tolerance, and terminal real-seal rows. It sits after the compact metric source of chapter 129, the continuous-map surface of chapter 130, the regular sequence readback of chapter 301, the dyadic tolerance core of chapter 291, and the real-name seal of chapter 38. The chapter names only the finite image carrier, its NameCert rows, and its Real-facing handoff; it does not assert a quotient image space, an ambient compactness theorem, countable choice, or host-level function equality.

Falsifiable prediction: A consumer that reads a compact-image Real endpoint without the displayed compact source, continuous-map row, uniform-modulus ledger, image witness, $\mathsf{RegSeqRat}^{\uparrow}$ readback, $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance row, and $\mathsf{Real}^{\uparrow}$ seal has left the $\mathsf{BishopCompactImage}^{\uparrow}$ packet.

Independence witness: compactmetric, continuousmap, regseqrat, dyadicratcore, real: no listed sibling supplies the whole compact-image packet, because $\mathsf{CompactMetric}^{\uparrow}$ names the compact source, $\mathsf{ContinuousMap}^{\uparrow}$ names the map row, $\mathsf{RegSeqRat}^{\uparrow}$ and $\mathsf{DyadicRatCore}^{\uparrow}$ name value readback, and $\mathsf{Real}^{\uparrow}$ seals endpoints while this chapter binds their finite image-witness route.

Definition 8929.1 (Bishop compact-image carrier)**.** *A* $\mathsf{BishopCompactImage}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$I = (K, F, M, W, R, D, E, H, C, P, N)$$

with the following displayed rows:

1. *K is the accepted* $\mathsf{CompactMetric}^{\uparrow}$ *compact-source row, including the finite cover or finite-net data exposed by that sibling packet.*
2. *F is the accepted* $\mathsf{ContinuousMap}^{\uparrow}$ *row naming the map from the displayed compact source into the displayed metric target.*
3. *M is the uniform-modulus ledger produced from the compact-source and continuous-map rows.*
4. *W is the image-witness table: each displayed image request points back to a compact-source row, a map-evaluation row, and the modulus row used to certify the requested tolerance.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the displayed image values.*
6. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row used by the modulus and readback comparisons.*

7. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal for the displayed image values.*
8. *H records componentwise* hsame *transport for $K, F, M, W, R, D, E, C, P, N$.*
9. *C records displayed* Cont *replay from compact-source requests through continuous-map evaluation, uniform-modulus use, image-witness inspection, regular rational readback, dyadic tolerance comparison, and the Real seal.*
10. *P is the* Pkg *provenance row naming exactly* $\mathsf{BishopCompactImage}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{BishopCompactImage}^{\uparrow}}$ *row.*

The local classifier compares accepted carriers only through these displayed rows. It has no coordinate for a quotient image set, a host subset equality, countable choice of preimages, or ambient compactness outside the named source.

Theorem 8929.2 (Bishop compact-image NameCert obligations)**.** *For every accepted* $\mathsf{BishopCompactImage}^{\uparrow}$ *carrier*

$$I = (K, F, M, W, R, D, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{BishopCompactImage}^{\uparrow}}$ *surface consists exactly of carrier exposure for I, compact-source exposure through K, continuous-map exposure through F, uniform-modulus handoff through M, image-witness exactness through W, regular rational readback through R, dyadic tolerance exposure through D, terminal Real-seal nonescape through E, componentwise* hsame *transport through H, displayed* Cont *replay through C, package provenance through P, and local naming through N.*

Proof. Project the carrier of Definition 8929.1. The rows K, F, M, W, R, D, E are the analytic route, and H, C, P, N are the structural rows.

The source-facing read begins at K and F. The compact metric row supplies only the displayed compact-source data, while the continuous-map row supplies only the named map-evaluation surface on that source.

The image-facing read then passes through M, W, R, D, E. The uniform-modulus ledger fixes the tolerance route, the witness table points each image request back to a displayed source and map-evaluation row, the regular rational row reads the requested values, the dyadic row supplies the tolerance arithmetic, and the Real row seals the displayed endpoint.

Transport, replay, provenance, and naming are exactly the rows H, C, P, N. Since no carrier coordinate names a quotient image set, a host subset equality, a choice function for all preimages, or ambient compactness beyond K, the listed obligations exhaust the local NameCert surface. □

Theorem 8929.3 (Bishop compact-image Real-completion handoff)**.** *Every Real-facing image consumer of an accepted* $\mathsf{BishopCompactImage}^{\uparrow}$ *carrier factors through the displayed compact source, continuous-map row, uniform-modulus ledger, image-witness table,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row, and* $\mathsf{Real}^{\uparrow}$ *seal:*

$$K, F, M, W, R, D, E, H, C, P, N.$$

The handoff exposes a finite constructive image route and no quotient image carrier, host-level function equality, countable preimage choice, ambient Heine–Borel principle, or completed image-space object.

Proof. Start with the NameCert obligations of Definition 8929.2. They identify the compact-source, continuous-map, modulus, witness, readback, dyadic, and Real rows as the whole Real-facing route.

A consumer that requests an image endpoint must first inspect K, F, M, W. These rows determine the displayed compact source, the displayed map evaluation, the modulus used for the request, and the finite witness that links the image read to a source row.

The endpoint read then passes through R, D, E. Regular rational readback and dyadic tolerance comparison produce the value data that the terminal $\mathsf{Real}^{\uparrow}$ seal may expose.

Finally H, C, P, N preserve the same route under transport, replay it under displayed continuation, name its sibling sources, and bind the local certificate. No listed row supplies an unbounded preimage selector, a quotient image set, or an ambient compactness theorem, so every Real-facing consumer remains inside the finite handoff. □

Closure status for $\mathsf{NameCert}_{\mathsf{BishopCompactImage}^{\uparrow}}$.

Constructive story: A $\mathsf{BishopCompactImage}^{\uparrow}$ packet is generated from a displayed compact metric source, continuous-map row, uniform-modulus ledger, image-witness table, regular rational readback, dyadic tolerance arithmetic, terminal Real seal, componentwise transport, displayed continuation replay, provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BishopCompactImage}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8929.1, Definition 8929.2, and Definition 8929.3 seed the finite constructive compact-image carrier and its Real-facing handoff.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BishopCompactImage}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient image spaces, ambient compactness theorems, countable preimage choice, host function equality, Lean verification, or bridge checking.

Upgrade path: A formal route can encode the finite carrier and prove compact-source exposure, continuous-map exposure, uniform-modulus handoff, image-witness exactness, Real-seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.BishopCompactImageUp.

Chapter 8930

A Concrete Naming Certificate for $\mathsf{UniformlyLocatedSet}^{\uparrow}$

Following Bishop and Bridges on located subsets of metric spaces, the $\mathsf{UniformlyLocatedSet}^{\uparrow}$ packet records the finite BEDC surface by which a displayed subset is read through uniform locator data before any Real or completion consumer inspects distances. It sits after the metric source row of chapter 57, the dyadic tolerance core of chapter 291, the finite observation windows of chapter 126, the regular rational readback of chapter 301, and the terminal Real seal of chapter 38. The packet names a constructive located-subset interface; it does not import host subsets, countable choice, quotient completions, or ambient Real completeness.

Definition 8930.1 (Uniformly located set carrier)**.** *A* $\mathsf{UniformlyLocatedSet}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$U = (M, L, D, W, Q, E, H, C, P, N)$$

with the following displayed rows:

1. *M is the* $\mathsf{Met}^{\uparrow}$ *source row, including the named point carrier and displayed metric comparison data.*
2. *L is the located-set row or locator-modulus row, recording the finite witness that answers distance-to-the-subset requests uniformly over the displayed metric source.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row that bounds each locator request by a dyadic precision and slack comparison.*
4. *W is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row through which the locator answer is observed.*
5. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row induced by the displayed window and tolerance rows.*
6. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row for the distance readback reached through D, W, Q.*
7. *H records componentwise* hsame *transport for metric source rows, locator rows, dyadic tolerances, finite windows, regular readbacks, Real seals, replay, provenance, and local naming.*
8. *C records displayed* Cont *replay from a distance-to-set request through $M, L, D, W, Q, E, H, P, N$.*
9. *P is the* Pkg *provenance over* $\mathsf{UniformlyLocatedSet}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{UniformlyLocatedSet}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $M, L, D, W, Q, E, H, C, P, N$. It has no coordinate for host subset membership, selected nearest points, countable choice over approximants, quotient completion, or ambient Real-completeness principles.

Theorem 8930.2 (Uniformly located set NameCert obligations)**.** *For every accepted* $\mathsf{UniformlyLocatedSet}^{\uparrow}$ *carrier*

$$U = (M, L, D, W, Q, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{UniformlyLocatedSet}^{\uparrow}}$ *surface consists exactly of carrier admission for the metric source row, located-set or locator-modulus row, dyadic tolerance row, finite StreamName observation, RegSeqRat readback, Real sealing, componentwise transport, displayed replay, provenance, and local naming. Every distance-to-set read must expose the route*

$$\mathsf{Met}^{\uparrow} \to \mathsf{LocatorModulus} \to \mathsf{DyadicRatCore}^{\uparrow} \to \mathsf{StreamName}^{\uparrow} \to \mathsf{RegSeqRat}^{\uparrow} \to \mathsf{Real}^{\uparrow}$$

before any Real or completion-facing consumer can inspect the located-subset interface.

Proof. Project the carrier of Definition 8930.1. The metric source and locator data are M and L, the finite tolerance-to-value route is D, W, Q, E, and the structural rows are H, C, P, N.

The source row supplies only named metric comparisons. The locator row answers a distance-to-set request by displaying a dyadic tolerance row, a finite observation window, a regular rational readback, and the Real seal reached through that readback.

The structural rows transport, replay, source, and name the same finite packet. Since the carrier has no host-subset coordinate, nearest-point selector, countable-choice ledger, quotient-completion row, or ambient-completeness row, the NameCert obligations are exhausted by the displayed carrier. □

Theorem 8930.3 (Uniformly located set Real and completion route)**.** *Every* $\mathsf{Real}^{\uparrow}$ *or completion-facing consumer of an accepted* $\mathsf{UniformlyLocatedSet}^{\uparrow}$ *packet must read the metric source row, located-set or locator-modulus row, dyadic tolerance row,* $\mathsf{StreamName}^{\uparrow}$ *finite windows,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback,* $\mathsf{Real}^{\uparrow}$ *seal,* hsame *transport,* Cont *replay,* Pkg *provenance, and local* $\mathsf{NameCert}$ *naming. The consumer receives a finite constructive located-subset interface, not a host subset, a selected nearest point, countable choice, quotient completion, or ambient Real completeness.*

Proof. Start with the accepted carrier $U = (M, L, D, W, Q, E, H, C, P, N)$. Carrier projection gives a Real or completion-facing consumer access only to those rows.

The source and locator rows M, L determine the distance-to-set request. The dyadic tolerance D, finite window W, regular readback Q, and Real seal E are the only value-facing route for that request.

The transport, replay, provenance, and local certificate rows preserve the same route without adding selectors or completion quotients. Therefore any downstream consumer reads a finite located-subset packet and not an ambient Real-completeness theorem. □

Falsifiable prediction: Every accepted $\mathsf{UniformlyLocatedSet}^{\uparrow}$ read displays MetricSpace source rows, located-set or locator-modulus rows, DyadicRatCore tolerance rows, StreamName finite windows, RegSeqRat readback, RealUp seals, hsame transport, Cont replay, Pkg provenance, and a local NameCert row before a Real or completion consumer can inspect the located-subset interface.

Independence witness: metricspace, dyadicratcore, streamname, regseqrat, real: $\mathsf{UniformlyLocatedSet}^{\uparrow}$ is not bijective to any listed sibling because it jointly binds a metric source, locator-modulus

evidence, dyadic precision, finite observation windows, regular rational readback, Real sealing, transport, replay, provenance, and local naming as one located-subset packet.

Closure status for $\mathsf{NameCert}_{\mathsf{UniformlyLocatedSet}^{\uparrow}}$.

Constructive story: A $\mathsf{UniformlyLocatedSet}^{\uparrow}$ packet is generated from MetricSpace source rows, located-set or locator-modulus rows, DyadicRatCore tolerance rows, StreamName finite windows, RegSeqRat readback, RealUp seals, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{UniformlyLocatedSet}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8930.1, Definition 8930.2, and Definition 8930.3 seed the finite constructive located-subset interface for Real and completion consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{UniformlyLocatedSet}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim host subset membership, nearest-point selection, countable choice, quotient completion, ambient Real completeness, Lean theorem checking, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, locator-modulus exposure, dyadic tolerance exactness, finite-window observation, RegSeqRat readback, Real sealing, transport, replay, provenance, and local naming for BEDC.Derived.UniformlyLocatedSetUp.

Chapter 8931

A Concrete Naming Certificate for $\mathsf{FiniteCoverIncidenceRealizer}^{\uparrow}$

Following the classical nerve construction for finite covers and the finite-incidence reading of simplicial chains, the $\mathsf{FiniteCoverIncidenceRealizer}^{\uparrow}$ packet records the BEDC rows that turn displayed cover membership and overlap data into a simplicial and homology-facing handoff. It sits after the topological source of chapter 88, the finite cover nerve of chapter 7597, the simplicial complex interface of chapter 238, the homology rows of chapter 98, and the categorical carrier of chapter 61. The packet names finite incidence data; it does not import a host cover, selected refinements, ambient chain complexes, or quotient homology.

Definition 8931.1 (Finite cover incidence realizer carrier)**.** *A* $\mathsf{FiniteCoverIncidenceRealizer}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$I = (T, K, M, O, F, S, A, G, H, C, P, N)$$

with the following displayed rows:

1. *T is the* $\mathsf{Topology}^{\uparrow}$ *source row for the covered object.*
2. *K is the* $\mathsf{FiniteCoverNerve}^{\uparrow}$ *cover row, including the finite cover index list and cover-member exposure.*
3. *M is the finite membership-incidence ledger pairing displayed source rows with displayed cover-index rows.*
4. *O is the overlap-incidence ledger for nonempty finite intersections.*
5. *F is the simplicial face ledger induced by M and O.*
6. *S is the* $\mathsf{SimplicialComplex}^{\uparrow}$ *handoff row that reads the finite face ledger as a simplicial carrier.*
7. *A is the* $\mathsf{Homology}^{\uparrow}$ *handoff row for finite chains generated from the accepted simplicial faces.*
8. *G is the* $\mathsf{Cat}^{\uparrow}$ *provenance row for functorial comparison of cover maps, face maps, and homology consumers.*
9. *H records componentwise* hsame *transport for topology, cover, membership, overlap, face, simplicial, homology, category, replay, provenance, and local naming rows.*
10. *C records displayed* Cont *replay from a cover-incidence request through $T, K, M, O, F, S, A, G, H, P, N$.*
11. *P is the* Pkg *provenance over* $\mathsf{FiniteCoverIncidenceRealizer}^{\uparrow}$, $\mathsf{Topology}^{\uparrow}$, $\mathsf{FiniteCoverNerve}^{\uparrow}$, $\mathsf{SimplicialComplex}^{\uparrow}$, $\mathsf{Homology}^{\uparrow}$, $\mathsf{Cat}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.

12. N is the local $\mathsf{NameCert}_{\mathsf{FiniteCoverIncidenceRealizer}^{\uparrow}}$ *row.*
The classifier compares accepted packets only through $T, K, M, O, F, S, A, G, H, C, P, N$. It has no coordinate for host open covers, selected refinements, ambient simplicial sets, quotient chain complexes, or global homology representatives.

Theorem 8931.2 (Finite cover incidence realizer NameCert obligations)**.** *For every accepted* $\mathsf{FiniteCoverIncidenceRealizer}^{\uparrow}$ *carrier*

$$I = (T, K, M, O, F, S, A, G, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{FiniteCoverIncidenceRealizer}^{\uparrow}}$ *surface consists exactly of carrier admission for topology source rows, finite cover rows, membership incidence, overlap incidence, simplicial face admission, simplicial-complex handoff, homology handoff, categorical provenance, componentwise transport, displayed replay, package provenance, and local naming. Every simplicial or homology consumer must expose the route*

$$\mathsf{Topology}^{\uparrow} \to \mathsf{FiniteCoverNerve}^{\uparrow} \to \mathsf{IncidenceLedger} \to \mathsf{SimplicialComplex}^{\uparrow} \to \mathsf{Homology}^{\uparrow}$$

with the $\mathsf{Cat}^{\uparrow}$ *provenance row displayed before functorial comparison is consumed.*

Proof. Project the carrier of Definition 8931.1. The topology and finite-cover inputs are T, K, the incidence ledgers are M, O, F, the downstream handoff rows are S, A, G, and the structural rows are H, C, P, N.

The finite membership and overlap rows determine exactly which finite faces are admitted. The simplicial-complex row consumes that face ledger, and the homology row consumes the finite-chain data generated from the same accepted faces.

The category provenance row records how cover maps, face maps, and homology-facing consumers compare without adding a host category of covers. The transport, replay, provenance, and local naming rows preserve this finite packet, so the NameCert obligations are exhausted by the displayed carrier. □

Falsifiable prediction: Every accepted $\mathsf{FiniteCoverIncidenceRealizer}^{\uparrow}$ read displays Topology source rows, FiniteCoverNerve cover rows, membership incidence, overlap incidence, simplicial face rows, SimplicialComplex handoff, Homology handoff, Category provenance, hsame transport, Cont replay, Pkg provenance, and a local NameCert row before a simplicial or homology consumer can inspect the incidence interface.

Independence witness: topology, finite-cover-nerve, simplicialcomplex, homology, category: $\mathsf{FiniteCoverIncidenceRealizer}^{\uparrow}$ is not bijective to any listed sibling because it jointly binds cover membership, overlap incidence, simplicial faces, homology handoff, categorical provenance, transport, replay, provenance, and local naming as one finite incidence packet.

Closure status for $\mathsf{NameCert}_{\mathsf{FiniteCoverIncidenceRealizer}^{\uparrow}}$**.**

Constructive story: A $\mathsf{FiniteCoverIncidenceRealizer}^{\uparrow}$ packet is generated from Topology source rows, FiniteCoverNerve cover rows, finite membership and overlap incidence ledgers, simplicial face rows, SimplicialComplex handoff rows, Homology handoff rows, Category provenance rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{FiniteCoverIncidenceRealizer}^{\uparrow}}$, seed)

Scope closed: Definition 8931.1 and Definition 8931.2 seed the finite cover-incidence interface for simplicial, homology, and categorical consumers.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{FiniteCoverIncidenceRealizer}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim host open covers, selected refinements, ambient simplicial sets, quotient chain complexes, global homology representatives, Lean theorem checking, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, membership-incidence exactness, overlap-incidence exactness, simplicial face handoff, homology handoff, categorical provenance, transport, replay, provenance, and local naming for BEDC.Derived.FiniteCoverIncidenceRealizerUp.

Chapter 8932

A Concrete Naming Certificate for $\mathsf{LocatedDyadicUniformMesh}^{\uparrow}$

Following Bishop and Bridges on constructive real analysis, the $\mathsf{LocatedDyadicUniformMesh}^{\uparrow}$ packet records the finite mesh object used when a Real or Completion consumer needs dyadic interval cells with located endpoints and regular readback. It sits after the dyadic arithmetic of chapter 291, the stream schedule rows of chapter 126, the regular rational readback of chapter 301, the terminal real seal of chapter 38, and the interval-cell surface of chapter 5966. The packet supplies a finite L10 mesh handoff without quotient representatives, choice-selected limits, host real equality, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 8932.1 (Located dyadic uniform mesh carrier)**.** *A* $\mathsf{LocatedDyadicUniformMesh}^{\uparrow}$ *carrier is a finite* BHist *packet* $M = (I, L, Q, S, R, H, C, P, N)$ *with the following displayed rows:*

1. *I is the* $\mathsf{DyadicIntervalNet}^{\uparrow}$ *row carrying a finite dyadic interval net and its cell-incidence ledger.*
2. *L is the located endpoint evidence row, recording left and right dyadic endpoint comparisons for each visible cell.*
3. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *tolerance readback row that exposes the mesh width and requested precision as regular rational data.*
4. *S is the* $\mathsf{StreamName}^{\uparrow}$ *observation row that schedules the finite windows inspected by the mesh consumer.*
5. *R is the terminal* $\mathsf{Real}^{\uparrow}$ *seal read only after I, L, Q, S have been displayed.*
6. *H, C, P, N are respectively componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and the local* $\mathsf{NameCert}_{\mathsf{LocatedDyadicUniformMesh}^{\uparrow}}$ *row.*

Theorem 8932.2 (LocatedDyadicUniformMesh NameCert obligations)**.** *For every accepted* $\mathsf{LocatedDyadicUniform}$ *carrier $M = (I, L, Q, S, R, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{LocatedDyadicUniformMesh}^{\uparrow}}$ *surface consists exactly of dyadic interval-net admission, located endpoint evidence, RegSeqRat tolerance readback, StreamName observation rows, terminal Real seal, componentwise transport, continuation replay, provenance, and local naming. A consumer can therefore inspect the mesh only through the finite route*

$$\mathsf{DyadicIntervalNet}^{\uparrow} \longmapsto \mathsf{DyadicRatCore}^{\uparrow} \longmapsto \mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}.$$

The obligation surface exports no quotient representative, selected limit, host real equality, countable-choice schedule, or ambient completeness theorem.

Proof. Project the carrier rows of Definition 8932.1. The dyadic interval-net row supplies finite cells, the endpoint row supplies located comparisons, and the tolerance and observation rows keep width and inspection data visible before the Real seal is read.

Replay the structural rows H, C, P, N. Transport, continuation replay, provenance, and local naming preserve the same finite route under classifier transport and do not add a coordinate for quotient equality, selected limits, choice schedules, host real equality, or ambient completeness. □

Theorem 8932.3 (LocatedDyadicUniformMesh refinement stability)**.** *Let $M = (I, L, Q, S, R, H, C, P, N)$ and $M' = (I', L', Q', S', R', H', C', P', N')$ be accepted* $\mathsf{LocatedDyadicUniformMesh}^{\uparrow}$ *carriers. If M' refines the dyadic interval net of M and the endpoint, tolerance, StreamName, RegSeqRat, Real-seal, and structural rows are transported by componentwise* hsame*, then every classifier accepted by M is accepted by M' through the same displayed finite route. The refinement exports only smaller dyadic cells with the same located endpoint and readback surface.*

Proof. Read the interval-net row I and its refined row I' through the dyadic interval-net carrier. Refinement replaces each visible cell by displayed dyadic subcells while preserving the endpoint order and incidence ledger.

Transport the endpoint evidence, tolerance readback, StreamName windows, RegSeqRat row, and Real seal along the stated hsame witnesses. Since the carrier exposes no coordinate outside these rows, classifier acceptance is stable under the refinement and remains tied to the same finite mesh route. □

Theorem 8932.4 (LocatedDyadicUniformMesh L10 handoff)**.** *Every L10 Real and Completion consumer of a* $\mathsf{LocatedDyadicUniformMesh}^{\uparrow}$ *packet must read the dyadic interval net I, located endpoint evidence L, RegSeqRat tolerance row Q, StreamName observation row S, and Real seal R before it treats the packet as a mesh for approximation, comparison, or completion-facing readback. The handoff supplies finite dyadic cells and located endpoint data only; it does not supply quotient real representatives, selected Cauchy limits, host real equality, choice schedules, or an ambient completeness principle.*

Proof. Apply the NameCert obligations above. They force the consumer to read the interval net, endpoint evidence, tolerance readback, observation schedule, and Real seal in the displayed order before any completion-facing use is public.

Now use refinement stability. Any later mesh refinement remains inside the same finite route and therefore cannot introduce an external representative, selected limit, choice schedule, host equality, or ambient completeness endpoint. □

Closure status for $\mathsf{NameCert}_{\mathsf{LocatedDyadicUniformMesh}^{\uparrow}}$**.**

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{LocatedDyadicUniformMesh}^{\uparrow}}$, seed)

Scope closed: Definition 8932.2 records the seed carrier and finite L10 mesh route over dyadic interval nets, located endpoints, RegSeqRat tolerance readback, StreamName observations, and Real seals.

Constructive story: A $\mathsf{LocatedDyadicUniformMesh}^{\uparrow}$ packet is generated from dyadic interval-net cells, located endpoint evidence, RegSeqRat tolerance readback, StreamName observation windows, a terminal Real seal, componentwise hsame transport, displayed Cont replay, package provenance, and a local NameCert row.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{LocatedDyadicUniformMesh}^{\uparrow}}$, formalTarget)

Lean target: `BEDC.Derived.LocatedDyadicUniformMeshUp`

Bridge status: none

Not claimed: This chapter does not close a public completion theorem, quotient-free Real equality, compactness theorem, or checked standard bridge.

Upgrade path: A scoped closure requires Lean-checked carrier obligations and refinement stability for the displayed mesh route.

Chapter 8933

A Concrete Naming Certificate for $\mathsf{CompactModulusMeshHandoff}^{\uparrow}$

Following the finite-net proof of Heine–Cantor, the $\mathsf{CompactModulusMeshHandoff}^{\uparrow}$ packet turns the compact-uniform-continuity vision of chapter 9237 into a concrete finite handoff. It reads compact finite-net data from chapter 60, pointwise continuity rows from chapter 59, dyadic tolerance arithmetic from chapter 291, regular rational readback from chapter 301, and the terminal real seal from chapter 38. The packet records the compact-net, pointwise-modulus, rational-fold, and uniform-modulus route as finite NameCert data rather than as an open-cover compactness principle.

Definition 8933.1 (Compact modulus mesh handoff carrier)**.** *A* $\mathsf{CompactModulusMeshHandoff}^{\uparrow}$ *carrier is a finite* BHist *packet* $K = (C, M, D, F, U, R, H, T, P, N)$ *with the following displayed rows:*

1. *C is the compact finite-net row over the* $\mathsf{Compact}^{\uparrow}$ *or* $\mathsf{CompactMetric}^{\uparrow}$ *source.*
2. *M is the pointwise-modulus row supplied by the* $\mathsf{Continuous}^{\uparrow}$ *or* $\mathsf{ContinuousMap}^{\uparrow}$ *source.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row for the requested mesh precision.*
4. *F is the rational lower-bound fold row over the finite probe bundle.*
5. *U is the* $\mathsf{UniformModulus}^{\uparrow}$ *handoff row produced by the fold.*
6. *R is the terminal* $\mathsf{Real}^{\uparrow}$ *seal for Real-valued consumers.*
7. *H, T, P, N are componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and the local* $\mathsf{NameCert}_{\mathsf{CompactModulusMeshHandoff}^{\uparrow}}$ *row.*

Theorem 8933.2 (CompactModulusMeshHandoff NameCert obligations)**.** *For every accepted* $\mathsf{CompactModulusMeshHandoff}^{\uparrow}$ *carrier* $K = (C, M, D, F, U, R, H, T, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{CompactModulusMeshHand}}$ *surface consists exactly of compact finite-net admission, pointwise-modulus exposure, dyadic tolerance arithmetic, rational lower-bound fold, UniformModulus handoff, Real seal, componentwise transport, replay, provenance, and local naming. The route exports finite compact-net and modulus data only; it exports no open-cover compactness oracle, selected Lebesgue number outside the fold, quotient function equality, host supremum, choice schedule, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the carrier of Definition 8933.1. The compact finite-net row supplies the centers, the pointwise-modulus row supplies local radii, the dyadic tolerance row supplies the requested precision, and the fold row computes the displayed lower bound before the UniformModulus handoff is public.

Replay H, T, P, N. These rows transport, order, source, and name the same finite packet, so the consumer receives the visible compact-net and modulus data without any external compactness oracle, selected number, quotient equality, host supremum, choice schedule, or ambient completeness coordinate. □

Theorem 8933.3 (CompactModulusMeshHandoff uniform modulus)**.** *Every compact-uniform-continuity consumer that reads an accepted* $\mathsf{CompactModulusMeshHandoff}^{\uparrow}$ *carrier obtains its* $\mathsf{UniformModulus}^{\uparrow}$ *row only after the compact finite-net row C, pointwise-modulus row M, dyadic tolerance row D, and rational lower-bound fold row F have been displayed. The resulting uniform modulus is the finite mesh handoff of the carrier and not a choice-selected modulus, open-cover compactness theorem, quotient function equality, or host supremum argument.*

Proof. Start from the NameCert obligations. They force the consumer through C, M, D, F before the uniform-modulus row U is exposed, and they keep the Real seal and structural rows downstream of that finite handoff.

The finite lower-bound fold is a displayed row of the carrier, so the modulus readback is internal to the packet. Consequently the consumer cannot replace the fold by an external selector, open-cover compactness theorem, quotient equality, host supremum, choice schedule, or ambient real-completeness principle. □

Closure status for $\mathsf{NameCert}_{\mathsf{CompactModulusMeshHandoff}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CompactModulusMeshHandoff}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8933.2 records the seed carrier and finite compact-net, pointwise-modulus, dyadic tolerance, rational-fold, UniformModulus, and Real-seal handoff.

Constructive story: A $\mathsf{CompactModulusMeshHandoff}^{\uparrow}$ packet is generated from compact finite-net data, pointwise-modulus rows, dyadic tolerance arithmetic, a rational lower-bound fold, a UniformModulus handoff, a terminal Real seal, componentwise hsame transport, displayed Cont replay, package provenance, and a local NameCert row.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CompactModulusMeshHandoff}^{\uparrow}}, \mathsf{formalTarget})$

Lean target: `BEDC.Derived.CompactModulusMeshHandoffUp`

Bridge status: none

Not claimed: This chapter does not close the full Heine–Cantor theorem, a compactness principle, a quotient function equality theorem, or a checked standard bridge.

Upgrade path: A scoped closure requires Lean-checked carrier obligations and uniform-modulus handoff stability for the displayed finite mesh route.

Chapter 8934

A Concrete Naming Certificate for $\mathsf{BishopLocatedRealReflection}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{BishopLocatedRealReflection}^{\uparrow}$ packet records the finite reflection surface by which located real data are read through the completion boundary and returned to the terminal real-name seal without quotienting the name. It sits over the located-real carrier of chapter 1933, the apartness-real route of chapter 304, the completion-reflection row of chapter 403, the stream schedules of chapter 126, the regular rational readback of chapter 301, the dyadic tolerance ledger of chapter 291, and the terminal real-name seal of chapter 38. The packet names a non-quotient reflection route for L10 Real and Completion consumers; it does not identify host real values, choose representatives, invoke countable choice, or assert ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 8934.1 (Bishop located real reflection carrier)**.** *A* $\mathsf{BishopLocatedRealReflection}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (A, B, F, S, Q, D, R, U, V, H, C, P, N)$$

with the following displayed rows:

1. *A is the* $\mathsf{LocatedReal}^{\uparrow}$ *source row, exposing only the located real-name observations admitted by the packet.*
2. *B is the* $\mathsf{ApartnessReal}^{\uparrow}$ *comparison row used when reflection consumers request positive separation data.*
3. *F is the* $\mathsf{CompletionReflection}^{\uparrow}$ *boundary row, recording that located data are read through the displayed completion-reflection surface.*
4. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row through which all source observations are scheduled.*
5. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *regular rational readback row attached to those windows.*
6. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row that bounds the located and reflected reads.*
7. *R is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached only after A, B, F, S, Q, D remain visible.*
8. *U is the unit row, recording the displayed entry of located real data into the reflection route.*
9. *V is the counit row, recording the displayed return from the completion-reflection boundary to the Real seal route.*
10. *H records componentwise* hsame *transport for the located, apartness, reflection, stream, readback, tolerance, seal, unit, counit, replay, provenance, and local naming rows.*

11. *C records displayed* Cont *replay of the route*

$$A, B, F, S, Q, D \longmapsto R, U, V, H, P, N.$$

12. *P is the* Pkg *provenance over* BishopLocatedRealReflection$^{\uparrow}$, LocatedReal$^{\uparrow}$, ApartnessReal$^{\uparrow}$, CompletionReflection$^{\uparrow}$ StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, Real$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

13. *N is the local* NameCert$_{\text{BishopLocatedRealReflection}^{\uparrow}}$ *row.*

The accepted carrier is exactly the displayed packet L. It has no coordinate for quotient stream equality, selected completed points, host real equality, countable choice, ambient Real$^{\uparrow}$ *completeness, or an external reflection theorem.*

Theorem 8934.2 (Bishop located real reflection NameCert obligations)**.** *For every accepted* BishopLocatedRealReflection$^{\uparrow}$ *carrier $L = (A, B, F, S, Q, D, R, U, V, H, C, P, N)$, the local* NameCert$_{\text{BishopLocatedRealRe}}$ *obligations are exhausted by carrier admission for the displayed located-real, apartness-real, completion-reflection, stream-window, regular-readback, dyadic-tolerance, Real-seal, unit, counit, transport, replay, provenance, and local naming rows. A consumer can therefore read the reflection packet only through*

$$A, B, F, S, Q, D, R, U, V, H, C, P, N.$$

No local obligation may call on quotient stream equality, a selected limit, host real equality, countable choice, ambient Real$^{\uparrow}$ *completeness, or a detached reflection principle.*

Proof. Project the carrier of Definition 8934.1. The accepted tuple displays exactly the located-real source, apartness comparison, completion-reflection boundary, stream-window, regular-readback, dyadic-tolerance, seal, unit, counit, transport, replay, provenance, and local naming rows.

Read the analytic rows first. The located row A and apartness row B are scheduled through S, interpreted by the regular readback row Q, and bounded by the dyadic tolerance row D before the terminal seal R is public.

The reflection row F and the unit-counit rows U, V are attached to that same finite route. Componentwise transport in H, replay in C, provenance in P, and local naming in N preserve the displayed carrier, so no excluded completion, equality, choice, or host-side principle is exported. □

Theorem 8934.3 (Bishop located real reflection unit-counit route)**.** *Let $L = (A, B, F, S, Q, D, R, U, V, H, C, P, N)$ be an accepted* BishopLocatedRealReflection$^{\uparrow}$ *carrier. Every unit-counit read enters through the* LocatedReal$^{\uparrow}$ *row A, the* StreamName$^{\uparrow}$ *window S, the* RegSeqRat$^{\uparrow}$ *readback Q, and the* DyadicRatCore$^{\uparrow}$ *tolerance row D, then passes through the* CompletionReflection$^{\uparrow}$ *row F before the counit row V returns to the terminal* Real$^{\uparrow}$ *seal R. The route remains downstream of B, U, H, C, P, N and exports no quotient completion equality, selected completed point, host real equality, countable-choice schedule, or ambient completeness theorem.*

Proof. Start with the source route. The located-real row A supplies the displayed name observations, while S, Q, D expose the finite windows, regular rational readback, and dyadic tolerances needed before a Real-facing consumer can inspect a value.

Next read the reflection boundary. The row F is the only completion-reflection coordinate in the packet, and the unit row U records entry into that route without choosing a representative or completed point.

Finally consume the counit row V and terminal seal R. The apartness row B remains a displayed comparison coordinate, and H, C, P, N preserve the same finite route by transport, replay, provenance, and naming. Since the carrier has no excluded coordinate, the unit-counit read cannot become quotient equality, selected completion data, host equality, choice, or ambient Real completeness. □

Closure status for $\mathsf{NameCert}_{\mathsf{BishopLocatedRealReflection}^{\uparrow}}$.

Constructive story: A $\mathsf{BishopLocatedRealReflection}^{\uparrow}$ packet is generated from LocatedReal source rows, ApartnessReal comparison rows, CompletionReflection boundary rows, StreamName windows, RegSeqRat readback, DyadicRatCore tolerances, a Real seal, unit and counit rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert rows.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BishopLocatedRealReflection}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8934.1, Definition 8934.2, and Definition 8934.3 seed the finite located-real reflection packet over located, apartness, completion-reflection, stream, readback, tolerance, seal, unit, counit, transport, replay, provenance, and local naming rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BishopLocatedRealReflection}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim quotient stream equality, selected completed limits, host real equality, countable choice, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, unit-counit routing, nonescape, transport, replay, provenance, and local naming for BEDC.Derived.BishopLocatedRealReflectionUp.

Chapter 8935

A Concrete Naming Certificate for $\mathsf{RealNameEliminator}^{\uparrow}$

Following Bishop–Bridges constructive real-number practice, the $\mathsf{RealNameEliminator}^{\uparrow}$ packet records the finite route by which a consumer may use a $\mathsf{Real}^{\uparrow}$ seal only through certified regular rational representatives. It sits over the dyadic arithmetic surface of chapter 291, the finite observation discipline of chapter 126, the regular-sequence readback of chapter 301, the completed real seal of chapter 38, and the modulus witness of chapter 292. The packet supplies a representative-consuming eliminator, not quotient equality, host real primitives, selected limits, or ambient real completeness.

Falsifiable prediction: A $\mathsf{Real}^{\uparrow}$ consumer that reads a completed real without displaying a certified $\mathsf{RegSeqRat}^{\uparrow}$ representative refutes the $\mathsf{RealNameEliminator}^{\uparrow}$ carrier surface.

Independence witness: dyadicratcore, streamname, regseqrat, real, cauchymodulus: $\mathsf{RealNameEliminator}^{\uparrow}$ is not bijective to any one sibling because it binds dyadic tolerance rows, finite stream windows, regular-sequence representatives, the Real seal, and modulus transport into one consumer-facing elimination packet.

Definition 8935.1 (Real-name eliminator carrier)**.** *A* $\mathsf{RealNameEliminator}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$E = (D, S, Q, R, M, H, C, P, N)$$

with the following displayed rows:

1. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance and comparison ledger used by the representative;*
2. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row listing the observations a consumer may inspect;*
3. *Q is the certified* $\mathsf{RegSeqRat}^{\uparrow}$ *representative readback served on those windows;*
4. *R is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row, available only after D, S, Q and the modulus data have been displayed;*
5. *M is the* $\mathsf{CauchyModulus}^{\uparrow}$ *row transporting precision requests back to finite representative windows;*
6. *H records componentwise* hsame *transport for the analytic and structural rows;*
7. *C records displayed* Cont *replay from representative admission to Real consumption;*

8. *P is the* Pkg *provenance over* $\mathsf{RealNameEliminator}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{CauchyModulus}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert*;*

9. *N is the local* $\mathsf{NameCert}_{\mathsf{RealNameEliminator}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $D, S, Q, R, M, H, C, P, N$. It has no coordinate for host real equality, quotient stream equality, selected representatives outside Q, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 8935.2 (Real-name eliminator NameCert obligations)**.** *For every accepted* $\mathsf{RealNameEliminator}^{\uparrow}$ *carrier*

$$E = (D, S, Q, R, M, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{RealNameEliminator}^{\uparrow}}$ *surface consists exactly of carrier exposure for E, dyadic tolerance and comparison exposure through D, finite window exposure through S, certified regular-rational representative readback through Q, Real seal exposure through R, modulus transport through M, componentwise* hsame *transport through H, displayed* Cont *replay through C, package provenance through P, and local naming through N.*

Proof. Project the carrier of Definition 8935.1. The displayed tuple lists precisely the dyadic ledger, stream window, regular representative, Real seal, modulus row, and structural rows.

Read the analytic rows in dependency order. The representative row Q is attached to the finite windows S and the dyadic ledger D, while the modulus row M transports later precision requests back to those displayed windows before the Real seal row R is consumed.

Finally inspect the structural rows. The rows H, C, P, N transport, replay, source, and name the same finite packet. Since the carrier has no further coordinate, the listed rows exhaust the local naming surface. □

Theorem 8935.3 (Real-name eliminator RegSeqRat determinacy)**.** *Every accepted* $\mathsf{Real}^{\uparrow}$ *consumer of a* $\mathsf{RealNameEliminator}^{\uparrow}$ *packet must factor through the certified* $\mathsf{RegSeqRat}^{\uparrow}$ *representative row Q and the finite route*

$$D, S, Q, R, M, H, C, P, N.$$

Thus two accepted consumers that agree on D, S, Q, M, H, C, P, N have the same local Real-name elimination surface, and any consumer that claims host real equality, quotient stream equality, a selected representative outside Q, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness has left the packet.*

Proof. Start with the NameCert obligations of Definition 8935.2. They place the regular representative row Q between the finite stream windows S and the terminal Real seal row R.

Use the modulus row M to replay every later precision request through the same representative windows. Agreement on D, S, Q, M therefore fixes the representative-consuming part of the eliminator before any structural transport is read.

The structural rows H, C, P, N preserve that same packet under componentwise transport, continuation replay, provenance, and naming. The excluded objects are absent from the carrier, so a read of any such object cannot be an accepted $\mathsf{RealNameEliminator}^{\uparrow}$ consumption. □

Closure status for $\mathsf{NameCert}_{\mathsf{RealNameEliminator}^{\uparrow}}$**.**

Constructive story: A $\mathsf{RealNameEliminator}^{\uparrow}$ packet is generated from DyadicRatCore tolerance rows, StreamName finite windows, RegSeqRat representative readback, a Real seal row, CauchyModulus precision transport, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{RealNameEliminator}^{\uparrow}}$, seed)

Scope closed: Definition 8935.1, Definition 8935.2, and Definition 8935.3 declare the representative-consuming Real-name eliminator surface.

Formal verification: FormalStatus(NameCert$_{\mathsf{RealNameEliminator}\uparrow}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close host real equality, quotient stream equality, selected representatives outside the displayed RegSeqRat row, countable choice, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, representative determinacy, modulus transport, Real-seal nonescape, and structural transport for BEDC.Derived.RealNameEliminatorUp.

Chapter 8936

A Concrete Naming Certificate for $\mathsf{RiemannMappingBoundary}^{\uparrow}$

Following Caratheodory and Pommerenke, the $\mathsf{RiemannMappingBoundary}^{\uparrow}$ packet records the finite boundary-extension surface attached to a Riemann mapping whose source boundary is displayed as a Jordan curve. It sits after the interior mapping route of chapter 6805, the Jordan-curve boundary source of chapter 4365, the circle carrier of chapter 58, the compact metric windows of chapter 129, and the continuous graph rows of chapter 130. The packet names boundary extension only as displayed NameCert data; it does not import prime-end quotients, selected boundary correspondences, host homeomorphism equality, or ambient compact-open completeness.

Definition 8936.1 (Riemann mapping boundary carrier)**.** *A* $\mathsf{RiemannMappingBoundary}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (R, J, S, K, F, Q, E, H, C, P, N)$$

with the following displayed rows:

1. *R is the existing* $\mathsf{RiemannMapping}^{\uparrow}$ *interior packet, read through the finite uniformization route of chapter 6805.*
2. *J is the* $\mathsf{JordanCurve}^{\uparrow}$ *boundary-source row, carrying the displayed simple closed curve, side classifier, polygonal subdivision, and orientation ledger.*
3. *S is the* $\mathsf{S}^{1\uparrow}$ *boundary-circle row whose finite parameter windows supply the source boundary schedule.*
4. *K is the* $\mathsf{CompactMetric}^{\uparrow}$ *finite-boundary-window row, recording only compact metric inspection windows along the displayed curve and circle source.*
5. *F is the* $\mathsf{ContinuousMap}^{\uparrow}$ *boundary-graph row, exposing the proposed boundary extension as finite graph and modulus data over the already displayed boundary windows.*
6. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for coordinate and modulus observations produced by the boundary graph.*
7. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *readback row for distances, radii, and continuity budgets attached to Q.*
8. *H records componentwise* hsame *transport for the interior packet, Jordan boundary source, circle boundary source, compact windows, boundary graph, readback, Real seal, replay, provenance, and local naming rows.*

9. *C records displayed* Cont *replay, forcing a consumer to read the interior mapping, boundary source, boundary circle, compact windows, graph, readback, and Real seal in the displayed order.*
10. *P is the* Pkg *provenance over* $\mathsf{RiemannMappingBoundary}^{\uparrow}$, $\mathsf{RiemannMapping}^{\uparrow}$, $\mathsf{JordanCurve}^{\uparrow}$, $\mathsf{S}^{1\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{RiemannMappingBoundary}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $R, J, S, K, F, Q, E, H, C, P, N$. It has no coordinate for a prime-end quotient, selected boundary homeomorphism, host equality of continuous extensions, ambient compact-open completion, or a boundary map detached from the displayed Jordan and circle rows.

Lean4 (statement) `BEDC.Derived.RiemannMappingBoundaryUp`

Falsifiable prediction: A purported $\mathsf{RiemannMappingBoundary}^{\uparrow}$ consumer that reads boundary extension without exposing the $\mathsf{RiemannMapping}^{\uparrow}$ interior packet, the $\mathsf{JordanCurve}^{\uparrow}$ source boundary, the $\mathsf{S}^{1\uparrow}$ boundary circle, the $\mathsf{CompactMetric}^{\uparrow}$ finite windows, the $\mathsf{ContinuousMap}^{\uparrow}$ graph, $\mathsf{RegSeqRat}^{\uparrow}$ readback, and the terminal $\mathsf{Real}^{\uparrow}$ seal is outside the carrier surface.

Independence witness: riemann-mapping, jordan-curve, s1, compactmetric, continuousmap, regseqrat, real: no listed sibling supplies the joint carrier containing the interior mapping packet, Jordan boundary source, circle boundary source, compact boundary windows, boundary graph, regular rational readback, Real seal, transport, replay, provenance, and local NameCert rows while refusing prime-end quotients, selected boundary homeomorphisms, and ambient compact-open completeness.

Closure status for $\mathsf{NameCert}_{\mathsf{RiemannMappingBoundary}^{\uparrow}}$.

Constructive story: A $\mathsf{RiemannMappingBoundary}^{\uparrow}$ packet is generated from a RiemannMappingUp interior row, JordanCurveUp boundary-source row, SOneUp boundary-circle row, CompactMetricUp finite-boundary windows, ContinuousMapUp boundary graph, RegSeqRatUp readback, RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{RiemannMappingBoundary}^{\uparrow}}$, seed)

Scope closed: Definition 8936.1 seeds the finite boundary-extension carrier over RiemannMappingUp, JordanCurveUp, SOneUp, CompactMetricUp, ContinuousMapUp, RegSeqRatUp, RealUp, hsame, Cont, Pkg, and local NameCert rows.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{RiemannMappingBoundary}^{\uparrow}}$, formalTarget)

Bridge status: none

Not claimed: This chapter does not close Lean verification, bridge checking, prime-end quotient construction, selected boundary homeomorphisms, host equality of continuous extensions, or ambient compact-open completeness.

Upgrade path: Obligation closure requires checked carrier admission, Jordan boundary exposure, circle parameter exactness, compact-window routing, graph readback, Real-seal routing, transport, replay, provenance, and local naming for BEDC.Derived.RiemannMappingBoundaryUp.

Chapter 8937

A Concrete Naming Certificate for $\mathsf{RegularLocatedCut}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{RegularLocatedCut}^{\uparrow}$ packet records located-cut boundary data as a finite comparison surface for the regular-sequence route to constructive real numbers. It reads dyadic comparison rows through chapter 291, regular rational representatives through chapter 301, located-real boundary language through **??**, and the completed Real seal through chapter 38. The packet is a comparison object for the Real and Completion phase, not a construction of $\mathsf{Real}^{\uparrow}$ by Dedekind cuts.

Falsifiable prediction: A located-cut consumer that compares against $\mathsf{RegSeqRat}^{\uparrow}$ without displaying dyadic brackets and regularity-modulus data is not an accepted $\mathsf{RegularLocatedCut}^{\uparrow}$ packet.

Independence witness: dyadicratcore, regseqrat, locatedreal, real: $\mathsf{RegularLocatedCut}^{\uparrow}$ is not bijective to any one sibling because it binds lower and upper cut rows, dyadic brackets, regularity modulus data, transport, continuation replay, provenance, and local naming into one comparison packet.

Definition 8937.1 (Regular located-cut carrier)**.** *A* $\mathsf{RegularLocatedCut}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (A, B, D, M, H, C, P, N)$$

with the following displayed rows:

1. *A is the lower cut row, listing the accepted rational lower approximants;*
2. *B is the upper cut row, listing the accepted rational upper approximants;*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *bracket row that records finite dyadic comparisons between the lower and upper sides;*
4. *M is the regularity modulus row that routes precision requests to a displayed bracket refinement;*
5. *H records componentwise* hsame *transport for the lower row, upper row, dyadic bracket row, modulus row, replay row, provenance row, and naming row;*
6. *C records displayed* Cont *replay for extending a bracket comparison without changing the finite carrier surface;*
7. *P is the* Pkg *provenance over* $\mathsf{RegularLocatedCut}^{\uparrow}$*,* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{LocatedReal}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*,* BHist*,* hsame*,* Cont*, and* NameCert*;*

8. N is the local $\mathsf{NameCert}_{\mathsf{RegularLocatedCut}^\uparrow}$ *row.*
The classifier compares accepted packets only through A, B, D, M, H, C, P, N. It has no coordinate for a host Dedekind cut, quotient equality of cuts, a selected Real representative, countable choice, or ambient $\mathsf{Real}^\uparrow$ *completeness.*

Theorem 8937.2 (Regular located-cut NameCert obligations)**.** *For every accepted* $\mathsf{RegularLocatedCut}^\uparrow$ *carrier*

$$L = (A, B, D, M, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{RegularLocatedCut}^\uparrow}$ *surface consists exactly of lower cut exposure through A, upper cut exposure through B, dyadic bracket exposure through D, regularity-modulus exposure through M, componentwise* hsame *transport through H, displayed* Cont *replay through C, package provenance through P, and local naming through N.*

Proof. Project the carrier of Definition 8937.1. The displayed tuple lists exactly the lower side, upper side, dyadic bracket, regularity modulus, and structural rows.

Read the analytic rows in comparison order. The lower and upper rows A, B are related only through the finite dyadic brackets D, and the modulus row M sends later precision requests back to displayed bracket refinements.

Inspect the structural rows. The rows H, C, P, N transport, replay, source, and name the same finite packet, so no additional cut object or Real-completeness principle can enter the local naming surface. □

Theorem 8937.3 (Regular located-cut RegSeqRat comparison boundary)**.** *Every comparison between an accepted* $\mathsf{RegularLocatedCut}^\uparrow$ *packet and the regular-sequence route to* $\mathsf{Real}^\uparrow$ *factors through the finite rows*

$$A, B, D, M, H, C, P, N.$$

The rows A and B provide located lower and upper approximants, D supplies dyadic brackets, and M supplies the regularity modulus needed to compare with $\mathsf{RegSeqRat}^\uparrow$ *representatives. This is a comparison boundary between located-cut language and the* $\mathsf{RegSeqRat}^\uparrow/\mathsf{Real}^\uparrow$ *route, not a Dedekind-cut construction of* $\mathsf{Real}^\uparrow$*.*

Proof. Start from the NameCert obligations of Definition 8937.2. They place every located lower and upper read inside the rows A, B and require dyadic bracket evidence through D.

Use the modulus row M to align a precision request with a finite bracket refinement. A comparison with a $\mathsf{RegSeqRat}^\uparrow$ representative therefore reads the displayed bracket data rather than selecting an ambient cut or a host limit.

The structural rows H, C, P, N preserve only that comparison route under transport, continuation replay, provenance, and naming. Since the carrier has no coordinate for a Dedekind construction of $\mathsf{Real}^\uparrow$, the theorem records a boundary between languages rather than an alternate construction of the Real seal. □

Closure status for $\mathsf{NameCert}_{\mathsf{RegularLocatedCut}^\uparrow}$**.**

Constructive story: A $\mathsf{RegularLocatedCut}^\uparrow$ packet is generated from lower cut rows, upper cut rows, dyadic bracket rows, regularity-modulus rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{RegularLocatedCut}^\uparrow}$, seed)

Scope closed: Definition 8937.1, Definition 8937.2, and Definition 8937.3 declare the located-cut comparison boundary for the RegSeqRat and Real route.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{RegularLocatedCut}^\uparrow}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close a Dedekind-cut construction of $\mathsf{Real}^{\uparrow}$, quotient equality of cuts, selected Real representatives, countable choice, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, lower-upper bracket obligations, regularity-modulus transport, RegSeqRat comparison boundary, and structural transport for BEDC.Derived.RegularLocatedCutUp.

Chapter 8938

A Concrete Naming Certificate for $\mathsf{SpectralProjection}^{\uparrow}$

Following Horn and Johnson's finite-dimensional matrix analysis, the packet records spectral projectors as displayed polynomial idempotent rows over a matrix carrier. It sits after the finite matrix carrier of chapter 49, the displayed polynomial surface of chapter 50, the field-extension rows of chapter 161, the vector-space carrier of chapter 47, and the finite spectral-radius boundary of chapter 2352. The chapter names only the finite polynomial projector packet; it does not import host spectral calculus, contour integrals, quotient eigenspaces, selected eigenbases, or analytic completeness.

Definition 8938.1 (Spectral projection carrier)**.** *A* $\mathsf{SpectralProjection}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (M, P, L, I, R, H, C, Q, N)$$

with the following displayed rows:

1. *M is the* $\mathsf{Mat}^{\uparrow}$ *source row, including the finite square matrix and its entry carrier.*
2. *P is the displayed* $\mathsf{Poly}^{\uparrow}$ *projector row whose coefficients are read over the same scalar field as M.*
3. *L is the eigenvalue or factor row, exposed through* $\mathsf{FieldExt}^{\uparrow}$ *when the projector is displayed after scalar extension.*
4. *I is the idempotence row recording that the evaluated polynomial projector satisfies $P(M)P(M) = P(M)$ inside the displayed matrix carrier.*
5. *R is the range/kernel visibility row: it records the visible image boundary, the visible kernel boundary, and the finite* $\mathsf{VecSpace}^{\uparrow}$ *rows consumed by downstream invariant-subspace readers.*
6. *H records componentwise* hsame *transport for the matrix source, polynomial projector, eigenvalue or factor row, idempotence row, range/kernel visibility, replay, provenance, and local naming rows.*
7. *C records displayed* Cont *replay from a spectral-projection request through M, P, L, I, R, H, Q, N.*
8. *Q is the* Pkg *provenance over* $\mathsf{SpectralProjection}^{\uparrow}$, $\mathsf{Mat}^{\uparrow}$, $\mathsf{Poly}^{\uparrow}$, $\mathsf{FieldExt}^{\uparrow}$, $\mathsf{VecSpace}^{\uparrow}$, $\mathsf{SpectralRadius}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
9. *N is the local* $\mathsf{NameCert}_{\mathsf{SpectralProjection}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $M, P, L, I, R, H, C, Q, N$. It has no coordinate for a host functional calculus, an implicit contour integral, a quotient eigenspace, a selected eigenbasis, or a completed spectral decomposition.

Theorem 8938.2 (Spectral projection NameCert obligations)**.** *For every accepted* $\mathsf{SpectralProjection}^{\uparrow}$ *carrier*

$$S = (M, P, L, I, R, H, C, Q, N),$$

the local $\mathsf{NameCert}_{\mathsf{SpectralProjection}^{\uparrow}}$ *surface consists exactly of carrier admission for the displayed matrix source, polynomial projector, eigenvalue or factor row, idempotence row, range/kernel visibility row, componentwise transport, displayed replay, package provenance, and local naming. Any consumer that reads a spectral projector must expose the matrix-polynomial route, the field-extension boundary when used, the finite vector-space visibility row, and the spectral-radius boundary before it may consume the projector as a named finite row.*

Proof. Project the carrier of Definition 8938.1. The matrix and polynomial inputs are M, P, the scalar or factor boundary is L, the idempotence witness is I, and the visible range/kernel boundary is R.

The transport and replay rows H, C preserve exactly those displayed rows. The provenance row Q records the consumed MatrixUp, PolynomialUp, FieldExtUp, VecSpaceUp, and SpectralRadiusUp siblings, while N names the local packet.

No additional spectral object is available to the classifier. Hence the NameCert obligations are exhausted by the displayed carrier rows. □

Theorem 8938.3 (Spectral projection matrix-polynomial handoff)**.** *Every accepted* $\mathsf{SpectralProjection}^{\uparrow}$ *packet exports its projector only through the finite handoff*

$$\mathsf{Mat}^{\uparrow} \times \mathsf{Poly}^{\uparrow} \times \mathsf{FieldExt}^{\uparrow} \to \mathsf{IdempotentMatrixRow} \to \mathsf{VecSpace}^{\uparrow}.$$

The $\mathsf{SpectralRadius}^{\uparrow}$ *row can bound the finite matrix side of the handoff, but it cannot replace the displayed polynomial projector, idempotence row, or range/kernel visibility row.*

Proof. Read the handoff from the carrier rows. The matrix source and polynomial projector produce the displayed matrix row $P(M)$, while the field-extension row records the scalar boundary used to display the eigenvalue or factor data.

The idempotence row I is the only row that lets the packet act as a projector. The range/kernel visibility row R is the only row exported to vector-space consumers.

The spectral-radius row appears only through provenance and finite matrix-side estimates. It therefore cannot supply the projector, the idempotence witness, or the visible subspace boundary by itself. □

Falsifiable prediction: Every accepted $\mathsf{SpectralProjection}^{\uparrow}$ consumer displays Matrix source rows, Polynomial projector rows, FieldExt eigenvalue or factor rows when used, idempotence rows, range/kernel visibility rows, hsame transport, Cont replay, Pkg provenance, and a local NameCert row before it can consume a spectral projector.

Independence witness: matrix, polynomial, fieldext, vecspace, spectralradius: $\mathsf{SpectralProjection}^{\uparrow}$ is not bijective to any listed sibling because it jointly binds a finite matrix source, a displayed polynomial projector, eigenvalue or factor exposure, idempotence, visible range/kernel rows, transport, replay, provenance, and local naming as one projector packet.

Closure status for $\mathsf{NameCert}_{\mathsf{SpectralProjection}^{\uparrow}}$**.**

Constructive story: A SpectralProjection$^{\uparrow}$ packet is generated from a MatrixUp source row, a PolynomialUp projector row, a FieldExtUp eigenvalue or factor row when used, an idempotence row, VecSpaceUp range/kernel visibility rows, a SpectralRadiusUp finite matrix-side boundary, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\text{SpectralProjection}^{\uparrow}}$, seed)

Scope closed: Definition 8938.1, Definition 8938.2, and Definition 8938.3 seed the finite polynomial projector interface over MatrixUp, PolynomialUp, FieldExtUp, VecSpaceUp, SpectralRadiusUp, BHist, hsame, Cont, Pkg, and NameCert rows.

Formal verification: FormalStatus(NameCert$_{\text{SpectralProjection}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim host spectral calculus, contour integrals, quotient eigenspaces, selected eigenbases, analytic completeness, Lean theorem checking, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, polynomial-projector exactness, idempotence exactness, range/kernel visibility, matrix-polynomial handoff, transport, replay, provenance, and local naming for BEDC.Derived.SpectralProjectionUp.

Chapter 8939

A Concrete Naming Certificate for $\mathsf{CauchyRegularizationFunctor}^{\uparrow}$

Following Bishop–Bridges regular Cauchy completion, Kelley filter language, and Bourbaki uniform-space bookkeeping, the $\mathsf{CauchyRegularizationFunctor}^{\uparrow}$ packet records the finite route by which a displayed Cauchy-filter presentation is read as a regular Cauchy rational name before any Real or Completion consumer may use it. It sits after the Cauchy-filter surface of chapter 333, the finite observation windows of chapter 126, the regular rational readback of chapter 301, the dyadic tolerance ledger of chapter 291, and the terminal real-name seal of chapter 38. The packet is a handoff from filter data to regular Cauchy names; it does not quotient filters, select a limit, invoke countable choice, or claim ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 8939.1 (Cauchy regularization functor carrier)**.** *A* $\mathsf{CauchyRegularizationFunctor}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$F = (A, W, R, D, E, H, K, P, N)$$

with the following displayed rows:

1. *A is the source row, either a* $\mathsf{CauchyFilter}^{\uparrow}$ *presentation or the refined* $\mathsf{CauchyFilterRegularization}^{\uparrow}$ *source whose finite filter requests are being regularized.*
2. *W is the* $\mathsf{StreamName}^{\uparrow}$ *window row listing the finite request schedule used to inspect the source filter.*
3. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row extracted from the source windows, recording the regular rational name seen by downstream consumers.*
4. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, carrying the dyadic precision, radius, comparison, and monotone budget rows used by the extraction.*
5. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row, available only after A, W, R, D have been displayed.*
6. *H is the componentwise* hsame *transport row for the source, window, readback, tolerance ledger, real seal, provenance, and local name.*
7. *K is the displayed* Cont *replay row, routing each accepted filter request through W, D, R before the real seal is exposed.*
8. *P records* Pkg *provenance over* $\mathsf{CauchyRegularizationFunctor}^{\uparrow}$, $\mathsf{CauchyFilter}^{\uparrow}$, $\mathsf{CauchyFilterRegularization}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.

9. *N is the local* $\mathsf{NameCert}_{\mathsf{CauchyRegularizationFunctor}^{\uparrow}}$ *row.*

The carrier has no coordinate for quotient equality of filters, a selected limit point, a countable-choice schedule, host real equality, or ambient completion of $\mathsf{Real}^{\uparrow}$.

Theorem 8939.2 (Cauchy regularization functor obligation surface)**.** *For every accepted* CauchyRegularizationFunc *carrier $F = (A, W, R, D, E, H, K, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{CauchyRegularizationFunctor}^{\uparrow}}$ *surface consists of the following finite rows:*

1. *source admission, requiring every input request to enter through the displayed* $\mathsf{CauchyFilter}^{\uparrow}$ *or* $\mathsf{CauchyFilterRegularization}^{\uparrow}$ *row A;*
2. *window discipline, requiring every inspected request to be listed in the* $\mathsf{StreamName}^{\uparrow}$ *row W before it contributes to a regular name;*
3. *dyadic regularity, requiring the* $\mathsf{DyadicRatCore}^{\uparrow}$ *ledger D to supply the precision and tolerance budget for the readback;*
4. *regular rational extraction, requiring the* $\mathsf{RegSeqRat}^{\uparrow}$ *row R to be produced from A, W, D before any* $\mathsf{Real}^{\uparrow}$ *seal is visible;*
5. *real-seal nonselection, requiring the* $\mathsf{Real}^{\uparrow}$ *row E to be consumed only as a terminal seal over the displayed regular name;*
6. *structural replay, requiring H, K, P, N to transport, replay, source, and locally name exactly the displayed packet.*

No obligation row exports quotient filters, selected representatives, countable choice, host real equality, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the carrier rows of Definition 8939.1. The source row is A, the finite inspection row is W, the tolerance row is D, the regular rational readback is R, and the terminal seal is E.

The NameCert obligation reads those rows in order. A filter request cannot reach R until it has been scheduled by W and budgeted by D, and the real seal E is not available before the regular readback row is displayed.

Finally read the structural rows. The rows H, K, P, N only transport, replay, source, and name the same packet, so they cannot add quotient filters, selected limits, countable choice, host real equality, or ambient completeness. □

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyRegularizationFunctor}^{\uparrow}}$.

Constructive story: A $\mathsf{CauchyRegularizationFunctor}^{\uparrow}$ packet is generated from a displayed CauchyFilter or CauchyFilterRegularization source, finite StreamName windows, a DyadicRatCore tolerance ledger, RegSeqRat readback, a terminal Real seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{CauchyRegularizationFunctor}^{\uparrow}}$, seed)

Scope closed: Definition 8939.1, Definition 8939.2, and Definition 8939.3 seed the finite L10 handoff from Cauchy-filter presentations to regular rational real-name data.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{CauchyRegularizationFunctor}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close quotient filter equality, selected limits, countable choice, host real equality, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked source admission, window discipline, dyadic regularity, regular rational extraction, Real-seal nonselection, transport, replay, provenance, and local naming for BEDC.Derived.CauchyRegularizationFunctorUp.

Theorem 8939.3 (Cauchy regularization functor L10 handoff)**.** *Every L10 Real or Completion consumer of an accepted* $\mathsf{CauchyRegularizationFunctor}^{\uparrow}$ *packet reaches the terminal Real boundary*

only through the displayed route

$$\mathsf{CauchyFilter}^{\uparrow} \textit{ or } \mathsf{CauchyFilterRegularization}^{\uparrow}, \quad \mathsf{StreamName}^{\uparrow}, \quad \mathsf{DyadicRatCore}^{\uparrow}, \quad \mathsf{RegSeqRat}^{\uparrow}, \quad \mathsf{Real}^{\uparrow}.$$

Equivalently, the handoff from filter presentations to regular Cauchy names is exposed as finite $\mathsf{StreamName}^{\uparrow}$ *windows,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledgers,* $\mathsf{RegSeqRat}^{\uparrow}$ *readbacks, and the terminal* $\mathsf{Real}^{\uparrow}$ *seal. A consumer asking for quotient filter equality, selected limits, countable choice, host real equality, or ambient completion has no row in the carrier.*

Proof. Start with the source row A. By the obligation surface of Definition 8939.2, each accepted request enters through the Cauchy-filter source and is then routed into the finite window W.

Next read the dyadic ledger and regular rational row. The ledger D supplies the tolerance budget for every scheduled request, and the readback R is the only regular Cauchy name exposed to downstream consumers.

The terminal seal E is downstream from A, W, D, R. Since the carrier has no coordinate for quotient filters, selected limits, countable choice, host equality, or ambient completeness, Real and Completion consumers can use only the displayed L10 route. □

Chapter 8940

A Concrete Naming Certificate for $\mathsf{EndpointBisectionCertificate}^{\uparrow}$

The $\mathsf{EndpointBisectionCertificate}^{\uparrow}$ packet realizes the endpoint-bisection certificate of section 9413.61 as finite NameCert data over RHRoute endpoint intervals, branch choices, preservation rows, and local half-split handoff. It reads the endpoint interval and branch replay surface encoded by BEDC.Derived.RHRoute.EndpointBisectionCertificate, hands the local split boundary to chapter 8881, and keeps the endpoint route separate from parity tower, oriented triadic, and zero-recursor cover routes. The packet names a finite endpoint bisection surface; it is not an RH proof, not a zero selector, and not a quotient over all endpoint models.

Definition 8940.1 (Endpoint bisection certificate carrier)**.** *An* $\mathsf{EndpointBisectionCertificate}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (I, \beta, R, S, L, H, K, P, N)$$

with the following displayed rows:

1. *I is the RHRoute endpoint-interval row, carrying an endpoint dyadic interval and its finite diameter data.*
2. *β is the branch-choice row, listing the finite lower/upper decisions used by endpoint replay.*
3. *R is the replay row, computing the endpoint interval reached by the displayed branch list.*
4. *S is the preservation row, recording the depth, width, and endpoint-location invariants kept by replay.*
5. *L is the local half-split handoff row, available only after I, β, R, S have been displayed.*
6. *H stores componentwise* hsame *transport for the endpoint interval, branch list, preservation row, local half-split row, provenance, and local name.*
7. *K stores displayed* Cont *replay from endpoint reads through the branch and preservation rows before any RHRoute conclusion is consumed.*
8. *P records* Pkg *provenance over* $\mathsf{EndpointBisectionCertificate}^{\uparrow}$*, RHRoute endpoint intervals, branch choices, preservation rows,* $\mathsf{LocalHalfSplitCertificate}^{\uparrow}$*,* BHist*,* hsame*,* Cont*, and* NameCert*.*
9. *N is the local* $\mathsf{NameCert}_{\mathsf{EndpointBisectionCertificate}^{\uparrow}}$ *row.*

The carrier has no coordinate for a global RH conclusion, a selected zero, a quotient over endpoint models, parity tower equality, oriented triadic equivalence, or zero-recursor cover boundary replacement.

Theorem 8940.2 (Endpoint bisection certificate NameCert surface)**.** *For every accepted* EndpointBisectionCertifica *carrier* $B = (I, \beta, R, S, L, H, K, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{EndpointBisectionCertificate}^{\uparrow}}$ *surface consists exactly of endpoint interval admission, branch-choice admission, replay determinacy, preservation visibility, local half-split handoff, componentwise transport, displayed continuation replay, provenance, and local naming. Any endpoint-bisection read that omits one of* $I, \beta, R, S, L, H, K, P, N$ *is outside the carrier surface.*

Proof. Project the carrier of Definition 8940.1. The analytic rows are the endpoint interval I, branch list β, replay row R, preservation row S, and local half-split handoff L.

Read the rows in dependency order. Replay depends on the displayed branch list, preservation is recorded only for the replayed interval, and the local half-split handoff is available only after replay and preservation have both been displayed.

The structural rows H, K, P, N transport, replay, source, and name the same packet. Since no coordinate carries a global RH conclusion, selected zero, quotient endpoint model, parity tower equality, oriented triadic equivalence, or zero-recursor cover boundary replacement, the listed rows exhaust the local NameCert surface. □

Theorem 8940.3 (Endpoint bisection certificate RHRoute handoff)**.** *Every RHRoute consumer of an accepted* $\mathsf{EndpointBisectionCertificate}^{\uparrow}$ *packet reaches an endpoint-facing conclusion only through endpoint interval, branch, preservation, local half-split,* hsame*,* Cont*,* Pkg*, and local* NameCert *rows. In carrier notation the route is*

$$I, \beta, R, S, L, H, K, P, N.$$

Thus the packet can hand endpoint-bisection data to RHRoute readers, but it does not by itself assert the Riemann hypothesis, select a zero, identify all endpoint models, or collapse the local half-split route into parity, triadic, or recursor-cover siblings.

Proof. Start with the NameCert surface of Definition 8940.2. It forces any accepted endpoint read to expose I, β, R, S, L before a route consumer can read the packet.

Next use the structural rows. Transport and replay keep the endpoint interval, branch list, preservation row, and local half-split row together as one finite packet, while provenance and local naming prevent the handoff from detaching into an untracked RHRoute conclusion.

The carrier omits global RH conclusions, zero selectors, quotient endpoint models, parity tower equality, oriented triadic equivalence, and zero-recursor cover replacement. Therefore every accepted RHRoute handoff remains the displayed finite endpoint-bisection route. □

Falsifiable prediction: Every accepted endpoint-bisection read factors through endpoint interval, branch, preservation, local half-split, hsame, Cont, Pkg, and NameCert rows before any RHRoute conclusion is consumed.

Independence witness: local-half-split-certificate, parity-closure-tower-certificate, oriented-triadic-certificate, zero-recursor-cover-boundary: none is bijective to $\mathsf{EndpointBisectionCertificate}^{\uparrow}$ because the local half-split sibling supplies only the split handoff, the parity tower route supplies parity closure data, the oriented triadic route supplies triadic orientation rows, and the zero-recursor cover boundary supplies recursor-cover rows, while this packet binds endpoint interval replay, branch choices, preservation, local half-split handoff, transport, replay, provenance, and local naming in one carrier.

The future TasteGate surface for $\mathsf{EndpointBisectionCertificate}^{\uparrow}$ must supply nontrivial endpoint-branch variation and field-faithful visibility for $I, \beta, R, S, L, H, K, P, N$ before the chapter can be promoted beyond this paper-side NameCert target.

Closure status for $\mathsf{NameCert}_{\mathsf{EndpointBisectionCertificate}^{\uparrow}}$.

Constructive story: An $\mathsf{EndpointBisectionCertificate}^{\uparrow}$ packet is generated from RHRoute endpoint interval rows, branch-choice rows, endpoint replay, preservation rows, a local half-split handoff, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{EndpointBisectionCertificate}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8940.1, Definition 8940.2, and Definition 8940.3 seed the endpoint-bisection NameCert route over RHRoute endpoint intervals and local half-split handoff.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{EndpointBisectionCertificate}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close the Riemann hypothesis, zero selection, quotient endpoint-model equality, parity tower equivalence, oriented triadic equivalence, zero-recursor cover replacement, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked endpoint interval admission, branch replay, preservation visibility, local half-split handoff, nontrivial endpoint variation, field-faithful row visibility, transport, replay, provenance, and local naming for BEDC.Derived.RHRoute.EndpointBisectionCertificate.

Chapter 8941

A Concrete Naming Certificate for $\mathsf{FiniteDyadicStaircase}^{\uparrow}$

Following Bishop–Bridges constructive integration and the Darboux use of finite partitions, the $\mathsf{FiniteDyadicStaircase}^{\uparrow}$ packet records a finite L10 staircase over dyadic cells. It refines the partition surface of chapter 1863, reads cell geometry through chapter 5966, hands intervalwise bounds to chapter 1880, keeps rational values on the regular route of chapter 301, and exposes any terminal value-facing seal only through chapter 38. The packet is a finite approximation object; it does not import open-cover compactness, selected mesh limits, quotient real equality, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Falsifiable prediction: A consumer that reads a finite dyadic staircase value without the partition row, interval-net cell row, Darboux-sum handoff row, RegSeqRat readback row, and terminal Real-facing seal has left the $\mathsf{FiniteDyadicStaircase}^{\uparrow}$ packet.

Independence witness: dyadic partition, dyadic interval net, darboux sum, regseqrat, real: $\mathsf{FiniteDyadicStaircase}^{\uparrow}$ is not bijective to any one sibling because it jointly carries a finite partition, cellwise rational heights, Darboux-facing interval ledgers, regular rational readback, terminal sealing, transport, replay, provenance, and local naming.

Definition 8941.1 (Finite dyadic staircase carrier)**.** *A* $\mathsf{FiniteDyadicStaircase}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (P, I, V, L, U, D, R, E, H, C, G, N)$$

with the following displayed rows:

1. *P is the accepted* $\mathsf{DyadicPartition}^{\uparrow}$ *row for the finite ordered dyadic partition;*
2. *I is the* $\mathsf{DyadicIntervalNet}^{\uparrow}$ *cell-net row exposing the inspected dyadic cells and their endpoint ledgers;*
3. *V is the finite value row assigning a* $\mathsf{RegSeqRat}^{\uparrow}$ *rational readback name to each displayed cell;*
4. *L and U are the lower and upper cell-bound ledgers exported to the Darboux route;*
5. *D is the* $\mathsf{DarbouxSum}^{\uparrow}$ *handoff row, reading exactly the partition row, interval-net row, value row, and bound ledgers;*
6. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the finite staircase values and Darboux ledgers;*
7. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal for value-facing consumers that are allowed to read a real name;*

8. *H records componentwise* hsame *transport for the partition, cell-net, value, lower-bound, upper-bound, Darboux, readback, seal, replay, provenance, and local naming rows;*
9. *C records displayed* Cont *replay from a staircase request through $P, I, V, L, U, D, R, E, H, G, N$;*
10. *G is the* Pkg *provenance over* $\mathsf{FiniteDyadicStaircase}^{\uparrow}$, $\mathsf{DyadicPartition}^{\uparrow}$, $\mathsf{DyadicIntervalNet}^{\uparrow}$, $\mathsf{DarbouxSum}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert*;*
11. *N is the local* $\mathsf{NameCert}_{\mathsf{FiniteDyadicStaircase}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through these rows. It has no coordinate for an open cover, a selected limiting mesh, quotient real equality, countable choice, or ambient real completeness.

Theorem 8941.2 (Finite dyadic staircase NameCert obligations)**.** *For every accepted* $\mathsf{FiniteDyadicStaircase}^{\uparrow}$ *carrier*

$$S = (P, I, V, L, U, D, R, E, H, C, G, N),$$

the local $\mathsf{NameCert}_{\mathsf{FiniteDyadicStaircase}^{\uparrow}}$ *surface consists exactly of partition admission through P, dyadic cell-net exposure through I, finite rational value exposure through V, lower and upper Darboux ledgers through L, U, Darboux handoff through D, regular rational readback through R, terminal real sealing through E, componentwise* hsame *transport through H, displayed* Cont *replay through C,* Pkg *provenance through G, and local naming through N.*

Proof. Project the carrier of Definition 8941.1. The partition row, interval-net row, finite value row, lower and upper bound ledgers, Darboux handoff, readback row, and Real seal are visible before the structural rows are read.

The finite partition route is fixed by P, I, V. A downstream consumer can inspect a cell only through the displayed dyadic partition and interval-net rows, and can inspect a height only through the finite RegSeqRat value row attached to that cell.

The Darboux route is fixed by L, U, D, R, E. The lower and upper ledgers feed the Darboux handoff row, the regular rational row reads the finite sums and heights, and the Real seal exposes only the terminal value-facing name.

The rows H, C, G, N transport, replay, source, and name the same packet. Since the carrier has no coordinate for the excluded host principles, the listed rows exhaust the local NameCert surface. □

Theorem 8941.3 (Finite dyadic staircase Darboux handoff)**.** *Every Darboux-facing consumer of an accepted* $\mathsf{FiniteDyadicStaircase}^{\uparrow}$ *packet must pass through*

$$P, I, V, L, U, D, R, E, H, C, G, N.$$

The consumer receives a finite dyadic partition, displayed interval-net cells, cellwise regular rational values, lower and upper Darboux ledgers, regular rational readback, and the terminal $\mathsf{Real}^{\uparrow}$ *seal. It receives no open-cover compactness theorem, selected mesh-limit object, quotient real equality, countable-choice row, or ambient completeness principle.*

Proof. Start with Definition 8941.2. It identifies the displayed rows as the whole local NameCert surface and gives no second source for partition, cell, value, Darboux, readback, or seal data.

The Darboux-facing evidence is carried by P, I, V, L, U, D. The partition and interval-net rows display the cells, the value row supplies the cellwise rational names, and the lower and upper ledgers are the only rows exported to the Darboux handoff.

The value route is fixed by R, E. A consumer that wants a value-facing endpoint first reads the finite regular rational data and only then reaches the terminal Real seal.

Therefore the Darboux handoff cannot switch to open-cover compactness, selected mesh limits, quotient real equality, countable choice, or ambient completeness. Those objects are absent from the carrier and from the local classifier. □

Closure status for $\mathsf{NameCert}_{\mathsf{FiniteDyadicStaircase}^{\uparrow}}$.

Constructive story: A $\mathsf{FiniteDyadicStaircase}^{\uparrow}$ packet is generated from a finite dyadic partition row, a dyadic interval-net cell row, finite RegSeqRat value rows, lower and upper Darboux ledgers, a Darboux handoff row, regular rational readback, a terminal Real seal, componentwise transport, continuation replay, provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{FiniteDyadicStaircase}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8941.1, Definition 8941.2, and Definition 8941.3 seed the finite L10 staircase carrier from dyadic partitions to Darboux-facing consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{FiniteDyadicStaircase}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close open-cover compactness, selected mesh limits, quotient real equality, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, Darboux handoff exactness, componentwise transport, replay, provenance, terminal sealing, and local naming for BEDC.Derived.FiniteDyadicStaircaseUp.

Chapter 8942

A Concrete Naming Certificate for $\mathsf{DirectedCauchyNet}^{\uparrow}$

Following Moore and Smith's theory of nets and Kelley's topology text, the $\mathsf{DirectedCauchyNet}^{\uparrow}$ packet records a directed Cauchy net as finite BEDC completion data. It sits after the directed-index substrate of chapter 1607, the finite stream-window surface of chapter 126, the regular rational readback route of chapter 301, the dyadic tolerance core of chapter 291, and the terminal real-name seal of chapter 38. The packet is a net-style L10 completion neighbour for the sequence-based $\mathsf{Real}^{\uparrow}$ route; it does not choose a cofinal sequence, quotient nets, selected limits, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Falsifiable prediction: A completion consumer that reads a directed Cauchy net without the directed-index row, finite cofinal windows, StreamName readback, RegSeqRat handoff, DyadicRatCore tolerance ledger, and terminal Real seal has left the $\mathsf{DirectedCauchyNet}^{\uparrow}$ packet.

Independence witness: directedset, streamname, regseqrat, dyadicratcore, real: $\mathsf{DirectedCauchyNet}^{\uparrow}$ is not bijective to any one sibling because it jointly carries directed-window data, Cauchy-tail stability, sequence-style readback, dyadic tolerances, terminal sealing, transport, replay, provenance, and local naming.

Definition 8942.1 (Directed Cauchy net carrier)**.** *A* $\mathsf{DirectedCauchyNet}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$N = (D, V, W, T, S, Q, Y, R, H, C, P, L)$$

with the following displayed rows:

1. *D is the* $\mathsf{DirectedSet}^{\uparrow}$ *row naming the inspected directed vertices, comparison rows, finite request windows, and common upper-window witnesses;*
2. *V is the net-value row storing the finite values visible at the inspected directed vertices;*
3. *W is the finite cofinal-window row whose entries compare directed tails before any completion consumer reads a Real-facing seal;*
4. *T is the Cauchy-tail stability row, stating that every requested dyadic tolerance is witnessed after a displayed upper window;*
5. *S is the* $\mathsf{StreamName}^{\uparrow}$ *row obtained by reading a retained cofinal window as a finite stream window;*

6. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff row that records the regular rational readback of the retained window;*
7. *Y is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger used by the tail-stability and regular readback rows;*
8. *R is the terminal* $\mathsf{Real}^{\uparrow}$ *seal for completion-facing consumers allowed to read a real name;*
9. *H records componentwise* hsame *transport for the directed-index, value, cofinal-window, tail-stability, stream, regular, dyadic, Real, replay, provenance, and local naming rows;*
10. *C records displayed* Cont *replay from a directed request through $D, V, W, T, S, Q, Y, R, H, P, L$;*
11. *P is the* Pkg *provenance over* $\mathsf{DirectedCauchyNet}^{\uparrow}$, $\mathsf{DirectedSet}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$ *rows, with sibling anchors in chapter 1607, chapter 126, chapter 301, chapter 291, and chapter 38;*
12. *L is the local* $\mathsf{NameCert}_{\mathsf{DirectedCauchyNet}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through these rows. It has no coordinate for a host net function, quotient of nets, selected cofinal sequence, selected limit, countable-choice schedule, or ambient completeness theorem.

Theorem 8942.2 (Directed Cauchy net NameCert obligations)**.** *For every accepted* $\mathsf{DirectedCauchyNet}^{\uparrow}$ *carrier*

$$N = (D, V, W, T, S, Q, Y, R, H, C, P, L),$$

the local $\mathsf{NameCert}_{\mathsf{DirectedCauchyNet}^{\uparrow}}$ *surface consists exactly of directed-index admission through D, finite value exposure through V, cofinal-window extraction through W, tail-stability evidence through T, StreamName readback through S, RegSeqRat handoff through Q, DyadicRatCore tolerance accounting through Y, terminal Real sealing through R, componentwise* hsame *transport through H, displayed* Cont *replay through C,* Pkg *provenance through P, and local naming through L.*

Proof. Project the carrier of Definition 8942.1. The directed-index row D, value row V, cofinal-window row W, and tail-stability row T are visible before the completion-facing readback rows.

The sequence-style readback is fixed by S, Q, Y, R. The retained window is read as a $\mathsf{StreamName}^{\uparrow}$ row, then as a $\mathsf{RegSeqRat}^{\uparrow}$ handoff controlled by the $\mathsf{DyadicRatCore}^{\uparrow}$ ledger, and only then reaches the terminal $\mathsf{Real}^{\uparrow}$ seal.

The rows H, C, P, L transport, replay, source, and name the same packet through hsame, Cont, Pkg, and $\mathsf{NameCert}$ rows. Since the carrier has no coordinate for the excluded host objects, the listed rows exhaust the local NameCert surface. □

Theorem 8942.3 (Directed Cauchy net finite window extraction)**.** *Every completion-facing read of an accepted* $\mathsf{DirectedCauchyNet}^{\uparrow}$ *packet extracts a finite cofinal window from the displayed* $\mathsf{DirectedSet}^{\uparrow}$ *row before it may inspect* $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, *or* $\mathsf{Real}^{\uparrow}$ *data. The extraction supplies only the finite window W and its common upper witnesses; it does not supply a selected cofinal sequence, quotient index, host net function, or countable-choice operator.*

Proof. Start with the directed substrate. The row D names the inspected directed vertices, comparison rows, and upper-window witnesses, and W records which finite windows are retained for completion readback.

The downstream rows cannot be read before this extraction. The $\mathsf{StreamName}^{\uparrow}$ row S, $\mathsf{RegSeqRat}^{\uparrow}$ handoff Q, $\mathsf{DyadicRatCore}^{\uparrow}$ ledger Y, and $\mathsf{Real}^{\uparrow}$ seal R all appear after D, V, W, T in the carrier, and their provenance is routed through the sibling certificates named in Definition 8942.1.

Therefore a consumer receives finite cofinal-window data, not a host-level cofinal sequence or quotient of directed indices. The structural rows H, C, P, L preserve that same finite extraction boundary. □

Theorem 8942.4 (Directed Cauchy net tail stability)**.** *In an accepted* $\mathsf{DirectedCauchyNet}^{\uparrow}$ *carrier, every dyadic tolerance requested by the completion route is witnessed by a displayed upper window in* W *and by the* $\mathsf{DyadicRatCore}^{\uparrow}$ *ledger* Y*. The resulting tail-stability row* T *is read through* BHist*, componentwise* hsame*, displayed* Cont*,* Pkg*, and the local* $\mathsf{NameCert}_{\mathsf{DirectedCauchyNet}^{\uparrow}}$ *row; it is not an external Cauchy principle over all directed indices.*

Proof. Read the tail-stability row T together with the tolerance ledger Y. The row T does not quantify over an unbounded host net; it points to the finite windows in W and to the dyadic tolerances recorded by $\mathsf{DyadicRatCore}^{\uparrow}$.

The directed side is supplied by D and V. The common upper-window witnesses named by $\mathsf{DirectedSet}^{\uparrow}$ are the only witnesses that the stability row may use.

Finally, H, C, P, L keep the stability evidence inside the BEDC packet. The hsame transports preserve row identity, the Cont row replays only the displayed route, the Pkg row records the sibling sources, and the local $\mathsf{NameCert}$ row names the packet. Hence T is a finite carrier row, not an external Cauchy theorem. □

Theorem 8942.5 (Directed Cauchy net Real-completion handoff)**.** *Every* $\mathsf{Real}^{\uparrow}$*-facing consumer of an accepted* $\mathsf{DirectedCauchyNet}^{\uparrow}$ *packet must pass through*

$$D, V, W, T, S, Q, Y, R, H, C, P, L.$$

The handoff compares the directed cofinal windows with the sequence-style route by reading $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{DyadicRatCore}^{\uparrow}$*, and* $\mathsf{Real}^{\uparrow}$ *in that order. It exports no selected Moore–Smith limit, quotient-net equality, countable-choice row, host real equality, or ambient completeness theorem.*

Proof. Apply the NameCert obligation theorem. It identifies $D, V, W, T, S, Q, Y, R, H, C, P, L$ as the whole local surface and gives no second source for directed tails, stream windows, regular rational readback, dyadic tolerances, or the Real seal.

The completion handoff is sequential only after it is finite and directed. The packet first reads the $\mathsf{DirectedSet}^{\uparrow}$ substrate and the cofinal-window stability rows, then reads the retained window through $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{DyadicRatCore}^{\uparrow}$ before serving the terminal $\mathsf{Real}^{\uparrow}$ seal.

The componentwise hsame row, displayed Cont replay, Pkg provenance, and local $\mathsf{NameCert}$ row preserve the same order of access. Thus the handoff compares net-style cofinal windows with the existing sequence-based Real route without adding a selected limit, quotient net, countable-choice schedule, host equality, or ambient completeness principle. □

Closure status for $\mathsf{NameCert}_{\mathsf{DirectedCauchyNet}^{\uparrow}}$**.**

Constructive story: A $\mathsf{DirectedCauchyNet}^{\uparrow}$ packet is generated from a DirectedSet row, finite net-value rows, cofinal-window rows, Cauchy-tail stability evidence, StreamName readback, RegSeqRat handoff, DyadicRatCore tolerance accounting, a terminal Real seal, componentwise transport, continuation replay, provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{DirectedCauchyNet}^{\uparrow}}$, seed)

Scope closed: Definition 8942.1, Definition 8942.2, Definition 8942.3, Definition 8942.4, and Definition 8942.5 seed the finite directed Cauchy-net carrier and its Real-completion handoff.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{DirectedCauchyNet}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close selected Moore–Smith limits, quotient-net equality, cofinal-choice schedules, host real equality, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, finite window extraction, tail stability, Real-completion handoff, componentwise transport, replay, provenance, and local naming for BEDC.Derived.DirectedCauchyNetUp.

Chapter 8943

A Concrete Naming Certificate for $\mathsf{OrderedSemiring}^{\uparrow}$

Following Bourbaki on ordered algebraic structures and Golan on semirings, the packet records a semiring carrier whose additive and multiplicative rows are compatible with a stable order classifier; it consumes chapter 327, chapter 1378, chapter 37, chapter 291, and chapter 38. The packet gives order-sensitive L10 arithmetic handoffs one named BEDC surface for monotone addition and positive-row multiplication, while keeping ordered rings, field order, quotient order, classical trichotomy, and any standard bridge outside the carrier.

Definition 8943.1 (Ordered semiring finite-history carrier)**.** *An* $\mathsf{OrderedSemiring}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$O = (S, Q, R, D, E, A, M, H, C, P, N)$$

with the following displayed rows:

1. *S is the* $\mathsf{Semiring}^{\uparrow}$ *source row naming the shared carrier, addition, multiplication, distributivity, zero-annihilation ledger, transport, replay, provenance, and local* $\mathsf{NameCert}$ *surface.*
2. *Q is the* $\mathsf{Order}^{\uparrow}$ *comparison row naming the stable order classifier attached to the same displayed carrier entries read by S.*
3. *R is the* $\mathsf{Rat}^{\uparrow}$ *arithmetic readback row used by rational order-facing consumers without importing field order.*
4. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *handoff row used by dyadic interval and sign-ledger consumers.*
5. *E is the* $\mathsf{Real}^{\uparrow}$ *terminal read row reached only after the semiring and order rows remain visible.*
6. *A records addition monotonicity rows: whenever two displayed input comparisons are accepted by Q, the corresponding sum comparison is replayed through the addition route of S.*
7. *M records multiplication monotonicity by positive rows: whenever Q displays a nonnegative or positive multiplier row admitted by the rational or dyadic handoff, the product comparison is replayed through the multiplication route of S.*
8. *H records componentwise* hsame *transport for the semiring row, order row, rational readback, dyadic handoff, Real read, monotonicity ledgers, replay, provenance, and local name.*
9. *C records displayed* Cont *replay from each order-aware arithmetic request through $S, Q, R, D, E, A, M, H, P, N$.*

10. *P is the* Pkg *provenance over* $\mathsf{OrderedSemiring}^{\uparrow}$, $\mathsf{Semiring}^{\uparrow}$, $\mathsf{Order}^{\uparrow}$, $\mathsf{Rat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*
11. *N is the local* $\mathsf{NameCert}_{\mathsf{OrderedSemiring}^{\uparrow}}$ *row.*

The carrier predicate asserts exactly that these rows form one finite order-compatible semiring packet. It has no coordinate for subtraction, additive inverses, field order, quotient order, trichotomy, ambient Real completeness, or a standard bridge.

Definition 8943.2 (Ordered semiring classifier)**.** *Two accepted* $\mathsf{OrderedSemiring}^{\uparrow}$ *carriers*

$$O = (S, Q, R, D, E, A, M, H, C, P, N) \quad \textit{and} \quad O' = (S', Q', R', D', E', A', M', H', C', P', N')$$

are classified together when the semiring rows classify through the displayed $\mathsf{Semiring}^{\uparrow}$ *classifier, the order rows classify through the displayed* $\mathsf{Order}^{\uparrow}$ *endpoint transport, the rational, dyadic, and Real handoff rows transport componentwise by* hsame*, and the addition and multiplication monotonicity ledgers replay the same* Cont *routes after that transport. The classifier compares no host ordered algebra and no quotient relation.*

Theorem 8943.3 (Ordered semiring NameCert obligations)**.** *For every accepted* $\mathsf{OrderedSemiring}^{\uparrow}$ *carrier* $O = (S, Q, R, D, E, A, M, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{OrderedSemiring}^{\uparrow}}$ *surface consists exactly of five finite rows:*

1. *carrier habitation: the displayed* BHist *packet of Definition 8943.1 is inhabited by a semiring row, an order row, rational and dyadic readback rows, a Real read row, monotonicity ledgers, transport, replay, provenance, and local naming;*
2. *classifier transport: the classifier of Definition 8943.2 transports semiring, order, rational, dyadic, Real, monotonicity, replay, provenance, and local name rows componentwise;*
3. *addition monotonicity: the ledger A records only the comparison of sums obtained by replaying the addition route of S after input comparisons supplied by Q;*
4. *multiplication monotonicity by positive rows: the ledger M records only product comparisons whose multiplier positivity is already displayed by Q together with the R or D handoff row;*
5. *ledger nonescape: the rows H, C, P, N preserve and replay only the displayed finite inventory and export no ordered ring, field order, classical trichotomy, quotient order, or standard bridge.*

No ordered semiring obligation is stored outside these five rows.

Proof. Project the carrier of Definition 8943.1. It exposes the $\mathsf{Semiring}^{\uparrow}$ operation row S, the $\mathsf{Order}^{\uparrow}$ comparison row Q, the rational, dyadic, and Real handoff rows R, D, E, and the two monotonicity ledgers A, M.

The classifier of Definition 8943.2 then fixes the only allowed transport. It moves semiring, order, rational, dyadic, Real, monotonicity, replay, provenance, and local naming rows componentwise, so an accepted comparison after transport is still a comparison of the same displayed packet.

The addition and multiplication clauses are read from A and M. The addition row allows only monotone sum replay through S after input order rows from Q; the multiplication row allows only product replay when the multiplier's positivity has already been displayed by Q and by the rational or dyadic handoff.

Finally H, C, P, N exhaust the ledger. Since the packet has no row for additive inverses, ordered rings, field order, quotient order, classical trichotomy, or a standard bridge, the five listed rows are the whole local $\mathsf{NameCert}_{\mathsf{OrderedSemiring}^{\uparrow}}$ surface. □

Theorem 8943.4 (Ordered semiring addition and multiplication order compatibility)**.** *Every order-aware arithmetic consumer of an accepted* $\mathsf{OrderedSemiring}^{\uparrow}$ *carrier reads addition monotonicity and positive-row multiplication monotonicity only through*

$$S, Q, R, D \longmapsto A, M, H, C, P, N.$$

In particular, a $\mathsf{Rat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, *or* $\mathsf{Real}^{\uparrow}$ *handoff may use the displayed semiring operations and stable order classifier, but it cannot extract an ordered ring, a field order, a quotient order, classical trichotomy, or any standard bridge from the packet.*

Proof. Begin with an order-aware arithmetic request. By Definition 8943.1, the available operation row is S and the available comparison row is Q; the rational and dyadic handoff rows R, D only record the finite readback needed by their own consumers.

Addition monotonicity is therefore forced through A. The ledger reads the two input comparisons from Q, applies the addition route of S, and records the sum comparison as a finite replay row.

Positive-row multiplication monotonicity is forced through M. The multiplier condition is not a host positivity predicate; it is the displayed positivity row already visible through Q and the R or D handoff. Only then may the multiplication route of S be replayed to produce the product comparison.

The Real-facing row E is downstream of these checks. Since the structural rows H, C, P, N preserve only the displayed route, no consumer can replace the route by ordered-ring structure, field order, quotient order, trichotomy, or a standard bridge. □

Theorem 8943.5 (Ordered semiring kernel scope)**.** *The* $\mathsf{OrderedSemiring}^{\uparrow}$ *kernel scope is exactly the finite BEDC packet consisting of the semiring carrier row, stable order classifier, rational readback, dyadic handoff, Real read boundary, addition monotonicity, positive-row multiplication monotonicity, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local* NameCert *row. Every L10 arithmetic handoff that claims this scope factors through those rows and through no stronger ordered-algebraic structure.*

Proof. The carrier definition lists the rows that form the packet, and the classifier definition states the only transport relation between accepted packets. Hence a kernel consumer receives exactly those named components.

The NameCert obligation theorem identifies the five finite rows that make the packet usable: habitation, classifier transport, addition monotonicity, multiplication monotonicity by positive rows, and ledger nonescape.

The compatibility theorem then identifies the allowed handoff route for $\mathsf{Rat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ consumers. Combining these three readings leaves no remaining coordinate for ordered rings, field order, quotient order, trichotomy, or a standard bridge, so the displayed finite packet is exactly the kernel scope. □

Falsifiable prediction: An accepted $\mathsf{OrderedSemiring}^{\uparrow}$ read that produces addition or multiplication order compatibility while bypassing the displayed semiring row, order classifier, rational or dyadic handoff, transport, replay, provenance, and local naming is outside the carrier surface.

Independence witness: semiring, order, rat, dyadicratcore, real: no listed sibling is bijective with $\mathsf{OrderedSemiring}^{\uparrow}$ because this packet binds semiring operations, stable order classification, rational and dyadic positivity handoffs, Real-facing read boundaries, monotonicity ledgers, transport, replay, provenance, and local naming as one order-aware arithmetic interface.

Closure status for $\mathsf{NameCert}_{\mathsf{OrderedSemiring}^{\uparrow}}$.

Constructive story: An $\mathsf{OrderedSemiring}^{\uparrow}$ packet is generated from a SemiringUp source row, an OrderUp classifier row, RatUp and DyadicRatCoreUp handoff rows, a RealUp read boundary, addition monotonicity, positive-row multiplication monotonicity, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{OrderedSemiring}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8943.1, Definition 8943.2, Definition 8943.3, Definition 8943.4, and Definition 8943.5 seed the finite order-aware semiring handoff surface for L10 arithmetic consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{OrderedSemiring}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter explicitly excludes ordered rings, field order, classical trichotomy, quotient order, and any standard bridge.

Upgrade path: Obligation closure requires checked carrier habitation, classifier transport, addition monotonicity, multiplication monotonicity by positive rows, ledger nonescape, and handoff scope for BEDC.Derived.OrderedSemiringUp.

Chapter 8944

A Concrete Naming Certificate for $\mathsf{MetricCompletionFilter}^{\uparrow}$

Following Bourbaki and Kelley filter completion, the $\mathsf{MetricCompletionFilter}^{\uparrow}$ packet records the filter-facing finite certificate surface for Cauchy completion. It sits between the metric-completion branch of chapter 1506, the Cauchy-filter route of chapter 333, the finite filter-base rows of chapter 1601, the stream-window presentation of chapter 126, the regular rational readback of chapter 301, and the terminal real-name seal of chapter 38. The packet names completion data as finite filter rows; it does not introduce quotient classes, selected limits, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Falsifiable prediction: A completion consumer that reads a filter limit without displaying the $\mathsf{CauchyFilter}^{\uparrow}$, $\mathsf{FilterBase}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ rows has left the $\mathsf{MetricCompletionFilter}^{\uparrow}$ packet.

Independence witness: metriccompletion, cauchyfilter, filterbase, streamname, regseqrat, real: $\mathsf{MetricCompletionFilter}^{\uparrow}$ is not bijective to any one sibling because it jointly carries completion admission, Cauchy-filter evidence, finite base refinement, stream windows, regular rational readback, terminal real sealing, transport, replay, provenance, and local naming.

Definition 8944.1 (MetricCompletionFilter carrier)**.** *A* $\mathsf{MetricCompletionFilter}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M = (X, d, F, B, S, R, E, H, C, P, N)$$

with the following displayed rows:

1. X, d *is the source metric row accepted by the* $\mathsf{MetricCompletion}^{\uparrow}$ *surface;*
2. F *is the* $\mathsf{CauchyFilter}^{\uparrow}$ *evidence row for the displayed completion-facing filter;*
3. B *is the* $\mathsf{FilterBase}^{\uparrow}$ *finite-base row refining the requested filter neighborhoods;*
4. S *is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row used to read the base tails;*
5. R *is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for regular rational tail data;*
6. E *is the terminal* $\mathsf{Real}^{\uparrow}$ *seal attached to the displayed readback;*
7. H *records componentwise* hsame *transport of the metric, Cauchy-filter, base, window, readback, and seal rows;*

8. *C records displayed* Cont *replay from metric-completion requests through Cauchy-filter evidence, finite base refinement, StreamName windows, RegSeqRat readback, and the Real seal;*
9. *P is the* Pkg *provenance over* $\mathsf{MetricCompletionFilter}^{\uparrow}$, $\mathsf{MetricCompletion}^{\uparrow}$, $\mathsf{CauchyFilter}^{\uparrow}$, $\mathsf{FilterBase}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert*;*
10. *N is the local* $\mathsf{NameCert}_{\mathsf{MetricCompletionFilter}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through these rows. It has no coordinate for a quotient completion class, selected filter limit, countable-choice schedule, or ambient real completeness theorem.

Theorem 8944.2 (MetricCompletionFilter tail-base refinement)**.** *Every completion-facing read of an accepted* $\mathsf{MetricCompletionFilter}^{\uparrow}$ *carrier*

$$M = (X, d, F, B, S, R, E, H, C, P, N)$$

must expose the $\mathsf{CauchyFilter}^{\uparrow}$ *row F, the* $\mathsf{FilterBase}^{\uparrow}$ *row B, the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row S, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row R, and the terminal* $\mathsf{Real}^{\uparrow}$ *seal E before it may be consumed as completion data. The finite base row B refines each displayed filter request to a tail window read through S and R, so the completion handoff is the displayed tail-base route rather than a quotient-class representative or a selected limit.*

Proof. Project the carrier of Definition 8944.1. The metric row and Cauchy-filter row are visible before any completion-facing read reaches the base, window, readback, or seal rows.

Use the finite row projection through B, S, R. The $\mathsf{FilterBase}^{\uparrow}$ row refines each displayed filter request to a named base tail, the $\mathsf{StreamName}^{\uparrow}$ row fixes the finite request window, and the $\mathsf{RegSeqRat}^{\uparrow}$ row reads that window as regular rational data.

The terminal $\mathsf{Real}^{\uparrow}$ seal is downstream of this readback. Componentwise hsame transport and displayed Cont replay preserve the same tail-base route, while Pkg provenance and the local NameCert row name the packet.

Thus every completion-facing consumer receives only the displayed Cauchy-filter, finite-base, StreamName, RegSeqRat, and Real-seal rows. No quotient class, selected limit, countable-choice schedule, or ambient completeness theorem is used. □

Theorem 8944.3 (MetricCompletionFilter obligation surface)**.** *For every accepted* $\mathsf{MetricCompletionFilter}^{\uparrow}$ *carrier*

$$M = (X, d, F, B, S, R, E, H, C, P, N),$$

the visible completion-filter obligation surface is the finite BHist *inventory consisting of the metric row (X, d), Cauchy-filter row F, filter-base row B,* $\mathsf{StreamName}^{\uparrow}$ *window S,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback R,* $\mathsf{Real}^{\uparrow}$ *seal E, componentwise* hsame *transport H, displayed* Cont *replay C,* Pkg *provenance P, and local* $\mathsf{NameCert}_{\mathsf{MetricCompletionFilter}^{\uparrow}}$ *naming row N. No completion obligation is stored outside these rows.*

Proof. Project the carrier of Definition 8944.1. The analytic rows are exactly $(X, d), F, B, S, R, E$, and the structural rows are exactly H, C, P, N.

Apply tail-base refinement from Definition 8944.2. It forces every completion-facing read to pass through the Cauchy-filter row, finite base row, finite StreamName window, regular rational readback, and terminal Real seal.

The remaining rows transport, replay, source, and locally name that same route. Since the carrier has no further coordinate, quotient completion classes, selected filter limits, countable-choice schedules, and ambient completeness cannot be part of the local obligation surface. □

Theorem 8944.4 (MetricCompletionFilter RegSeqRat handoff)**.** *Every accepted* $\mathsf{MetricCompletionFilter}^{\uparrow}$ *read that exports tail data to a completion-facing consumer must pass from the* $\mathsf{FilterBase}^{\uparrow}$ *row* B *and* $\mathsf{StreamName}^{\uparrow}$ *window* S *through the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row* R *before any* $\mathsf{Real}^{\uparrow}$ *seal is visible. The handoff therefore records regular rational tail data as finite BEDC rows, with* hsame *transport,* Cont *replay,* Pkg *provenance, and* NameCert *naming carried along the same route.*

Proof. Use Definition 8944.2. The theorem already places B, S, R between the Cauchy-filter row and the terminal seal.

Read the obligation surface of Definition 8944.3. It identifies R as the unique regular rational readback row in the carrier, so a consumer cannot replace it by a selected filter limit or host completion representative.

The rows H, C, P, N preserve the same handoff under transport, replay, provenance, and naming. Thus the RegSeqRat handoff is the displayed route through B, S, R and not an ambient completeness principle. □

Theorem 8944.5 (MetricCompletionFilter Real-seal boundary)**.** *The terminal* $\mathsf{Real}^{\uparrow}$ *seal row* E *of an accepted* $\mathsf{MetricCompletionFilter}^{\uparrow}$ *carrier is available only after the metric row, Cauchy-filter row, filter-base row, StreamName window, and RegSeqRat readback have been displayed and transported through* H, C, P, N*. A Real-facing consumer may therefore read* E *only as the end of the finite completion-filter route, not as quotient completion equality, a selected limit, a countable-choice schedule, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start with the tail-base theorem Definition 8944.2. It places the seal row downstream of F, B, S, R for every completion-facing read.

Apply Definition 8944.4. The regular rational readback row is already displayed before the seal, and the structural rows H, C, P, N carry the same route.

Finally use the carrier projection from Definition 8944.1. The carrier has no coordinate for quotient completion equality, selected limits, countable-choice schedules, or ambient Real completeness, so the Real seal is confined to the finite route just described. □

Closure status for $\mathsf{NameCert}_{\mathsf{MetricCompletionFilter}^{\uparrow}}$**.**

Constructive story: A $\mathsf{MetricCompletionFilter}^{\uparrow}$ packet is generated from a source metric row, a Cauchy-filter row, a finite FilterBase refinement, StreamName windows, RegSeqRat readback, a terminal Real seal, componentwise transport, displayed continuation replay, package provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{MetricCompletionFilter}^{\uparrow}}$, seed)

Scope closed: Definition 8944.1 and Definition 8944.2 bind the finite filter-completion carrier and tail-base refinement route.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{MetricCompletionFilter}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close quotient completion classes, selected filter limits, countable-choice schedules, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, tail-base refinement, transport, replay, provenance, and local naming for BEDC.Derived.MetricCompletionFilterUp.

Chapter 8945

A Concrete Naming Certificate for $\mathsf{BishopLTenCompletionTerminal}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{BishopLTenCompletionTerminal}^{\uparrow}$ packet records the terminal finite seal route by which the L10 Real and Completion phase reaches $\mathsf{Real}^{\uparrow}$ without importing quotient stream equality, countable choice, a hidden tail oracle, a detached completion seal, or ambient completeness. It sits after the dyadic arithmetic of chapter 291, the finite stream interface of chapter 126, the regular rational readback of chapter 301, the terminal real-name seal of chapter 38, the finite tail selection route of chapter 1354, and the witness-gluing route of chapter 1110. The packet also reads the exact completion boundary of chapter 1120 as a sibling surface rather than as an external completeness theorem.

Definition 8945.1 (Bishop L10 completion-terminal carrier)**.** *A* $\mathsf{BishopLTenCompletionTerminal}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$T = (D, S, Q, A, G, B, R, E, H, C, P, N)$$

with the following displayed rows:

1. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance and comparison ledger consumed by the terminal route.*
2. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row through which the route observes a Cauchy name.*
3. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *regular-rational readback row produced from the displayed windows and dyadic tolerances.*
4. *A is the* $\mathsf{CanonicalTailChoice}^{\uparrow}$ *finite tail-choice row, read only as the displayed L10 tail selection surface.*
5. *G is the* $\mathsf{CauchyWitnessGluing}^{\uparrow}$ *witness-gluing row binding the witness ledger, tail envelope, synchronizer, and completion-seal classifier.*
6. *B is the* $\mathsf{RealCompletionExactBoundaryUp}$ *exact-boundary row, reached after D, S, Q, A, G have been displayed.*
7. *R is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row served to the Real and Completion consumer.*
8. *E is the completion-terminal edge stating that D, S, Q, A, G, B, R are read as one finite terminal route.*
9. *H records componentwise* hsame *transport for every displayed object row, the edge, provenance, and local naming.*

10. *C records displayed* Cont *replay from dyadic tolerance data through stream windows, regular readback, finite tail choice, witness gluing, exact boundary, and terminal Real sealing.*

11. *P is the* Pkg *provenance over* $\mathsf{BishopLTenCompletionTerminal}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{CanonicalTailChoice}^{\uparrow}$, $\mathsf{CauchyWitnessGluing}^{\uparrow}$, RealCompletionExactBoundaryUp, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

12. *N is the local* $\mathsf{NameCert}_{\mathsf{BishopLTenCompletionTerminal}^{\uparrow}}$ *row.*

The carrier has no coordinate for quotient stream equality, a countable-choice schedule, a hidden tail oracle, a detached completion seal, selected host limits, host real equality, metric completeness, or ambient completeness of $\mathsf{Real}^{\uparrow}$.

Theorem 8945.2 (Bishop L10 completion-terminal NameCert obligations)**.** *For every accepted* $\mathsf{BishopLTenCompletionTerminal}^{\uparrow}$ *carrier* $T = (D, S, Q, A, G, B, R, E, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{BishopLTenCompleti}}$ *surface consists exactly of the following five obligation rows:*

1. *dyadic, stream, and regular readback admission through D, S, Q;*
2. *finite tail and witness admission through A, G;*
3. *exact-boundary and terminal Real sealing through B, R, E;*
4. *componentwise transport and displayed replay through H, C;*
5. *package provenance and local naming through P, N.*

These five rows exhaust the completion-terminal obligation surface and add no quotient stream, choice, hidden-tail, detached-seal, or ambient-completeness coordinate.

Proof. Project the carrier of Definition 8945.1. Its object rows are D, S, Q, A, G, B, R, its edge row is E, and its structural rows are H, C, P, N.

The first obligation row reads the finite observational stack. The dyadic tolerance ledger D budgets the finite windows S, and the regular rational row Q is the only readback exported from those observations.

The second row binds the completion witness side. The canonical tail-choice row A supplies the finite tail selection route, while the witness-gluing row G binds the witness ledger, tail envelope, synchronizer, and completion-seal classifier before the exact boundary is read.

The third row serves the terminal boundary. The exact-boundary row B and Real seal R are connected by the completion-terminal edge E, so no detached completion seal can be consumed apart from the displayed packet.

The remaining two rows are structural. Rows H, C transport and replay the displayed route, while P, N source and name it. Since no listed row contains quotient stream equality, countable choice, hidden tail data, detached seals, selected host limits, host real equality, metric completeness, or ambient completeness, the five rows exhaust the obligation surface. □

Theorem 8945.3 (Bishop L10 completion-terminal seal factorization)**.** *Every accepted Real and Completion consumer of a* $\mathsf{BishopLTenCompletionTerminal}^{\uparrow}$ *packet reaches the terminal seal only through the displayed factorization*

$$\mathsf{DyadicRatCore}^{\uparrow} \longmapsto \mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{CanonicalTailChoice}^{\uparrow} \longmapsto \mathsf{CauchyWitnessGluing}^{\uparrow} \longmapsto \mathsf{RealCo}$$

The structural rows H, C, P, N preserve this route under hsame *transport,* Cont *replay,* Pkg *provenance, and local* NameCert *naming.*

Proof. Start with the readback stack. The dyadic row D, stream row S, and regular row Q display the finite rational observation route before any completion-facing object is available.

Next read the L10 tail and witness surfaces. The finite tail-choice row A and witness-gluing row G expose the tail and witness data as named sibling packets, so a consumer cannot replace them by a host-selected subsequence or a hidden tail oracle.

Then read the terminal boundary. The exact-boundary row B is downstream of D, S, Q, A, G, and the terminal $\mathsf{Real}^{\uparrow}$ row R is served only across the edge E.

Finally apply the structural rows. The transports H, replays C, provenance P, and local name N carry the same factorization and do not add another completion route. Therefore every accepted consumer reaches $\mathsf{Real}^{\uparrow}$ through the displayed chain. □

Theorem 8945.4 (Bishop L10 completion-terminal refusal ledger)**.** *An accepted* $\mathsf{BishopLTenCompletionTerminal}^{\uparrow}$ *packet refuses quotient stream equality, countable choice, hidden tail oracles, detached completion seals, selected host limits, host real equality, metric completeness, and ambient completeness. Any consumer asking for one of those objects is outside the displayed rows* $D, S, Q, A, G, B, R, E, H, C, P, N$ *and therefore outside the local* $\mathsf{NameCert}_{\mathsf{BishopLTenCompletionTerminal}^{\uparrow}}$ *surface.*

Proof. The carrier definition lists all rows of the accepted packet. None of $D, S, Q, A, G, B, R, E, H, C, P, N$ is a quotient-stream row, a choice schedule, a hidden tail oracle, a detached seal, a selected host limit, a host real equality row, a metric-completeness row, or an ambient-completeness theorem.

The NameCert obligations of Definition 8945.2 exhaust the same row inventory. The seal factorization of Definition 8945.3 then forces every terminal read through the listed sibling surfaces before $\mathsf{Real}^{\uparrow}$ is served.

Thus any requested object named in the refusal statement has no carrier coordinate, no transport coordinate, no replay coordinate, and no naming coordinate in the packet. It cannot be consumed as part of the accepted terminal route. □

Falsifiable prediction: Every accepted $\mathsf{BishopLTenCompletionTerminal}^{\uparrow}$ consumer displays dyadic tolerance, stream-window, regular readback, canonical tail-choice, witness-gluing, exact-boundary, terminal Real, transport, replay, provenance, and local naming rows before the terminal seal is consumed.

Independence witness: dyadicratcore, streamname, regseqrat, canonicaltailchoice, cauchywitnessgluing, realcompletionexactboundary, real: $\mathsf{BishopLTenCompletionTerminal}^{\uparrow}$ is not bijective to any listed sibling because it carries all seven object rows together with the terminal edge and structural NameCert rows in one packet.

Closure status for $\mathsf{NameCert}_{\mathsf{BishopLTenCompletionTerminal}^{\uparrow}}$.

Constructive story: A $\mathsf{BishopLTenCompletionTerminal}^{\uparrow}$ packet is generated from DyadicRatCore, StreamName, RegSeqRat, CanonicalTailChoice, CauchyWitnessGluing, RealCompletionExactBoundary, RealUp, completion-terminal edge, hsame, Cont, Pkg, and local NameCert rows.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{BishopLTenCompletionTerminal}^{\uparrow}}$, seed)

Scope closed: Definition 8945.1, Definition 8945.2, Definition 8945.3, Definition 8945.4, the falsifiable prediction, and the independence witness seed the finite terminal seal route from L10 completion data to $\mathsf{Real}^{\uparrow}$.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{BishopLTenCompletionTerminal}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close quotient stream equality, countable choice, hidden tail oracles, detached completion seals, selected host limits, host real equality, metric completeness, ambient completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, five-row NameCert obligations, terminal seal factorization, refusal-ledger exactness, transport stability, replay stability, provenance non-escape, and local naming for BEDC.Derived.BishopLTenCompletionTerminalUp.

Chapter 8946

A Concrete Naming Certificate for $\mathsf{CauchyApartnessModulus}^{\uparrow}$

Following Bishop and Bridges on constructive real analysis, the $\mathsf{CauchyApartnessModulus}^{\uparrow}$ packet records the finite witness by which two regular Cauchy real names are read as apart before any order, quotient, or trichotomy principle is available. It sits between the stream schedules of chapter 126, the regular rational readback of chapter 301, the dyadic tolerance core of chapter 291, the terminal real-name seal of chapter 38, and the apartness surface of chapter 1881. The packet names a displayed positive separation window for regular Cauchy names; it does not assert trichotomy, quotient-real equality, selected limits, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 8946.1 (Cauchy apartness modulus carrier)**.** *A* $\mathsf{CauchyApartnessModulus}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$A = (S, Q, D, R, J, H, C, P, N)$$

with the following displayed rows:

1. *S is the* $\mathsf{StreamName}^{\uparrow}$ *window row naming the two inspected Cauchy streams and the finite precision request at which they are compared.*
2. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the two regular rational names on that window.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row carrying the dyadic positive gap and the comparison budget used to read it.*
4. *R is the* $\mathsf{Real}^{\uparrow}$ *seal row reached only after the stream window, regular rational readback, and dyadic gap budget have been displayed.*
5. *J is the* $\mathsf{CauchyRealApartness}^{\uparrow}$ *apartness row witnessing that the displayed dyadic gap is the public apartness evidence for the two Cauchy real names.*
6. *H records componentwise* hsame *transport for the StreamName, RegSeqRat, DyadicRatCore, Real, apartness, replay, provenance, and local naming rows.*
7. *C records displayed* Cont *replay from a Cauchy-apartness request through the stream window, regular rational readback, dyadic gap budget, Real seal, and apartness row.*
8. *P records* Pkg *provenance over* $\mathsf{CauchyApartnessModulus}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{CauchyRealApartness}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
9. *N is the local* $\mathsf{NameCert}_{\mathsf{CauchyApartnessModulus}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through $S, Q, D, R, J, H, C, P, N$. It has no coordinate for total order trichotomy, quotient representatives, selected moduli, countable-choice schedules, or ambient real completeness.

Theorem 8946.2 (Cauchy apartness modulus NameCert obligations)**.** *For every accepted* $\mathsf{CauchyApartnessModulus}$ *carrier*

$$A = (S, Q, D, R, J, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{CauchyApartnessModulus}^{\uparrow}}$ *surface consists exactly of StreamName window admission, RegSeqRat readback, DyadicRatCore positive-gap budgeting, Real-seal visibility, CauchyRealApartness witness alignment, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. The surface supplies apartness evidence only through the displayed finite window and exports no trichotomy, quotient-real equality, selected Cauchy limit, countable-choice schedule, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness principle.*

Proof. Project the carrier of Definition 8946.1. The rows S, Q, D expose the inspected stream window, regular rational readback, and dyadic gap budget before the Real seal or apartness row can be consumed.

The apartness witness is then read through J. Since J is downstream of the same S, Q, D, R route, a consumer sees a positive separation window rather than a detached order decision or quotient representative.

Finally H, C, P, N preserve and name that displayed route. The carrier has no coordinate for trichotomy, chosen representatives, selected limits, countable choice, or ambient completeness, so none is exported by the local NameCert surface. □

Theorem 8946.3 (Cauchy apartness modulus regular window)**.** *Every* $\mathsf{CauchyApartnessModulus}^{\uparrow}$ *read that reaches the apartness row J must first display the* $\mathsf{StreamName}^{\uparrow}$ *window S, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback Q, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row D, and the terminal* $\mathsf{Real}^{\uparrow}$ *seal R. Thus the apartness modulus is a regular-window route*

$$\mathsf{StreamName}^{\uparrow}, \quad \mathsf{RegSeqRat}^{\uparrow}, \quad \mathsf{DyadicRatCore}^{\uparrow}, \quad \mathsf{Real}^{\uparrow}, \quad \mathsf{CauchyRealApartness}^{\uparrow}$$

and not an external order oracle or quotient-real comparison.

Proof. Start from a consumer read of J. By Definition 8946.1, the apartness row is attached to the displayed StreamName, RegSeqRat, DyadicRatCore, and Real rows.

The regular rational readback and dyadic tolerance budget determine the public positive gap. The terminal Real seal is visible only after those rows have been opened, so the apartness row is a finite regular-window witness.

Replay through H, C, P, N preserves the same route. A consumer that omits any of S, Q, D, R has not reached the named apartness modulus and cannot read J as public evidence. □

Theorem 8946.4 (Cauchy apartness modulus ledger refusal)**.** *An accepted* $\mathsf{CauchyApartnessModulus}^{\uparrow}$ *packet refuses every attempted ledger read that omits one of $S, Q, D, R, J, H, C, P, N$. In particular, a route that supplies only a Real seal, only a dyadic inequality, or only an apartness label is boundary evidence, not a public apartness modulus for* $\mathsf{CauchyRealApartness}^{\uparrow}$.

Proof. Use the obligation surface of Definition 8946.2. It lists all rows that the local certificate admits, including the stream window, regular rational readback, dyadic tolerance budget, Real seal, and apartness witness.

Apply the regular-window route of Definition 8946.3. Any public apartness read reaches J only through S, Q, D, R and then through the structural rows H, C, P, N.

Therefore a ledger read missing one of these rows lies outside the accepted carrier. Such a read may be boundary evidence for a later consumer, but it is not a $\mathsf{CauchyApartnessModulus}^{\uparrow}$ certificate and cannot be exported as a public apartness modulus. □

Falsifiable prediction: A consumer that exports $\mathsf{CauchyRealApartness}^{\uparrow}$ evidence while omitting the $\mathsf{StreamName}^{\uparrow}$ window, $\mathsf{RegSeqRat}^{\uparrow}$ readback, $\mathsf{DyadicRatCore}^{\uparrow}$ positive-gap row, $\mathsf{Real}^{\uparrow}$ seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, or local naming row has left the $\mathsf{CauchyApartnessModulus}^{\uparrow}$ packet.

Independence witness: streamname, regseqrat, dyadicratcore, real, cauchyrealapartness: CauchyApartnessModu is not bijective to any listed sibling because it joins a StreamName comparison window, RegSeqRat readback, DyadicRatCore positive-gap budget, Real seal, CauchyRealApartness witness, transport, replay, provenance, and local NameCert as one finite apartness-modulus packet.

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyApartnessModulus}^{\uparrow}}$.

Constructive story: A $\mathsf{CauchyApartnessModulus}^{\uparrow}$ packet is generated from a StreamName comparison window, RegSeqRat readback, DyadicRatCore positive-gap budget, a Real seal, a CauchyRealApartness witness row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CauchyApartnessModulus}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8946.1, Definition 8946.2, Definition 8946.3, and Definition 8946.4 seed the finite Cauchy apartness modulus route over $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{CauchyRealApartness}^{\uparrow}$, BHist, hsame, Cont, Pkg, and NameCert rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CauchyApartnessModulus}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close total order trichotomy, quotient-real equality, selected Cauchy limits, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, regular-window readback, dyadic positive-gap budgeting, Real-seal visibility, apartness witness alignment, transport, replay, provenance, and local naming for BEDC.Derived.CauchyApartnessModulusUp.

Chapter 8947

A Concrete Naming Certificate for $\mathsf{DirichletFunction}^{\uparrow}$

Following Dirichlet and Bishop–Bridges constructive analysis, the $\mathsf{DirichletFunction}^{\uparrow}$ packet records the classical rational-versus-irrational boundary example as finite BEDC data. It sits after the rational carrier of chapter 37, the rational-density surface of chapter 1409, the stream naming surface of chapter 126, the regular rational-sequence readback of chapter 301, the real seal of chapter 38, the continuous-map packet of chapter 130, and the boundary comparison supplied by chapter 6525. Its role is not to assert a host function equality or a complete classical discontinuity theorem, but to expose the finite NameCert route by which a Real-facing consumer sees rational density, irrational-boundary refusal, stream windows, regular readback, and a terminal $\mathsf{Real}^{\uparrow}$ seal.

Falsifiable prediction: An accepted $\mathsf{DirichletFunction}^{\uparrow}$ packet that omits rational-density evidence, treats the irrational-boundary refusal as a continuity proof, or reads the terminal seal without a displayed StreamName window refutes this carrier.

Independence witness: rat, rationaldensityreal, streamname, regseqrat, real, continuous-map, thomae-function: none is bijective because DirichletFunctionUp binds rational-density branching, irrational-boundary refusal, finite stream windows, regular rational readback, Real-seal delivery, transport, continuation replay, provenance, and local naming in one packet.

Definition 8947.1 (Dirichlet-function carrier)**.** *A* $\mathsf{DirichletFunction}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$D = (R, \Delta, I, W, G, A, H, C, P, N)$$

with the following displayed rows:

1. *R is the* $\mathsf{Rat}^{\uparrow}$ *source row for rational probes and rational values;*
2. *Δ is the rational-density evidence row over the surrounding* $\mathsf{Real}^{\uparrow}$ *boundary;*
3. *I is the irrational-boundary refusal row, recording that a non-rational boundary read is not converted into a rational witness;*
4. *W is the finite* $\mathsf{StreamName}^{\uparrow}$ *window through which the boundary read is opened;*
5. *G is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row attached to the same window;*
6. *A is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached only after R, Δ, I, W, G are displayed;*
7. *H records componentwise* hsame *transport for the rational, density, refusal, window, readback, seal, provenance, and naming rows;*

8. *C records displayed* Cont *replay of the packet as a syntactic continuation route, not as a continuity claim;*
9. *P is the* Pkg *provenance over* $\mathsf{Rat}^{\uparrow}$, $\mathsf{RationalDensityReal}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{ThomaeFunction}^{\uparrow}$, BHist, hsame, Cont, *and local certificate rows;*
10. *N is the local* $\mathsf{NameCert}_{\mathsf{DirichletFunction}^{\uparrow}}$ *row.*

The local classifier compares accepted carriers only through the visible rows $R, \Delta, I, W, G, A, H, C, P, N$. It has no coordinate for quotient real equality, host function extensionality, a continuity proof, a complete discontinuity-set classifier, or an omniscient rationality decision.

Theorem 8947.2 (Dirichlet-function NameCert obligations)**.** *For the carrier of Definition 8947.1, the local* $\mathsf{NameCert}_{\mathsf{DirichletFunction}^{\uparrow}}$ *surface consists of carrier admission for $D = (R, \Delta, I, W, G, A, H, C, P, N)$, rational-probe exposure through R, rational-density evidence through Δ, irrational-boundary refusal through I, finite* $\mathsf{StreamName}^{\uparrow}$ *window exposure through W,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback through G, terminal* $\mathsf{Real}^{\uparrow}$ *seal delivery through A, componentwise* hsame *stability through H, displayed* Cont *replay through C,* Pkg *provenance through P, and local naming through N.*

Proof. Carrier admission is projection from the displayed tuple in Definition 8947.1. The rational row, density evidence, refusal row, stream window, regular readback, seal, transport, replay, provenance, and naming row are all visible coordinates of one finite packet.

The obligations are then read in order. The rational row supplies the rational branch, the density row records the nearby rational evidence, and the refusal row prevents an irrational-boundary read from being reclassified as a rational witness.

The window and readback rows open the finite StreamName and RegSeqRat route before the Real seal is delivered. The remaining rows transport, replay, source, and name the same packet, so there is no hidden coordinate for extensional equality, continuity, complete discontinuity classification, or omniscient rationality. □

Theorem 8947.3 (Dirichlet-function rational and irrational boundary)**.** *Every accepted* $\mathsf{DirichletFunction}^{\uparrow}$ *read keeps the rational-density branch and the irrational-boundary refusal simultaneously visible. The rational side may be consumed only through $R, \Delta, W, G, A, H, C, P, N$, while the non-rational boundary side remains a refusal row I and cannot be upgraded into a host decision procedure, quotient real equality, or a continuity statement.*

Proof. Use the obligation surface of Definition 8947.2. It exposes both the rational-density evidence row Δ and the irrational-boundary refusal row I before any Real-facing seal can be read.

The StreamName and RegSeqRat rows keep the boundary read finite. They supply a window and regular rational readback attached to the displayed packet, not an ambient equality of real functions or a host-level decision of rationality.

Since I is a refusal row and no additional classifier coordinate exists, a non-rational boundary read cannot be repackaged as continuity, quotient real equality, or a complete discontinuity-set theorem. The packet therefore preserves the rational and non-rational boundary sides as distinct displayed obligations. □

Theorem 8947.4 (Dirichlet-function Real-seal factorization)**.** *For every accepted* $\mathsf{DirichletFunction}^{\uparrow}$ *carrier*

$$D = (R, \Delta, I, W, G, A, H, C, P, N),$$

each completion-facing read of the terminal $\mathsf{Real}^{\uparrow}$ *seal row A factors through the displayed rational row R, rational-density row Δ, irrational-boundary refusal row I, finite* $\mathsf{StreamName}^{\uparrow}$ *window*

W, and $\mathsf{RegSeqRat}^{\uparrow}$ *readback G. The factorization uses* hsame *transport,* Cont *replay,* Pkg *provenance, and local* NameCert *rows only for the same finite packet, and it exports no continuity theorem, classical discontinuity-set completeness, host function extensionality, quotient real equality, or countable-choice selector.*

Proof. Project the carrier. The seal row A appears only after the rational, density, refusal, window, and readback rows in the displayed tuple.

Apply Definition 8947.2. Any accepted seal read must preserve the same rational evidence, refusal row, StreamName window, RegSeqRat readback, transport, replay, provenance, and local naming.

Now use the boundary theorem Definition 8947.3. It prevents the refusal row from becoming a host rationality decision and keeps the rational-density branch separate from continuity or discontinuity-set claims. Thus the Real seal factors through exactly the displayed BEDC rows and no stronger analytic principle. □

Closure status for $\mathsf{NameCert}_{\mathsf{DirichletFunction}^{\uparrow}}$.

Constructive story: A $\mathsf{DirichletFunction}^{\uparrow}$ packet is generated from rational probes, rational-density evidence, an irrational-boundary refusal row, finite StreamName windows, RegSeqRat readback, a terminal RealUp seal, componentwise hsame transport, displayed Cont replay, package provenance, and local naming.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{DirichletFunction}^{\uparrow}}$, seed)

Scope closed: Definition 8947.2, Definition 8947.3, and Definition 8947.4 expose the seed carrier surface for rational-density branching and irrational-boundary refusal.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{DirichletFunction}^{\uparrow}}$, unformalized)

Bridge status: none

Origin: human

Not claimed: This chapter does not claim continuity, classical discontinuity-set completeness, host function extensionality, quotient real equality, countable choice, or Lean verification.

Upgrade path: Scoped closure requires checked local obligations tying the carrier rows to the concrete RatUp, StreamNameUp, RegSeqRatUp, RealUp, ContinuousMapUp, and ThomaeFunctionUp sibling surfaces.

Chapter 8948

A Concrete Naming Certificate for $\mathsf{FiniteImageStreamWindow}^{\uparrow}$

Following Bishop and Bridges on finite means in constructive analysis, the $\mathsf{FiniteImageStreamWindow}^{\uparrow}$ packet records the finite image of a displayed $\mathsf{StreamName}^{\uparrow}$ observation window before any Real or Completion consumer reads it as a completed set of values. It sits after the finite stream-name surface of chapter 126, the regular rational readback route of chapter 301, the continuous-map interface of chapter 130, and the terminal real-name seal of chapter 38. The packet names only finite source rows, finite image rows, readback ledgers, classifier transport, replay, provenance, and local naming; it does not select a limit, form a host image set, quotient stream equality, or import ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 8948.1 (Finite image stream-window carrier)**.** *A* $\mathsf{FiniteImageStreamWindow}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$W = (S, J, F, I, Q, R, H, C, P, N)$$

with the following displayed rows:

1. *S is the* $\mathsf{StreamName}^{\uparrow}$ *source row whose inspected entries are named by the packet;*
2. *J is the finite window-index row, recording the displayed positions of S that are inspected;*
3. *F is the* $\mathsf{ContinuousMap}^{\uparrow}$ *or certified readback row applied to the inspected source entries;*
4. *I is the finite image ledger, listing the image endpoints obtained from the entries indexed by J;*
5. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the finite rational approximants attached to the image ledger;*
6. *R is the* $\mathsf{Real}^{\uparrow}$ *seal row visible only after the stream window and regular rational rows have been read;*
7. *H stores componentwise* hsame *transport for the source, index, map, image, readback, and seal rows;*
8. *C stores displayed* Cont *continuation from the finite source window through the image ledger and real seal;*
9. *P is the* Pkg *provenance over* $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* NameCert *rows;*
10. *N is the local* $\mathsf{NameCert}_{\mathsf{FiniteImageStreamWindow}^{\uparrow}}$ *row.*

The carrier has no coordinate for an infinite image set, a selected limiting image, a quotient of streams, or a completed compactness object.

Theorem 8948.2 (Finite image stream-window NameCert obligations)**.** *For the carrier of Definition 8948.1, the local* $\mathsf{NameCert}_{\mathsf{FiniteImageStreamWindow}^{\uparrow}}$ *surface consists exactly of carrier exposure for*

$$W = (S, J, F, I, Q, R, H, C, P, N),$$

finite source-window exposure through S *and* J*, certified map exposure through* F*, finite image ledger exposure through* I*, regular rational readback through* Q*, Real-facing seal visibility through* R*, componentwise* hsame *transport through* H*, displayed* Cont *replay through* C*, provenance through* P*, and local naming through* N*.*

Proof. Project the displayed carrier. The rows S, J, F, I expose the finite source window and its image before any rational readback or Real-facing seal is available.

The rows Q and R are read only as handoff rows. They do not create new image endpoints; they record the regular rational and Real-facing surfaces attached to the finite ledger already displayed by I.

Finally, H, C, P, N transport, replay, source, and name the same finite packet. Since no row contains an infinite image set or selected limit, the NameCert obligations are exactly the displayed finite rows. □

Theorem 8948.3 (Finite image stream-window classifier stability)**.** *If two accepted* $\mathsf{FiniteImageStreamWindow}^{\uparrow}$ *packets are related by the displayed classifier, then their source window rows, certified map rows, finite image ledgers, regular rational readbacks, Real-facing seals, transport rows, replay rows, provenance rows, and local names are matched componentwise. In particular, classifier transport cannot replace a finite image ledger by an ambient host image set.*

Proof. Read the classifier through the carrier rows of Definition 8948.1. A classified replacement must preserve the entries named by S and J, the applied readback row F, and the finite image ledger I.

The readback and seal rows Q and R are downstream of that same finite ledger, so they transport only with the displayed image entries. The structural rows H, C, P, N then repack the transported packet as another finite image window, not as a host image object. □

Theorem 8948.4 (Finite image stream-window RegSeqRat handoff)**.** *Every* $\mathsf{RegSeqRat}^{\uparrow}$ *consumer of a* $\mathsf{FiniteImageStreamWindow}^{\uparrow}$ *packet must first read the finite source window* S, J*, the certified map row* F*, and the finite image ledger* I*. The consumer may then read* Q *as the regular rational handoff for those displayed image entries, but it cannot infer a stream quotient or a selected limit from the handoff alone.*

Proof. The carrier places Q after the source window, certified map row, and finite image ledger. A regular rational consumer therefore receives Q only together with the displayed finite image rows that generated it.

Since Q records readback for the entries of I, it does not identify all future stream entries, select a convergent image, or quotient two streams. Those conclusions would require rows absent from the carrier. □

Theorem 8948.5 (Finite image stream-window Real seal nonescape)**.** *Every Real-facing read of an accepted* $\mathsf{FiniteImageStreamWindow}^{\uparrow}$ *packet factors through*

$$S, J, F, I, Q, R, H, C, P, N$$

before the $\mathsf{Real}^{\uparrow}$ *seal row is visible. The seal exports only the finite image-window readback already certified by the packet; it does not broaden the packet to ambient Real completeness or selected image limits.*

Proof. By Definition 8948.2, the Real-facing row R is part of one packet with the source window, image ledger, and regular rational readback rows.

A Real-facing consumer must therefore read S, J, F, I, Q before R can be interpreted. The classifier stability theorem prevents replacing I by a host image set during transport, so the seal remains attached to the displayed finite image window. □

Falsifiable prediction: An accepted $\mathsf{FiniteImageStreamWindow}^{\uparrow}$ packet is refuted by any Real or Completion consumer that reads the $\mathsf{Real}^{\uparrow}$ seal while skipping the displayed $\mathsf{StreamName}^{\uparrow}$ window, $\mathsf{RegSeqRat}^{\uparrow}$ readback, or finite image ledger.

Independence witness: streamname, regseqrat, continuousmap, real: StreamNameUp supplies source observations but not image ledgers; RegSeqRatUp supplies rational readback but not a finite image surface; ContinuousMapUp supplies certified map rows but not the inspected window; RealUp supplies a terminal seal without recording the finite source-to-image ledger. None is bijective to the full $\mathsf{FiniteImageStreamWindow}^{\uparrow}$ carrier under NameCert-row preservation.

The Lean follow-up file `lean4/BEDC/Derived/FiniteImageStreamWindowUp.lean` must provide the concrete carrier, the NameCert obligation theorem, classifier stability, the regular-rational handoff, and the Real-seal nonescape theorem without adding any host image-set primitive.

Closure status for $\mathsf{NameCert}_{\mathsf{FiniteImageStreamWindow}^{\uparrow}}$.

Constructive story: A $\mathsf{FiniteImageStreamWindow}^{\uparrow}$ packet is generated from a StreamName source row, a finite window-index row, a certified ContinuousMap or readback row, a finite image ledger, RegSeqRat readback, a terminal Real seal, componentwise transport, displayed continuation replay, package provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{FiniteImageStreamWindow}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8948.1, Definition 8948.2, Definition 8948.3, Definition 8948.4, and Definition 8948.5 seed the finite image-window carrier and its Real-facing handoff.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{FiniteImageStreamWindow}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host image sets, selected image limits, quotient stream equality, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, NameCert obligations, classifier stability, RegSeqRat handoff, Real-seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.FiniteImageStreamWindowUp.

Chapter 8949

A Concrete Naming Certificate for $\mathsf{MeasurementResidueLedger}^{\uparrow}$

The $\mathsf{MeasurementResidueLedger}^{\uparrow}$ packet realizes the measurement-residue grammar of section 9414.12 as finite NameCert data. It sits beside the quantum-state source of chapter 217, the observable readout surface of chapter 218, and the mixed-state ledger of chapter 220. Those siblings name state, observable, and density rows separately; this packet binds a source row, measurement-interface projection row, visible outcome, residual fiber, section-update certificate, and audit ledger into one finite boundary object.

Definition 8949.1 (Measurement residue ledger carrier)**.** *A* $\mathsf{MeasurementResidueLedger}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (T, M, P, O, F, U, A, H, C, G, N)$$

with the following displayed rows:

1. *T is the source row, such as a* $\mathsf{QuantumState}^{\uparrow}$ *or* $\mathsf{DensityMatrix}^{\uparrow}$ *input surface;*
2. *M is the measurement-context row, recording preparation, observable or probe family, instrument data, and public ledger scope;*
3. *P is the* MeasurementInterface *projection row from the source surface to the outcome carrier;*
4. *O is the visible outcome row produced by the projection;*
5. *F is the residual-fiber row, recording the source distinctions not separated by the chosen interface;*
6. *U is the section-update certificate row, recording when a post-outcome section into the residual fiber is licensed;*
7. *A is the audit ledger, recording replay, acceptance, refusal, and public-export boundaries;*
8. *H stores componentwise* hsame *transport for the source, context, projection, outcome, residue, update, and audit rows;*
9. *C stores displayed* Cont *continuation through the measurement projection, residual fiber, and section-update rows;*
10. *G is the* Pkg *provenance over* $\mathsf{QuantumState}^{\uparrow}$, $\mathsf{Observable}^{\uparrow}$, $\mathsf{DensityMatrix}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* NameCert *rows;*

11. *N is the local* $\mathsf{NameCert}_{\mathsf{MeasurementResidueLedger}^{\uparrow}}$ *row.*

The carrier has no coordinate for a hidden classical assignment, a global common refinement of all measurements, a Born-weight law, or an unlicensed collapse operation.

Theorem 8949.2 (Measurement residue ledger NameCert obligations)**.** *For the carrier of Definition 8949.1, the local* $\mathsf{NameCert}_{\mathsf{MeasurementResidueLedger}^{\uparrow}}$ *surface consists exactly of carrier exposure for*

$$L = (T, M, P, O, F, U, A, H, C, G, N),$$

source exposure through T, measurement-context exposure through M, interface projection through P, visible outcome exposure through O, residual-fiber exposure through F, section-update certification through U, audit-ledger exposure through A, componentwise hsame *transport through H, displayed* Cont *replay through C, provenance through G, and local naming through N.*

Proof. Project the finite packet. The rows T, M, P, O expose the source, measurement context, projection, and visible outcome before the residue or section rows are interpreted.

The residual row F records source distinctions retained by that chosen interface, while U records only licensed section-style updates into the displayed residual fiber. The audit row A records replay and refusal boundaries for that same packet.

The structural rows H, C, G, N transport, replay, source, and name the displayed ledger. Since no row supplies a hidden classical assignment or global common refinement, the NameCert obligations are exactly the listed finite rows. □

Theorem 8949.3 (Measurement residue ledger interface projection)**.** *Every public outcome exported by an accepted* $\mathsf{MeasurementResidueLedger}^{\uparrow}$ *packet factors through the displayed* MeasurementInterface *projection row P. A ledger row that carries a visible outcome O without the matching source row T, context row M, and projection row P is not an accepted public outcome ledger for this packet.*

Proof. The carrier places O after the source, context, and projection rows. Therefore a public read of O must preserve the source row T, the measurement context M, and the interface projection P.

If an alleged ledger row keeps O while dropping P, it no longer displays the map from the source surface to the outcome carrier. The NameCert obligations then fail at the projection row, so the row cannot export a public outcome ledger as $\mathsf{MeasurementResidueLedger}^{\uparrow}$. □

Theorem 8949.4 (Measurement residue ledger non-hidden-variable boundary)**.** *The residual-fiber row F of an accepted* $\mathsf{MeasurementResidueLedger}^{\uparrow}$ *packet is not a hidden-variable assignment. It records exactly the source distinctions not separated by the displayed projection row P, and it cannot be read as a simultaneous visible outcome for measurement contexts not displayed by M.*

Proof. Read F together with T, M, P, O. The fiber is attached to one source surface, one measurement context, one projection row, and one visible outcome.

A hidden-variable assignment would have to provide visible outcomes across contexts not named by M or a common classicalizing refinement not present in the carrier. Since neither row exists in L, the residual fiber remains a ledger of unseparated source structure for the chosen projection only. □

Theorem 8949.5 (Measurement residue ledger section-update handoff)**.** *Every section-style update exported by an accepted* $\mathsf{MeasurementResidueLedger}^{\uparrow}$ *packet must read the visible outcome O, the residual-fiber row F, the section-update certificate U, and the audit ledger A. Without those rows, a post-outcome state selection is not licensed by this NameCert packet.*

Proof. The section row U is displayed only after the source, context, projection, outcome, and residual-fiber rows have been fixed. It therefore licenses a section into the residual fiber of the accepted outcome rather than a primitive state change.

The audit row A records replay and public-export boundaries for that section. If O, F, U, A are not all present, the packet lacks either the outcome, the target fiber, the section license, or the audit replay needed for the handoff. □

Falsifiable prediction: An accepted $\mathsf{MeasurementResidueLedger}^{\uparrow}$ row without a matching $\mathsf{MeasurementInterface}$ projection row cannot export a public outcome ledger.

Independence witness: quantumstate, observable, densitymatrix, quantumchannel: QuantumStateUp supplies source-state rows without measurement residue sections; ObservableUp supplies readout operators without residual-fiber ledgers; DensityMatrixUp supplies mixed-state trace ledgers without projection-specific residue rows; QuantumChannelUp supplies state-transform rows without the measurement-interface projection and section-update certificate. The non-bijection is witnessed by the missing residue-section rows.

The Lean follow-up file `lean4/BEDC/Derived/MeasurementResidueLedgerUp.lean` must provide explicit $\mathsf{Nontrivial}\ \mathsf{MeasurementResidueLedger}^{\uparrow}$ and $\mathsf{FieldFaithful}\ \mathsf{MeasurementResidueLedger}^{\uparrow}$ instances, together with the projection, non-hidden-variable boundary, and section-update handoff theorems.

Closure status for $\mathsf{NameCert}_{\mathsf{MeasurementResidueLedger}^{\uparrow}}$.

Constructive story: A $\mathsf{MeasurementResidueLedger}^{\uparrow}$ packet is generated from a quantum source row, a measurement-context row, a MeasurementInterface projection row, a visible outcome row, a residual-fiber row, a section-update certificate, an audit ledger, componentwise transport, displayed continuation replay, package provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{MeasurementResidueLedger}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8949.1, Definition 8949.2, Definition 8949.3, Definition 8949.4, and Definition 8949.5 seed the finite measurement-residue ledger and its projection, residue, section-update, and audit boundaries.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{MeasurementResidueLedger}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close the Born rule, Hilbert-space dynamics, hidden-variable assignments, global common refinements, unlicensed collapse operations, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, NameCert obligations, projection exactness, non-hidden-variable boundary, section-update handoff, transport, replay, provenance, and local naming for BEDC.Derived.MeasurementResidue

Chapter 8950

A Concrete Naming Certificate for $\mathsf{CompactCauchyRealizer}^{\uparrow}$

Following Bishop–Bridges constructive compact metric spaces, the $\mathsf{CompactCauchyRealizer}^{\uparrow}$ packet records the finite route by which compact finite-net data and displayed Cauchy windows are realized as a completion-facing regular rational name before any terminal Real seal is read. It sits after the compact metric finite-net surface of chapter 129, the completion-filter route of chapter 8944, the compact Cauchy filter packet of chapter 8097, the compact Cauchy net packet of chapter 7735, the dyadic tolerance ledger of chapter 291, the finite $\mathsf{StreamName}^{\uparrow}$ windows, the $\mathsf{RegSeqRat}^{\uparrow}$ readback, and the terminal $\mathsf{Real}^{\uparrow}$ seal. The packet realizes only displayed compact-net and Cauchy-window data; it does not quotient streams, select limits, invoke countable choice, or assert ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 8950.1 (Compact Cauchy realizer carrier)**.** *A* $\mathsf{CompactCauchyRealizer}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Z = (K, Q, M, W, D, S, R, E, H, C, P, N)$$

with the following displayed rows:

1. *K is the accepted* $\mathsf{CompactMetric}^{\uparrow}$ *finite-net source row.*
2. *Q is the compact Cauchy row, read through the* $\mathsf{CompactCauchyFilter}^{\uparrow}$ *or* $\mathsf{CompactCauchyNet}^{\uparrow}$ *sibling surface.*
3. *M is the* $\mathsf{MetricCompletionFilter}^{\uparrow}$ *completion-filter row attached to the same compact source and Cauchy request.*
4. *W records the local Cauchy window whose compatibility is inspected before completion handoff.*
5. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row for mesh, Cauchy-window, and readback comparisons.*
6. *S is the finite* $\mathsf{StreamName}^{\uparrow}$ *request row used to inspect the displayed windows.*
7. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row produced from K, Q, M, W, D, S.*
8. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal exposed only after the regular readback row is displayed.*
9. *H records componentwise* hsame *transport for compact source, Cauchy row, completion-filter row, window, tolerance, StreamName, readback, seal, replay, provenance, and naming rows.*
10. *C records displayed* Cont *replay of the same compact Cauchy realization route.*

11. *P is the* Pkg *provenance over* $\mathsf{CompactCauchyRealizer}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{MetricCompletionFilter}^{\uparrow}$, $\mathsf{CompactCauchyFilter}^{\uparrow}$, $\mathsf{CompactCauchyNet}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

12. *N is the local* $\mathsf{NameCert}_{\mathsf{CompactCauchyRealizer}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through these displayed rows. It has no coordinate for quotient stream equality, selected Cauchy representatives, countable-choice schedules, open-cover compactness, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 8950.2 (Compact Cauchy realizer NameCert obligations)**.** *For every accepted* $\mathsf{CompactCauchyRealizer}^{\uparrow}$ *carrier*

$$Z = (K, Q, M, W, D, S, R, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{CompactCauchyRealizer}^{\uparrow}}$ *surface consists exactly of compact finite-net admission, compact Cauchy row exposure, completion-filter routing through* $\mathsf{MetricCompletionFilter}^{\uparrow}$*, local Cauchy-window display, dyadic tolerance exposure, StreamName finite-window exposure, RegSeqRat readback, Real sealing, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming.*

Proof. Project the carrier of Definition 8950.1. The rows K, Q, M, W, D, S, R, E are the only analytic rows, and H, C, P, N are the only structural rows.

Read compactness through the sibling finite-net data. The compact metric row K and compact Cauchy row Q keep the source finite, while the completion-filter row M routes the Cauchy request through chapter 8944.

The local window, tolerance, StreamName, and RegSeqRat rows then produce the displayed readback. The terminal seal E is downstream of that readback, and the structural rows transport, replay, source, and name the same route.

Since the carrier has no additional coordinate, quotient streams, selected limits, countable-choice schedules, open-cover compactness, and ambient Real completeness are not obligations of the local certificate. □

Theorem 8950.3 (Compact Cauchy realizer completion handoff)**.** *Every completion-facing consumer of an accepted* $\mathsf{CompactCauchyRealizer}^{\uparrow}$ *carrier must pass through the compact finite-net row K, compact Cauchy row Q,* $\mathsf{MetricCompletionFilter}^{\uparrow}$ *row M, local Cauchy window W,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row D, finite* $\mathsf{StreamName}^{\uparrow}$ *row S, and* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row R before the* $\mathsf{Real}^{\uparrow}$ *seal E is available. The handoff realizes compact Cauchy data as a displayed regular rational route, not as a quotient stream, selected limit, countable-choice schedule, or ambient completeness theorem.*

Proof. Apply the NameCert obligations of Definition 8950.2. They expose the compact finite-net, compact Cauchy, completion-filter, local window, tolerance, StreamName, RegSeqRat, and Real-seal rows in the carrier order.

Use the completion-filter dependency of chapter 8944. The row M forces the completion read to remain a finite filter-facing route before any Real-facing consumer may inspect the seal.

The dyadic tolerance, StreamName, and RegSeqRat rows then convert the displayed windows into a regular rational readback. The terminal Real seal is therefore reached only after K, Q, M, W, D, S, R have been displayed and transported through H, C, P, N. □

Theorem 8950.4 (Compact Cauchy realizer L10 scope)**.** *The* $\mathsf{CompactCauchyRealizer}^{\uparrow}$ *packet supplies an L10 Real-and-Completion scope consisting of compact finite-net data, compact Cauchy rows, completion-filter routing, dyadic tolerance rows, finite StreamName windows, RegSeqRat*

readback, Real sealing, transport, replay, provenance, and local naming. It may feed completion, density-net, or compact-realization consumers, but it does not close quotient stream equality, selected representatives, countable choice, open-cover compactness, ambient $\mathsf{Real}^{\uparrow}$ *completeness, Lean verification, or bridge checking.*

Proof. Start with the carrier and obligation surface, Definition 8950.1 and Definition 8950.2. They bind the visible L10 rows to $K, Q, M, W, D, S, R, E, H, C, P, N$.

Apply the completion handoff of Definition 8950.3. Any completion-facing read must traverse the compact finite-net row, compact Cauchy row, completion-filter row, dyadic tolerance row, StreamName row, and RegSeqRat row before the Real seal.

Finally compare with the sibling compact Cauchy and density-net routes of chapter 8097, chapter 7735, and chapter 6003. Those consumers may read the displayed packet as L10 completion data, but none of them adds the excluded quotient, choice, open-cover, ambient-completeness, Lean-verification, or bridge rows. □

Closure status for $\mathsf{NameCert}_{\mathsf{CompactCauchyRealizer}\uparrow}$.

Constructive story: A $\mathsf{CompactCauchyRealizer}^{\uparrow}$ packet is generated from compact finite-net rows, compact Cauchy rows, MetricCompletionFilter rows, local Cauchy windows, DyadicRatCore tolerance data, StreamName windows, RegSeqRat readback, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CompactCauchyRealizer}\uparrow}, \mathsf{seed})$

Scope closed: Definition 8950.1, Definition 8950.2, Definition 8950.3, and Definition 8950.4 seed the compact finite-net Cauchy realization route for L10 Real-and-Completion consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CompactCauchyRealizer}\uparrow}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient stream equality, selected representatives, countable choice, open-cover compactness, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, compact finite-net exposure, compact Cauchy routing, completion-filter handoff, dyadic tolerance exactness, StreamName coverage, RegSeqRat readback, Real-seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.CompactCauchyRealizerUp.

Chapter 8951

A Concrete Naming Certificate for $\mathsf{CauchyTailTriangle}^{\uparrow}$

Following Bishop and Bridges' use of explicit Cauchy tail estimates, the $\mathsf{CauchyTailTriangle}^{\uparrow}$ packet records a finite triangle ledger for composing two tail-diameter controls into a third. It consumes the tail-diameter surface of chapter 1746, the regular-tail composition route of chapter 1747, the finite observation schedule of chapter 126, the regular rational readback of chapter 301, the dyadic tolerance core of chapter 291, and the terminal real seal of chapter 38. The packet is a NameCert for displayed tail-diameter composition; it is not ambient metric completeness, quotient equality of real names, a selected limit, countable choice, or a host triangle theorem outside the finite ledger.

Definition 8951.1 (CauchyTailTriangle carrier)**.** *A* $\mathsf{CauchyTailTriangle}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Q = (A, B, C, T_{AB}, T_{BC}, T_{AC}, D, W, R, E, H, K, P, N)$$

with the following displayed rows:

1. *A, B, C are the three tail-name rows whose finite windows are read through the accepted* $\mathsf{StreamName}^{\uparrow}$ *and* $\mathsf{RegSeqRat}^{\uparrow}$ *surfaces.*
2. *T_{AB} is the* $\mathsf{CauchyTailDiameter}^{\uparrow}$ *row bounding the tail distance from A to B after the displayed threshold.*
3. *T_{BC} is the* $\mathsf{CauchyTailDiameter}^{\uparrow}$ *row bounding the tail distance from B to C after the displayed threshold.*
4. *T_{AC} is the target tail-diameter row for the composed A to C comparison.*
5. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger that stores the two input tolerances, their displayed sum, and the target tolerance budget.*
6. *W is the common finite tail window on which the three names and all three tail-diameter rows are simultaneously readable.*
7. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the rational bounds extracted from D and W.*
8. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal available only after the dyadic and regular-rational rows have been displayed.*
9. *H stores componentwise* hsame *transport for the three names, three tail-diameter rows, tolerance ledger, common window, regular readback, real seal, provenance, and naming row.*

10. *K stores the displayed* Cont *replay routes for projecting either input tail-diameter witness and for feeding them through the* $\mathsf{RegularCauchyTailComposition}^{\uparrow}$ *row.*
11. *P is the* Pkg *provenance over* $\mathsf{CauchyTailTriangle}^{\uparrow}$, $\mathsf{CauchyTailDiameter}^{\uparrow}$, $\mathsf{RegularCauchyTailComposition}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*
12. *N is the local* $\mathsf{NameCert}_{\mathsf{CauchyTailTriangle}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $A, B, C, T_{AB}, T_{BC}, T_{AC}, D, W, R, E, H, K, P, N$. It exports no ambient metric space, completed limit, quotient real equality, chosen modulus, countable choice, or host triangle inequality.

Theorem 8951.2 (CauchyTailTriangle NameCert obligations)**.** *For every accepted* $\mathsf{CauchyTailTriangle}^{\uparrow}$ *carrier*

$$Q = (A, B, C, T_{AB}, T_{BC}, T_{AC}, D, W, R, E, H, K, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{CauchyTailTriangle}^{\uparrow}}$ *surface consists of carrier admission for the three tail-name rows, projection of the two input* $\mathsf{CauchyTailDiameter}^{\uparrow}$ *witnesses, display of the composed T_{AC} row, dyadic tolerance accounting through D, common-window readability through W, regular-rational readback through R, terminal real sealing through E, componentwise transport through H, continuation replay through K, package provenance through P, and local naming through N.*

Proof. Carrier admission is the tuple of Definition 8951.1. The rows A, B, C bind the three names, while T_{AB}, T_{BC}, T_{AC} bind the two input diameter witnesses and the target diameter row.

The tolerance and window obligations are the rows D, W, R, E. The dyadic row D stores the two input budgets and their displayed sum, the window W is the common tail domain where all three estimates are visible, and the rows R, E route the regular rational readback into the terminal real seal.

The structural obligations are H, K, P, N. Transport preserves each displayed coordinate, K replays the two projections and the tail-composition row, and provenance plus naming repack the same finite packet. Since no excluded host object is a coordinate, these rows exhaust the local NameCert surface. □

Theorem 8951.3 (CauchyTailTriangle composition)**.** *Every accepted* $\mathsf{CauchyTailTriangle}^{\uparrow}$ *packet exposes a finite composition route*

$$T_{AB}, T_{BC}, D, W, R, E, K \longrightarrow T_{AC}.$$

The route first projects the two tail-diameter witnesses, then reads the shared dyadic budget and common tail window, and only then feeds the two witnesses through the displayed $\mathsf{RegularCauchyTailComposition}^{\uparrow}$ *row to expose the A to C tail-diameter witness.*

Proof. Project the rows T_{AB} and T_{BC} from the carrier. These are the only two input tail-diameter witnesses available to the packet.

Next read the shared ledger. The rows D and W display the finite tolerance addition and the common window on which both input estimates and the target estimate are readable; R and E keep the readback within regular-rational and real-seal rows.

Finally use K. Its continuation replay row is precisely the route from the two projected witnesses through $\mathsf{RegularCauchyTailComposition}^{\uparrow}$ to the displayed target row T_{AC}, so the composition remains inside the finite packet. □

Theorem 8951.4 (CauchyTailTriangle RegSeqRat handoff)**.** *Any* $\mathsf{RegSeqRat}^{\uparrow}$ *or* $\mathsf{Real}^{\uparrow}$ *consumer of a* $\mathsf{CauchyTailTriangle}^{\uparrow}$ *packet must pass through*

$$D, W, R, E$$

after the two input tail-diameter rows have been displayed. Thus the triangle ledger hands rational tail bounds to completion-facing consumers through the existing regular-rational and real-name surfaces, not through an untracked ambient completeness principle.

Proof. Begin with a consumer request for a rational or real bound. The carrier gives no direct bound coordinate except the dyadic ledger D, the common tail window W, the regular-rational readback R, and the terminal seal E.

The two input diameter rows must already be visible, because D records the displayed sum of their budgets and W is the common window on which those estimates are read.

Once R and E are consumed, the downstream route has only the accepted $\mathsf{RegSeqRat}^{\uparrow}$ and $\mathsf{Real}^{\uparrow}$ surfaces. No selected limit, quotient real equality, or ambient completion theorem is introduced by the handoff. □

Theorem 8951.5 (CauchyTailTriangle non-escape)**.** *The public information exported by a* $\mathsf{CauchyTailTriangle}^{\uparrow}$ *carrier is exactly the displayed packet*

$$A, B, C, T_{AB}, T_{BC}, T_{AC}, D, W, R, E, H, K, P, N.$$

In particular, a consumer cannot extract ambient metric completeness, a chosen limit, quotient equality of real names, countable choice, or a host triangle inequality from the certificate.

Proof. Read the carrier coordinates. The three tail-name rows, the three tail-diameter rows, and the dyadic, window, regular-rational, and real-seal rows are all explicitly listed in Definition 8951.1.

The structural rows do not add new mathematical objects. The transport row H preserves displayed coordinates, the continuation row K replays only the two projections and the regular-tail composition route, and P, N provide provenance and local naming for the same packet.

Therefore every public read factors through the displayed rows. None of the excluded host objects is present as a coordinate or produced by the replay route. □

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyTailTriangle}^{\uparrow}}$**.**

Constructive story: A $\mathsf{CauchyTailTriangle}^{\uparrow}$ packet is generated from three tail-name rows, two input tail-diameter witnesses, a target tail-diameter row, dyadic tolerance accounting, a common finite window, regular-rational readback, a terminal RealUp seal, componentwise hsame transport, continuation replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CauchyTailTriangle}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8951.1, Definition 8951.2, Definition 8951.3, Definition 8951.4, and Definition 8951.5 seed the finite triangle ledger for composing Cauchy tail-diameter rows through dyadic, regular-rational, and real-seal handoffs.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CauchyTailTriangle}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close Lean verification, bridge checking, ambient metric completeness, selected limits, quotient real equality, countable choice, or a host triangle inequality.

Upgrade path: Obligation closure requires checked carrier admission, projection of both input tail-diameter rows, target tail-diameter exposure, dyadic tolerance accounting, common-window readability, regular-rational handoff, real sealing, transport, continuation replay, provenance, local naming, and ledger non-escape for BEDC.Derived.CauchyTailTriangleUp.

Chapter 8952

A Concrete Naming Certificate for $\mathsf{AbelIdentity}^{\uparrow}$

Following Coddington–Levinson and the Sturm–Liouville tradition, the $\mathsf{AbelIdentity}^{\uparrow}$ packet records the finite boundary at which the Wronskian route may read an Abel identity without importing a host ODE theorem. It sits beside the Wronskian certificate of chapter 6877, the derivative rows of chapter 122, the regular rational readback of chapter 301, the dyadic tolerance arithmetic of chapter 291, and the terminal real-name seal of chapter 38. The packet names the coefficient, derivative-admission, Wronskian, and integrating-factor ledgers as BEDC rows; it does not identify them with host solutions of a differential equation.

Definition 8952.1 (AbelIdentity carrier)**.** *An* $\mathsf{AbelIdentity}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$A = (Q, D, W, I, S, R, E, H, C, P, N)$$

with the following displayed rows:

1. *Q is the coefficient row for the displayed first-order trace term in the Abel identity route;*
2. *D is the* $\mathsf{Derivative}^{\uparrow}$ *derivative-admission row for the coefficient and Wronskian reads;*
3. *W is the* $\mathsf{Wronskian}^{\uparrow}$ *row supplied by the sibling packet of chapter 6877;*
4. *I is the integrating-factor ledger, including the exponential readback route used to compare adjacent Wronskian windows;*
5. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row for the inspected coefficient and Wronskian requests;*
6. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for coefficient, integral-ledger, and Wronskian values;*
7. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal for the displayed Abel-identity readback;*
8. *H records componentwise* hsame *transport of coefficient, derivative, Wronskian, integrating-factor, window, readback, and seal rows;*
9. *C records displayed* Cont *replay from coefficient requests through derivative admission, Wronskian rows, integrating-factor ledger, StreamName windows, RegSeqRat readback, and the Real seal;*
10. *P is the* Pkg *provenance over* $\mathsf{AbelIdentity}^{\uparrow}$, $\mathsf{Wronskian}^{\uparrow}$, $\mathsf{Derivative}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$ *rows;*

11. *N is the local* $\mathsf{NameCert}_{\mathsf{AbelIdentity}^\uparrow}$ *row.*

The classifier compares accepted carriers only through these finite rows. It has no coordinate for host ODE equality, selected fundamental systems, classical exponential uniqueness, quotient real equality, countable choice, or ambient completeness.

Lean4 ✓ `BEDC.Derived.AbelIdentityUp.TasteGate.AbelIdentityTasteGate single carrier alignment`

Theorem 8952.2 (AbelIdentity NameCert obligations)**.** *For every accepted* $\mathsf{AbelIdentity}^\uparrow$ *carrier*

$$A = (Q, D, W, I, S, R, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{AbelIdentity}^\uparrow}$ *surface consists exactly of coefficient exposure through Q, derivative admission through D, Wronskian exposure through W, integrating-factor and exponential-ledger exposure through I, finite-window exposure through S, regular rational readback through R, terminal real sealing through E, componentwise* hsame *transport through H, displayed* Cont *replay through C,* Pkg *provenance through P, and local naming through N.*

Proof. Project the carrier of Definition 8952.1. The coefficient row, derivative-admission row, Wronskian row, integrating-factor ledger, finite windows, readback row, and Real seal are visible before any structural transport or replay is read.

Read the dependency route in order. The coefficient row Q and derivative-admission row D supply the finite ODE-facing data, while W imports only the already displayed Wronskian packet surface from chapter 6877. The ledger I records the integrating-factor and exponential comparison as finite data, not as an ambient uniqueness theorem.

The value-facing route then passes through S, R, E. The $\mathsf{StreamName}^\uparrow$ row fixes inspected requests, $\mathsf{RegSeqRat}^\uparrow$ reads coefficient and Wronskian values with $\mathsf{DyadicRatCore}^\uparrow$ tolerance arithmetic, and $\mathsf{Real}^\uparrow$ seals only that displayed readback.

The rows H, C, P, N transport, replay, source, and name the same packet. Since the carrier has no coordinate for host ODE equality, selected bases, quotient Real equality, countable choice, or ambient completeness, the listed rows exhaust the local NameCert surface. □

Lean4 ✓ `BEDC.Derived.AbelIdentityUp.AbelIdentityCarrier namecert obligations`

Falsifiable prediction: An accepted Abel-identity read that uses host solution equality, a selected fundamental system, or an unledgered exponential uniqueness theorem refutes the $\mathsf{AbelIdentity}^\uparrow$ packet.

Independence witness: wronskian, derivative, continuousmap, streamname, regseqrat, dyadicratcore, real: $\mathsf{AbelIdentity}^\uparrow$ is not bijective to any listed sibling because it jointly carries coefficient rows, derivative admission, Wronskian rows, integrating-factor and exponential ledgers, rational readback, Real sealing, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{AbelIdentity}^\uparrow}$**.**

Constructive story: An $\mathsf{AbelIdentity}^\uparrow$ packet is generated from coefficient rows, derivative-admission rows, a Wronskian row, an integrating-factor and exponential ledger, finite StreamName requests, RegSeqRat readback, a RealUp seal, componentwise transport, continuation replay, package provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{AbelIdentity}^\uparrow}$, seed)

Scope closed: Definition 8952.1, Definition 8952.2, the falsifiable prediction, and the independence witness seed the Abel identity boundary packet for Wronskian and ODE-facing consumers.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{AbelIdentity}^\uparrow}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close host ODE equality, selected fundamental systems, classical exponential uniqueness, quotient real equality, countable choice, ambient $\mathsf{Real}^\uparrow$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, coefficient exposure, derivative-route admission, Wronskian handoff, integrating-factor ledger exactness, StreamName coverage, RegSeqRat readback, Real-seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.AbelIdentityUp.

Chapter 8953

A Concrete Naming Certificate for $\mathsf{FiberFarEndDigestBoundary}^{\uparrow}$

The $\mathsf{FiberFarEndDigestBoundary}^{\uparrow}$ packet realizes the hash-like apophatic fixed-point distinction of Definition 9402.13: the visible digest value is a local token, while the fiber far end is an apophatic boundary role behind the token. It sits beside the digest-fiber ledger of chapter 1067, the apophatic fixed-point packet of chapter 1068, the hash-apophatic seal of chapter 1079, and the hash digest-fiber boundary of chapter 1087. Its distinguishing role is narrower: it records the refusal boundary that prevents a consumer from identifying the visible digest value with the apophatic far end of the fiber.

Definition 8953.1 (FiberFarEndDigestBoundary carrier)**.** *A* $\mathsf{FiberFarEndDigestBoundary}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (D, F, T, G, R, H, C, P, N)$$

with the following displayed rows:

1. *D is the visible digest-value row;*
2. *F is the source-fiber row behind D;*
3. *T is the apophatic fiber far-end row, read as boundary role rather than digest value;*
4. *G is the* GAP *provenance row keeping the source side and far-end boundary auditable;*
5. *R is the refusal row blocking any accepted read from equating D with T;*
6. *H records componentwise* hsame *transport for digest, fiber, far-end, GAP, refusal, replay, provenance, and local naming rows;*
7. *C records displayed* Cont *replay through the same digest, fiber, far-end, GAP, and refusal route;*
8. *P is the* Pkg *provenance over* $\mathsf{FiberFarEndDigestBoundary}^{\uparrow}$, $\mathsf{DigestFiberLedger}^{\uparrow}$, $\mathsf{ApophaticFixedPoint}^{\uparrow}$, $\mathsf{HashApophaticSeal}^{\uparrow}$, $\mathsf{HashDigestFiberBoundary}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$ *rows;*
9. *N is the local* $\mathsf{NameCert}_{\mathsf{FiberFarEndDigestBoundary}^{\uparrow}}$ *row.*

The carrier has no coordinate for a global universe digest, source equality from digest equality, selected preimage, internal T *object, or quotient collapse of fiber membership.*

Theorem 8953.2 (FiberFarEndDigestBoundary NameCert obligations)**.** *For every accepted* FiberFarEndDigestBou *carrier*

$$B = (D, F, T, G, R, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{FiberFarEndDigestBoundary}^{\uparrow}}$ *surface consists exactly of visible digest exposure through* D*, source-fiber exposure through* F*, apophatic far-end boundary exposure through* T*, GAP provenance through* G*, digest/far-end equality refusal through* R*, componentwise* hsame *transport through* H*, displayed* Cont *replay through* C*,* Pkg *provenance through* P*, and local naming through* N*.*

Proof. Project the accepted carrier of Definition 8953.1. The visible row D and the source-fiber row F are distinct coordinates, and the far-end row T is exposed only as an apophatic boundary role.

Read the refusal route through G and R. The GAP provenance row keeps the fiber and far-end boundary attached to the digest, while the refusal row blocks the digest value from being read as the far-end identity.

The transport, replay, provenance, and local naming rows preserve the same boundary. Since no carrier coordinate stores source equality from digest equality, a selected preimage, an internal far-end object, a global digest, or quotient collapse, those readings are absent from the local NameCert surface. □

Theorem 8953.3 (Fiber far-end digest nonescape)**.** *Every accepted* $\mathsf{FiberFarEndDigestBoundary}^{\uparrow}$ *consumer that reads the visible digest row* D *must keep the source-fiber row* F*, apophatic far-end row* T*, GAP provenance row* G*, refusal row* R*, componentwise transport* H*, continuation replay* C*, package provenance* P*, and local naming* N *in the same packet. Therefore digest equality cannot be used as fiber far-end identity, source equality, selected preimage, internal* T *object, global universe digest, or quotient fiber collapse.*

Proof. Start from the obligation surface of Definition 8953.2. It makes $D, F, T, G, R, H, C, P, N$ the complete inventory for any accepted read.

The nonescape claim follows by inspecting that inventory. The digest row is only the visible value; the far-end row is only the apophatic boundary role; and the refusal row keeps those readings apart for every transported or replayed consumer.

No additional coordinate remains from which a consumer could construct source equality, a selected preimage, an internal far-end object, a global digest, or a quotient collapse. The packet therefore preserves the digest/fiber/far-end distinction of Definition 9402.13. □

Falsifiable prediction: Any accepted read equating the visible digest value with fiber far-end identity refutes the $\mathsf{FiberFarEndDigestBoundary}^{\uparrow}$ packet.

Independence witness: apophaticfixedpoint, apophaticfixedpointfiber, hashapophaticseal, gap, namecert: $\mathsf{FiberFarEndDigestBoundary}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries visible digest value, source fiber, apophatic far-end boundary, GAP provenance, digest/far-end refusal, transport, replay, provenance, and local naming.

The Lean TasteGate boundary is `lean4/BEDC/Derived/FiberFarEndDigestBoundaryUp/TasteGate.lean`. It must provide `Nontrivial FiberFarEndDigestBoundaryUp` and `FieldFaithful FiberFarEndDigestBoundaryU` for the displayed digest, fiber, far-end, GAP, refusal, transport, replay, provenance, and naming carrier.

Closure status for $\mathsf{NameCert}_{\mathsf{FiberFarEndDigestBoundary}^{\uparrow}}$**.**

Constructive story: A $\mathsf{FiberFarEndDigestBoundary}^{\uparrow}$ packet is generated from a visible digest value, source-fiber row, apophatic far-end boundary row, GAP provenance, digest/far-end refusal, componentwise transport, displayed replay, package provenance, and local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{FiberFarEndDigestBoundary}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8953.1, Definition 8953.2, Definition 8953.3, the falsifiable prediction, the independence witness, and the TasteGate boundary line seed the visible-digest versus fiber-far-end distinction.

Formal verification: FormalStatus(NameCert$_{\text{FiberFarEndDigestBoundary}\uparrow}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close source equality from digest equality, selected preimages, internal far-end objects, global universe digests, quotient fiber collapse, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, digest exposure, fiber exposure, apophatic far-end boundary exposure, GAP provenance, digest/far-end refusal, transport, replay, provenance, local naming, and TasteGate instances for BEDC.Derived.FiberFarEndDigestBoundaryUp.

Chapter 8954

A Concrete Naming Certificate for $\mathsf{GromovProduct}^{\uparrow}$

Following Gromov, the $\mathsf{GromovProduct}^{\uparrow}$ packet records the basepointed metric comparison row

$$(x, y)_b$$

as finite BEDC NameCert data. It sits beside the metric source of chapter 57, the real-distance seal of chapter 38, the dyadic bound carrier of chapter 1562, the hyperbolic consumer of chapter 6073, and the branch-comparison route of chapter 7303. The packet names only displayed distance reads, basepoint membership, dyadic comparison budgets, transport, replay, provenance, and local naming; it is not an ambient completion, selected geodesic, quotient boundary, or host hyperbolic space.

Definition 8954.1 (Gromov product carrier)**.** *A* $\mathsf{GromovProduct}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$G = (M, b, x, y, D, T, H, C, P, N)$$

with the following displayed rows:

1. *M is the* $\mathsf{Met}^{\uparrow}$ *source row, exposing the distance observations available to the packet.*
2. *b, x, y are the displayed basepoint and endpoint rows over the same metric source.*
3. *D is the* $\mathsf{Real}^{\uparrow}$ *distance-readback row for $d(x, b)$, $d(y, b)$, and $d(x, y)$.*
4. *T is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *comparison-budget row, recording the finite tolerances used to read the half-sum expression and any downstream inequality window.*
5. *H records componentwise* hsame *transport for the metric source, point rows, distance reads, dyadic budgets, replay, provenance, and local naming.*
6. *C records displayed* Cont *replay from metric admission through the three distance reads and the dyadic comparison row.*
7. *P is the* Pkg *provenance over* $\mathsf{GromovProduct}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$ *rows.*
8. *N is the local* $\mathsf{NameCert}_{\mathsf{GromovProduct}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $M, b, x, y, D, T, H, C, P, N$. It has no coordinate for ambient completeness, selected geodesics, quotient boundary points, host hyperbolicity, or external Real equality.

Theorem 8954.2 (Gromov product NameCert obligations)**.** *For every accepted* $\mathsf{GromovProduct}^{\uparrow}$ *carrier*

$$G = (M, b, x, y, D, T, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{GromovProduct}^{\uparrow}}$ *surface consists exactly of metric-source admission through* M*, basepoint and endpoint exposure through* b, x, y*,* $\mathsf{Real}^{\uparrow}$ *distance readback through* D*,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance exposure through* T*, componentwise* hsame *transport through* H*, displayed* Cont *replay through* C*,* Pkg *provenance through* P*, and local naming through* N*.*

Proof. Project the carrier of Definition 8954.1. The metric row M is the only source of distance observations, and the point rows b, x, y are displayed before any product comparison is read.

Read the distance and budget rows next. The row D exposes exactly the three $\mathsf{Real}^{\uparrow}$ distance reads needed for the basepointed comparison, and T records the finite dyadic tolerances used by downstream inequality consumers.

The structural rows H, C, P, N preserve the same finite packet. Since no row supplies ambient completeness, selected geodesics, quotient boundary points, host hyperbolicity, or external Real equality, the listed rows exhaust the local NameCert obligations. □

Theorem 8954.3 (Gromov product metric-completion handoff)**.** *Every* $\mathsf{HyperbolicGromovProduct}^{\uparrow}$*,* $\mathsf{RealTree}^{\uparrow}$*, or completion-facing consumer of an accepted* $\mathsf{GromovProduct}^{\uparrow}$ *packet receives only the finite route*

$$M, b, x, y, D, T, H, C, P, N.$$

The consumer may inspect displayed metric distances, basepointed comparison data, and dyadic tolerance rows, but it cannot read ambient completeness, selected geodesic representatives, quotient boundary equality, or a host hyperbolic structure from the packet.

Proof. Start with the NameCert obligations of Definition 8954.2. They force every read to pass through the metric source, the three point rows, the Real distance row, and the dyadic comparison row before structural replay is available.

The hyperbolic sibling in chapter 6073 may consume the displayed basepointed comparison as one row in a boundary-shadow packet. The real-tree sibling in chapter 7303 may consume the same distance comparison as a branch or tripod budget. A completion-facing consumer may carry the row forward only through the displayed metric and Real readbacks.

Transport, replay, provenance, and local naming remain attached to M, b, x, y, D, T. Thus the handoff is a metric-completion neighbour rather than a completed metric object, a chosen geodesic model, or a quotient-boundary construction. □

Falsifiable prediction: An accepted $\mathsf{GromovProduct}^{\uparrow}$ read is refuted whenever it uses a basepointed product without displaying the common $\mathsf{Met}^{\uparrow}$ source, the three point rows, the three $\mathsf{Real}^{\uparrow}$ distance reads, and the $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance row.

Independence witness: metric, real, dyadic-rat-core, hyperbolic-gromov-product, real-tree: no listed sibling is bijective to $\mathsf{GromovProduct}^{\uparrow}$ because this packet jointly binds the metric source, basepoint, endpoints, distance readbacks, dyadic comparison budget, transport, replay, provenance, and local naming rows.

Closure status for $\mathsf{NameCert}_{\mathsf{GromovProduct}^{\uparrow}}$**.**

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{GromovProduct}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8954.1, Definition 8954.2, and Definition 8954.3 seed the basepointed metric product packet over displayed metric, point, Real-distance, dyadic-tolerance, transport, replay, provenance, and local naming rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{GromovProduct}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close ambient completions, selected geodesics, quotient boundaries, host hyperbolic structures, external Real equality, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked metric-source admission, point exposure, Real distance readback, dyadic tolerance exposure, transport, replay, provenance, and local naming for BEDC.Derived.GromovProductUp.

Constructive story: A GromovProduct$^{\uparrow}$ packet is generated from a MetricUp source row, displayed basepoint and endpoint rows, RealUp distance readbacks, a DyadicRatCoreUp tolerance row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 8955

A Concrete Naming Certificate for $\mathsf{SolvableGroup}^{\uparrow}$

Following Rotman and Hall on finite group theory, the $\mathsf{SolvableGroup}^{\uparrow}$ packet records solvability by a finite normal derived-series certificate rather than by an ambient classification theorem. It sits over the $\mathsf{Group}^{\uparrow}$ carrier of chapter 41, the subgroup and normal-subgroup rows of chapter 80, the quotient rows of chapter 82, and the abelian quotient surface of chapter 42. The downstream consumers are the Galois obstruction in chapter 285 and the radical-tower interface in chapter 286.

Definition 8955.1 (Solvable group carrier)**.** *A* $\mathsf{SolvableGroup}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (G, D, Q, A, H, C, P, N)$$

with the following displayed rows:

1. *G is a* $\mathsf{Group}^{\uparrow}$ *source row: carrier, multiplication, unit, inverse, classifier, and local group NameCert data.*
2. *D is a finite derived-series row*

$$G = D_0 \rhd D_1 \rhd \cdots \rhd D_m = \{e\},$$

   where each D_{i+1} is the commutator subgroup row of D_i and each inclusion is recorded as a $\mathsf{NormalSubgroup}^{\uparrow}$ *witness over the same* $\mathsf{Group}^{\uparrow}$ *carrier.*
3. *Q lists the quotient-group rows D_i/D_{i+1} with their* $\mathsf{QuotientGroup}^{\uparrow}$ *source, classifier, transport, and ledger coordinates.*
4. *A lists the* $\mathsf{AbGroup}^{\uparrow}$ *witnesses showing that every quotient row D_i/D_{i+1} is abelian.*
5. *H records componentwise* hsame *transport for the group row, derived-series rows, normal-subgroup inclusions, quotient rows, and abelian quotient witnesses.*
6. *C records displayed* Cont *replay from the group source row through derived-series construction, normality checking, quotient formation, abelian quotient witnessing, and terminal trivial-subgroup exposure.*
7. *P is the* Pkg *provenance over* $\mathsf{SolvableGroup}^{\uparrow}$, $\mathsf{Group}^{\uparrow}$, $\mathsf{Subgroup}^{\uparrow}$, $\mathsf{NormalSubgroup}^{\uparrow}$, $\mathsf{QuotientGroup}^{\uparrow}$, $\mathsf{AbGroup}^{\uparrow}$, *derived-series rows,* BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
8. *N is the local* $\mathsf{NameCert}_{\mathsf{SolvableGroup}^{\uparrow}}$ *row.*

The classifier compares solvable-group packets only through G, D, Q, A, H, C, P, N. It has no coordinate for a classification of all finite groups, Galois correspondence, radical solvability, polynomial roots, or an unstored simplicity theorem.

Theorem 8955.2 (Solvable group NameCert obligations)**.** *For every* $\mathsf{SolvableGroup}^{\uparrow}$ *packet*

$$S = (G, D, Q, A, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{SolvableGroup}^{\uparrow}}$ *surface consists exactly of group-source exposure, finite derived-series display, normal-subgroup inclusion rows, quotient-group rows, abelian quotient witnesses, componentwise* hsame *transport,* Cont *replay,* Pkg *provenance, and local naming. A downstream BEDC consumer may cite solvability only through those finite rows, and may not replace them by a general classification of finite groups, a Galois correspondence theorem, radical-tower adequacy, or a polynomial solution claim.*

Proof. Project the coordinates of Definition 8955.1. The group row G, derived-series row D, quotient row list Q, and abelian witness list A are displayed coordinates of the same finite packet.

The certificate obligations are inherited rowwise. The $\mathsf{Group}^{\uparrow}$ source supplies the ambient group carrier; the $\mathsf{Subgroup}^{\uparrow}$ and $\mathsf{NormalSubgroup}^{\uparrow}$ rows expose the series inclusions; the $\mathsf{QuotientGroup}^{\uparrow}$ rows expose each quotient; and the $\mathsf{AbGroup}^{\uparrow}$ rows witness the abelian quotient condition.

Transport, replay, provenance, and naming are supplied by H, C, P, N. Since no coordinate stores a finite-group classification, a Galois correspondence, radical-tower adequacy, or a polynomial solution claim, the local NameCert obligations stop at the displayed solvable-group packet. □

Theorem 8955.3 (Solvable group derived-series handoff)**.** *The derived-series row D of a* $\mathsf{SolvableGroup}^{\uparrow}$ *packet supplies the exact finite handoff needed by* $\mathsf{AbelRuffini}^{\uparrow}$ *and* $\mathsf{SolvableRadicals}^{\uparrow}$*: it exposes a normal series, the quotient rows D_i/D_{i+1}, abelian quotient witnesses, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local* NameCert *evidence. The handoff does not assert that a Galois group has been computed, that a radical tower exists, or that a polynomial is solvable by radicals.*

Proof. Read the finite series from D and the quotient list from Q. For each adjacent pair, the packet records normality of D_{i+1} in D_i and a quotient row D_i/D_{i+1}.

Read the abelian witness list A. These rows are the only solvability witnesses exported by the packet: they say that the displayed quotients are abelian in the sense of the local $\mathsf{AbGroup}^{\uparrow}$ surface.

The handoff to $\mathsf{AbelRuffini}^{\uparrow}$ and $\mathsf{SolvableRadicals}^{\uparrow}$ is therefore a finite carrier route, not a semantic theorem about polynomials or field towers. The transport, replay, provenance, and naming rows H, C, P, N keep the downstream read confined to the displayed derived-series data. □

Closure status for $\mathsf{NameCert}_{\mathsf{SolvableGroup}^{\uparrow}}$**.**

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{SolvableGroup}^{\uparrow}}$, obligation)

Scope closed: Definition 8955.1, Definition 8955.2, and Definition 8955.3 bind the finite derived-series carrier, normal quotient rows, abelian quotient witnesses, transport, replay, provenance, and local naming surface for solvable groups.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{SolvableGroup}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close a classification of finite groups, Galois correspondence, radical-tower adequacy, polynomial root extraction, or Lean verification.

Upgrade path: Formal closure requires carrier admission, quotient-row exactness, abelian quotient witness replay, and downstream handoff proofs for BEDC.Derived.SolvableGroupUp.

Constructive story: A $\mathsf{SolvableGroup}^{\uparrow}$ packet is generated from a $\mathsf{Group}^{\uparrow}$ source row, a finite normal derived series, quotient rows, abelian quotient witnesses, componentwise transport, continuation replay, package provenance, and a local NameCert row.

Chapter 8956

A Concrete Naming Certificate for $\mathsf{CauchyCompletionComparisonFunctor}^{\uparrow}$

Following Mac Lane on comparison functors and Bishop–Bridges/Kelley on constructive completion, the $\mathsf{CauchyCompletionComparisonFunctor}^{\uparrow}$ packet records the finite BEDC route from the Kleisli presentation of Cauchy completion to the Eilenberg–Moore algebra presentation. It sits after the completion monad of chapter 378, the Kleisli category of chapter 3826, the Eilenberg–Moore category of chapter 7845, the categorical source rows of chapter 61, chapter 62, and chapter 63, and the L10 completion readback route of chapter 126, chapter 301, chapter 291, and chapter 38. The packet compares the two category-level completion interfaces through displayed finite rows; it is not a quotient completion, a selected representative construction, host equality of completed objects, choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 8956.1 (Cauchy completion comparison functor carrier)**.** *A* $\mathsf{CauchyCompletionComparisonFunctor}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$J = (M, K, E, B, F, A, T, L, H, C, P, N)$$

with the following displayed rows:

1. *M is the* $\mathsf{CauchyCompletionMonad}^{\uparrow}$ *row, exposing the unit, bind, finite windows, regular-rational readback, dyadic tolerance ledger, and terminal* $\mathsf{Real}^{\uparrow}$ *seal route.*
2. *K is the* $\mathsf{CauchyCompletionKleisliCategory}^{\uparrow}$ *source row, displaying completion objects, unit arrows, Kleisli arrows, bind composition, and its real-completion handoff.*
3. *E is the* $\mathsf{EilenbergMooreCategory}^{\uparrow}$ *target row, displaying algebra objects, structure maps, law rows, homomorphisms, and composition ledgers.*
4. *B is the base* $\mathsf{Cat}^{\uparrow}$ *row shared by the Kleisli source and the Eilenberg–Moore target.*
5. *F is the displayed* $\mathsf{Functor}^{\uparrow}$ *comparison row from K to E.*
6. *A is the* $\mathsf{NatTrans}^{\uparrow}$ *action row, recording the unit and multiplication compatibility of the comparison functor with the completion monad.*
7. *T is the L10 readback row through* $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$ *before any completion-facing consumer reads the comparison.*
8. *L is the comparison ledger, recording that objects, arrows, unit routes, bind routes, and algebra law routes are compared only through M, K, E, B, F, A, T.*

9. *H records componentwise* hsame *transport for monad, Kleisli, Eilenberg–Moore, base-category, functor, naturality, readback, ledger, replay, provenance, and local naming rows.*
10. *C records displayed* Cont *replay for each comparison read from the monad route through the source and target category rows.*
11. *P is the* Pkg *provenance over* $\mathsf{CauchyCompletionComparisonFunctor}^{\uparrow}$, $\mathsf{CauchyCompletionMonad}^{\uparrow}$, $\mathsf{CauchyCompletionKleisliCategory}^{\uparrow}$, $\mathsf{EilenbergMooreCategory}^{\uparrow}$, $\mathsf{Cat}^{\uparrow}$, $\mathsf{Functor}^{\uparrow}$, $\mathsf{NatTrans}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
12. *N is the local* $\mathsf{NameCert}_{\mathsf{CauchyCompletionComparisonFunctor}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $M, K, E, B, F, A, T, L, H, C, P, N$. It has no coordinate for quotient completion, host equality of completed objects, choice-selected representatives, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 8956.2 (Cauchy completion comparison functor NameCert obligations)**.** *For every accepted* $\mathsf{CauchyCompletionComparisonFunctor}^{\uparrow}$ *carrier*

$$J = (M, K, E, B, F, A, T, L, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{CauchyCompletionComparisonFunctor}^{\uparrow}}$ *surface consists exactly of carrier exposure, completion-monad exposure, Kleisli source exposure, Eilenberg–Moore target exposure, base-category exposure, comparison-functor exposure, naturality and monad-compatibility exposure, L10 readback exposure, comparison-ledger exposure, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming.*

Proof. Project the carrier of Definition 8956.1. The monad row M, the Kleisli row K, the Eilenberg–Moore row E, and the base row B are displayed before any comparison can be consumed.

The functor row F and naturality row A then record the comparison itself. They read the unit and bind schedules from M, the source composition route from K, and the algebra-law route from E.

The L10 readback row T keeps every completion-facing request on the displayed $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ route. The ledger L records that object, arrow, unit, bind, and algebra-law comparisons are all made through those visible rows.

Finally H, C, P, N transport, replay, source, and name the same packet. Since the carrier contains no quotient-completion, host-equality, representative-choice, or ambient-completeness coordinate, the listed rows exhaust the local NameCert obligations. □

Theorem 8956.3 (Cauchy completion comparison functor handoff)**.** *Every completion-facing consumer of an accepted* $\mathsf{CauchyCompletionComparisonFunctor}^{\uparrow}$ *packet receives the comparison functor only through the route*

$$\mathsf{CauchyCompletionMonad}^{\uparrow},\ \mathsf{CauchyCompletionKleisliCategory}^{\uparrow},\ \mathsf{EilenbergMooreCategory}^{\uparrow},\ \mathsf{Cat}^{\uparrow},\ \mathsf{Functor}^{\uparrow},\ \mathsf{NatTrans}^{\uparrow}$$

The consumer may inspect the displayed unit, bind, Kleisli composition, algebra structure, functorial action, and naturality rows, but it cannot read a quotient completion, host equality, choice-selected representative, or ambient $\mathsf{Real}^{\uparrow}$ *completeness theorem from the packet.*

Proof. Begin with the completion monad row M. It supplies the unit and bind schedules together with finite stream windows, regular-rational readback, dyadic tolerance rows, and the terminal Real seal route.

Read the source and target category rows next. The Kleisli row K exposes objects, arrows, and bind composition, while the Eilenberg–Moore row E exposes algebra objects, structure maps, law rows, homomorphisms, and composition ledgers over the same base row B.

The comparison rows F and A are then available as displayed functor and naturality data. Their consumer route is recorded by L and must pass through the L10 readback row T before any Real-facing seal is consumed.

The structural rows H, C, P, N keep the handoff inside the displayed packet. Because the excluded objects are absent from the carrier inventory, no consumer can obtain them from the comparison functor route. □

Theorem 8956.4 (Cauchy completion comparison functor nonescape)**.** *No consumer of an accepted* $\mathsf{CauchyCompletionComparisonFunctor}^{\uparrow}$ *carrier may export quotient completion equality, host equality of completed objects, a choice-selected representative, an ambient* $\mathsf{Real}^{\uparrow}$ *completeness theorem, or an external comparison between the Kleisli and Eilenberg–Moore presentations. The consumer may export only the displayed comparison surface on* $M, K, E, B, F, A, T, L, H, C, P, N$ *and the local* $\mathsf{NameCert}_{\mathsf{CauchyCompletionComparisonFunctor}^{\uparrow}}$ *evidence attached to those rows.*

Proof. Inspect the carrier inventory in Definition 8956.1. The tuple contains only the completion monad, Kleisli source, Eilenberg–Moore target, base category, functor, naturality, L10 readback, comparison ledger, and structural naming rows.

Definition 8956.2 exhausts the local obligation surface. Every allowed read is tied to one of the displayed rows, and no excluded coordinate is introduced by the obligation theorem.

Definition 8956.3 fixes the completion-facing route through the monad, categorical, functorial, naturality, stream, regular-rational, dyadic, and Real rows. Hence any accepted export remains inside the finite comparison packet. □

Falsifiable prediction: An accepted $\mathsf{CauchyCompletionComparisonFunctor}^{\uparrow}$ read is refuted whenever it compares Kleisli and Eilenberg–Moore completion presentations without displaying the completion monad, both category rows, the comparison functor row, the naturality row, the L10 stream, regular-rational, dyadic, and Real readback rows, and the local transport, replay, provenance, and naming rows.

Independence witness: cauchycompletionmonad, cauchy-completion-kleisli-category, eilenberg-moore-category, category, functor, nattrans, streamname, regseqrat, dyadicratcore, real: none is bijective to $\mathsf{CauchyCompletionComparisonFunctor}^{\uparrow}$ because this packet jointly binds the completion monad, Kleisli source, Eilenberg–Moore target, base category, functor action, naturality, L10 readback, comparison ledger, transport, replay, provenance, and local naming rows.

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyCompletionComparisonFunctor}^{\uparrow}}$.

Constructive story: A $\mathsf{CauchyCompletionComparisonFunctor}^{\uparrow}$ packet is generated from a CauchyCompletionMonad row, a CauchyCompletionKleisliCategory source row, an EilenbergMooreCategory target row, a Category base row, Functor and NatTrans comparison rows, StreamName, RegSeqRat, DyadicRatCore, and Real readback rows, a comparison ledger, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CauchyCompletionComparisonFunctor}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8956.1, Definition 8956.2, Definition 8956.3, and Definition 8956.4 seed the finite L10 comparison-functor packet from the Kleisli completion presentation to the Eilenberg–Moore algebra presentation.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CauchyCompletionComparisonFunctor}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient completions, host equality of completed objects, choice-selected representatives, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, monad exposure, Kleisli source exposure, Eilenberg–Moore target exposure, functorial action, naturality, L10 readback, comparison-ledger exactness, transport stability, replay stability, provenance exhaustion, and non-escape for BEDC.Derived.CauchyCompletionComparisonFunctorUp.

Chapter 8957

A Concrete Naming Certificate for $\mathsf{CauchyTailSelectorFusion}^{\uparrow}$

Following Bishop and Bridges' diagonal selection practice for constructive Cauchy arguments, the $\mathsf{CauchyTailSelectorFusion}^{\uparrow}$ packet records the finite route by which a regular tail selector, a cofinal stream selector, and a tail-meet ledger are fused before a Real and Completion consumer reads a terminal seal. It sits over the regular tail-selection surface of $\mathsf{RegularCauchyTailSelector}^{\uparrow}$, the cofinal stream route of $\mathsf{CofinalStreamTailSelector}^{\uparrow}$, the finite meet row of chapter 560, the dyadic tolerance core of chapter 291, the finite stream-window interface of chapter 126, the regular rational readback of chapter 301, and the terminal real-name seal of chapter 38. The packet names Bishop-style diagonal tail selection as finite data; it is not a selected completed limit, quotient stream equality, trichotomy, countable choice, or ambient completeness of $\mathsf{Real}^{\uparrow}$.

Definition 8957.1 (CauchyTailSelectorFusion carrier)**.** *A* $\mathsf{CauchyTailSelectorFusion}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$F = (S, C, M, D, W, Q, R, H, K, P, N)$$

with the following displayed rows:

1. *S is the* $\mathsf{RegularCauchyTailSelector}^{\uparrow}$ *row recording the regular tail threshold selected for the displayed tolerance request.*
2. *C is the* $\mathsf{CofinalStreamTailSelector}^{\uparrow}$ *row recording the cofinal stream window through which the selected tail is inspected.*
3. *M is the* $\mathsf{RegularCauchyTailMeet}^{\uparrow}$ *row binding the regular selector and the cofinal stream selector to one common tail window.*
4. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger that stores the requested precision, the selector budget, and the meet budget.*
5. *W is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row on which the source stream, selected tail, and common meet are simultaneously readable.*
6. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the rational data extracted from D, W, S, C, M.*
7. *R is the terminal* $\mathsf{Real}^{\uparrow}$ *seal available only after the selector, cofinal, meet, dyadic, stream, and regular-rational rows have been displayed.*
8. *H records componentwise* hsame *transport for every displayed object row, the provenance row, and the local naming row.*

9. *K records displayed* Cont *replay from the regular selector and cofinal selector through the meet row and into the regular-rational and real-seal handoff.*
10. *P is the* Pkg *provenance over* $\mathsf{CauchyTailSelectorFusion}^{\uparrow}$, $\mathsf{RegularCauchyTailSelector}^{\uparrow}$, $\mathsf{CofinalStreamTailSelector}^{\uparrow}$, $\mathsf{RegularCauchyTailMeet}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*
11. *N is the local* $\mathsf{NameCert}_{\mathsf{CauchyTailSelectorFusion}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $S, C, M, D, W, Q, R, H, K, P, N$. It exports no selected limit, quotient stream equality, trichotomy of real names, countable-choice schedule, hidden tail oracle, or ambient completeness theorem for $\mathsf{Real}^{\uparrow}$.

Theorem 8957.2 (CauchyTailSelectorFusion NameCert obligations)**.** *For every accepted* $\mathsf{CauchyTailSelectorFusion}^{\uparrow}$ *carrier*

$$F = (S, C, M, D, W, Q, R, H, K, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{CauchyTailSelectorFusion}^{\uparrow}}$ *surface consists exactly of regular selector admission through S, cofinal stream selector admission through C, common-tail meet exposure through M, dyadic tolerance accounting through D, finite stream-window readability through W, regular rational readback through Q, terminal real sealing through R, componentwise transport through H, continuation replay through K, package provenance through P, and local naming through N.*

Proof. Project the carrier of Definition 8957.1. The rows S, C, M are the selector rows: S chooses the regular tail threshold for the displayed tolerance request, C chooses the cofinal stream window, and M records their finite meet.

The numerical and completion-facing rows are D, W, Q, R. The dyadic ledger D stores the precision budgets, the stream row W exposes the finite inspection window, and Q, R hand the displayed rational data to the terminal real seal.

The structural rows are H, K, P, N. Transport preserves each displayed coordinate, replay factors the diagonal tail route through the selector and meet rows, and provenance plus naming repack the same finite packet. Since none of the excluded host objects is a carrier coordinate, these rows exhaust the local NameCert surface. □

Theorem 8957.3 (CauchyTailSelectorFusion selector coherence)**.** *Every accepted* $\mathsf{CauchyTailSelectorFusion}^{\uparrow}$ *packet exposes a coherent diagonal tail route*

$$S, C, M, D, W, Q, R, K$$

in which the regular tail selector and the cofinal stream selector are both consumed before the common meet row is read, and the regular-rational and real-seal handoff is consumed only after that meet row has fixed the finite tail window.

Proof. Begin with the two selector rows. The regular selector S answers the tolerance request, while the cofinal selector C supplies the stream window on which that answer can be inspected.

Next read the meet row M. It is the only row that binds the two selector outputs to one common finite tail window, so no downstream regular-rational read can bypass the fusion point.

Finally consume D, W, Q, R, K. The dyadic ledger and stream window display the data read at the common tail, the regular-rational row translates it into the accepted rational readback surface, and the terminal real seal is reached only along the replay row K. Thus the diagonal selector route remains finite and coherent inside the displayed packet. □

Theorem 8957.4 (CauchyTailSelectorFusion non-escape)**.** *The public information exported by a* $\mathsf{CauchyTailSelectorFusion}^{\uparrow}$ *carrier is exactly*

$$S, C, M, D, W, Q, R, H, K, P, N.$$

In particular, no consumer can extract a selected completed limit, quotient stream equality, trichotomy of real names, countable-choice schedule, hidden tail oracle, or ambient $\mathsf{Real}^{\uparrow}$ *completeness theorem from the packet.*

Proof. Inspect the carrier coordinates. The only object rows are the regular selector, cofinal selector, meet, dyadic tolerance, stream-window, regular-rational readback, and terminal real-seal rows.

The structural rows add no hidden object. The transport row preserves the displayed coordinates, the replay row factors the same selector-fusion route, and provenance plus local naming identify the same packet.

Therefore any request for a selected limit, quotient stream equality, trichotomy, countable choice, hidden tail oracle, or ambient completeness theorem reaches no carrier coordinate and no replay coordinate. The packet exports only the finite selector-fusion surface. □

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyTailSelectorFusion}^{\uparrow}}$.

Constructive story: A $\mathsf{CauchyTailSelectorFusion}^{\uparrow}$ packet is generated from regular tail selector, cofinal stream selector, regular tail meet, dyadic tolerance, stream-window, regular-rational readback, terminal Real seal, transport, replay, provenance, and local NameCert rows.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CauchyTailSelectorFusion}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8957.1, Definition 8957.2, Definition 8957.3, and Definition 8957.4 seed the finite Bishop-style diagonal tail selector fusion route for Real and Completion consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CauchyTailSelectorFusion}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close selected limits, quotient stream equality, trichotomy, countable choice, hidden tail oracles, Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked selector admission, cofinal stream admission, meet exposure, dyadic tolerance accounting, finite-window readability, regular-rational handoff, terminal Real sealing, transport, replay, provenance, local naming, and non-escape for BEDC.Derived.CauchyTailSelectorFusionUp.

Chapter 8958

A Concrete Naming Certificate for $\mathsf{KreinMilman}^{\uparrow}$

Following Krein and Milman, the $\mathsf{KreinMilman}^{\uparrow}$ packet records the theorem-level NameCert wrapper that reads the compact-convex sibling of chapter 7460 together with the finite-extreme sibling of chapter 3610. The packet names the public theorem boundary as finite BEDC rows; it does not import host choice, selected supporting functionals, quotient compactness, or ambient locally convex completeness.

Definition 8958.1 (KreinMilman carrier)**.** *A* $\mathsf{KreinMilman}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (C, E, F, W, H, R, P, N)$$

with the following displayed rows:

1. *C is the* $\mathsf{KreinMilmanCompactConvex}^{\uparrow}$ *sibling row, reading the compact, locally convex, convex-set, weak-window, face, scalar, transport, replay, provenance, and naming surface of chapter 7460;*
2. *E is the* $\mathsf{KreinMilmanFiniteExtreme}^{\uparrow}$ *sibling row, reading the exposed-face, candidate extreme-point, separating-functional, scalar, metric, transport, replay, provenance, and naming surface of chapter 3610;*
3. *F is the finite theorem-facing hull ledger tying the compact-convex row to the finite extreme witness row;*
4. *W is the weak-window compatibility row through which theorem-level consumers read the compact and extreme-point siblings in one packet;*
5. *H records componentwise* hsame *transport for the compact-convex, finite-extreme, hull-ledger, weak-window, replay, provenance, and naming rows;*
6. *R records displayed* Cont *replay through the same finite theorem-facing route;*
7. *P is the* Pkg *provenance over* $\mathsf{KreinMilman}^{\uparrow}$, $\mathsf{KreinMilmanCompactConvex}^{\uparrow}$, $\mathsf{KreinMilmanFiniteExtreme}^{\uparrow}$, $\mathsf{Compact}^{\uparrow}$, $\mathsf{ConvexSet}^{\uparrow}$, $\mathsf{LocallyConvexSpace}^{\uparrow}$, $\mathsf{WeakTopology}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$ *rows;*
8. *N is the local* $\mathsf{NameCert}_{\mathsf{KreinMilman}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through these rows. It has no coordinate for a host Hahn–Banach theorem, selected extreme point, quotient convex body, global choice principle, or ambient compactness theorem.

Lean4 (statement) `BEDC.Derived.KreinMilmanUp`

Theorem 8958.2 (KreinMilman theorem-level NameCert obligations)**.** *For every accepted* $\mathsf{KreinMilman}^{\uparrow}$ *carrier*

$$K = (C, E, F, W, H, R, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{KreinMilman}^{\uparrow}}$ *surface consists exactly of compact-convex sibling exposure through* C*, finite-extreme sibling exposure through* E*, finite hull-ledger visibility through* F*, weak-window compatibility through* W*, componentwise* hsame *transport through* H*, displayed* Cont *replay through* R*,* Pkg *provenance through* P*, and local naming through* N*.*

Proof. Project the carrier of Definition 8958.1. The compact-convex row and finite-extreme row are the only theorem-level mathematical inputs, and they are read from the two displayed sibling chapters.

The hull ledger and weak-window row then bind those siblings into one theorem-facing packet. They record finite BEDC dependency data rather than a selected extreme point or an ambient host proof.

The structural rows H, R, P, N transport, replay, source, and name the same packet. Since the carrier has no coordinate for choice, host Hahn–Banach, quotient convex bodies, selected representatives, or ambient compactness, the listed rows exhaust the local NameCert surface. □

Closure status for $\mathsf{NameCert}_{\mathsf{KreinMilman}^{\uparrow}}$**.**

Constructive story: A $\mathsf{KreinMilman}^{\uparrow}$ packet is generated from compact-convex sibling rows, finite-extreme sibling rows, a theorem-facing hull ledger, weak-window compatibility, componentwise transport, displayed replay, package provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{KreinMilman}^{\uparrow}}$, seed)

Scope closed: Definition 8958.1 and Definition 8958.2 seed the theorem-level wrapper over the compact-convex and finite-extreme Krein–Milman siblings.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{KreinMilman}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close host Hahn–Banach, selected extreme points, quotient convex bodies, global choice principles, ambient compactness, Lean theorem verification, or bridge checking.

Upgrade path: Obligation closure requires checked compact-convex sibling exposure, finite-extreme sibling exposure, hull-ledger visibility, weak-window compatibility, transport, replay, provenance, and local naming for BEDC.Derived.KreinMilmanUp.

Chapter 8959

A Concrete Naming Certificate for $\mathsf{HyperbolicObserverPhaseTransport}^{\uparrow}$

The $\mathsf{HyperbolicObserverPhaseTransport}^{\uparrow}$ packet realizes the reversible observer-phase transport branch of chapter 9463 as finite NameCert data. It sits over the disk-metric readout of chapter 6209, the visual-boundary surface of chapter 4181, the observer-expansion route of chapter 4167, the observer-phase packet of chapter 7112, the phase-transport budget of chapter 7134, the boundary-shadow packet of chapter 3813, and the complex phase-fiber row of chapter 6044. The packet names reversible disk-phase, boundary-shadow, visual-boundary, provenance, and refusal rows; it is not a completed hyperbolic disk, a physical observer, a quotient boundary, a chosen global phase, or a cosmological transport law.

Definition 8959.1 (HyperbolicObserverPhaseTransport carrier)**.** *A* $\mathsf{HyperbolicObserverPhaseTransport}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$T = (D, M, V, O, G, A, B, F, E, H, C, P, N)$$

with the following displayed rows:

1. *D is the Poincare disk-coordinate row read through* $\mathsf{PoincareDiskMetric}^{\uparrow}$*.*
2. *M is the hyperbolic metric comparison row over the same displayed disk data.*
3. *V is the* $\mathsf{HyperbolicVisualBoundary}^{\uparrow}$ *row displaying the visible boundary face.*
4. *O is the* $\mathsf{HyperbolicObserverExpansion}^{\uparrow}$ *row exposing the observer-expansion window.*
5. *G is the* $\mathsf{ObserverPhaseGroupoid}^{\uparrow}$ *row recording reversible composition of observer-phase arrows.*
6. *A is the* $\mathsf{HyperbolicObserverPhase}^{\uparrow}$ *phase-read row consumed by the transport.*
7. *B is the* $\mathsf{HyperbolicBoundaryShadow}^{\uparrow}$ *row binding the transport to a finite boundary shadow.*
8. *F is the* $\mathsf{ComplexPhaseSurfaceFiber}^{\uparrow}$ *provenance-fiber row that prevents the phase read from becoming a hidden source equality.*
9. *E is the* $\mathsf{HyperbolicPhaseTransportBudget}^{\uparrow}$ *energy and curvature-budget row for the accepted transport.*
10. *H records componentwise* hsame *transport for every displayed object row, provenance, and local naming.*

11. *C records displayed* Cont *replay through disk metric, visual boundary, observer expansion, groupoid composition, phase read, boundary shadow, fiber provenance, and transport budget.*

12. *P is the* Pkg *provenance over* HyperbolicObserverPhaseTransport$^{\uparrow}$, PoincareDiskMetric$^{\uparrow}$, HyperbolicVisualBoundary HyperbolicObserverExpansion$^{\uparrow}$, ObserverPhaseGroupoid$^{\uparrow}$, HyperbolicObserverPhase$^{\uparrow}$, HyperbolicBoundaryShadow$^{\uparrow}$ ComplexPhaseSurfaceFiber$^{\uparrow}$, HyperbolicPhaseTransportBudget$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*

13. *N is the local* $\mathsf{NameCert}_{\mathsf{HyperbolicObserverPhaseTransport}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $D, M, V, O, G, A, B, F, E, H, C, P, N$. It exports no completed disk, quotient visual boundary, selected global phase, physical observer, cosmological transport law, or hidden fiber equality.

Theorem 8959.2 (HyperbolicObserverPhaseTransport NameCert obligations)**.** *For every accepted* HyperbolicObserverPhaseTransport$^{\uparrow}$ *carrier*

$$T = (D, M, V, O, G, A, B, F, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{HyperbolicObserverPhaseTransport}^{\uparrow}}$ *surface consists exactly of disk-coordinate admission through D, metric comparison through M, visual-boundary exposure through V, observer-expansion exposure through O, reversible observer-phase groupoid composition through G, phase readback through A, boundary-shadow binding through B, provenance-fiber exposure through F, phase-transport budget accounting through E, componentwise transport through H, displayed replay through C, package provenance through P, and local naming through N.*

Proof. Project the carrier of Definition 8959.1. The rows D, M, V, O are the geometric source rows: disk coordinates, metric comparison, visual boundary, and observer expansion must all be displayed before transport is consumed.

The phase rows are G, A, B, F, E. The groupoid row records reversible observer-phase composition, the phase-read row is the local phase surface, the boundary-shadow row ties it to the far boundary, the fiber row records provenance, and the budget row accounts for the accepted transport.

The structural rows are H, C, P, N. Transport, replay, provenance, and local naming preserve exactly the displayed rows. Since no excluded host object appears as a coordinate, the listed rows exhaust the local NameCert surface. □

Theorem 8959.3 (HyperbolicObserverPhaseTransport boundary coherence)**.** *Every accepted* HyperbolicObserverP *read exposes boundary-shadow and provenance rows before phase transport is consumed. In particular, the route*

$$D, M, V, O, G, A \longmapsto B, F, E$$

is coherent only when B records the finite boundary shadow, F records the provenance fiber, and E records the transport budget before any downstream consumer reads the transported observer phase.

Proof. Start with the disk and visual rows. The disk coordinate, metric comparison, visual-boundary, and observer-expansion rows determine the visible surface on which the phase read is meaningful.

Next consume the reversible phase rows. The observer-phase groupoid row and phase-read row give a transport candidate, but they do not yet license a boundary-level consumer.

Finally read B, F, E. The boundary-shadow row binds the candidate to the visual boundary, the fiber row displays provenance, and the budget row records the accepted transport cost. A consumer

that skips one of these rows has no displayed boundary-shadow or provenance coordinate, so it cannot consume the transported phase as an accepted packet. □

Theorem 8959.4 (HyperbolicObserverPhaseTransport non-escape)**.** *The public information exported by a* $\mathsf{HyperbolicObserverPhaseTransport}^{\uparrow}$ *carrier is exactly*

$$D, M, V, O, G, A, B, F, E, H, C, P, N.$$

Thus a consumer cannot extract a completed hyperbolic disk, quotient visual boundary, selected global phase, physical observer, cosmological transport law, or hidden fiber equality from the packet.

Proof. Inspect the carrier rows. The object rows are exactly the disk, metric, visual-boundary, observer-expansion, groupoid, phase-read, boundary-shadow, fiber, and budget rows.

The structural rows preserve the same inventory. Componentwise transport, displayed replay, provenance, and local naming do not add a completed disk, quotient boundary, selected phase, physical observer, cosmological law, or hidden fiber equality.

Therefore every public read factors through the displayed packet and the excluded objects remain outside the local NameCert surface. □

Falsifiable prediction: Every accepted $\mathsf{HyperbolicObserverPhaseTransport}^{\uparrow}$ read must expose boundary-shadow and provenance rows before phase transport is consumed.

Independence witness: poincare-disk-metric, hyperbolic-visual-boundary, observer-phase-groupoid, hyperbolic-observer-expansion, complex-phase-surface-fiber: no listed sibling is bijective to HyperbolicObserverPhase because this packet jointly carries disk metric, visual-boundary, observer-expansion, reversible observer-phase groupoid, phase read, boundary-shadow, provenance-fiber, budget, transport, replay, provenance, and local NameCert rows.

The Lean TasteGate for this packet will require explicit Nontrivial $\mathsf{HyperbolicObserverPhaseTransport}^{\uparrow}$ and FieldFaithful $\mathsf{HyperbolicObserverPhaseTransport}^{\uparrow}$ instances before a checked carrier-alignment theorem can serve as a public TasteGate realization.

Closure status for $\mathsf{NameCert}_{\mathsf{HyperbolicObserverPhaseTransport}^{\uparrow}}$.

Constructive story: A $\mathsf{HyperbolicObserverPhaseTransport}^{\uparrow}$ packet is generated from disk-coordinate, metric, visual-boundary, observer-expansion, observer-phase groupoid, phase-read, boundary-shadow, provenance-fiber, transport-budget, hsame, Cont, Pkg, and local NameCert rows.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{HyperbolicObserverPhaseTransport}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8959.1, Definition 8959.2, Definition 8959.3, Definition 8959.4, the falsifiable prediction, and the independence witness seed the finite observer-phase transport surface over disk, boundary, phase, provenance, and refusal rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{HyperbolicObserverPhaseTransport}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close completed hyperbolic disks, quotient visual boundaries, selected global phases, physical observers, cosmological transport laws, hidden fiber equality, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked disk and metric visibility, visual-boundary exposure, observer-expansion exposure, groupoid composition, phase readback, boundary-shadow binding, fiber provenance, transport-budget exactness, TasteGate nontriviality, field faithfulness, replay stability, provenance exhaustion, and local naming for BEDC.Derived.HyperbolicObs

Chapter 8960

A Concrete Naming Certificate for BishopDiagonalProductCauchy$^{\uparrow}$

Following Bishop and Bridges, the BishopDiagonalProductCauchy$^{\uparrow}$ packet records the finite product-diagonal route by which two regular Cauchy reads are synchronized before a Real and Completion consumer asks for a product observation. It sits next to the dyadic tolerance core of chapter 291, the finite stream scheduler of chapter 126, the regular rational readback of chapter 301, the terminal real seal of chapter 38, and the tail comparison surface of chapter 387. The packet is a finite-means product certificate: it displays the common window, the two readback rows, the dyadic product budget, and the Real seal, without quotient sequence equality, selected representatives, countable choice, trichotomy, or ambient completeness of Real$^{\uparrow}$.

Definition 8960.1 (Bishop diagonal product Cauchy carrier)**.** *A* BishopDiagonalProductCauchy$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$P = (W_X, W_Y, D_X, D_Y, R_X, R_Y, T, M, S, H, C, G, N)$$

with the following displayed rows:

1. W_X *and* W_Y *are finite* StreamName$^{\uparrow}$ *window rows for the two product coordinates.*
2. D_X *and* D_Y *are* DyadicRatCore$^{\uparrow}$ *tolerance rows attached to the same requested product scale.*
3. R_X *and* R_Y *are* RegSeqRat$^{\uparrow}$ *readback rows served from* W_X, D_X *and* W_Y, D_Y*.*
4. T *is the* CauchyTailComparison$^{\uparrow}$ *row witnessing that the two coordinates are compared only after a common finite tail threshold has been displayed.*
5. M *is the diagonal-product row. It records the finite rule that reads both coordinates at the shared threshold and forms the product observation from the displayed rational data.*
6. S *is the downstream* Real$^{\uparrow}$ *seal row for the accepted product observation.*
7. H *records componentwise* hsame *transport for the two windows, two tolerance rows, two readbacks, tail comparison, product row, Real seal, replay, provenance, and local naming.*
8. C *records displayed* Cont *replay from the requested product scale through the common window, dyadic tolerances, regular readbacks, tail comparison, product row, and Real seal.*
9. G *is the* Pkg *provenance over* BishopDiagonalProductCauchy$^{\uparrow}$*,* StreamName$^{\uparrow}$*,* DyadicRatCore$^{\uparrow}$*,* RegSeqRat$^{\uparrow}$*,* CauchyTailComparison$^{\uparrow}$*,* Real$^{\uparrow}$*,* BHist*,* hsame*,* Cont*, and* NameCert*.*

10. *N is the local* $\mathsf{NameCert}_{\mathsf{BishopDiagonalProductCauchy}^{\uparrow}}$ *row.*

The carrier has no coordinate for quotient sequence equality, selected representatives, hidden tail choice, countable-choice schedules, trichotomy, host real multiplication, host equality, or ambient completeness of $\mathsf{Real}^{\uparrow}$*.*

Theorem 8960.2 (Bishop diagonal product Cauchy carrier exactness)**.** *Every accepted* BishopDiagonalProductCauc *carrier exposes exactly the rows*

$$W_X, W_Y, D_X, D_Y, R_X, R_Y, T, M, S, H, C, G, N$$

before a product observation is served. In particular, the product route is determined by finite $\mathsf{StreamName}^{\uparrow}$ *windows,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerances,* $\mathsf{RegSeqRat}^{\uparrow}$ *readbacks, the* $\mathsf{CauchyTailComparison}^{\uparrow}$ *common-tail row, the diagonal-product row, and the terminal* $\mathsf{Real}^{\uparrow}$ *seal.*

Proof. Project the carrier of Definition 8960.1. The analytic rows are the two stream windows, two dyadic tolerance rows, two regular readbacks, the tail comparison row, the product row, and the Real seal.

The structural rows are separate. Row H transports the displayed rows componentwise, row C replays the finite route, row G records provenance, and row N names the packet.

No other coordinate occurs in the carrier. Therefore an accepted product observation can be served only after the listed rows have been displayed. □

Theorem 8960.3 (Bishop diagonal product Cauchy classifier)**.** *Let* $P = (W_X, W_Y, D_X, D_Y, R_X, R_Y, T, M, S, H, C$ *be an accepted* $\mathsf{BishopDiagonalProductCauchy}^{\uparrow}$ *carrier. Any classifier read of P first consumes the common finite route*

$$\mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{DyadicRatCore}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{CauchyTailComparison}^{\uparrow}$$

on both coordinates, then reads M and S. Thus the classifier may use the displayed product observation and its $\mathsf{Real}^{\uparrow}$ *seal, but it cannot branch through quotient Cauchy classes, host sequence equality, selected representatives, trichotomy, hidden tail choice, countable choice, or ambient Real completeness.*

Proof. Start with the two coordinate routes. The classifier must read W_X, D_X, R_X for the first coordinate and W_Y, D_Y, R_Y for the second coordinate before the common-tail row T is meaningful.

The tail comparison row T supplies the shared finite threshold. Only downstream of that row can M form the product observation and S serve the $\mathsf{Real}^{\uparrow}$ seal.

The transport, replay, provenance, and naming rows preserve the same order of consumption. Since none of the carrier coordinates is a quotient Cauchy class, host sequence equality, selected representative, trichotomy branch, hidden tail choice, choice schedule, or ambient-completeness theorem, no accepted classifier read can branch through those objects. □

Theorem 8960.4 (Bishop diagonal product Cauchy ledger)**.** *The local* $\mathsf{NameCert}_{\mathsf{BishopDiagonalProductCauchy}^{\uparrow}}$ *ledger for an accepted packet consists exactly of the following five rows:*

1. *two finite* $\mathsf{StreamName}^{\uparrow}$ *windows and their* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance rows;*
2. *two* $\mathsf{RegSeqRat}^{\uparrow}$ *readbacks served from the displayed windows and tolerances;*
3. *one* $\mathsf{CauchyTailComparison}^{\uparrow}$ *common-tail row and one diagonal-product row;*
4. *the downstream* $\mathsf{Real}^{\uparrow}$ *seal with componentwise* hsame *transport and displayed* Cont *replay;*

5. Pkg *provenance and local naming.*

These rows exhaust the finite product-diagonal obligation surface.

Proof. The first two ledger rows are the coordinate data. They are exactly the windows, tolerances, and readbacks named by $W_X, W_Y, D_X, D_Y, R_X, R_Y$.

The third row is the product synchronization surface. The common-tail row T fixes the shared finite threshold, and the row M records the product observation at that threshold.

The fourth and fifth rows are structural and terminal. The Real seal S, transports H, replay C, provenance G, and local name N account for every remaining coordinate. No additional obligation row is present in the carrier, so the ledger is exhausted. □

Falsifiable prediction: Every accepted $\mathsf{BishopDiagonalProductCauchy}^{\uparrow}$ product read displays two $\mathsf{StreamName}^{\uparrow}$ windows, two $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance rows, two $\mathsf{RegSeqRat}^{\uparrow}$ readbacks, a $\mathsf{CauchyTailComparison}^{\uparrow}$ common-tail row, a diagonal-product row, a $\mathsf{Real}^{\uparrow}$ seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert naming.

Independence witness: dyadicratcore, streamname, regseqrat, real, cauchy-tail-comparison: $\mathsf{BishopDiagonalProductCauchy}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries two synchronized coordinate routes, a common-tail comparison row, a diagonal-product row, a Real seal, and structural NameCert rows in one packet.

Closure status for $\mathsf{NameCert}_{\mathsf{BishopDiagonalProductCauchy}^{\uparrow}}$.

Constructive story: A $\mathsf{BishopDiagonalProductCauchy}^{\uparrow}$ packet is generated from two StreamName windows, two DyadicRatCore tolerance rows, two RegSeqRat readbacks, a CauchyTailComparison common-tail row, a diagonal-product row, a Real seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BishopDiagonalProductCauchy}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8960.1, Definition 8960.2, Definition 8960.3, and Definition 8960.4 seed the finite product-diagonal Cauchy route over StreamName, DyadicRatCore, RegSeqRat, CauchyTailComparison, and Real rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BishopDiagonalProductCauchy}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close Lean verification, quotient sequence equality, selected representatives, hidden tail choice, countable choice, trichotomy, host real multiplication, host equality, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Upgrade path: Obligation closure requires checked carrier admission, classifier determinacy, ledger exactness, product-window stability, transport stability, replay stability, provenance non-escape, and local naming for BEDC.Derived.BishopDiagonalProductCauchy

Chapter 8961

A Concrete Naming Certificate for $\mathsf{PrueferTransformation}^{\uparrow}$

Following the Sturm–Liouville and Pruefer phase-transform tradition, the $\mathsf{PrueferTransformation}^{\uparrow}$ packet records the finite phase-angle read by which a displayed second-order real differential system is routed from amplitude and derivative rows into a Sturm-facing oscillation surface. It sits after the Wronskian determinant corridor of chapter 6877, the separation consumer of chapter 8378, the root-counting consumer of chapter 3612, the derivative-admission route of chapter 122, the continuous-map admission route of chapter 130, the dyadic tolerance ledger of chapter 291, the regular rational readback of chapter 301, and the terminal real-name seal of chapter 38. The packet names only a displayed finite phase-angle carrier; it does not import full spectral theory, selected eigenfunctions, host phase equality, quotient real equality, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 8961.1 (Pruefer transformation carrier)**.** *A* $\mathsf{PrueferTransformation}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$T = (F, D, A, \Theta, W, S, Z, R, E, H, C, P, N)$$

with the following displayed rows:

1. *F is the source function-family row, read through* $\mathsf{ContinuousMap}^{\uparrow}$ *before any phase request is inspected.*
2. *D is the derivative-admission row, exposing the first derivative and second-order source data only through* $\mathsf{Derivative}^{\uparrow}$*.*
3. *A is the amplitude ledger, recording the displayed radius-squared and nonzero-window requests used before a phase angle is named.*
4. *Θ is the phase-angle row, listing the finite angle windows produced from the displayed amplitude and derivative rows.*
5. *W is the* $\mathsf{Wronskian}^{\uparrow}$ *determinant handoff row, keeping zero and nonzero separation reads attached to the finite determinant ledger.*
6. *S is the Sturm consumer row, available only through the* $\mathsf{SturmSeparation}^{\uparrow}$ *and* $\mathsf{SturmRootCount}^{\uparrow}$ *sibling routes.*
7. *Z is the zero-window discipline row, recording which displayed windows may be treated as phase-crossing candidates.*

8. *R is the regular rational readback row through* $\mathsf{RegSeqRat}^{\uparrow}$.
9. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal reached only after the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger and R have been displayed.*
10. *H records componentwise* hsame *transport for the source, derivative, amplitude, phase, Wronskian, Sturm, zero-window, readback, seal, replay, provenance, and naming rows.*
11. *C records displayed* Cont *replay from a phase request through source admission, derivative admission, amplitude readback, Wronskian handoff, Sturm consumer routing, dyadic tolerance, regular rational readback, Real sealing, transport, provenance, and local naming.*
12. *P is the* Pkg *provenance over* $\mathsf{PrueferTransformation}^{\uparrow}$, $\mathsf{Wronskian}^{\uparrow}$, $\mathsf{SturmSeparation}^{\uparrow}$, $\mathsf{SturmRootCount}^{\uparrow}$, $\mathsf{Derivative}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
13. *N is the local* $\mathsf{NameCert}_{\mathsf{PrueferTransformation}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these rows. It has no coordinate for a host phase function, a selected eigenfunction, quotient real equality, countable choice, full spectral decomposition, or ambient completeness of $\mathsf{Real}^{\uparrow}$.

Theorem 8961.2 (Pruefer transformation NameCert obligations)**.** *For every accepted* $\mathsf{PrueferTransformation}^{\uparrow}$ *carrier*

$$T = (F, D, A, \Theta, W, S, Z, R, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{PrueferTransformation}^{\uparrow}}$ *surface consists exactly of carrier admission for the displayed packet, continuous source admission through F, derivative admission through D, amplitude and phase-window exposure through A, Θ, Z, Wronskian determinant handoff through W, Sturm separation and root-count consumer routing through S, dyadic tolerance and regular rational readback through R, E, componentwise* hsame *transport through H, displayed* Cont *replay through C, provenance through P, local naming through N, and nonescape from full spectral theory, selected eigenfunctions, host phase equality, quotient real equality, countable choice, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the carrier of Definition 8961.1. The tuple displays source functions, derivative rows, amplitude windows, phase windows, Wronskian handoff, Sturm consumer routing, zero-window discipline, regular rational readback, Real sealing, transport, replay, provenance, and local naming as separate rows.

The source and differentiability data are read first. The rows F and D force every phase request through $\mathsf{ContinuousMap}^{\uparrow}$ and $\mathsf{Derivative}^{\uparrow}$, so the carrier cannot begin from an unnamed host solution or an external differentiability witness.

Next inspect A, Θ, Z, W, S. These rows expose only finite amplitude and phase windows, route determinant separation through $\mathsf{Wronskian}^{\uparrow}$, and send Sturm-facing reads through the displayed $\mathsf{SturmSeparation}^{\uparrow}$ and $\mathsf{SturmRootCount}^{\uparrow}$ sibling surfaces.

Finally pass through R, E, H, C, P, N. The regular rational readback, dyadic tolerance, terminal Real seal, transport, replay, provenance, and naming rows preserve the same finite route. Since no row supplies spectral decomposition, selected eigenfunctions, host phase equality, quotient real equality, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness, the listed rows exhaust the local NameCert surface. □

Theorem 8961.3 (Pruefer transformation Wronskian–Sturm handoff)**.** *Every* $\mathsf{SturmSeparation}^{\uparrow}$ *or* $\mathsf{SturmRootCount}^{\uparrow}$ *consumer that reads a* $\mathsf{PrueferTransformation}^{\uparrow}$ *phase window must first expose the*

Wronskian row W, the source and derivative rows F, D, the amplitude and phase rows A, Θ, Z, and the Real-facing readback rows R, E. The consumer receives the handoff only as a displayed route through Wronskian$^{\uparrow}$, Derivative$^{\uparrow}$, ContinuousMap$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, RegSeqRat$^{\uparrow}$, *and* Real$^{\uparrow}$, *with no host zero theorem, selected eigenfunction, host phase equality, quotient real equality, countable choice, or ambient completeness.*

Proof. Start with a Sturm-facing phase request. The carrier makes the phase row Θ downstream of the source row F, derivative row D, and amplitude ledger A, so no phase read is available before the continuous and derivative admissions have been displayed.

Use the Wronskian row W to route zero and nonzero separation through the determinant corridor. The consumer therefore reads the same finite Wronskian surface before it can treat a phase crossing as a separation or root-count input.

Now inspect the Sturm row S. It sends the read to the SturmSeparation$^{\uparrow}$ and SturmRootCount$^{\uparrow}$ sibling chapters as consumers of the displayed finite route, not as new coordinates inside the transformation packet.

Finally apply the readback and seal rows R, E together with H, C, P, N. They preserve the handoff under regular rational readback, dyadic tolerance, Real sealing, componentwise transport, replay, provenance, and local naming. The refused endpoints are absent because none of these rows names a host zero theorem, selected eigenfunction, host phase equality, quotient real equality, countable-choice schedule, or ambient completeness principle. □

Falsifiable prediction: Every accepted PrueferTransformation$^{\uparrow}$ read displays continuous source rows, derivative rows, amplitude and phase windows, Wronskian determinant handoff, Sturm separation and root-count consumer routing, dyadic tolerance, regular rational readback, terminal Real sealing, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming.

Independence witness: wronskian, sturm-separation, sturm-root-count, derivative, continuousmap, dyadicratcore, regseqrat, real: PrueferTransformation$^{\uparrow}$ is not bijective to any listed sibling because it binds amplitude and phase windows, Wronskian determinant handoff, zero-window discipline, Sturm consumer routing, and Real-facing readback into one finite NameCert packet.

Closure status for NameCert$_{\text{PrueferTransformation}^{\uparrow}}$.

Theory closure: TheoryGate(NameCert$_{\text{PrueferTransformation}^{\uparrow}}$, seed)

Scope closed: Definition 8961.1, Definition 8961.2, and Definition 8961.3 seed the finite source, derivative, amplitude, phase-window, Wronskian, Sturm-consumer, dyadic, readback, Real-seal, transport, replay, provenance, and local naming route.

Formal verification: FormalStatus(NameCert$_{\text{PrueferTransformation}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim full spectral theory, selected eigenfunctions, host phase equality, quotient real equality, countable choice, ambient Real$^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, continuous and derivative admission, amplitude and phase-window exactness, Wronskian determinant handoff, Sturm consumer routing, Real-seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.PrueferTransformationUp.

Constructive story: A PrueferTransformation$^{\uparrow}$ packet is generated from displayed source rows, derivative rows, amplitude and phase windows, a Wronskian determinant handoff, Sturm separation and root-count consumer routing, dyadic tolerance, regular rational readback, a terminal Real seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 8962

A Concrete Naming Certificate for BishopLocatedCauchyCriterion$^{\uparrow}$

Following Bishop and Bridges, the BishopLocatedCauchyCriterion$^{\uparrow}$ packet records the finite located Cauchy test that lets the L10 Real and Completion chain read a rational stream as a real-name candidate without quotient streams, ambient completeness, trichotomy, or a selected limit. It sits after the dyadic arithmetic of chapter 291, the finite stream interface of chapter 126, the regular rational readback of chapter 301, the modulus surface of chapter 8512, and the terminal real-name seal of chapter 38. Its role is to name the located comparison criterion that later RealSequenceLimit$^{\uparrow}$ and Bishop sequence-limit packets can consume before any completion theorem is available.

Definition 8962.1 (Bishop located Cauchy criterion carrier)**.** *A* BishopLocatedCauchyCriterion$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (S, L, D, W, Q, R, H, C, P, N)$$

with the following displayed rows:

1. *S is the sequence-source row, recording the rational stream only through a named* StreamName$^{\uparrow}$ *observation route.*
2. *L is the located-comparison row, recording the finite comparison by which two observed rational values are witnessed to be within or apart from a requested dyadic tolerance.*
3. *D is the dyadic tolerance-request row, read through* DyadicRatCore$^{\uparrow}$ *and aligned with the modulus scale of* CauchySequenceModulus$^{\uparrow}$*.*
4. *W is the finite* StreamName$^{\uparrow}$ *window row requested by D.*
5. *Q is the* RegSeqRat$^{\uparrow}$ *readback row produced from the displayed windows and dyadic tolerance request.*
6. *R is the* Real$^{\uparrow}$ *seal row reached only after S, L, D, W, Q have been displayed together.*
7. *H records componentwise* hsame *transport for the source, located comparison, tolerance request, windows, readback, real seal, provenance, and naming rows.*
8. *C records displayed* Cont *replay through source observation, located comparison, dyadic tolerance, stream windows, regular readback, real sealing, transport, provenance, and local naming.*
9. *P is the* Pkg *provenance over* BishopLocatedCauchyCriterion$^{\uparrow}$*,* DyadicRatCore$^{\uparrow}$*,* StreamName$^{\uparrow}$*,* RegSeqRat$^{\uparrow}$*,* CauchySequenceModulus$^{\uparrow}$*,* Real$^{\uparrow}$*,* BHist*,* hsame*,* Cont*, and* NameCert*.*

10. N is the local $\mathsf{NameCert}_{\mathsf{BishopLocatedCauchyCriterion}^{\uparrow}}$ *row.*
The carrier contains no quotient-stream equality, no countable choice schedule, no hidden tail selector, no ambient completeness principle, no trichotomy on reals, and no selected host limit.

Theorem 8962.2 (Bishop located Cauchy criterion NameCert obligations)**.** *For every accepted* $\mathsf{BishopLocatedCauchyCriterion}^{\uparrow}$ *carrier*

$$B = (S, L, D, W, Q, R, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{BishopLocatedCauchyCriterion}^{\uparrow}}$ *surface consists exactly of source admission through S, located comparison through L, dyadic tolerance request through D, finite window observation through W, regular rational readback through Q, real sealing through R, componentwise transport through H, continuation replay through C, provenance through P, and local naming through N.*

These rows are the complete finite criterion surface. A consumer may read the Cauchy test only by displaying the tolerance request, the windows answering it, the regular rational readback, and the located comparison that keeps the test apart from quotient-stream equality.

Proof. Project the carrier of Definition 8962.1. Its object rows are S, L, D, W, Q, R, and its structural rows are H, C, P, N.

The dyadic and stream rows form the finite request boundary. Row D names the tolerance scale, row W names the finite windows requested at that scale, and row Q is the only rational readback exported from those observations.

The located comparison row L is the criterion row. It relates the two readback values to the dyadic request without adding quotient-stream equality, a selected tail, or a total order on real names.

Finally R, H, C, P, N seal, transport, replay, source, and name the same finite packet. Since no coordinate names quotient equality, countable choice, hidden tail selection, ambient completeness, real trichotomy, or a host limit, the listed rows exhaust the local NameCert obligations. □

Theorem 8962.3 (Bishop located Cauchy criterion real handoff)**.** *Every accepted Real and Completion consumer of a* $\mathsf{BishopLocatedCauchyCriterion}^{\uparrow}$ *packet reaches the* $\mathsf{Real}^{\uparrow}$ *seal only through the displayed handoff*

$$\mathsf{DyadicRatCore}^{\uparrow} \longmapsto \mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{CauchySequenceModulus}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}.$$

The handoff keeps the located comparison row L attached to the tolerance request D, window row W, readback row Q, and support rows H, C, P, N.

Proof. Start with the finite tolerance request. The row D supplies the dyadic scale, and the row W records the finite stream windows requested at that scale.

Read back the rational data next. The row Q is served through $\mathsf{RegSeqRat}^{\uparrow}$, so the criterion sees regular rational values rather than a quotient stream or a host sequence.

Attach the located comparison. The row L compares the readback values at the requested dyadic tolerance, while the modulus sibling $\mathsf{CauchySequenceModulus}^{\uparrow}$ records why that comparison is the Cauchy criterion visible to the packet.

Only after those rows are present may the consumer read the real seal R. The structural rows H, C, P, N carry the same handoff under transport, replay, provenance, and local naming, so no ambient completeness theorem or selected host limit enters the route. □

Falsifiable prediction: Every accepted $\mathsf{BishopLocatedCauchyCriterion}^{\uparrow}$ consumer displays source, located comparison, dyadic tolerance, finite window, regular readback, Real seal, transport, replay, provenance, and local naming rows before treating the rational stream as a real-name candidate.

Independence witness: dyadicratcore, streamname, regseqrat, cauchysequencemodulus, real: $\mathsf{BishopLocatedCauchyCriterion}^{\uparrow}$ is not bijective to any listed sibling because it carries the located comparison row and the Real handoff row together with the tolerance, window, readback, transport, replay, provenance, and local naming rows in one packet.

Closure status for $\mathsf{NameCert}_{\mathsf{BishopLocatedCauchyCriterion}^{\uparrow}}$.

Constructive story: A $\mathsf{BishopLocatedCauchyCriterion}^{\uparrow}$ packet is generated from sequence source, located comparison, dyadic tolerance request, StreamName window, RegSeqRat readback, Real seal, hsame transport, Cont replay, Pkg provenance, and local NameCert rows.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BishopLocatedCauchyCriterion}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8962.1, Definition 8962.2, Definition 8962.3, the falsifiable prediction, and the independence witness seed the finite located Cauchy criterion route for the L10 Real and Completion chain.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BishopLocatedCauchyCriterion}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient stream equality, countable choice, hidden tail selection, ambient completeness, real trichotomy, selected host limits, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, located-comparison exactness, dyadic tolerance request stability, StreamName window coverage, RegSeqRat readback stability, Real seal handoff, transport, replay, provenance, and local naming for BEDC.Derived.BishopLocatedCauchyCriterionUp.

Chapter 8963

A Concrete Naming Certificate for $\mathsf{LocatedRealCofinalBracket}^{\uparrow}$

Following Bishop and Bridges on located real numbers and regular rational approximations, the $\mathsf{LocatedRealCofinalBracket}^{\uparrow}$ packet records the finite cofinal-bracket surface by which a located real read is inspected through nested dyadic windows. It sits after the located-real carrier of **??**, the located-interval carrier of chapter 394, the regular rational readback of chapter 301, the stream-window surface of chapter 126, the dyadic arithmetic core of chapter 291, and the terminal real-name seal of chapter 38. The packet names only the finite bracket windows and their cofinal refinement ledger; it does not assert quotient real equality, trichotomy, selected limits, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 8963.1 (LocatedReal cofinal bracket carrier)**.** *A* $\mathsf{LocatedRealCofinalBracket}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (L, I, S, Q, D, W, E, R, H, C, P, N)$$

with the following displayed rows:

1. *L is the* $\mathsf{LocatedReal}^{\uparrow}$ *source row whose locatedness requests are being bracketed.*
2. *I is the* $\mathsf{LocatedInterval}^{\uparrow}$ *row recording the current rational interval face around the inspected read.*
3. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row naming the observed prefixes used by the bracket.*
4. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *regular rational readback row extracted from those windows.*
5. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance and endpoint-comparison row.*
6. *W is the cofinal bracket-window ledger, recording displayed pairs $q_k^- \leq q_k^+$ and the finite refinement relation between consecutive windows.*
7. *E is the endpoint-exposure row, recording that each displayed bracket endpoint is read through I, S, Q, D before any real-facing seal is consumed.*
8. *R is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row, available only after L, I, S, Q, D, W, E have been displayed.*
9. *H records componentwise* hsame *transport for located-real, located-interval, stream, regular-rational, dyadic, bracket, endpoint, real-seal, replay, provenance, and local naming rows.*
10. *C records displayed* Cont *replay for each bracket read from locatedness requests through stream windows, rational readback, dyadic comparison, and real sealing.*

11. *P is the* Pkg *provenance over* $\mathsf{LocatedRealCofinalBracket}^{\uparrow}$, $\mathsf{LocatedReal}^{\uparrow}$, $\mathsf{LocatedInterval}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*

12. *N is the local* $\mathsf{NameCert}_{\mathsf{LocatedRealCofinalBracket}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $L, I, S, Q, D, W, E, R, H, C, P, N$. It has no coordinate for quotient real equality, trichotomy, a selected limiting real, countable choice, or an ambient completeness theorem for $\mathsf{Real}^{\uparrow}$.

Theorem 8963.2 (LocatedReal cofinal bracket NameCert obligations)**.** *For every accepted* LocatedRealCofinalBrac *carrier*

$$B = (L, I, S, Q, D, W, E, R, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{LocatedRealCofinalBracket}^{\uparrow}}$ *surface consists exactly of located-real source exposure through L, located-interval exposure through I, finite stream-window exposure through S, regular rational readback through Q, dyadic tolerance and endpoint comparison through D, cofinal bracket-window accounting through W, endpoint exposure through E, terminal real sealing through R, componentwise* hsame *transport through H, displayed* Cont *replay through C,* Pkg *provenance through P, and local naming through N.*

Proof. Project the carrier of Definition 8963.1. The located source row L supplies the displayed locatedness request, while I supplies the interval face in which the current bracket is read.

The finite readback rows are S, Q, D, W, E. Stream windows expose inspected prefixes, regular rational readback turns those windows into rational data, the dyadic row records endpoint comparison and tolerance, the bracket ledger records cofinal refinement, and the endpoint row records that endpoints are consumed only through those displayed rows.

The real seal R is downstream of the bracket data, and H, C, P, N preserve, replay, source, and name the same finite packet. Since the carrier has no coordinate for quotient equality, trichotomy, selected limits, countable choice, or ambient completeness, the listed rows exhaust the local NameCert surface. □

Theorem 8963.3 (LocatedReal cofinal bracket nested readback)**.** *Every accepted* $\mathsf{LocatedRealCofinalBracket}^{\uparrow}$ *read factors through a nested finite route*

$$\mathsf{LocatedReal}^{\uparrow} \longmapsto \mathsf{LocatedInterval}^{\uparrow} \longmapsto \mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{DyadicRatCore}^{\uparrow} \longmapsto W \longmapsto \mathsf{Real}^{\uparrow}.$$

The route exposes each requested bracket window and its refinement relation before the terminal real seal may be used. It exports no quotient real equality, trichotomy, selected limiting representative, countable-choice schedule, or ambient $\mathsf{Real}^{\uparrow}$ *completeness theorem.*

Proof. Begin with L and I. A located-real request is visible only as a displayed source row together with a located interval face, so no real-facing consumer can skip directly to the terminal seal.

Next read S, Q, D. The stream row supplies finite observations, the regular rational row supplies the corresponding rational readback, and the dyadic row supplies tolerance and endpoint comparison data.

Then read W and E. The bracket ledger records the nested cofinal windows, and the endpoint row records that the endpoints used by the bracket were produced by the displayed finite route.

Finally consume R, H, C, P, N. These rows seal, transport, replay, source, and name the same packet without adding any quotient, trichotomy, selection, choice, or completeness coordinate. □

Theorem 8963.4 (LocatedReal cofinal bracket nonescape)**.** *The public information exported by an accepted* $\mathsf{LocatedRealCofinalBracket}^{\uparrow}$ *carrier is exactly*

$$L, I, S, Q, D, W, E, R, H, C, P, N.$$

Thus a consumer may inspect finite cofinal bracket windows and their nested readback route, but cannot extract quotient real equality, trichotomy, a selected limit, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness from the packet.*

Proof. Inspect the carrier inventory. The rows L, I, S, Q, D, W, E, R are the only mathematical data rows, and the rows H, C, P, N are the structural transport, replay, provenance, and naming rows.

Definition 8963.2 fixes the NameCert obligations to exactly those rows. Definition 8963.3 fixes the order in which real-facing reads may consume them.

Any quotient equality, trichotomy decision, selected limiting representative, countable-choice schedule, or completeness theorem would require a coordinate outside the displayed packet. Since no such coordinate is present, accepted exports remain inside the finite cofinal-bracket surface. □

Falsifiable prediction: An accepted $\mathsf{LocatedRealCofinalBracket}^{\uparrow}$ read is refuted whenever it reaches the terminal $\mathsf{Real}^{\uparrow}$ seal without first displaying the located-real source, located-interval face, stream window, regular rational readback, dyadic tolerance row, cofinal bracket-window ledger, endpoint row, transport, replay, provenance, and local naming rows.

Independence witness: locatedreal, locatedinterval, regseqrat, streamname, dyadicratcore, real: no listed sibling is bijective to $\mathsf{LocatedRealCofinalBracket}^{\uparrow}$ because this packet jointly binds located reads, interval faces, finite stream windows, regular rational readback, dyadic endpoint comparison, cofinal bracket refinement, real sealing, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{LocatedRealCofinalBracket}^{\uparrow}}$**.**

Constructive story: A $\mathsf{LocatedRealCofinalBracket}^{\uparrow}$ packet is generated from LocatedReal source rows, LocatedInterval faces, StreamName windows, RegSeqRat readback, DyadicRatCore tolerance and endpoint comparisons, cofinal bracket-window ledgers, endpoint-exposure rows, RealUp seals, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{LocatedRealCofinalBracket}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8963.1, Definition 8963.2, Definition 8963.3, and Definition 8963.4 seed the finite cofinal-bracket packet for located real reads through nested dyadic windows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{LocatedRealCofinalBracket}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient real equality, trichotomy, selected limits, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, located source exposure, interval-face exactness, stream-window readback, regular rational readback, dyadic endpoint comparison, cofinal bracket refinement, endpoint exposure, real-seal nonescape, transport stability, replay stability, provenance exhaustion, and local naming for BEDC.Derived.LocatedRealCofinalBracketUp.

Chapter 8964

A Concrete Naming Certificate for $\mathsf{NewtonForwardSeries}^{\uparrow}$

Following Boole and Whittaker–Robinson, the $\mathsf{NewtonForwardSeries}^{\uparrow}$ packet records the finite forward-difference series route by which a displayed table is repacked as a Newton coefficient row and then handed to polynomial and regular-Cauchy consumers. It sits after the finite-difference surface of chapter 5135, the finite-difference table of chapter 7065, the polynomial carrier of chapter 50, and the regular rational readback of chapter 301. The packet supplies a finite-calculus interface for L10 Real and Completion estimates; it does not claim analytic convergence, quotient real equality, selected limits, host function extensionality, or ambient completeness.

Definition 8964.1 (Newton forward series carrier)**.** *A* $\mathsf{NewtonForwardSeries}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (X, D, C, P, R, W, H, T, G, N)$$

with the following displayed rows:

1. *X records the basepoint row, step row, and finite source-window observations used by the forward table.*
2. *D is the forward-difference table row, read through the finite-difference and finite-difference-table siblings before any coefficient is exposed.*
3. *C is the Newton coefficient row, storing the finite binomial-basis coefficients determined by D.*
4. *P is the polynomial reconstruction row, reading C as a finite polynomial or finite Newton-series section through* $\mathsf{Poly}^{\uparrow}$*.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *regular readback row for window estimates derived from the displayed finite section.*
6. *W is the regular-Cauchy window compatibility row used by L10 Real and Completion consumers.*
7. *H records componentwise* hsame *transport for the basepoint, step, table, coefficient, reconstruction, readback, window, provenance, and local naming rows.*
8. *T is the displayed* Cont *route*

$$X, D \longmapsto C \longmapsto P \longmapsto R \longmapsto W.$$

9. *G is the* Pkg *provenance over* $\mathsf{NewtonForwardSeries}^{\uparrow}$*,* $\mathsf{FiniteDifference}^{\uparrow}$*,* $\mathsf{FiniteDifferenceTable}^{\uparrow}$*,* $\mathsf{Poly}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*, regular-Cauchy window rows,* BHist*,* hsame*,* Cont*, and* $\mathsf{NameCert}$*.*

10. N is the local $\mathsf{NameCert}_{\mathsf{NewtonForwardSeries}^{\uparrow}}$ *row.*

The carrier has no coordinate for an infinite analytic series, a host function graph, quotient real equality, selected convergence, Taylor remainder completeness, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 8964.2 (Newton forward series NameCert obligations)**.** *For the carrier of Definition 8964.1, the local* $\mathsf{NameCert}_{\mathsf{NewtonForwardSeries}^{\uparrow}}$ *surface consists exactly of the finite obligation rows for basepoint and step admission through X, forward-difference table admission through D, Newton coefficient exposure through C, polynomial or finite-series reconstruction through P, regular readback and window compatibility through R, W, componentwise transport through H, displayed continuation through T, provenance through G, and local naming through N.*

Lean4 (statement) `BEDC.Derived.NewtonForwardSeriesUp`

Proof. Project the carrier rows of Definition 8964.1. The basepoint, step, and source-window data are displayed in X, and the finite forward-difference table is displayed in D before any coefficient row can be read.

The coefficient row C is then the only route to the polynomial or finite-series reconstruction row P. A polynomial consumer therefore receives a finite Newton section rather than an ambient function graph or an infinite analytic series.

The regular readback row R and the window row W are downstream of the same finite table and coefficient rows. Componentwise transport, continuation replay, provenance, and local naming preserve this displayed route and do not add quotient real equality, selected convergence, or completeness data. □

Closure status for $\mathsf{NameCert}_{\mathsf{NewtonForwardSeries}^{\uparrow}}$.

Constructive story: A $\mathsf{NewtonForwardSeries}^{\uparrow}$ packet is generated from a basepoint and step row, a finite forward-difference table, a Newton coefficient row, a polynomial or finite-series reconstruction row, RegSeqRat readback, regular-Cauchy window compatibility, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{NewtonForwardSeries}^{\uparrow}}$, seed)

Scope closed: Definition 8964.1 and Definition 8964.2 seed the finite Newton forward-series packet over finite-difference, polynomial, regular readback, regular-Cauchy window, transport, replay, provenance, and naming rows.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{NewtonForwardSeries}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close analytic convergence, infinite series completeness, quotient real equality, selected limits, host function extensionality, Lean verification, or a standard bridge.

Upgrade path: Obligation closure requires checked basepoint and step admission, forward-difference table admission, Newton coefficient exposure, polynomial reconstruction, regular readback, regular-Cauchy window compatibility, transport, provenance, and local naming for BEDC.Derived.NewtonForwardSeriesUp.

Chapter 8965

A Concrete Naming Certificate for MetaCICGeneratorClosureAlgebra$^{\uparrow}$

The MetaCICGeneratorClosureAlgebra$^{\uparrow}$ packet realizes the generator-closure classifier algebra of Definition 9389.8 and Definition 9389.9 as finite MetaCIC NameCert rows. It sits beside the generator-closure certificate of chapter 486, the MetaCIC closure-preservation packet of chapter 788, the MetaCIC audit matrix of chapter 904, and the MetaCIC identity packet of chapter 860. The packet names identity, composition, alternation, restriction, finite iteration, product, and sum closure rows for classifier-preserving generators; it does not assert unrestricted induction, arbitrary higher-order closure, proof irrelevance, quotient syntax equality, or host evaluator soundness.

Definition 8965.1 (MetaCIC generator-closure algebra carrier)**.** *A* MetaCICGeneratorClosureAlgebra$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$A = (U, K, R, C, O, W, T, P, S, L, H, Q, G, N)$$

with the following displayed rows:

1. *U is the carrier row naming the fixed MetaCIC object family on which classifiers are read.*
2. *K is the classifier row, recording the displayed predicate preserved by the generator rows.*
3. *R is the identity generator row corresponding to* `GeneratorClosureClassifier.refl`*.*
4. *C is the composition row corresponding to* `GeneratorClosureClassifier.comp`*.*
5. *O is the alternation row corresponding to* `GeneratorClosureClassifier.union`*.*
6. *W is the restriction row corresponding to* `GeneratorClosureClassifier.weaken`*.*
7. *T is the finite-iteration row corresponding to* `GeneratorClosureClassifier.iterate`*.*
8. *P is the product row corresponding to* `GeneratorClosureClassifier.product`*.*
9. *S is the sum row corresponding to* `GeneratorClosureClassifier.sum`*.*
10. *L is the algebra ledger, recording that the seven closure rows are consumed only as classifier-preserving generator operations.*
11. *H records componentwise* hsame *transport for carrier, classifier, algebra-operation, ledger, replay, provenance, and local naming rows.*

12. *Q records displayed* Cont *replay through the identity, composition, alternation, restriction, finite-iteration, product, and sum rows.*
13. *G is the* Pkg *provenance over* MetaCICGeneratorClosureAlgebra$^{\uparrow}$, GeneratorClosure$^{\uparrow}$, MetaCICClosurePreservation$^{\uparrow}$ MetaCICAuditMatrix$^{\uparrow}$, MetaCICIdentity$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*
14. *N is the local* NameCert$_{\text{MetaCICGeneratorClosureAlgebra}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $U, K, R, C, O, W, T, P, S, L, H, Q, G, N$. It has no coordinate for unrestricted induction, arbitrary higher-order generator closure, proof irrelevance, quotient syntax equality, or host evaluator soundness.

Theorem 8965.2 (MetaCIC generator-closure algebra NameCert obligations)**.** *For every accepted* MetaCICGeneratorClosureAlgebra$^{\uparrow}$ *carrier*

$$A = (U, K, R, C, O, W, T, P, S, L, H, Q, G, N),$$

the local NameCert$_{\text{MetaCICGeneratorClosureAlgebra}^{\uparrow}}$ *surface consists exactly of carrier admission through U, classifier exposure through K, identity closure through R, composition closure through C, alternation closure through O, restriction closure through W, finite-iteration closure through T, product closure through P, sum closure through S, algebra-ledger exactness through L, componentwise transport through H, displayed replay through Q, package provenance through G, and local naming through N.*

Proof. Project the carrier of Definition 8965.1. The rows U and K fix the carrier and classifier whose preservation is being certified.

Read the seven algebra rows next. Identity, composition, alternation, restriction, finite iteration, product, and sum are each displayed as a classifier-preserving generator operation, and none is read as a free-standing induction principle.

The ledger L records that all seven rows are consumed only through that generator-closure interpretation. Finally H, Q, G, N transport, replay, source, and name the same packet. Since the carrier contains no unrestricted induction, higher-order closure, proof-irrelevance, quotient-syntax, or host-evaluator coordinate, the listed rows exhaust the local NameCert surface. □

Theorem 8965.3 (MetaCIC generator-closure algebra operation readback)**.** *Every accepted* MetaCICGeneratorClos *read of a compound generator must factor through the finite operation route*

$$U, K \longmapsto R, C, O, W, T, P, S \longmapsto L, H, Q, G, N.$$

The route may certify identity, composition, alternation, restriction, finite iteration, product, and sum preservation for displayed classifiers, but it cannot be read as unrestricted induction or as closure under arbitrary generator formation.

Proof. Begin with U, K. A generator-closure operation has no public meaning until the carrier and classifier rows are fixed.

Next read the operation rows R, C, O, W, T, P, S. Each row records one finite algebra operation from the classifier principle and preserves the displayed classifier by the corresponding generator rule.

Then read the ledger and structural rows. The ledger keeps the operation inside the seven displayed cases, while H, Q, G, N transport, replay, source, and name the packet. No step adds a row for arbitrary generator formation or unrestricted induction. □

Theorem 8965.4 (MetaCIC generator-closure algebra nonescape)**.** *The public information exported by an accepted* MetaCICGeneratorClosureAlgebra$^{\uparrow}$ *carrier is exactly*

$$U, K, R, C, O, W, T, P, S, L, H, Q, G, N.$$

Thus downstream MetaCIC consumers may cite the displayed generator-closure algebra rows, but must separately supply any typing, conversion, confluence, normalization, quotient-syntax, or host-evaluator evidence they consume.

Proof. Inspect the carrier inventory. The only operation rows are identity, composition, alternation, restriction, finite iteration, product, and sum, all tied to the displayed carrier and classifier.

Definition 8965.2 fixes the NameCert surface to those rows. Definition 8965.3 fixes the route by which compound generators may be consumed.

Typing, conversion, confluence, normalization, quotient syntax, and host evaluator soundness are not coordinates of A. Any downstream use of those facts must cite a separate packet, so this algebra surface does not escape beyond classifier-preserving generator closure. □

Falsifiable prediction: Any accepted MetaCICGeneratorClosureAlgebra$^{\uparrow}$ read that treats identity, composition, alternation, restriction, finite iteration, product, or sum closure as unrestricted induction or arbitrary generator formation violates the algebra ledger.

Independence witness: generatorclosure, metacicclosurepreservation, metacic-audit-matrix, metacicidentity: no listed sibling is bijective to MetaCICGeneratorClosureAlgebra$^{\uparrow}$ because this packet jointly carries carrier and classifier rows, seven algebra-operation rows, ledger exactness, transport, replay, provenance, and local naming.

The Lean TasteGate expectation for this packet is explicit: a checked realization must provide a non-smoke Nontrivial MetaCICGeneratorClosureAlgebra$^{\uparrow}$ witness, a FieldFaithful MetaCICGeneratorClosureAlgebra$^{\uparrow}$ witness for the displayed rows $U, K, R, C, O, W, T, P, S, L, H, Q, G, N$, and a carrier-alignment theorem for the same fields before public TasteGate use.

Closure status for NameCert$_{\text{MetaCICGeneratorClosureAlgebra}^{\uparrow}}$.

Constructive story: A MetaCICGeneratorClosureAlgebra$^{\uparrow}$ packet is generated from a MetaCIC carrier row, a classifier row, identity, composition, alternation, restriction, finite-iteration, product, and sum generator-closure rows, an algebra ledger, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\text{MetaCICGeneratorClosureAlgebra}^{\uparrow}}$, seed)

Scope closed: Definition 8965.1, Definition 8965.2, Definition 8965.3, Definition 8965.4, the falsifiable prediction, the independence witness, and the TasteGate expectation seed the finite MetaCIC generator-closure algebra packet.

Formal verification: FormalStatus(NameCert$_{\text{MetaCICGeneratorClosureAlgebra}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close unrestricted induction, arbitrary higher-order generator closure, proof irrelevance, quotient syntax equality, host evaluator soundness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, classifier exposure, identity closure, composition closure, alternation closure, restriction closure, finite-iteration closure, product closure, sum closure, algebra-ledger exactness, TasteGate nontriviality, field faithfulness, transport stability, replay stability, provenance exhaustion, and local naming for BEDC.Derived.MetaCICGeneratorClosureAlgebraUp.

Chapter 8966

A Concrete Naming Certificate for $\mathsf{SchauderFiniteNetFixedPoint}^{\uparrow}$

Following Schauder, Brouwer, and Bishop–Bridges finite-net fixed-point arguments, the SchauderFiniteNetFixedPoin packet records the finite BEDC route by which a compact convex continuous self-map exposes an approximate fixed-point net before any endpoint consumer may read a fixed-point boundary. It sits over the Schauder packet of chapter 1923, the finite approximate fixed-point handoff of chapter 6087, the finite compact-map residual route of chapter 8184, the compact metric surface of chapter 129, the convex carrier of chapter 208, and the continuous-map row of chapter 130. The packet names finite nets, displacement ledgers, residual rows, transport, replay, provenance, and local naming; it is not a host fixed-point selector, open-cover compactness theorem, quotient equality of approximants, countable-choice schedule, or ambient completeness principle.

Definition 8966.1 (Schauder finite-net fixed-point carrier)**.** *A* $\mathsf{SchauderFiniteNetFixedPoint}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$T = (K, Q, F, M, A, E, D, R, H, C, P, N)$$

with the following displayed rows:

1. *K is the* $\mathsf{CompactMetric}^{\uparrow}$ *source row, exposing the finite compact-metric inspection windows used by the net.*
2. *Q is the* $\mathsf{ConvexSet}^{\uparrow}$ *row, recording membership and finite affine-combination stability for the compact convex carrier.*
3. *F is the* $\mathsf{ContinuousMap}^{\uparrow}$ *self-map row, carrying graph access, source membership, target membership, and displayed continuity data.*
4. *M is the* $\mathsf{SchauderFiniteCompactMap}^{\uparrow}$ *residual route, binding compact metric, convex, continuous-map, modulus, finite-net, displacement, and residual reads into one compact-map packet.*
5. *A is the* $\mathsf{FiniteApproximateFixedPoint}^{\uparrow}$ *handoff row, listing the accepted finite mesh, coverage, displacement tolerance, and approximate fixed-point read.*
6. *E is the finite-net exposure row, naming the centers, cells, tolerance requests, and projection reads actually inspected by the packet.*
7. *D is the displacement ledger comparing each inspected net point with its image through F at the displayed tolerance.*

8. *R is the fixed-point residual row exported toward* $\mathsf{SchauderFixedPoint}^{\uparrow}$ *after* K, Q, F, M, A, E, D *have been displayed.*
9. *H records componentwise* hsame *transport for the compact source, convex carrier, self-map, compact-map route, approximate handoff, net exposure, displacement ledger, residual row, replay, provenance, and local naming row.*
10. *C records displayed* Cont *replay from a fixed-point request through* $K, Q, F, M, A, E, D, R, H, P, N$.
11. *P is the* Pkg *provenance over* $\mathsf{SchauderFiniteNetFixedPoint}^{\uparrow}$, $\mathsf{SchauderFixedPoint}^{\uparrow}$, $\mathsf{FiniteApproximateFixedPoint}^{\uparrow}$, $\mathsf{SchauderFiniteCompactMap}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{ConvexSet}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
12. *N is the local* $\mathsf{NameCert}_{\mathsf{SchauderFiniteNetFixedPoint}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $K, Q, F, M, A, E, D, R, H, C, P, N$. *It has no coordinate for a selected fixed point, host compactness, open-cover compactness, quotient equality of approximants, countable choice, or ambient completeness.*

Theorem 8966.2 (Schauder finite-net fixed-point NameCert obligations)**.** *For every accepted* $\mathsf{SchauderFiniteNetFixedPoint}^{\uparrow}$ *carrier*

$$T = (K, Q, F, M, A, E, D, R, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{SchauderFiniteNetFixedPoint}^{\uparrow}}$ *surface consists exactly of compact metric admission through K, convex carrier admission through Q, continuous self-map admission through F, compact-map residual routing through M, finite approximate fixed-point handoff through A, finite-net exposure through E, displacement-ledger comparison through D, fixed-point residual export through R, componentwise* hsame *transport, displayed* Cont *replay, package provenance, local naming, and non-escape from host fixed-point selection, open-cover compactness, quotient approximants, countable choice, and ambient completeness.*

Proof. Project the carrier of Definition 8966.1. The accepted packet displays exactly the rows $K, Q, F, M, A, E, D, R, H, C, P, N$, so no consumer can read compactness, convexity, continuity, finite-net data, displacement, residual evidence, transport, replay, provenance, or naming outside this list.

Read the geometric source rows first. The compact metric row K supplies the inspected finite windows, the convex row Q supplies membership and affine-combination stability, and the continuous-map row F supplies the self-map data over that same displayed carrier.

The approximation route then passes through M and A. The compact-map row M packages the residual route of chapter 8184, while the approximate fixed-point row A supplies the finite mesh and tolerance handoff of chapter 6087.

Finally E, D, R, H, C, P, N expose the inspected net, compare displacements, export the residual row, transport the same components, replay the displayed request, record provenance, and register the local name. Since none of those rows names a host fixed-point selector, open-cover compactness theorem, quotient approximant, countable-choice schedule, or ambient completeness object, the listed obligations exhaust the local certificate. □

Theorem 8966.3 (Schauder finite-net approximate route)**.** *Every* $\mathsf{SchauderFixedPoint}^{\uparrow}$ *consumer of an accepted* $\mathsf{SchauderFiniteNetFixedPoint}^{\uparrow}$ *carrier factors through the finite route*

$\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{ConvexSet}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{SchauderFiniteCompactMap}^{\uparrow}$, $\mathsf{FiniteApproximateFixedPoint}^{\uparrow}$, BHist

The consumer may inspect the residual row R only after the compact metric source, convex carrier, continuous self-map, compact-map residual route, finite approximate fixed-point handoff, finite-net exposure, displacement ledger, transport, replay, provenance, and local naming rows have all been displayed.

Proof. Start with a fixed-point consumer. The continuation row C is the only replay route, and it displays K, Q, F, M, A, E, D before R can be consumed.

The source side is finite and carried. Rows K and Q bind the compact convex carrier, while F gives the displayed self-map over that carrier. These rows are the only route to the compact metric, convex, and continuous-map siblings cited by the packet.

The fixed-point side is approximate. Row M carries the finite compact-map residual route, row A carries the finite approximate fixed-point handoff, row E exposes the net actually inspected, and row D records the displacement comparisons that feed R.

Thus the residual read exported to $\mathsf{SchauderFixedPoint}^{\uparrow}$ is the finite route displayed in the theorem. The transport, replay, provenance, and local naming rows preserve that route and add no selected fixed point, quotient equality, open-cover compactness, countable choice, or ambient completeness. □

Closure status for $\mathsf{NameCert}_{\mathsf{SchauderFiniteNetFixedPoint}^{\uparrow}}$.

Constructive story: A $\mathsf{SchauderFiniteNetFixedPoint}^{\uparrow}$ packet is generated from CompactMetric source rows, ConvexSet carrier rows, ContinuousMap self-map rows, SchauderFiniteCompactMap residual rows, FiniteApproximateFixedPoint handoff rows, finite-net exposure rows, displacement ledgers, residual rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{SchauderFiniteNetFixedPoint}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8966.1, Definition 8966.2, and Definition 8966.3 seed the finite-net fixed-point packet over compact metric, convex, continuous-map, compact-map residual, finite approximate fixed-point, displacement, residual, transport, replay, provenance, and local naming rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{SchauderFiniteNetFixedPoint}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close exact fixed-point selection, a host Schauder theorem, open-cover compactness, quotient equality of approximants, countable choice, ambient completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, compact metric exposure, convex carrier exposure, continuous-map replay, compact-map residual routing, approximate fixed-point handoff, finite-net exposure, displacement-ledger exactness, residual export, transport, replay, provenance, and local naming for BEDC.Derived.SchauderFiniteNetFixedPoin

Chapter 8967

A Concrete Naming Certificate for $\mathsf{RegularCauchyWindowAssociator}^{\uparrow}$

Following Bishop and Bridges on regular Cauchy sequence arithmetic, the $\mathsf{RegularCauchyWindowAssociator}^{\uparrow}$ packet records the finite window reassociation route used when a regular rational product or paired completion read is regrouped before reaching the terminal Real seal. It sits over the finite schedule surface of chapter 126, the regular rational readback of chapter 301, the dyadic tolerance core of chapter 291, the product rows of chapter 464 and chapter 461, and the value-facing boundary of chapter 38. The packet is a finite reassociation certificate for displayed windows; it does not assert associativity of completed real multiplication, quotient stream equality, selected representatives, countable choice, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 8967.1 (Regular Cauchy window associator carrier)**.** *A* $\mathsf{RegularCauchyWindowAssociator}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$A = (W_L, W_M, W_R, D_L, D_M, D_R, Q_L, Q_M, Q_R, P_L, P_R, S, H, C, G, N)$$

with the following displayed rows:

1. W_L, W_M, W_R *are the three finite* $\mathsf{StreamName}^{\uparrow}$ *windows being reassociated.*
2. D_L, D_M, D_R *are the corresponding* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance rows at the shared requested scale.*
3. Q_L, Q_M, Q_R *are the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback rows served from those windows and tolerances.*
4. P_L *and* P_R *are the left- and right-parenthesized product-window rows read through* $\mathsf{CauchyProduct}^{\uparrow}$ *and* $\mathsf{RegularCauchyProduct}^{\uparrow}$.
5. S *is the terminal* $\mathsf{Real}^{\uparrow}$ *seal reached only after the three windows, three tolerance rows, three readbacks, and both parenthesized product rows remain visible.*
6. H *records componentwise* hsame *transport for the windows, tolerances, readbacks, product rows, seal, replay, provenance, and local naming.*
7. C *records displayed* Cont *replay from a reassociation request through the same finite rows.*
8. G *is the* Pkg *provenance over* $\mathsf{RegularCauchyWindowAssociator}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{CauchyProduct}^{\uparrow}$, $\mathsf{RegularCauchyProduct}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
9. N *is the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyWindowAssociator}^{\uparrow}}$ *row.*

The carrier has no coordinate for quotient sequence equality, selected representatives, hidden infinite reassociation, countable choice, host multiplication, or ambient completeness of $\mathsf{Real}^{\uparrow}$.

Theorem 8967.2 (Regular Cauchy window associator NameCert obligations)**.** *For every accepted* $\mathsf{RegularCauchyWindowAssociator}^{\uparrow}$ *carrier*

$$A = (W_L, W_M, W_R, D_L, D_M, D_R, Q_L, Q_M, Q_R, P_L, P_R, S, H, C, G, N),$$

the local $\mathsf{NameCert}_{\mathsf{RegularCauchyWindowAssociator}^{\uparrow}}$ *surface consists exactly of carrier admission for the displayed packet, three finite* $\mathsf{StreamName}^{\uparrow}$ *windows, three* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance rows, three* $\mathsf{RegSeqRat}^{\uparrow}$ *readbacks, the two parenthesized product-window rows* P_L, P_R*, the terminal* $\mathsf{Real}^{\uparrow}$ *seal, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, local naming, and nonescape from quotient stream equality, selected representatives, hidden infinite reassociation, countable choice, host multiplication, trichotomy, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the carrier of Definition 8967.1. The tuple displays the three windows, three dyadic tolerance rows, three regular rational readbacks, two parenthesized product rows, terminal seal, transport, replay, provenance, and local naming as separate coordinates.

The product rows are downstream of the finite windows. Row P_L reads the left-parenthesized window route, and row P_R reads the right-parenthesized route, both through the existing CauchyProduct and RegularCauchyProduct sibling surfaces.

Finally inspect S, H, C, G, N. The Real seal, componentwise transport, replay, provenance, and local naming preserve the same displayed rows. Since no carrier coordinate stores quotient stream equality, selected representatives, hidden infinite reassociation, countable choice, host multiplication, trichotomy, or ambient completeness, the listed rows exhaust the NameCert surface. □

Theorem 8967.3 (Regular Cauchy window associator RegSeqRat handoff)**.** *Every RegSeqRat or Real-facing consumer of an accepted* $\mathsf{RegularCauchyWindowAssociator}^{\uparrow}$ *carrier must expose the three* $\mathsf{StreamName}^{\uparrow}$ *windows, the three* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance rows, the three* $\mathsf{RegSeqRat}^{\uparrow}$ *readbacks, and both parenthesized product-window rows before it may inspect the terminal* $\mathsf{Real}^{\uparrow}$ *seal. The reassociation handoff is therefore a finite displayed route through StreamName, RegSeqRat, DyadicRatCore, CauchyProduct, RegularCauchyProduct, and Real rows, not an ambient completeness or quotient-stream principle.*

Proof. Start with a RegSeqRat-facing reassociation request. The readback rows Q_L, Q_M, Q_R are meaningful only after the corresponding windows W_L, W_M, W_R and tolerance rows D_L, D_M, D_R have been exposed.

Use the product rows P_L and P_R to compare the two parenthesized routes. Both rows are product-window data attached to the same three displayed windows and dyadic scales, so neither can introduce a hidden product representative or a host multiplication coordinate.

The terminal seal S is then read only through the preserved finite route. Transport, replay, provenance, and local naming keep that route attached to the accepted packet, leaving no coordinate for quotient stream equality, selected representatives, countable choice, trichotomy, host multiplication, or ambient $\mathsf{Real}^{\uparrow}$ completeness. □

Falsifiable prediction: Every accepted $\mathsf{RegularCauchyWindowAssociator}^{\uparrow}$ read displays three $\mathsf{StreamName}^{\uparrow}$ windows, three $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance rows, three $\mathsf{RegSeqRat}^{\uparrow}$ readbacks, two parenthesized product-window rows, a terminal $\mathsf{Real}^{\uparrow}$ seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming.

Independence witness: streamname, regseqrat, dyadicratcore, cauchyproduct, regularcauchyproduct, real: RegularCauchyWindowAssociator$^{\uparrow}$ is not bijective to any listed sibling because it carries both parenthesized product-window routes over one three-window regular Cauchy readback surface.

Closure status for NameCert$_{\text{RegularCauchyWindowAssociator}^{\uparrow}}$.

Constructive story: A RegularCauchyWindowAssociator$^{\uparrow}$ packet is generated from three StreamName windows, three DyadicRatCore tolerance rows, three RegSeqRat readbacks, two parenthesized product-window rows, a terminal Real seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\text{RegularCauchyWindowAssociator}^{\uparrow}}$, seed)

Scope closed: Definition 8967.1, Definition 8967.2, and Definition 8967.3 seed the finite reassociation route over StreamName, RegSeqRat, DyadicRatCore, product, and Real rows.

Formal verification: FormalStatus(NameCert$_{\text{RegularCauchyWindowAssociator}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close Lean verification, associativity of completed real multiplication, quotient stream equality, selected representatives, hidden infinite reassociation, countable choice, trichotomy, host multiplication, or ambient Real$^{\uparrow}$ completeness.

Upgrade path: Obligation closure requires checked carrier admission, product-window exactness, RegSeqRat handoff determinacy, transport stability, replay stability, provenance non-escape, and local naming for BEDC.Derived.RegularCauchyWindowAssociatorU

Chapter 8968

A Concrete Naming Certificate for $\mathsf{FiniteObservationDiagonalRouter}^{\uparrow}$

The $\mathsf{FiniteObservationDiagonalRouter}^{\uparrow}$ packet realizes the transported stationary diagonal route as finite NameCert data rather than as a completeness principle. It reads a displayed observation window through chapter 126, the regular rational boundary of chapter 301, the dyadic tolerance ledger of chapter 291, the diagonal seal of chapter 4241, and the terminal real-name boundary of chapter 38. The router records only the finite path by which a diagonal row is inspected; it does not select limits, quotient streams, host real representatives, countable-choice schedules, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 8968.1 (Finite observation diagonal router carrier)**.** *A* $\mathsf{FiniteObservationDiagonalRouter}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$R = (W, Q, D, \Delta, E, S, H, C, P, N)$$

with the following displayed rows:

1. W *is the* $\mathsf{StreamName}^{\uparrow}$ *finite observation window for the transported diagonal row.*
2. Q *is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback surface consumed at that window.*
3. D *is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger attached to the same observation request.*
4. Δ *is the diagonal-routing row, recording the finite transport from the displayed window to the selected diagonal read.*
5. E *is the* $\mathsf{RegularCauchyDiagonalSeal}^{\uparrow}$ *row that seals the diagonal read before the Real-facing boundary is public.*
6. S *is the terminal* $\mathsf{Real}^{\uparrow}$ *seal read only after* W, Q, D, Δ, E *remain visible.*
7. H *records componentwise* hsame *transport for the window, readback, dyadic ledger, diagonal route, seal, replay, provenance, and local naming.*
8. C *records displayed* Cont *replay from the observation request through the same finite rows.*
9. P *is the* Pkg *provenance over* $\mathsf{FiniteObservationDiagonalRouter}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegularCauchyDiagonalSeal}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
10. N *is the local* $\mathsf{NameCert}_{\mathsf{FiniteObservationDiagonalRouter}^{\uparrow}}$ *row.*

The carrier has no coordinate for an infinite diagonal selector, quotient stream equality, selected representatives, countable choice, host real equality, or ambient completeness of $\mathsf{Real}^{\uparrow}$.

Theorem 8968.2 (Finite observation diagonal router NameCert obligations)**.** *For every accepted* $\mathsf{FiniteObservationDiagonalRouter}^{\uparrow}$ *carrier*

$$R = (W, Q, D, \Delta, E, S, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{FiniteObservationDiagonalRouter}^{\uparrow}}$ *surface consists exactly of StreamName window admission through* W*, RegSeqRat readback through* Q*, dyadic tolerance exposure through* D*, finite diagonal routing through* Δ*, regular Cauchy diagonal sealing through* E*, terminal Real sealing through* S*, componentwise* hsame *transport through* H*, displayed* Cont *replay through* C*, provenance through* P*, local naming through* N*, and nonescape from infinite diagonal selection, quotient stream equality, selected representatives, countable choice, host real equality, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the carrier of Definition 8968.1. The analytic rows are exactly the finite observation window, regular rational readback, dyadic tolerance ledger, diagonal route, diagonal seal, and Real-facing seal.

The diagonal route is downstream of the displayed window. Row Δ can be inspected only after W, Q, D have been exposed, and row E seals that finite route through the regular Cauchy diagonal seal rather than through an infinite selector.

Finally read S, H, C, P, N. The terminal seal, transport, replay, provenance, and local naming preserve the same finite path. Because no carrier coordinate stores quotient stream equality, selected representatives, countable choice, host real equality, or ambient completeness, the listed rows exhaust the local NameCert surface. □

Theorem 8968.3 (Finite observation diagonal router Real handoff)**.** *Every Real-facing read from an accepted* $\mathsf{FiniteObservationDiagonalRouter}^{\uparrow}$ *carrier must expose the* $\mathsf{StreamName}^{\uparrow}$ *window* W*,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback* Q*,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger* D*, finite diagonal route* Δ*, and* $\mathsf{RegularCauchyDiagonalSeal}^{\uparrow}$ *row* E *before it may consume the terminal* $\mathsf{Real}^{\uparrow}$ *seal* S*. The handoff is therefore a finite observation route through StreamName, RegSeqRat, DyadicRatCore, RegularCauchyDiagonalSeal, and Real rows, not a proof of Real completeness.*

Proof. Start with the observation window. The regular rational readback Q and dyadic ledger D are attached to the same finite request W, so no Real-facing row is public before those three rows are visible.

Use the diagonal route Δ and seal E. They route the displayed finite window through the regular Cauchy diagonal seal, keeping the diagonal read as packet data rather than as an ambient limit choice.

The terminal seal S is then consumed with H, C, P, N still attached. Transport, replay, provenance, and local naming preserve the finite route and add no coordinate for quotient stream equality, selected representatives, countable choice, host real equality, or ambient $\mathsf{Real}^{\uparrow}$ completeness. □

Falsifiable prediction: Every accepted $\mathsf{FiniteObservationDiagonalRouter}^{\uparrow}$ read displays a $\mathsf{StreamName}^{\uparrow}$ finite window, a $\mathsf{RegSeqRat}^{\uparrow}$ readback row, a $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance ledger, a finite diagonal-route row, a $\mathsf{RegularCauchyDiagonalSeal}^{\uparrow}$ row, a terminal $\mathsf{Real}^{\uparrow}$ seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming.

Independence witness: streamname, regseqrat, dyadicratcore, real, regular-cauchy-diagonal-seal: $\mathsf{FiniteObservationDiagonalRouter}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries the finite observation window, diagonal-routing row, diagonal seal, terminal Real seal, and structural NameCert rows in one packet.

Closure status for $\mathsf{NameCert}_{\mathsf{FiniteObservationDiagonalRouter}^{\uparrow}}$.

Constructive story: A $\mathsf{FiniteObservationDiagonalRouter}^{\uparrow}$ packet is generated from a StreamName finite observation window, RegSeqRat readback, DyadicRatCore tolerance ledger, finite diagonal-routing row, RegularCauchyDiagonalSeal row, terminal Real seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{FiniteObservationDiagonalRouter}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8968.1, Definition 8968.2, and Definition 8968.3 seed the finite diagonal observation route over StreamName, RegSeqRat, DyadicRatCore, RegularCauchyDiagonalSeal, and Real rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{FiniteObservationDiagonalRouter}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close Lean verification, infinite diagonal selection, quotient stream equality, selected representatives, countable choice, host real equality, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Upgrade path: Obligation closure requires checked carrier admission, finite observation routing, diagonal seal exactness, Real handoff non-escape, transport stability, replay stability, provenance non-escape, and local naming for BEDC.Derived.FiniteObservationDiagonalRouterUp.

Chapter 8969

A Concrete Naming Certificate for $\mathsf{KunnethFormula}^{\uparrow}$

Following Eilenberg and Mac Lane, the $\mathsf{KunnethFormula}^{\uparrow}$ packet records the finite BEDC surface at which homology of a tensor product is read through displayed source complexes, tensor rows, homology projections, and the retained Tor obstruction. It sits beside the homology certificate of chapter 98, the cohomology certificate of chapter 99, the tensor product certificate of chapter 87, and the abelian-group source of chapter 42. The packet names a finite algebraic-topology route; it does not import a host exact-sequence theorem, selected splitting, quotient homology equality, universal coefficient theorem, spectral sequence, or ambient category of chain complexes.

Definition 8969.1 (KunnethFormula carrier)**.** *A* $\mathsf{KunnethFormula}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (C, D, T, H, Q, O, S, R, P, N)$$

with the following displayed rows:

1. *C is the first chain-complex source row, exposing only the inspected differential, cycle, boundary, and degree-window data through* $\mathsf{Homology}^{\uparrow}$*.*
2. *D is the second chain-complex source row, with the same visible homology-facing data for the paired source.*
3. *T is the* $\mathsf{TensorProduct}^{\uparrow}$ *row, displaying the tensor product of the two source windows and the induced differential ledger for the inspected degree.*
4. *H is the homology projection row, reading the visible homology outputs of C, D, and T through* $\mathsf{Homology}^{\uparrow}$ *rather than through host quotient groups.*
5. *Q is the cohomology-adjacent comparison row, available only as a sibling reference to* $\mathsf{Cohomology}^{\uparrow}$ *when a consumer asks for dual bookkeeping of the same finite degree window.*
6. *O is the retained* Tor*-boundary obstruction row over the displayed* $\mathsf{AbGroup}^{\uparrow}$ *source data.*
7. *S records componentwise* hsame *transport for the source, tensor, homology, cohomology-adjacent, obstruction, replay, provenance, and naming rows.*
8. *R records displayed* Cont *replay from source admission through tensor formation, homology projection, obstruction retention, transport, provenance, and local naming.*
9. *P is the* Pkg *provenance over* $\mathsf{KunnethFormula}^{\uparrow}$*,* $\mathsf{Homology}^{\uparrow}$*,* $\mathsf{Cohomology}^{\uparrow}$*,* $\mathsf{TensorProduct}^{\uparrow}$*,* $\mathsf{AbGroup}^{\uparrow}$*,* BHist*,* hsame*,* Cont*, and* $\mathsf{NameCert}$ *rows.*

10. N is the local $\mathsf{NameCert}_{\mathsf{KunnethFormula}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these rows. It has no coordinate for a host exact sequence, selected splitting, quotient homology equality, a spectral sequence, countable choice, or an ambient abelian category.

Theorem 8969.2 (KunnethFormula NameCert obligations)**.** *For every accepted* $\mathsf{KunnethFormula}^{\uparrow}$ *carrier*

$$K = (C, D, T, H, Q, O, S, R, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{KunnethFormula}^{\uparrow}}$ *surface consists exactly of carrier admission for the displayed packet, source-chain exposure through C, D, tensor compatibility through T, homology projection through H, cohomology-adjacent bookkeeping through Q, retained* Tor *obstruction through O, classifier stability through componentwise* hsame *transport S, displayed* Cont *replay through R,* Pkg *provenance through P, local naming through N, and nonescape from host exact sequences, selected splittings, quotient homology equality, spectral sequences, countable choice, or ambient category structure.*

Proof. Project the carrier of Definition 8969.1. The rows $C, D, T, H, Q, O, S, R, P, N$ display source admission, tensor formation, homology projection, cohomology-adjacent bookkeeping, obstruction retention, transport, replay, provenance, and local naming as separate finite coordinates.

First inspect the source rows. The rows C and D expose only the chain-complex windows read through $\mathsf{Homology}^{\uparrow}$, while T records the $\mathsf{TensorProduct}^{\uparrow}$ route that combines those windows before any product homology row is inspected.

Next read the homology-facing rows H, Q, O. The homology projection is tied to the displayed tensor row; the cohomology-adjacent row is only sibling bookkeeping; and the Tor row remains an obstruction rather than a selected splitting or an exact-sequence discharge.

Finally pass through S, R, P, N. The componentwise transport, replay, provenance, and local name preserve the same finite packet. Since no row contains a host exact sequence, selected splitting, quotient homology equality, spectral sequence, countable-choice schedule, or ambient abelian category, the listed rows exhaust the local NameCert surface. □

Falsifiable prediction: Every accepted $\mathsf{KunnethFormula}^{\uparrow}$ read displays source homology rows, a tensor-product row, a homology projection row, a retained Tor obstruction, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming before any Kunneth-facing consumer may inspect the packet.

Independence witness: homology, cohomology, tensorproduct, abgroup: $\mathsf{KunnethFormula}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries two source chain windows, tensor compatibility, homology projection, cohomology-adjacent bookkeeping, a retained Tor obstruction, transport, replay, provenance, and local naming in one finite packet.

Closure status for $\mathsf{NameCert}_{\mathsf{KunnethFormula}^{\uparrow}}$**.**

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{KunnethFormula}^{\uparrow}}$, seed)

Scope closed: Definition 8969.1 and Definition 8969.2 seed the source-chain, tensor-product, homology-projection, cohomology-adjacent, Tor-obstruction, transport, replay, provenance, and local naming route.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{KunnethFormula}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim a host exact sequence, selected splitting, quotient homology equality, universal coefficient theorem, spectral sequence, countable choice, ambient abelian category, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, source-chain exposure, tensor compatibility, homology projection, Tor-obstruction retention, classifier stability, replay, provenance, and local naming for BEDC.Derived.KunnethFormulaUp.

Constructive story: A KunnethFormula$^{\uparrow}$ packet is generated from two displayed homology source windows, a tensor-product row, a homology projection row, a cohomology-adjacent bookkeeping row, a retained Tor-obstruction row, componentwise hsame transport, displayed Cont replay, package provenance, and a local NameCert row.

Chapter 8970

A Concrete Naming Certificate for $\mathsf{PoincareDuality}^{\uparrow}$

Following Hatcher and Spanier, the $\mathsf{PoincareDuality}^{\uparrow}$ packet records the finite BEDC route by which an oriented compact manifold fundamental-class row pairs cohomology and homology through the cap-product surface. It sits beside the manifold source of chapter 96, the homology carrier of chapter 98, the cohomology carrier of chapter 99, and the chain-cochain action route of chapter 7629. The packet names only displayed orientation, degree-window, cap-product, homology, cohomology, transport, replay, provenance, and local naming rows; it does not import host triangulation choice, quotient chain equality, excision, universal coefficients, or an ambient duality theorem.

Definition 8970.1 (Poincare duality carrier)**.** *A* $\mathsf{PoincareDuality}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$D = (M, O, H, G, C, Q, T, R, P, N)$$

with the following displayed rows:

1. *M is the* $\mathsf{Manifold}^{\uparrow}$ *source row, exposing the compact oriented manifold data only through the registered manifold NameCert surface.*
2. *O is the orientation and fundamental-class row, recording the displayed top-dimensional homology class used by the packet.*
3. *H is the* $\mathsf{Homology}^{\uparrow}$ *row that carries the target homology degree and the fundamental-class endpoint.*
4. *G is the* $\mathsf{Cohomology}^{\uparrow}$ *row that carries the source cohomology degree inspected by the duality read.*
5. *C is the* $\mathsf{CapProduct}^{\uparrow}$ *action row, tying the cohomology read and the fundamental-class row to the resulting homology read.*
6. *Q is the degree-window row, naming the manifold dimension, cohomology degree, and complementary homology degree used by the displayed action.*
7. *T records componentwise* hsame *transport for manifold, orientation, homology, cohomology, cap-product, degree-window, replay, provenance, and local naming rows.*
8. *R records displayed* Cont *replay from a Poincare-duality request through $M, O, H, G, C, Q, T, P, N$.*
9. *P is the* Pkg *provenance over* $\mathsf{PoincareDuality}^{\uparrow}$, $\mathsf{Manifold}^{\uparrow}$, $\mathsf{Homology}^{\uparrow}$, $\mathsf{Cohomology}^{\uparrow}$, $\mathsf{CapProduct}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* $\mathsf{NameCert}$.

10. N is the local $\mathsf{NameCert}_{\mathsf{PoincareDuality}^{\uparrow}}$ *row.*
The classifier compares accepted packets only through $M, O, H, G, C, Q, T, R, P, N$. It has no coordinate for a selected triangulation, quotient chain equality, a host manifold theorem, universal coefficient data, excision, or bridge checking.

Theorem 8970.2 (Poincare duality NameCert obligations)**.** *For every accepted* $\mathsf{PoincareDuality}^{\uparrow}$ *carrier*

$$D = (M, O, H, G, C, Q, T, R, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{PoincareDuality}^{\uparrow}}$ *surface consists exactly of manifold-source admission through M, orientation and fundamental-class exposure through O, homology exposure through H, cohomology exposure through G, cap-product action exposure through C, degree-window exposure through Q, componentwise* hsame *transport through T, displayed* Cont *replay through R,* Pkg *provenance through P, and local naming through N.*

Proof. Project the carrier of Definition 8970.1. The displayed packet contains the manifold source, orientation row, homology row, cohomology row, cap-product row, degree window, and structural rows.

Read the algebraic-topology route in order. The manifold row M supplies only the registered finite manifold surface, while O displays the orientation and fundamental class. The rows G and H expose the cohomology and homology sides to be paired.

The cap-product row C is the only action coordinate. It consumes the cohomology and fundamental-class rows at the degree window Q before any homology-facing output is read.

Finally T, R, P, N transport, replay, source, and name the same finite route. Since the carrier has no selected triangulation, quotient chain equality, universal coefficient data, excision, host theorem, or bridge row, the listed rows exhaust the NameCert surface. □

Theorem 8970.3 (Poincare duality scope boundary)**.** *Every duality read exported by an accepted* $\mathsf{PoincareDuality}^{\uparrow}$ *packet factors through*

$$M, O, H, G, C, Q, T, R, P, N.$$

A consumer may read the displayed manifold source, orientation and fundamental-class row, cohomology row, cap-product action, complementary homology row, degree window, transport, replay, provenance, and local name. The consumer may not read a selected triangulation, chain-level quotient equality, universal coefficient theorem, excision theorem, ambient manifold theorem, or bridge-checked standard schema from the packet.

Proof. Start with the obligation theorem. It identifies the complete visible row inventory for the local certificate and gives no coordinate outside $M, O, H, G, C, Q, T, R, P, N$.

Use the sibling route. The manifold chapter supplies M, homology supplies H and the fundamental-class endpoint named by O, cohomology supplies G, and cap product supplies the displayed action row C at the degree window Q.

The structural rows preserve this route under hsame transport and Cont replay. Because the excluded host principles are absent from the carrier and from the local classifier, any consumer claiming them has left the $\mathsf{PoincareDuality}^{\uparrow}$ packet. □

Falsifiable prediction: Every accepted $\mathsf{PoincareDuality}^{\uparrow}$ read exposes ManifoldUp, HomologyUp, CohomologyUp, CapProductUp, orientation, degree-window, transport, replay, provenance, and local NameCert rows before a duality-facing consumer reads a complementary homology output.

Independence witness: manifold, homology, cohomology, cap-product: none is bijective to $\mathsf{PoincareDuality}^{\uparrow}$ because this packet alone binds an oriented manifold fundamental-class row to the cohomology-to-homology cap-product route in one finite NameCert surface.

Closure status for $\mathsf{NameCert}_{\mathsf{PoincareDuality}^{\uparrow}}$.

Constructive story: A $\mathsf{PoincareDuality}^{\uparrow}$ packet is generated from a ManifoldUp source row, orientation and fundamental-class rows, HomologyUp and CohomologyUp rows, a CapProductUp action row, a complementary degree-window row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{PoincareDuality}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8970.1, Definition 8970.2, and Definition 8970.3 seed the finite oriented-manifold cap-product route from displayed cohomology rows to complementary homology rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{PoincareDuality}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close selected triangulations, quotient chain equality, universal coefficient data, excision, ambient manifold duality, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, orientation and fundamental-class exposure, homology and cohomology row exposure, cap-product action exactness, degree-window exactness, transport, replay, provenance, and local naming for BEDC.Derived.PoincareDualityUp.

Chapter 8971

A Concrete Naming Certificate for $\mathsf{IntervalBisectionChain}^{\uparrow}$

Following Bishop and Bridges constructive interval bisection, the $\mathsf{IntervalBisectionChain}^{\uparrow}$ packet records a finite nested row of dyadic intervals before any infinite branch, Dedekind cut, selected limit, or ambient completeness principle is available. It sits after the single-step routes of chapter 7168 and chapter 7273, reads dyadic endpoint and width arithmetic through chapter 291, exports finite windows to chapter 126, hands regular rational readback to chapter 301, and reaches a terminal real-facing seal only through chapter 38. The finite chain is the carrier-level source for the nested route of chapter 7290; it does not supply interval choice, Heine–Borel compactness, quotient real equality, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Falsifiable prediction: A consumer that reads an interval bisection chain without endpoint rows, containment rows, width-halving rows, finite StreamName windows, RegSeqRat readback, DyadicRatCore arithmetic, structural transport, continuation replay, provenance, and local NameCert rows has left the $\mathsf{IntervalBisectionChain}^{\uparrow}$ packet.

Independence witness: bishop interval bisection, dyadic interval bisection, nested interval principle, stream name, regseqrat, dyadicratcore, real: $\mathsf{IntervalBisectionChain}^{\uparrow}$ is not bijective to any one sibling because it jointly carries the whole finite nested row, per-step dyadic arithmetic, window generation, regular readback, terminal sealing, transport, replay, provenance, and local naming.

Definition 8971.1 (Interval bisection chain carrier)**.** *An* $\mathsf{IntervalBisectionChain}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$C = (I_0, \ldots, I_n, E, K, W, S, R, Q, H, T, P, N)$$

where each $I_i = [a_i, b_i]$ *is a displayed dyadic interval row and the packet exposes the following data:*

1. *E is the endpoint ledger, listing the dyadic endpoints a_i, b_i and their* $\mathsf{DyadicRatCore}^{\uparrow}$ *admission rows.*
2. *K is the containment ledger, recording $I_{i+1} \subseteq I_i$ for every displayed successor step.*
3. *W is the width-halving ledger, recording $b_{i+1} - a_{i+1} \leq (b_i - a_i)/2$ through dyadic arithmetic rows.*
4. *S is the finite* $\mathsf{StreamName}^{\uparrow}$ *window schedule generated from the endpoint rows and successor depth n.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row attached to the midpoint or endpoint selector read from the finite windows.*

6. *Q is the terminal* $\mathsf{Real}^{\uparrow}$ *seal available only after E, K, W, S, R have all been displayed.*
7. *H records componentwise* hsame *transport for the interval rows, endpoint ledger, containment ledger, width ledger, window schedule, regular readback, real seal, replay, provenance, and local name.*
8. *T records displayed* Cont *replay from an interval-chain request through $I_0, \ldots, I_n, E, K, W, S, R, Q, H, P, N$.*
9. *P records* Pkg *provenance over* $\mathsf{IntervalBisectionChain}^{\uparrow}$, $\mathsf{BishopIntervalBisection}^{\uparrow}$, $\mathsf{DyadicIntervalBisection}^{\uparrow}$, $\mathsf{NestedIntervalPrinciple}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{IntervalBisectionChain}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through these displayed rows. It has no coordinate for a chosen infinite branch, Dedekind cut, interval choice principle, Heine–Borel cover argument, quotient real equality, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 8971.2 (Interval bisection chain NameCert obligations)**.** *For every accepted* $\mathsf{IntervalBisectionChain}^{\uparrow}$ *carrier*

$$C = (I_0, \ldots, I_n, E, K, W, S, R, Q, H, T, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{IntervalBisectionChain}^{\uparrow}}$ *surface consists exactly of finite interval-row admission for $I_0, \ldots, I_n$, endpoint admission through E, successor containment through K, width-halving exactness through W, finite window generation through S, regular rational readback through R, terminal real sealing through Q, componentwise* hsame *transport through H, displayed* Cont *replay through T,* Pkg *provenance through P, and local naming through N.*

Proof. Project the carrier of Definition 8971.1. The analytic rows are the displayed intervals, endpoint ledger, containment ledger, width-halving ledger, finite window schedule, regular rational readback, and terminal real seal.

The successor rows are read in order. Endpoint admission supplies the dyadic arithmetic inputs, containment keeps each retained child inside its predecessor, and the width ledger records the displayed halving budget for the same successor step.

The value-facing rows are downstream. The StreamName schedule is generated from the finite endpoint rows, the RegSeqRat readback reads the finite windows, and the Real seal is available only after those rows have been displayed.

Finally H, T, P, N transport, replay, source, and name the same packet. Since no coordinate carries a chosen infinite branch, Dedekind cut, interval choice, Heine–Borel cover argument, quotient real equality, countable choice, or ambient completeness, the listed rows exhaust the local NameCert surface. □

Theorem 8971.3 (Interval bisection chain regular Cauchy window)**.** *Every* $\mathsf{RegSeqRat}^{\uparrow}$ *or* $\mathsf{Real}^{\uparrow}$ *consumer of an accepted* $\mathsf{IntervalBisectionChain}^{\uparrow}$ *packet must first read the finite route*

$$I_0, \ldots, I_n, E, K, W, S, R, Q, H, T, P, N.$$

The route supplies a regular Cauchy window from nested dyadic intervals by finite endpoint arithmetic, successor containment, and width-halving rows. It exports no selected infinite branch, no Dedekind cut, no interval-choice rule, no Heine–Borel subcover, no quotient real equality, and no ambient $\mathsf{Real}^{\uparrow}$ *completeness theorem.*

Proof. Begin with the obligation surface of Definition 8971.2. Any accepted consumer must expose the interval rows, endpoint ledger, containment ledger, and width-halving ledger before it can read a window or a value-facing seal.

The regular Cauchy window is finite. The displayed depth n bounds the row inspection, the StreamName schedule S records exactly the inspected windows, and the RegSeqRat row R reads only those finite windows together with the dyadic tolerance budget supplied by E and W.

The terminal Real read is therefore downstream of the finite chain. The seal Q is not a selected limit or quotient real equality; it is only the real-facing boundary reached after the chain, window, and readback rows have been displayed.

The structural rows H, T, P, N keep the same packet attached to the read. Since the excluded principles are absent from the carrier and from the local classifier, no consumer can obtain them from the interval bisection chain route. □

Closure status for $\mathsf{NameCert}_{\mathsf{IntervalBisectionChain}^{\uparrow}}$.

Constructive story: An $\mathsf{IntervalBisectionChain}^{\uparrow}$ packet is generated from finite dyadic interval rows, endpoint ledgers, successor containment rows, width-halving rows, finite StreamName windows, RegSeqRat readback, a terminal Real seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{IntervalBisectionChain}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8971.1, Definition 8971.2, and Definition 8971.3 seed the finite nested dyadic bisection-chain route from Bishop and dyadic bisection rows to regular Cauchy windows and Real-facing consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{IntervalBisectionChain}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close selected infinite branches, Dedekind cuts, interval choice, Heine–Borel compactness, quotient real equality, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, endpoint exactness, successor containment, width-halving exactness, window generation, regular readback, Real sealing, transport, replay, provenance, and local naming for BEDC.Derived.IntervalBisectionChainUp.

Chapter 8972

A Concrete Naming Certificate for $\mathsf{BishopRegularCauchyModulus}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{BishopRegularCauchyModulus}^{\uparrow}$ packet records the explicit dyadic modulus budget carried by a regular Cauchy rational name before the L10 Real and Completion route reads it as a value-facing object. It sits over the finite scheduling surface of chapter 126, the dyadic tolerance core of chapter 291, the regular rational readback of chapter 301, the sequence-space route of chapter 5965, and the terminal real-name seal of chapter 38. The packet names only the displayed modulus rows; it does not add quotient stream equality, selected representatives, countable choice, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 8972.1 (Bishop regular Cauchy modulus carrier)**.** *A* $\mathsf{BishopRegularCauchyModulus}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (R, D, M, S, H, C, P, L)$$

with the following displayed rows:

1. *R is the regular Cauchy row, read through the* $\mathsf{RegSeqRat}^{\uparrow}$ *surface.*
2. *D is the dyadic budget row, read through* $\mathsf{DyadicRatCore}^{\uparrow}$ *and attached to each requested precision scale.*
3. *M is the modulus row, assigning to every displayed dyadic request the finite observation window that witnesses the regular Cauchy bound.*
4. *S is the shift row, recording the* $\mathsf{StreamName}^{\uparrow}$ *reindexing by which a tail or translated name is read with the same displayed budget.*
5. *H records componentwise* hsame *transport for the regular Cauchy row, dyadic budget row, modulus row, shift row, replay row, provenance row, and local naming row.*
6. *C records displayed* Cont *replay through regular readback, dyadic request, modulus lookup, StreamName reindexing, transport, provenance, and local naming.*
7. *P is the* Pkg *provenance over* $\mathsf{BishopRegularCauchyModulus}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegularSequenceSpace}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
8. *L is the local* $\mathsf{NameCert}_{\mathsf{BishopRegularCauchyModulus}^{\uparrow}}$ *ledger row.*

The carrier contains no coordinate for a host choice function, quotient real equality, selected representative stream, hidden infinite tail choice, real trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 8972.2 (Bishop regular Cauchy modulus NameCert obligations)**.** *For every accepted* $\mathsf{BishopRegularCauchyModulus}^{\uparrow}$ *carrier*

$$B = (R, D, M, S, H, C, P, L),$$

the local $\mathsf{NameCert}_{\mathsf{BishopRegularCauchyModulus}^{\uparrow}}$ *surface consists exactly of the following five obligation rows:*

1. *carrier admission for the displayed finite packet;*
2. *regular Cauchy readback through R and dyadic budget admission through D;*
3. *modulus lookup through M and StreamName reindexing through S;*
4. *componentwise* hsame *transport and displayed* Cont *replay through H and C;*
5. Pkg *provenance and local NameCert ledgering through P and L.*

No obligation row may replace this surface by quotient stream equality, selected representatives, countable choice, trichotomy, hidden tail choice, host completion, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the carrier of Definition 8972.1. The rows R, D, M, S are the object-facing data, and the rows H, C, P, L are the structural data.

The regular Cauchy and dyadic rows form the budget boundary. Row R supplies the regular rational readback, while row D names the dyadic request scale against which the Cauchy estimate is checked.

The modulus and shift rows keep the boundary finite. Row M records the requested observation window, and row S records how the same request is read after a StreamName reindexing. These rows do not store a selected infinite tail.

Finally H, C, P, L transport, replay, source, and name the same displayed packet. Since no carrier coordinate names quotient equality, selected representatives, choice, trichotomy, hidden tail choice, host completion, or ambient completeness, the five rows exhaust the local NameCert surface. □

Theorem 8972.3 (Bishop regular Cauchy modulus shift stability)**.** *Let*

$$B = (R, D, M, S, H, C, P, L)$$

be an accepted $\mathsf{BishopRegularCauchyModulus}^{\uparrow}$ *carrier. If a consumer shifts the regular Cauchy name by the displayed* $\mathsf{StreamName}^{\uparrow}$ *reindexing row S, then the dyadic budget displayed by D and the modulus lookup displayed by M remain the budget read by the shifted name. Equivalently, the shifted read factors through the same* $\mathsf{RegSeqRat}^{\uparrow}$ *row R, the same dyadic budget row D, and the same modulus row M, with only the StreamName indices readdressed by S.*

Proof. Start with the regular Cauchy row R. Its consumer-facing observations are read only through the finite StreamName windows named in the packet, not through a host sequence or a quotient representative.

Apply the shift row S. The row reindexes the displayed StreamName addresses, so the same observation request is read at the shifted addresses while preserving the packet's dyadic request row D.

Use the modulus row M after reindexing. Because M is attached to the dyadic request row and not to an external choice of representative, the shifted consumer obtains the same displayed budget for the shifted regular name.

The transport and replay rows H and C then carry the reindexed read through provenance P and local ledger L. Thus shifting changes only the visible StreamName addresses; it does not introduce a new modulus, a hidden tail selector, quotient equality, countable choice, or ambient completeness. □

Falsifiable prediction: Every accepted $\mathsf{BishopRegularCauchyModulus}^{\uparrow}$ shifted read displays the same dyadic budget and modulus rows after applying its StreamName reindexing row.

Independence witness: regseqrat, streamname, dyadicratcore, regularsequencespace, real: BishopRegularCauchy is not bijective to any listed sibling because it carries the regular Cauchy row, dyadic budget row, explicit modulus row, StreamName shift row, transport, replay, provenance, and NameCert ledger in one packet.

Closure status for $\mathsf{NameCert}_{\mathsf{BishopRegularCauchyModulus}^{\uparrow}}$.

Constructive story: A $\mathsf{BishopRegularCauchyModulus}^{\uparrow}$ packet is generated from regular Cauchy readback, dyadic budget, explicit modulus, StreamName shift, hsame transport, Cont replay, Pkg provenance, and local NameCert ledger rows.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BishopRegularCauchyModulus}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8972.1, Definition 8972.2, Definition 8972.3, the falsifiable prediction, and the independence witness seed the finite explicit-modulus route for regular Cauchy rational names.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BishopRegularCauchyModulus}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close Lean verification, quotient stream equality, selected representatives, countable choice, trichotomy, hidden tail choice, host completion, ambient $\mathsf{Real}^{\uparrow}$ completeness, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, regular Cauchy row exactness, dyadic budget stability, modulus lookup determinacy, shift stability, transport, replay, provenance, and local ledgering for BEDC.Derived.BishopRegularCauchy

Chapter 8973

A Concrete Naming Certificate for $\mathsf{ZeroSignatureFaithfulness}^{\uparrow}$

The $\mathsf{ZeroSignatureFaithfulness}^{\uparrow}$ packet realizes the mirror-slot faithfulness branch of section 9413.32 as finite NameCert data. It sits over the critical-strip source of chapter 72, the zero-source rows of chapter 73, the critical-line witness boundary of chapter 548, the complex-coordinate carrier of chapter 39, and the real-coordinate seal of chapter 38. The packet records a classifier that reads only displayed zero signatures and mirror slots; it does not assert RH, analytic continuation completeness, zero simplicity, Euler product closure, or an unledgered zero observable.

Definition 8973.1 (Zero signature faithfulness carrier)**.** *A* $\mathsf{ZeroSignatureFaithfulness}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Z = (Z, J, \Sigma, F, H, C, P, L)$$

with the following displayed rows:

1. *Z is the accepted zero-source row, read through* $\mathsf{ZetaZeros}^{\uparrow}$ *inside the* $\mathsf{CritStrip}^{\uparrow}$ *boundary.*
2. *J is the mirror-slot row, recording the functional-equation companion slot visible to the zero source.*
3. *Σ is the displayed zero signature row, consisting of zero atom type, spectral time, and mirror slot as in Definition 9413.420.*
4. *F is the packet classifier row: two accepted zero-source rows with equal displayed Σ rows are assigned to the same mirror slot.*
5. *H records componentwise* hsame *transport for zero source, mirror slot, signature, classifier, replay, provenance, and local naming.*
6. *C records displayed* Cont *replay through zero-source admission, mirror-slot readback, signature readback, classifier comparison, transport, provenance, and local naming.*
7. *P is the* Pkg *provenance over* $\mathsf{ZeroSignatureFaithfulness}^{\uparrow}$, $\mathsf{CritStrip}^{\uparrow}$, $\mathsf{ZetaZeros}^{\uparrow}$, $\mathsf{CriticalLineWitness}^{\uparrow}$, $\mathsf{Complex}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
8. *L is the local* $\mathsf{NameCert}_{\mathsf{ZeroSignatureFaithfulness}^{\uparrow}}$ *ledger row.*

The carrier contains no coordinate for an unledgered fourth zero observable, an RH proof object, a hidden analytic continuation theorem, zero simplicity, Euler product closure, or host-level equality of complex zeros.

Theorem 8973.2 (Zero signature faithfulness NameCert obligations)**.** *For every accepted* ZeroSignatureFaithfulness *carrier*

$$Q = (Z, J, \Sigma, F, H, C, P, L),$$

the local $\mathsf{NameCert}_{\mathsf{ZeroSignatureFaithfulness}^{\uparrow}}$ *surface consists exactly of the following rows:*

1. *zero-source admission through the* $\mathsf{CritStrip}^{\uparrow}$ *and* $\mathsf{ZetaZeros}^{\uparrow}$ *sibling rows;*
2. *mirror-slot readback through* J *and displayed signature readback through* Σ*;*
3. *packet classifier faithfulness through* F*;*
4. *componentwise* hsame *transport and displayed* Cont *replay through* H *and* C*;*
5. Pkg *provenance and local NameCert ledgering through* P *and* L*.*

These rows expose the mirror-slot faithfulness packet only as finite NameCert data. They do not supply RH, analytic continuation completeness, zero simplicity, Euler product closure, hidden zero observables, or host-level equality of complex zeros.

Proof. Project the carrier of Definition 8973.1. The rows Z, J, Σ, F are the zero-source, mirror-slot, signature, and classifier data; the rows H, C, P, L are the structural data.

The zero-source row is bounded by the concrete sibling chapters. It is read through the critical-strip and zeta-zero surfaces before the mirror slot or signature can be inspected.

The classifier row is the faithfulness surface. It compares displayed zero signatures and returns equality of mirror slots inside the packet classifier, without adding a fourth zero observable.

Finally H, C, P, L transport, replay, source, and name the same finite packet. Since no coordinate stores RH, analytic continuation completeness, zero simplicity, Euler product closure, hidden observables, or host-level equality of complex zeros, the listed rows exhaust the local NameCert surface. □

Theorem 8973.3 (Zero signature faithfulness mirror-slot rigidity)**.** *Let two accepted zero-source rows be read by a* $\mathsf{ZeroSignatureFaithfulness}^{\uparrow}$ *carrier. If their displayed zero signatures agree, then the packet classifier row* F *assigns them to the same mirror slot. Thus equal displayed zero signatures force the same mirror slot under the finite classifier surface of the packet.*

Proof. Read the two zero-source rows through Z. Each row first passes through the critical-strip and zeta-zero sibling surfaces, so the comparison is internal to the displayed zero-source boundary.

Compare the signature rows through Σ. Equality of the displayed signatures means equality of the zero atom type, spectral time, and mirror-slot component recorded by the carrier.

Apply the classifier row F. By the definition of the packet classifier, equal displayed Σ rows are classified into the same mirror slot.

The transport and replay rows H and C preserve this comparison under accepted readback, while P and L keep the result attached to package provenance and local naming. The conclusion is finite mirror-slot rigidity, not an RH theorem or a host equality principle for complex zeros. □

Falsifiable prediction: If two accepted zero-source rows share the displayed signature but occupy distinct mirror slots, then $\mathsf{ZeroSignatureFaithfulness}^{\uparrow}$ fails the mirror-slot rigidity theorem.

Independence witness: criticalstripzetazerowitness, criticallinewitness, zetazeros, nontrivialzeroclassifier: $\mathsf{ZeroSignatureFaithfulness}^{\uparrow}$ is not bijective to any listed sibling because it carries the zero-source row, mirror-slot row, displayed zero signature, packet classifier, transport, replay, provenance, and local NameCert ledger in one packet.

The Lean follow-up must provide `Nontrivial ZeroSignatureFaithfulnessUp` and `FieldFaithful ZeroSignatureFaithfulnessUp` instances for the displayed carrier. The existing RH-route context at `BEDC.Derived.RHRoute.ZeroSignatureFaithfulness` supplies the zero-signature carrier-map boundary but does not yet define the concrete chapter carrier.

Closure status for $\mathsf{NameCert}_{\mathsf{ZeroSignatureFaithfulness}^{\uparrow}}$.

Constructive story: A $\mathsf{ZeroSignatureFaithfulness}^{\uparrow}$ packet is generated from zero-source, mirror-slot, displayed zero-signature, classifier, hsame transport, Cont replay, Pkg provenance, and local NameCert ledger rows.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{ZeroSignatureFaithfulness}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8973.1, Definition 8973.2, Definition 8973.3, the falsifiable prediction, and the independence witness seed the finite mirror-slot faithfulness route for zero-source signatures.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{ZeroSignatureFaithfulness}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close RH, zero simplicity, analytic continuation completeness, Euler product closure, host-level equality of complex zeros, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, zero-source row exactness, mirror-slot readback, signature comparison, classifier faithfulness, transport, replay, provenance, local ledgering, and TasteGate instances for BEDC.Derived.ZeroSignatureFaithfulnessUp.

Chapter 8974

A Concrete Naming Certificate for $\mathsf{ChoquetBoundary}^{\uparrow}$

Following Bishop-de Leeuw and Choquet, the $\mathsf{ChoquetBoundary}^{\uparrow}$ packet records the finite boundary surface by which a compact convex function-system read exposes peak-boundary and representing-measure evidence before any boundary representation is consumed. It sits over the compact carrier of chapter 60, the convex-set rows of chapter 208, the continuous-map surface of chapter 130, the scalar seal of chapter 38, and the order-vector context of chapter 3620 and chapter 3386. The packet names a boundary certificate for displayed function-system data; it is not a host Shilov boundary, a selected representing measure, a quotient state space, or an appeal to ambient compactness beyond the sibling rows.

Definition 8974.1 (ChoquetBoundary carrier)**.** *A* $\mathsf{ChoquetBoundary}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$C = (K, A, P, E, R, H, T, G, N)$$

with the following displayed rows:

1. *K is the compact source row for the inspected state space, read through the* $\mathsf{Compact}^{\uparrow}$ *certificate.*
2. *A is the convex function-system row over K, read through* $\mathsf{ConvexSet}^{\uparrow}$*,* $\mathsf{ContinuousMap}^{\uparrow}$*, and the* $\mathsf{Real}^{\uparrow}$ *scalar seal.*
3. *P is the peak-boundary observation row: it records the finite peak tests and exposed boundary witnesses inspected by the packet.*
4. *E is the extremal handoff row that keeps exposed-point or extremal-state evidence visible before a boundary representation row is consumed.*
5. *R is the representing-measure handoff row; it records only the displayed measure or barycentric route presented to the packet.*
6. *H records componentwise* hsame *transport for compact source rows, function-system rows, peak observations, extremal or representing-measure handoffs, replay rows, provenance, and the local naming row.*
7. *T records the displayed* Cont *replay from compact source data to function-system data, then to peak observations, then to extremal or representing-measure handoff rows.*
8. *G is the* Pkg *provenance over* $\mathsf{ChoquetBoundary}^{\uparrow}$*,* $\mathsf{Compact}^{\uparrow}$*,* $\mathsf{ConvexSet}^{\uparrow}$*,* $\mathsf{ContinuousMap}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*,* $\mathsf{RieszSpace}^{\uparrow}$*,* $\mathsf{LocallyConvexSpace}^{\uparrow}$*,* BHist*,* hsame*,* Cont*, and* $\mathsf{NameCert}$*.*

9. N is the local $\mathsf{NameCert}_{\mathsf{ChoquetBoundary}^{\uparrow}}$ *row.*
The carrier has no coordinate for a host-selected boundary, Shilov minimality, quotient state equality, countable choice, a selected representing measure, or an ambient compactness principle detached from the displayed sibling certificates.

Theorem 8974.2 (ChoquetBoundary NameCert obligations)**.** *For the carrier of Definition 8974.1, the local* $\mathsf{NameCert}_{\mathsf{ChoquetBoundary}^{\uparrow}}$ *surface consists exactly of carrier admission for* $C = (K, A, P, E, R, H, T, G, N)$*, compact source exposure through* K*, convex function-system exposure through* A*, peak-boundary observation exposure through* P*, extremal handoff exposure through* E*, representing-measure handoff exposure through* R*, componentwise* hsame *transport through* H*, displayed* Cont *replay through* T*,* Pkg *provenance through* G*, and local naming through* N*.*

Proof. Carrier admission is tuple projection from the displayed packet C. The analytic rows expose the compact source, convex function-system data, peak observations, extremal evidence, and representing-measure handoff.

The structural rows are exactly H, T, G, N. They transport the same displayed rows, replay the same finite dependency route, record provenance for the named packets, and bind the local certificate.

No additional boundary object is available. Since the excluded principles are not carrier coordinates, the local NameCert cannot export them. □

Theorem 8974.3 (ChoquetBoundary peak route)**.** *Every accepted* $\mathsf{ChoquetBoundary}^{\uparrow}$ *carrier routes a boundary-facing read through the compact source row* K*, the convex function-system row* A*, and the peak-boundary observation row* P *before any extremal handoff* E *or representing-measure handoff* R *is consumed. The route preserves the* $\mathsf{Real}^{\uparrow}$ *scalar seal and the* hsame *transport rows, and it exports no host-selected boundary, Shilov minimality claim, quotient state equality, countable-choice schedule, selected representing measure, or detached compactness principle.*

Proof. Project the carrier of Definition 8974.1. Its only source rows for boundary analysis are the compact row K, the function-system row A, and the peak-observation row P.

Apply the NameCert obligations of Definition 8974.2. They place the extremal and representing-measure handoffs after those rows and keep the replay, transport, provenance, and local name attached to the same packet.

It remains to check non-escape. The carrier has no coordinate for the excluded host boundary, minimality, quotient, choice, selected-measure, or detached compactness principles, so a consumer can only read the displayed peak route. □

Closure status for $\mathsf{NameCert}_{\mathsf{ChoquetBoundary}^{\uparrow}}$**.**

Constructive story: A $\mathsf{ChoquetBoundary}^{\uparrow}$ packet is generated from compact source rows, convex function-system rows, peak-boundary observations, extremal or representing-measure handoff rows, Real scalar seals, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{ChoquetBoundary}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8974.1, Definition 8974.2, and Definition 8974.3 seed the finite carrier and peak-route obligation surface for later representation packets.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{ChoquetBoundary}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim Shilov minimality, a selected representing measure, quotient state equality, countable choice, ambient compactness, Lean verification, or bridge checking.

Upgrade path: Scoped closure requires a public route theorem that packages the peak-boundary and representing-measure handoff rows into a downstream comparison boundary.

Chapter 8975

A Concrete Naming Certificate for $\mathsf{IncidenceAlgebra}^{\uparrow}$

Following Rota and Stanley on incidence algebras of finite posets, the $\mathsf{IncidenceAlgebra}^{\uparrow}$ packet records the convolution carrier that makes zeta and Mobius rows inspectable before any inversion consumer reads them. It sits after the order source of chapter 53, the scalar operation rows of chapter 43, the finite tabular carrier of chapter 49, and the inversion consumer route of chapter 8007. The packet names interval-supported functions and their finite convolution ledger; it does not import an infinite algebra, a host function ring, quotient equality of functions, unbounded sums, or selected inverse matrices.

Definition 8975.1 (Incidence algebra carrier)**.** *An* $\mathsf{IncidenceAlgebra}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$I = (P, R, F, S, M, Z, U, H, C, G, N)$$

with the following displayed rows:

1. *P is the* $\mathsf{Poset}^{\uparrow}$ *source row, including the displayed finite comparable-pair ledger.*
2. *R is the* $\mathsf{Ring}^{\uparrow}$ *scalar row used for addition, multiplication, zero, and one on interval coefficients.*
3. *F is the interval-supported function table, assigning a scalar coefficient only to displayed pairs $x \leq y$.*
4. *S is the finite support ledger, refusing every non-comparable pair and every pair outside the displayed finite source.*
5. *M is the* $\mathsf{Mat}^{\uparrow}$ *table view of the same interval-supported data, indexed by the finite poset enumeration.*
6. *Z is the zeta row, with unit coefficients on accepted comparable pairs and zero outside the interval support.*
7. *U is the finite convolution row, listing exactly the intermediate z with $x \leq z \leq y$ for every product read.*
8. *H records componentwise* hsame *transport for the poset source, scalar row, function table, support ledger, matrix view, zeta row, convolution row, replay, provenance, and local naming.*
9. *C records displayed* Cont *replay from a convolution request through $P, R, F, S, M, Z, U, H, G, N$.*

10. *G is the* Pkg *provenance over* $\mathsf{IncidenceAlgebra}^{\uparrow}$, $\mathsf{Poset}^{\uparrow}$, $\mathsf{Ring}^{\uparrow}$, $\mathsf{Mat}^{\uparrow}$, $\mathsf{MobiusInversion}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

11. *N is the local* $\mathsf{NameCert}_{\mathsf{IncidenceAlgebra}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $P, R, F, S, M, Z, U, H, C, G, N$. It has no coordinate for an infinite incidence algebra, host function equality, unbounded summation, selected inverse matrices, or ambient algebraic completion.

Theorem 8975.2 (Incidence algebra NameCert obligations)**.** *For every accepted* $\mathsf{IncidenceAlgebra}^{\uparrow}$ *carrier*

$$I = (P, R, F, S, M, Z, U, H, C, G, N),$$

the local $\mathsf{NameCert}_{\mathsf{IncidenceAlgebra}^{\uparrow}}$ *surface consists exactly of carrier admission for the finite poset source, scalar ring row, interval-supported function table, support ledger, matrix view, zeta row, finite convolution row, componentwise transport, displayed replay, package provenance, and local naming.*

Proof. Project the carrier of Definition 8975.1. The rows P, R, F, S, M, Z, U are the displayed mathematical data, and H, C, G, N are the structural rows that transport, replay, source, and name the same packet.

The support row S and convolution row U keep every product read inside a finite interval of the displayed poset. The matrix row M is only a finite table view of the same interval-supported data, so it cannot add host matrix inversion or quotient function equality.

Since no accepted coordinate stores infinite support, unbounded summation, selected inverses, or ambient completion, the listed rows exhaust the NameCert obligations. □

Theorem 8975.3 (Incidence algebra convolution stability)**.** *Every convolution read of two accepted* $\mathsf{IncidenceAlgebra}^{\uparrow}$ *packets over the same P and R remains an* $\mathsf{IncidenceAlgebra}^{\uparrow}$ *read over the displayed route*

$$P, R, F, S, M, Z, U, H, C, G, N.$$

The product coefficient at $x \leq y$ may use only the finite intermediates recorded by U for that interval.

Proof. Start with the common poset and scalar rows P, R. The support rows of the two packets restrict both coefficient tables to comparable pairs in the same finite source.

For a displayed interval $x \leq y$, read the convolution row U. It lists the only intermediate elements available for the product coefficient, and the scalar multiplication and addition are the operations exposed by R.

The resulting table has the same finite support boundary and the same matrix view over the finite poset enumeration. Transport, replay, provenance, and local naming are inherited through H, C, G, N, so the product remains inside the stated carrier surface. □

Theorem 8975.4 (Incidence algebra Mobius consumer route)**.** *Every* $\mathsf{MobiusInversion}^{\uparrow}$ *consumer that reads zeta or Mobius rows from an* $\mathsf{IncidenceAlgebra}^{\uparrow}$ *packet must first expose the finite poset source, scalar row, interval-supported table, support ledger, matrix view, zeta row, and convolution row of that packet. The consumer receives a finite incidence carrier; it does not receive an ambient function algebra or a selected inverse object.*

Proof. Use the provenance row G to identify the Mobius inversion consumer and the incidence carrier it reads. The consumer starts from the same finite $\mathsf{Poset}^{\uparrow}$ source and $\mathsf{Ring}^{\uparrow}$ scalar row as the incidence packet.

The zeta row Z is visible only after the interval support and matrix table have been displayed. The Mobius-facing inverse check can then consume the finite convolution row U, matching the finite interval ledger used by chapter 8007.

Because the route is through $P, R, F, S, M, Z, U, H, C, G, N$, no downstream consumer can replace it by host function equality, an infinite incidence algebra, unbounded summation, or a selected matrix inverse. □

Falsifiable prediction: Every accepted $\mathsf{IncidenceAlgebra}^{\uparrow}$ convolution read displays PosetUp source rows, RingUp scalar rows, interval-supported function tables, support ledgers, MatrixUp table views, zeta rows, finite convolution windows, hsame transport, Cont replay, Pkg provenance, and local NameCert rows before any MobiusInversionUp consumer can read it.

Independence witness: poset, ring, matrix, mobius-inversion: none of the listed siblings jointly carries interval-supported function rows, finite support refusal, matrix table view, zeta rows, finite convolution windows, transport, replay, provenance, and local NameCert data as one incidence-algebra packet.

Closure status for $\mathsf{NameCert}_{\mathsf{IncidenceAlgebra}^{\uparrow}}$.

Constructive story: An $\mathsf{IncidenceAlgebra}^{\uparrow}$ packet is generated from a PosetUp source row, a RingUp scalar row, interval-supported function rows, finite support refusal, a MatrixUp table view, zeta rows, finite convolution windows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{IncidenceAlgebra}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8975.1, Definition 8975.2, Definition 8975.3, and Definition 8975.4 seed the finite incidence-algebra route consumed by Mobius inversion.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{IncidenceAlgebra}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim infinite incidence algebras, host function rings, quotient equality of functions, unbounded summation, selected inverse matrices, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, interval-support exactness, convolution stability, Mobius consumer routing, transport, replay, provenance, and local naming for BEDC.Derived.IncidenceAlgebraUp.

Chapter 8976

A Concrete Naming Certificate for $\mathsf{HyperbolicVisualMeasure}^{\uparrow}$

The $\mathsf{HyperbolicVisualMeasure}^{\uparrow}$ packet realizes the boundary-measure branch of chapter 9463 as a finite NameCert surface. It sits after the visual-boundary rows of chapter 4181, the boundary-shadow window of chapter 3813, the metric comparison surface of chapter 3474, and the terminal scalar seal of chapter 38. The packet names visual weights only as displayed finite shadow-window data; it does not construct a host sigma-algebra, a completed measure space, a quotient boundary, a global Patterson–Sullivan density, or ambient analytic regularity.

Definition 8976.1 (Hyperbolic visual measure carrier)**.** *A* $\mathsf{HyperbolicVisualMeasure}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$V = (B, S, M, R, W, T, F, H, C, P, N)$$

with the following displayed rows:

1. *B is the* $\mathsf{HyperbolicVisualBoundary}^{\uparrow}$ *row, exposing the boundary face visible to the observer.*
2. *S is the* $\mathsf{HyperbolicBoundaryShadow}^{\uparrow}$ *row, listing the finite shadow windows on which visual weights are read.*
3. *M is the* $\mathsf{HyperbolicMetric}^{\uparrow}$ *comparison row attached to the same displayed disk or metric source.*
4. *R is the* $\mathsf{Real}^{\uparrow}$ *scalar-readback row for finite nonnegative weights and total-window comparisons.*
5. *W is the visual-weight table, assigning a displayed scalar only to shadow windows listed by S.*
6. *T is the finite-total ledger, recording the finite sum of weights over the current visual window and refusing unlisted boundary regions.*
7. *F is the TasteGate-facing field-faithfulness row, requiring the same packet to support Nontrivial and FieldFaithful readings before a scalar consumer treats R as a faithful weight surface.*
8. *H records componentwise* hsame *transport for boundary, shadow, metric, scalar, weight, total, TasteGate-facing, replay, provenance, and local naming rows.*
9. *C records displayed* Cont *replay from a visual-measure request through $B, S, M, R, W, T, F, H, P, N$.*
10. *P is the* Pkg *provenance over* $\mathsf{HyperbolicVisualMeasure}^{\uparrow}$, $\mathsf{HyperbolicVisualBoundary}^{\uparrow}$, $\mathsf{HyperbolicBoundaryShadow}^{\uparrow}$ $\mathsf{HyperbolicMetric}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{HyperbolicVisualMeasure}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $B, S, M, R, W, T, F, H, C, P, N$. It has no coordinate for completed measures, host measurable subsets, quotient ideal boundary equality, selected densities, or ambient analytic regularity.

Theorem 8976.2 (Hyperbolic visual measure NameCert obligations)**.** *For every accepted* $\mathsf{HyperbolicVisualMeasure}^{\uparrow}$ *carrier*

$$V = (B, S, M, R, W, T, F, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{HyperbolicVisualMeasure}^{\uparrow}}$ *surface consists exactly of carrier admission for the visual-boundary row, boundary-shadow window, hyperbolic metric comparison, Real scalar readback, visual-weight table, finite-total ledger, TasteGate-facing field-faithfulness row, componentwise transport, displayed replay, package provenance, and local naming.*

Proof. Project the carrier of Definition 8976.1. The boundary, shadow, metric, scalar, weight, total, and TasteGate-facing rows are B, S, M, R, W, T, F, while H, C, P, N transport, replay, source, and name the same packet.

The shadow row S bounds the visual windows available to the measure read. The scalar row R and finite-total row T then expose only finite weight comparisons on those displayed windows.

Since the packet has no coordinate for completed measures, host measurable subsets, quotient boundary equality, selected densities, or ambient regularity, the listed rows exhaust the NameCert obligations. □

Theorem 8976.3 (Hyperbolic visual measure shadow support)**.** *Every visual-measure read from an accepted* $\mathsf{HyperbolicVisualMeasure}^{\uparrow}$ *packet is supported on the finite boundary-shadow windows listed by S. A consumer may sum weights through T only after displaying the visual-boundary row B, the shadow row S, the metric row M, and the scalar readback row R.*

Proof. Begin with the displayed boundary and shadow rows. The visual-boundary row names the observer-visible boundary face, and the boundary-shadow row lists the finite windows that may receive weights.

The metric row supplies the comparison data used to index the shadow windows, while the Real row supplies the scalar readback. The visual-weight table W assigns values only to those listed windows.

The finite-total ledger T can therefore sum only the displayed shadow support. Transport and replay preserve this route, so a consumer cannot turn the packet into a completed measure on an unlisted boundary region. □

Theorem 8976.4 (Hyperbolic visual measure TasteGate route)**.** *The TasteGate-facing obligations for* $\mathsf{HyperbolicVisualMeasure}^{\uparrow}$ *are bound to the same finite packet*

$$B, S, M, R, W, T, F, H, C, P, N.$$

In particular, `lean4/BEDC/Derived/HyperbolicVisualMeasureUp/TasteGate.lean` *must provide Nontrivial and FieldFaithful instances for this carrier before a downstream scalar consumer treats the visual-weight table as a faithful measurement row.*

Proof. Read the field-faithfulness row F from the carrier. It is displayed beside the boundary, shadow, metric, scalar, weight, and total rows, so it cannot be supplied by a different hyperbolic sibling.

The provenance row P identifies the consumed visual-boundary, boundary-shadow, hyperbolic-metric, and Real rows. The replay row C preserves their order before a scalar consumer can inspect W or T.

Thus the Nontrivial and FieldFaithful requirements are obligations on the local $\mathsf{HyperbolicVisualMeasure}^{\uparrow}$ packet. They do not assert a global measure theory, a completed boundary, or an ambient analytic density. □

Falsifiable prediction: Every accepted $\mathsf{HyperbolicVisualMeasure}^{\uparrow}$ read displays HyperbolicVisualBoundaryUp, HyperbolicBoundaryShadowUp, HyperbolicMetricUp, RealUp scalar readback, finite visual weights, finite-total ledgers, TasteGate-facing field-faithfulness rows, hsame transport, Cont replay, Pkg provenance, and local NameCert data before any visual measure consumer may read the packet.

Independence witness: hyperbolic-visual-boundary, hyperbolic-boundary-shadow, hyperbolic-metric, hyperbolic-observer-expansion, hyperbolic-visual-metric: none of these siblings jointly carries finite visual-weight rows, finite-total ledgers, TasteGate-facing field-faithfulness rows, transport, replay, provenance, and local NameCert data as one visual-measure packet.

Closure status for $\mathsf{NameCert}_{\mathsf{HyperbolicVisualMeasure}^{\uparrow}}$.

Constructive story: A $\mathsf{HyperbolicVisualMeasure}^{\uparrow}$ packet is generated from HyperbolicVisualBoundaryUp boundary rows, HyperbolicBoundaryShadowUp finite shadow windows, HyperbolicMetricUp comparison rows, RealUp scalar readbacks, finite visual-weight rows, finite-total ledgers, TasteGate-facing Nontrivial and FieldFaithful obligations, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{HyperbolicVisualMeasure}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8976.1, Definition 8976.2, Definition 8976.3, and Definition 8976.4 seed the finite visual-measure route over boundary, shadow, metric, scalar, field-faithfulness, transport, replay, provenance, and local naming rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{HyperbolicVisualMeasure}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim host sigma-algebras, completed measure spaces, quotient boundary equality, selected densities, global Patterson–Sullivan theory, ambient analytic regularity, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, shadow support exactness, finite-total exactness, TasteGate Nontrivial and FieldFaithful rows, transport, replay, provenance, and local naming for BEDC.Derived.HyperbolicVisualMeasureUp.

Chapter 8977

A Concrete Naming Certificate for $\mathsf{RealClosedField}^{\uparrow}$

Following Artin and van der Waerden on real closed fields, the $\mathsf{RealClosedField}^{\uparrow}$ packet records the finite ordered-algebra surface by which a displayed field is read as real-closed without importing a host algebraic closure, selected roots, or classical trichotomy. It sits over the real-name boundary of chapter 38, the field carrier of chapter 45, the polynomial carrier of chapter 50, the root-isolation surface of chapter 2269, and the Sturm-chain route of chapter 2079. The packet names only the displayed order, polynomial, odd-degree root, positive-square, isolation, transport, replay, provenance, and local certificate rows.

Definition 8977.1 (Real closed field carrier)**.** *A* $\mathsf{RealClosedField}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$F = (R, K, O, P, S, I, A, Q, H, C, G, N)$$

with the following displayed rows:

1. *R is the* $\mathsf{Real}^{\uparrow}$ *source row naming the real-facing carrier boundary.*
2. *K is the* $\mathsf{Field}^{\uparrow}$ *row naming addition, multiplication, units, inverse-on-witnesses, and field classifier transport.*
3. *O is the order row attached to the same displayed carrier as K, with positivity and comparison data read only through finite BEDC rows.*
4. *P is the* $\mathsf{Poly}^{\uparrow}$ *row for coefficient lists, degree ledgers, formal derivatives, and evaluation requests over the displayed field.*
5. *S is the* $\mathsf{SturmSequence}^{\uparrow}$ *row carrying finite sign-variation and endpoint ledger data for the polynomial request.*
6. *I is the* $\mathsf{RealRootIsolation}^{\uparrow}$ *row exporting retained isolating windows and no selected host root.*
7. *A is the odd-degree root route: for each displayed odd-degree polynomial row admitted by P, it records the Sturm/isolation handoff through S and I to a retained* $\mathsf{Real}^{\uparrow}$ *seal.*
8. *Q is the positive-square route: every displayed positive field element is paired with a square witness row, and every square witness remains tied to the same order classifier.*
9. *H records componentwise* hsame *transport for the real, field, order, polynomial, Sturm, isolation, root, square, replay, provenance, and local naming rows.*

10. *C records displayed* Cont *replay from any real-closed-field read through $R, K, O, P, S, I, A, Q, H$.*
11. *G is the* Pkg *provenance over* $\mathsf{RealClosedField}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{Field}^{\uparrow}$, $\mathsf{Poly}^{\uparrow}$, $\mathsf{SturmSequence}^{\uparrow}$, $\mathsf{RealRootIsolation}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*
12. *N is the local* $\mathsf{NameCert}_{\mathsf{RealClosedField}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these rows. It has no coordinate for host algebraic closure, a selected algebraic root outside the isolating window, quotient polynomial equality, classical trichotomy, choice of signs, or ambient completeness.

Theorem 8977.2 (Real closed field NameCert obligations)**.** *For every accepted* $\mathsf{RealClosedField}^{\uparrow}$ *carrier $F = (R, K, O, P, S, I, A, Q, H, C, G, N)$, the local* $\mathsf{NameCert}_{\mathsf{RealClosedField}^{\uparrow}}$ *surface consists exactly of these finite obligations:*

1. *carrier admission for the real, field, order, polynomial, Sturm, root-isolation, odd-degree root, positive-square, transport, replay, provenance, and local naming rows;*
2. *field/order compatibility through K and O on the same displayed carrier;*
3. *polynomial admission through the finite coefficient, degree, derivative, and evaluation rows of P;*
4. *odd-degree root exposure through the route P, S, I, A before any* $\mathsf{Real}^{\uparrow}$ *seal is available;*
5. *positive-square exposure through O, K, Q, with the square witness tied to the displayed order classifier;*
6. *componentwise transport, continuation replay, provenance, and local naming through H, C, G, N.*

No other real-closed-field obligation is part of the packet.

Proof. Project the carrier of Definition 8977.1. Its rows already list the complete finite surface: real boundary, field operations, order data, polynomial requests, Sturm variation, root isolation, root and square routes, and BEDC structural rows.

The odd-degree clause is read through the polynomial row P, then through the Sturm row S, then through the isolating-window row I, and only then through the root route A. Thus an accepted root read cannot be replaced by an ambient algebraic closure or selected host element.

The positive-square clause is separate. It uses the order classifier O, the field row K, and the displayed witness row Q, so positivity and squareness remain rows of the same packet.

Finally H, C, G, N transport, replay, source, and name the same rows. Since no coordinate stores host algebraic closure, quotient polynomial equality, classical trichotomy, or a choice schedule, the listed obligations exhaust the local $\mathsf{NameCert}_{\mathsf{RealClosedField}^{\uparrow}}$ surface. □

Theorem 8977.3 (Real closed field order-root route)**.** *Every real-closed-field read from an accepted* $\mathsf{RealClosedField}^{\uparrow}$ *packet factors through*

$$R, K, O, P \longmapsto S, I, A, Q \longmapsto H, C, G, N.$$

Odd-degree root reads must pass through the $\mathsf{Poly}^{\uparrow}$, $\mathsf{SturmSequence}^{\uparrow}$, *and* $\mathsf{RealRootIsolation}^{\uparrow}$ *rows before exposing a retained* $\mathsf{Real}^{\uparrow}$ *seal; positive-square reads must pass through the displayed order and field rows before exposing the square witness. No read may bypass these routes by appealing to host algebraic closure, a selected root, quotient real equality, trichotomy, choice, or ambient completeness.*

Proof. Start with an odd-degree root request. The polynomial source is the row P, so coefficients, degree, derivative, and evaluation requests are displayed before any root data is considered.

Next the Sturm and isolation rows are read. The row S supplies the sign-variation ledger, and the row I supplies the retained isolating window. The root route A can therefore expose only the retained $\mathsf{Real}^{\uparrow}$ seal attached to those rows.

For a positive-square request, the order row O supplies positivity and the field row K supplies multiplication. The witness row Q records the square witness over that same displayed carrier and classifier.

The structural rows H, C, G, N then preserve and replay the same packet. Because no listed row contains host algebraic closure, quotient equality, trichotomy, choice, or ambient completeness data, the displayed route is the whole order-root interface. □

Falsifiable prediction: Every accepted $\mathsf{RealClosedField}^{\uparrow}$ consumer that reads an odd-degree root without the $\mathsf{Poly}^{\uparrow}$, $\mathsf{SturmSequence}^{\uparrow}$, and $\mathsf{RealRootIsolation}^{\uparrow}$ rows, or reads a positive-square witness without the displayed field and order rows, is outside the carrier surface.

Independence witness: real, field, polynomial, sturm-sequence, real-root-isolation: no listed sibling is bijective with $\mathsf{RealClosedField}^{\uparrow}$ because this packet binds one real-facing field carrier to order data, polynomial requests, Sturm variation, isolating windows, odd-degree root exposure, positive-square witnesses, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{RealClosedField}^{\uparrow}}$.

Constructive story: A $\mathsf{RealClosedField}^{\uparrow}$ packet is generated from RealUp, FieldUp, order, PolynomialUp, SturmSequenceUp, RealRootIsolationUp, odd-degree root, positive-square, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert rows.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RealClosedField}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8977.1, Definition 8977.2, and Definition 8977.3 seed the finite ordered-algebra packet for real-closed-field reads.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RealClosedField}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host algebraic closure, selected roots outside isolating windows, quotient polynomial equality, classical trichotomy, choice of signs, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, field/order compatibility, polynomial admission, odd-degree root exposure, positive-square exposure, transport, replay, provenance, and local naming for BEDC.Derived.RealClosedFieldUp.

Chapter 8978

A Concrete Naming Certificate for $\mathsf{FenchelMoreauBiconjugation}^{\uparrow}$

Following Rockafellar convex analysis and Boyd–Vandenberghe, the $\mathsf{FenchelMoreauBiconjugation}^{\uparrow}$ packet names the biconjugation boundary by finite primal functional rows, conjugate rows, biconjugate comparison rows, lower-semicontinuity witnesses, convex epigraph rows, real-order seals, transport, replay, provenance, and local naming. It consumes the conjugacy surface of chapter 3563, the primal-dual route of chapter 321, the local subgradient boundary of chapter 3712, the convex-set carrier of chapter 208, the vector-space source of chapter 47, and the terminal real-name boundary of chapter 38. The packet records only displayed BEDC rows; it does not import host suprema, quotient function spaces, ambient locally convex completions, or an external Fenchel–Moreau theorem.

Definition 8978.1 (Fenchel–Moreau biconjugation carrier)**.** *A* $\mathsf{FenchelMoreauBiconjugation}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (F, V, K, D, E, L, S, H, C, P, N)$$

with the following displayed rows:

1. *F is the primal proper convex functional row read through* $\mathsf{ConvexSet}^{\uparrow}$, $\mathsf{VecSpace}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$*;*
2. *V is the vector-space source row naming the primal and dual-facing carrier interfaces;*
3. *K is the consumed* $\mathsf{ConvexConjugate}^{\uparrow}$ *row, including the pairing and displayed supremum-budget coordinates;*
4. *D is the* $\mathsf{FenchelDuality}^{\uparrow}$ *dependency row that records the primal-dual handoff through the same finite conjugacy packet;*
5. *E is the biconjugate comparison row, exposing only finite real-order and epigraph comparisons between the original functional and its displayed biconjugate read;*
6. *L is the lower-semicontinuity and closed-epigraph ledger row used to decide when the comparison row is public;*
7. *S is the* $\mathsf{Subdifferential}^{\uparrow}$ *handoff row, available to consumers that read supporting-functional evidence from the same conjugacy surface;*
8. *H records componentwise* hsame *transport for the primal functional, vector-space source, conjugate row, duality row, comparison row, closed-epigraph ledger, subdifferential handoff, replay, provenance, and local naming rows;*

9. *C records displayed* Cont *replay from primal reads to conjugate reads, from conjugate reads to biconjugate comparisons, and from those comparisons to the closed-epigraph ledger;*
10. *P is the* Pkg *provenance over* $\mathsf{FenchelMoreauBiconjugation}^{\uparrow}$, $\mathsf{ConvexConjugate}^{\uparrow}$, $\mathsf{FenchelDuality}^{\uparrow}$, $\mathsf{Subdifferential}^{\uparrow}$, $\mathsf{ConvexSet}^{\uparrow}$, $\mathsf{VecSpace}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert*;*
11. *N is the local* $\mathsf{NameCert}_{\mathsf{FenchelMoreauBiconjugation}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $F, V, K, D, E, L, S, H, C, P, N$. It has no coordinate for a host supremum operator, quotient function equality, selected support functional, ambient dual completion, or external biconjugation theorem.

Lean4 (statement) `BEDC.Derived.FenchelMoreauBiconjugationUp`

Theorem 8978.2 (Fenchel–Moreau biconjugation NameCert obligations)**.** *For every accepted* $\mathsf{FenchelMoreauBiconjugation}^{\uparrow}$ *carrier $B = (F, V, K, D, E, L, S, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{FenchelMoreauBiconjugation}}$ *surface consists exactly of carrier admission for the displayed rows, conjugate-row exposure through K, primal-dual handoff through D, biconjugate comparison through E, closed-epigraph ledger visibility through L, optional subdifferential handoff through S, componentwise* hsame *transport through H, displayed* Cont *replay through C,* Pkg *provenance through P, and local naming through N.*

Proof. Project the carrier of Definition 8978.1. The visible rows are exactly $F, V, K, D, E, L, S, H, C, P, N$, so every local admission and classifier read is componentwise on those rows.

The conjugacy and duality rows are consumed before the biconjugate comparison is public. The row K supplies the displayed $\mathsf{ConvexConjugate}^{\uparrow}$ pairing and budget data, while D records that the same finite packet is available to the $\mathsf{FenchelDuality}^{\uparrow}$ route.

The comparison row E is then guarded by the lower-semicontinuity ledger L and by the real-order and convex-epigraph dependencies named in P. Transport and replay preserve only that displayed route.

Since host suprema, quotient function equality, selected support functionals, ambient completions, and external biconjugation theorems are absent from the carrier, the listed rows exhaust the local NameCert surface. □

Theorem 8978.3 (Fenchel–Moreau conjugate handoff)**.** *Every* $\mathsf{ConvexConjugate}^{\uparrow}$, $\mathsf{FenchelDuality}^{\uparrow}$, *or* $\mathsf{Subdifferential}^{\uparrow}$ *consumer that reads an accepted* $\mathsf{FenchelMoreauBiconjugation}^{\uparrow}$ *packet receives the displayed route*

$$F, V, K, D, E, L, S \longmapsto H, C, P, N.$$

The consumer may inspect primal functional rows, vector-space source rows, conjugate rows, duality rows, biconjugate comparison rows, lower-semicontinuity ledger rows, subdifferential handoff rows, transport, replay, provenance, and local naming. It receives no host supremum, quotient function space, selected subgradient, ambient dual completion, or external Fenchel–Moreau theorem.

Proof. Use Definition 8978.2. It forces every biconjugation-facing read through the displayed rows before any structural replay or provenance row can source the answer.

For a conjugate consumer, the row K is the only path to $\mathsf{ConvexConjugate}^{\uparrow}$. For a duality consumer, the row D records the compatible $\mathsf{FenchelDuality}^{\uparrow}$ handoff. For a subdifferential consumer, the row S exposes supporting-functional evidence only after the same conjugacy and comparison rows have been displayed.

The structural rows H, C, P, N preserve, replay, source, and name that route. Because the excluded host objects are not coordinates of the carrier, the handoff supplies exactly the finite BEDC packet and no ambient analytic theorem. □

Closure status for $\mathsf{NameCert}_{\mathsf{FenchelMoreauBiconjugation}^{\uparrow}}$.

Constructive story: A $\mathsf{FenchelMoreauBiconjugation}^{\uparrow}$ packet is generated from primal functional rows, vector-space source rows, conjugate and duality rows, biconjugate comparison rows, lower-semicontinuity ledger rows, subdifferential handoff rows, transport, replay, provenance, and local naming.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{FenchelMoreauBiconjugation}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8978.1, Definition 8978.2, and Definition 8978.3 seed the finite biconjugation NameCert surface over the existing convex-analysis siblings.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{FenchelMoreauBiconjugation}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host Fenchel–Moreau equality, selected suprema, quotient function equality, ambient dual completion, global separation theorems, Lean theorem verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, conjugate-row exposure, duality handoff, biconjugate comparison, closed-epigraph ledger visibility, subdifferential handoff, transport, replay, provenance, and local naming for BEDC.Derived.FenchelMoreauBiconjugationUp.

Chapter 8979

A Concrete Naming Certificate for $\mathsf{AskSigGapRoute}^{\uparrow}$

The $\mathsf{AskSigGapRoute}^{\uparrow}$ packet realizes the L3–L5 kernel spine of chapter 9352 as finite route data. It is a structural reconstruction of the generated asking, signature, package, gap, exact-globalization, and naming-certificate interface: no mature analytic, algebraic, geometric, or computational object is added by the carrier. The packet gives later finite-data classifiers one concrete NameCert landing surface for the route from Ask events to visible Pkg tokens, Gap ledgers, ExactGlobalizeBase fields, and local NameCert rows.

The same generated Ask/Sig/Pkg/Gap route is read by downstream finite-name consumers before Real and Completion arguments inspect generated classifier tokens. In particular, the finite $\mathsf{StreamName}^{\uparrow}$ scheduling surface of chapter 126 and the regular rational readback surface of chapter 301 consume this route as a visible token boundary, not as a semantic oracle or hidden quotient classifier.

Definition 8979.1 (Ask–Sig–Pkg–Gap route carrier)**.** *An* $\mathsf{AskSigGapRoute}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$R = (B, D, A, S, E, P, G, X, N, H, C, L)$$

with the following displayed rows:

1. *B is the probe-bundle row, naming the finite* Bundle *of probes whose answers generate the route.*
2. *D is the admitted-domain row over source histories.*
3. *A is the* Ask *row, recording each probe request, emitted mark, and event evidence for admitted histories.*
4. *S is the* Sig *row, recording the generated answer history and evidence ledger assembled from A.*
5. *E is the* sameSig *row, comparing generated answer histories only by internal* hsame *witnesses.*
6. *P is the* Pkg *row, naming visible package tokens for generated answer histories.*
7. *G is the* Gap *row, recording package-token membership for admitted source histories.*
8. *X is the* ExactGlobalizeBase *row, carrying coverage, base soundness, and base completeness for the displayed gap-signature route.*
9. *N is the local* $\mathsf{NameCert}_{\mathsf{AskSigGapRoute}^{\uparrow}}$ *row, with source, pattern, classifier, stability, and ledger fields read from B, D, A, S, E, P, G, X.*

10. *H records componentwise* hsame *transport for bundle, domain, ask, signature, signature-sameness, package, gap, exactness, naming, replay, and ledger rows.*
11. *C records displayed* Cont *replay from a route request through $B, D, A, S, E, P, G, X, N, H$.*
12. *L is the* Pkg *provenance row for* $\mathsf{AskSigGapRoute}^{\uparrow}$, Ask, Sig, Pkg, Gap, ExactGlobalizeBase, NameCert, BHist, hsame, *and* Cont.

The classifier compares accepted route packets only through these rows. It has no coordinate for a semantic oracle, hidden source classifier, quotient package equality, external global object, or mature downstream carrier.

Theorem 8979.2 (Ask–Sig–Pkg–Gap route NameCert obligations)**.** *For every accepted* $\mathsf{AskSigGapRoute}^{\uparrow}$ *carrier $R = (B, D, A, S, E, P, G, X, N, H, C, L)$, the local* $\mathsf{NameCert}_{\mathsf{AskSigGapRoute}^{\uparrow}}$ *surface consists exactly of these finite obligations:*

1. *carrier admission for bundle, domain, ask, signature, signature-sameness, package, gap, exactness, local naming, transport, replay, and provenance rows;*
2. *ask totality and determinacy only for admitted histories in D and probes in B;*
3. *signature construction and determinacy through the generated* Sig *row S and the* sameSig *row E;*
4. *package-token visibility and reflection through P;*
5. *gap coverage and same-source separation through G;*
6. *exact local classification through the coverage, base-soundness, and base-completeness fields of X;*
7. *source, pattern, classifier, stability, ledger, transport, replay, and provenance discipline through N, H, C, L.*

No NameCert obligation for a downstream mature object is stored in this route packet.

Proof. Project the carrier of Definition 8979.1. The rows B, D, A display exactly the finite probe bundle, admitted source domain, and ask-event ledger, so an ask read has no access to an external oracle.

The signature and package rows are downstream. The row S assembles answer histories from ask events, E compares those answer histories by hsame, and P exposes only visible package tokens backed by generated signatures.

The gap and exactness rows complete the route. The row G records package-token membership for admitted histories, while X supplies precisely the coverage, base-soundness, and base-completeness fields of ExactGlobalizeBase.

Finally N, H, C, L name, transport, replay, and source the same finite data. Since the carrier has no semantic oracle, hidden quotient, external classifier, or downstream mature-object coordinate, the listed obligations exhaust the local $\mathsf{NameCert}_{\mathsf{AskSigGapRoute}^{\uparrow}}$ surface. □

Theorem 8979.3 (Ask–Sig–Pkg–Gap route exactness)**.** *Every exact route read from an accepted* $\mathsf{AskSigGapRoute}^{\uparrow}$ *packet factors through*

$$B, D, A \longmapsto S, E \longmapsto P, G, X \longmapsto N, H, C, L.$$

Thus two visible package tokens are classified together only after the corresponding ask-generated signatures, gap memberships, and ExactGlobalizeBase *fields have been displayed. The route exports no quotient package equality, semantic source equality, external global classifier, or mature downstream object.*

Proof. Start with the source side. The bundle row B and domain row D fix which probes may be asked, and A records the emitted marks and evidence rows for those admitted asks.

The signature side is then forced through S and E. The generated answer histories are assembled by the signature row and compared only by the internal hsame witness carried by sameSig.

The visible-token side is forced through P and G. Package tokens are introduced from generated answer histories, and gap memberships tie those tokens back to admitted source histories.

The exactness row X supplies coverage, base soundness, and base completeness for exactly those displayed memberships. Therefore local classification reaches package-token sameness only through the route already named, and the structural rows N, H, C, L cannot add a quotient, oracle, external classifier, or downstream carrier. □

Falsifiable prediction: Every accepted $\mathsf{AskSigGapRoute}^{\uparrow}$ consumer that reads package-token exactness without first displaying the probe bundle, admitted domain, ask events, generated signatures, signature-sameness row, package row, gap row, and ExactGlobalizeBase row is outside the carrier surface.

Independence witness: ask, sig, pkg, gap, exact-globalize-base, namecert: no single listed kernel component is bijective with $\mathsf{AskSigGapRoute}^{\uparrow}$ because this packet binds them into one finite route from probe requests to visible exact package classification.

Closure status for $\mathsf{NameCert}_{\mathsf{AskSigGapRoute}^{\uparrow}}$**.**

Constructive story: An $\mathsf{AskSigGapRoute}^{\uparrow}$ packet is generated from a probe-bundle row, admitted-domain row, Ask event rows, Sig generation rows, sameSig comparison rows, Pkg token rows, Gap membership rows, ExactGlobalizeBase fields, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{AskSigGapRoute}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8979.1, Definition 8979.2, and Definition 8979.3 seed the finite L3–L5 route from ask events to exact package classification.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{AskSigGapRoute}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close a mature downstream object, quotient package equality, semantic source equality, an external global classifier, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, ask determinacy, signature determinacy, package visibility, gap coverage, exact base classification, transport, replay, provenance, and local naming for BEDC.Derived.AskSigGapRouteUp.

Chapter 8980

A Concrete Naming Certificate for $\mathsf{HausdorffCompletionAdjointness}^{\uparrow}$

Following Bourbaki and Kelley on completion and Hausdorff reflection, the $\mathsf{HausdorffCompletionAdjointness}^{\uparrow}$ packet records the finite unit-counit surface by which a displayed completion source is routed through separated reflection before any regular-rational or Real-facing seal is consumed. It sits over the completion carrier of chapter 95, the metric-completion carrier of chapter 1506, the separated-completion boundary of chapter 1612, the finite observation windows of chapter 126, the regular rational readback of chapter 301, and the terminal Real seal of chapter 38. The packet names the adjointness route as displayed BEDC data; it does not identify quotient completion classes, choose representatives, import countable choice, compare host completed objects, or assert ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 8980.1 (Hausdorff completion adjointness carrier)**.** *A* $\mathsf{HausdorffCompletionAdjointness}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$A = (C, H, U, V, S, R, E, T, K, P, N)$$

with the following displayed rows:

1. *C is the completion source row, recording the* $\mathsf{Completion}^{\uparrow}$ *or* $\mathsf{MetricCompletion}^{\uparrow}$ *request, its inspected source carrier, and the finite completion-facing branch exposed before any separated reflection is read.*
2. *H is the Hausdorff or separated reflection row, tying the completion source to the* $\mathsf{SeparatedCompletion}^{\uparrow}$ *boundary used to compare completed names.*
3. *U is the unit row, sending each displayed source observation into the completion-reflection packet through C and H.*
4. *V is the counit row, returning any completion-facing separated consumer to the same displayed completion-reflection surface.*
5. *S is the* $\mathsf{StreamName}^{\uparrow}$ *window row. It records the finite observation windows that must be open before the unit or counit rows can be consumed by downstream readers.*
6. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row, exposing regular rational data only after C, H, U, V, S have been displayed.*
7. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached only downstream of the completion source, separated reflection, unit row, counit row, StreamName windows, and RegSeqRat readback.*

8. *T records componentwise* hsame *transport for the completion source, Hausdorff reflection, unit, counit, StreamName windows, RegSeqRat readback, Real seal, replay, provenance, and local naming rows.*

9. *K records displayed* Cont *replay from the completion source through reflection, unit, counit, finite windows, rational readback, and Real sealing.*

10. *P is the* Pkg *provenance over* $\mathsf{HausdorffCompletionAdjointness}^{\uparrow}$, $\mathsf{Completion}^{\uparrow}$, $\mathsf{MetricCompletion}^{\uparrow}$, $\mathsf{SeparatedCompletion}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

11. *N is the local* $\mathsf{NameCert}_{\mathsf{HausdorffCompletionAdjointness}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $C, H, U, V, S, R, E, T, K, P, N$. It has no coordinate for quotient completion equality, selected representatives, countable-choice schedules, host equality of completed objects, detached Real equality, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 (statement) `BEDC.Derived.HausdorffCompletionAdjointnessUp`

Theorem 8980.2 (Hausdorff completion adjointness NameCert obligations)**.** *For every accepted* $\mathsf{HausdorffCompletionAdjointness}^{\uparrow}$ *carrier $A = (C, H, U, V, S, R, E, T, K, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{HausdorffCompletionAdj}}$ *surface consists exactly of the following five obligation rows:*

1. *completion-source admission, requiring the displayed* $\mathsf{Completion}^{\uparrow}$ *or* $\mathsf{MetricCompletion}^{\uparrow}$ *row C before any adjointness data are read;*

2. *Hausdorff-reflection admission, requiring the* $\mathsf{SeparatedCompletion}^{\uparrow}$ *row H before completed names may be compared;*

3. *unit-counit visibility, requiring the unit row U and counit row V to be exposed as finite rows over the same C, H route;*

4. *finite readback routing, requiring* $\mathsf{StreamName}^{\uparrow}$ *windows through S and* $\mathsf{RegSeqRat}^{\uparrow}$ *readback through R before the* $\mathsf{Real}^{\uparrow}$ *seal E is available;*

5. *nonescape under structure, requiring T, K, P, N to transport, replay, source, and name only the displayed route, with no quotient completion equality, selected representatives, countable choice, host equality, detached Real equality, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the carrier of Definition 8980.1. The completion source is C, the separated-reflection boundary is H, and the unit-counit rows are exactly U, V.

The readback rows are downstream of that route. The finite StreamName windows are stored in S, the regular rational readback is stored in R, and the Real-facing seal is stored in E.

The structural rows cannot add new analytic content. The row T transports the displayed components by hsame, K replays the same route by Cont, P records provenance, and N names the local packet.

Since the carrier has no coordinate for the excluded quotient, selector, choice, host-equality, detached-Real, or ambient-completeness objects, the five listed rows exhaust the NameCert surface. □

Theorem 8980.3 (Hausdorff completion adjointness unit-counit route)**.** *Every completion-facing consumer of an accepted* $\mathsf{HausdorffCompletionAdjointness}^{\uparrow}$ *carrier must expose the unit row U and counit row V over the finite route*

$$C \longmapsto H \longmapsto U, V \longmapsto S \longmapsto R \longmapsto E \longmapsto T, K, P, N$$

before any $\mathsf{RegSeqRat}^{\uparrow}$ *readback or* $\mathsf{Real}^{\uparrow}$ *seal is read. In particular, the packet permits downstream completion, regular-rational, and Real consumers to see the adjointness boundary only as displayed unit-counit data over the same completion and Hausdorff-reflection rows.*

Proof. Start with a completion-facing consumer. Carrier admission exposes no rational readback or Real seal until the completion source C and Hausdorff-reflection row H have been read.

The unit and counit rows are the next public rows on the route. The row U sends source observations into the completion-reflection packet, while V returns separated completion consumers to that same packet.

Only after U, V are visible can the consumer inspect finite observations and rational readback. These are the rows S and R, and the terminal Real seal E is downstream of both.

Finally T, K, P, N transport, replay, source, and name the displayed route. They cannot introduce quotient classes, selected representatives, countable choice, host equality, detached Real equality, or ambient completeness because no such coordinate is carried. □

Falsifiable prediction: Every accepted $\mathsf{HausdorffCompletionAdjointness}^{\uparrow}$ completion-facing read exposes a completion source row, a Hausdorff or separated reflection row, unit and counit rows, finite StreamName windows, RegSeqRat readback, a Real seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert data before any downstream consumer reads the terminal seal.

Independence witness: completion, metriccompletion, separatedcompletion, streamname, regseqrat, real: $\mathsf{HausdorffCompletionAdjointness}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries completion source admission, Hausdorff reflection, unit and counit visibility, finite-window routing, regular rational readback, Real sealing, transport, replay, provenance, and local naming rows.

Closure status for $\mathsf{NameCert}_{\mathsf{HausdorffCompletionAdjointness}^{\uparrow}}$.

Constructive story: A $\mathsf{HausdorffCompletionAdjointness}^{\uparrow}$ packet is generated from a completion source row, a Hausdorff or separated reflection row, a unit row, a counit row, StreamName windows, RegSeqRat readback, a Real seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{HausdorffCompletionAdjointness}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8980.1, Definition 8980.2, and Definition 8980.3 seed the completion adjointness boundary over completion source, Hausdorff reflection, unit, counit, finite-window, regular-readback, Real-seal, transport, replay, provenance, and local naming rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{HausdorffCompletionAdjointness}^{\uparrow}}, \mathsf{formalTarget})$

Lean target: `BEDC.Derived.HausdorffCompletionAdjointnessUp`

Bridge status: none

Not claimed: This chapter does not close quotient completion equality, selected representatives, countable choice, host equality, detached Real equality, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, Hausdorff reflection exposure, unit and counit visibility, StreamName window routing, RegSeqRat readback, Real-seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.HausdorffCompletionAdjointnessUp.

Chapter 8981

A Concrete Naming Certificate for $\mathsf{ApollonianGasket}^{\uparrow}$

Following Descartes circle theorem and the classical Apollonian gasket construction, the $\mathsf{ApollonianGasket}^{\uparrow}$ packet records one finite replacement window of mutually tangent circles before any infinite packing, limiting set, or measure-theoretic boundary is read. It sits beside the circle carrier of chapter 4010, the Ford-circle tangency ledger of chapter 8445, the metric source of chapter 57, the dyadic interval-net route of chapter 5966, and the terminal real-name seal of chapter 38. The packet names only finite Descartes replacement data and its local sibling lattice.

Definition 8981.1 (Apollonian gasket carrier)**.** *An* $\mathsf{ApollonianGasket}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$G = (C, T, K, D, M, R, L, H, Q, P, N)$$

with the following displayed rows:

1. *C is the ordered Descartes cluster row, listing four displayed* $\mathsf{Circle}^{\uparrow}$ *entries together with their tangency incidence.*
2. *T is the tangent-pair ledger, recording exactly the six pairwise tangencies inspected in the current window.*
3. *K is the curvature row, carrying the four signed curvature reads used by the Descartes relation.*
4. *D is the replacement row, naming the alternate circle obtained by replacing one member of the cluster while keeping the other three tangent circles fixed.*
5. *M is the* $\mathsf{Met}^{\uparrow}$ *contact row used to read tangency and separation in the ambient displayed metric surface.*
6. *R is the* $\mathsf{Real}^{\uparrow}$ *readback row for curvature, center-coordinate, and contact-radius comparisons.*
7. *L is the* $\mathsf{DyadicIntervalNet}^{\uparrow}$ *finite localization row for the inspected centers and radii.*
8. *H records componentwise* hsame *transport for the cluster, tangency, curvature, replacement, metric, real, localization, replay, provenance, and local naming rows.*
9. *Q records displayed* Cont *replay from a Descartes replacement request through $C, T, K, D, M, R, L, H, P, N$.*
10. *P is the* Pkg *provenance over* $\mathsf{ApollonianGasket}^{\uparrow}$, $\mathsf{Circle}^{\uparrow}$, $\mathsf{FordCircle}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{DyadicIntervalNet}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.

11. N is the local $\mathsf{NameCert}_{\mathsf{ApollonianGasket}^{\uparrow}}$ *row.*
The classifier compares accepted packets only through $C, T, K, D, M, R, L, H, Q, P, N$. It has no coordinate for an infinite gasket, a limiting dust set, a selected infinite replacement branch, a completed curvature spectrum, area measure, or host Euclidean plane.

Theorem 8981.2 (Apollonian gasket NameCert obligations)**.** *For every accepted* $\mathsf{ApollonianGasket}^{\uparrow}$ *carrier*

$$G = (C, T, K, D, M, R, L, H, Q, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{ApollonianGasket}^{\uparrow}}$ *surface consists exactly of carrier admission for the displayed Descartes cluster, tangent-pair ledger, curvature row, one-circle replacement row, metric contact row, Real readback row, dyadic localization row, componentwise transport, displayed replay, package provenance, and local naming.*

Proof. Project the carrier of Definition 8981.1. The rows C, T, K, D, M, R, L are the mathematical data of the inspected replacement window, and H, Q, P, N are the structural rows that transport, replay, source, and name the same packet.

The Descartes cluster and tangent-pair ledger expose only four circles and six tangencies. The curvature row and replacement row then name one finite replacement step, not an infinite branch of replacements.

The metric, Real, and dyadic localization rows keep contact and curvature reads inside displayed finite data. Since no carrier coordinate stores a limiting set, selected infinite path, completed curvature spectrum, or measure surface, the listed rows exhaust the NameCert obligations. □

Theorem 8981.3 (Apollonian gasket Descartes replacement stability)**.** *Let $G = (C, T, K, D, M, R, L, H, Q, P, N)$ be an accepted* $\mathsf{ApollonianGasket}^{\uparrow}$ *carrier. Replacing one circle of the displayed Descartes cluster by the alternate circle named in D preserves the public route*

$$C, T, K, D, M, R, L, H, Q, P, N$$

for the resulting finite window. The replacement can be consumed through the same circle, metric, dyadic localization, and Real readback rows, and it exports no infinite gasket, selected replacement branch, limiting dust, area measure, or ambient-plane completeness principle.

Proof. Begin with the tangent-pair ledger T. The replacement row D keeps the three fixed tangent circles visible and records the alternate circle only as a row of the same finite carrier.

Read the curvature row K through the Descartes relation. The Real readback R supplies the displayed curvature and contact-radius comparisons, while the metric row M supplies the tangency and separation vocabulary used by the local replacement.

Use the dyadic localization row L to keep centers and radii inside the inspected finite window. Componentwise transport H and replay Q then carry the replacement packet forward without changing its public rows.

Finally P and N source and name the resulting window as an $\mathsf{ApollonianGasket}^{\uparrow}$ packet. Because the carrier has no infinite-branch, measure, limiting-set, or ambient-plane coordinate, the replacement stability statement is confined to the displayed Descartes window. □

Theorem 8981.4 (Apollonian gasket sibling lattice)**.** *Every* $\mathsf{ApollonianGasket}^{\uparrow}$ *read factors through the sibling lattice*

$$\mathsf{Circle}^{\uparrow},\ \mathsf{FordCircle}^{\uparrow},\ \mathsf{Met}^{\uparrow},\ \mathsf{DyadicIntervalNet}^{\uparrow},\ \mathsf{Real}^{\uparrow}$$

before a consumer may inspect the Descartes replacement row. The circle and Ford-circle rows supply tangency vocabulary, the metric row supplies contact comparison, the dyadic interval-net row supplies finite localization, and the Real row supplies curvature and radius readback.

Proof. Project the provenance row P of Definition 8981.1. It names the circle, Ford-circle, metric, dyadic localization, and Real siblings as the only external packet surfaces available to an Apollonian replacement read.

The Descartes cluster row C and tangent ledger T are read through the circle and Ford-circle surfaces. The metric row M then fixes the contact relation before curvature and radius data are read by R.

The dyadic interval-net row L supplies the finite localization boundary for centers and radii. Transport, replay, provenance, and local naming preserve the same route, so downstream consumers receive a finite sibling lattice rather than an ambient plane, a completed packing, or a hidden choice of replacement branch. □

Falsifiable prediction: Every accepted $\mathsf{ApollonianGasket}^{\uparrow}$ replacement read displays four circle rows, six tangent-pair rows, curvature readback, one replacement row, metric contact, dyadic localization, Real sealing, hsame transport, Cont replay, Pkg provenance, and local NameCert data before any gasket consumer may read it.

Independence witness: circle, ford-circle, metric, dyadic-interval-net, real: none of the listed siblings jointly carries a Descartes cluster, tangent-pair ledger, curvature row, one-circle replacement row, localization row, transport, replay, provenance, and local NameCert data as one finite gasket packet.

Closure status for $\mathsf{NameCert}_{\mathsf{ApollonianGasket}^{\uparrow}}$.

Constructive story: An $\mathsf{ApollonianGasket}^{\uparrow}$ packet is generated from a finite Descartes circle cluster, tangent-pair ledger, curvature row, one-circle replacement row, metric contact row, Real readback row, dyadic localization row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{ApollonianGasket}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8981.1, Definition 8981.2, Definition 8981.3, and Definition 8981.4 seed the finite Descartes replacement route for one Apollonian gasket window.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{ApollonianGasket}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim an infinite gasket, a limiting dust set, a selected infinite replacement branch, a completed curvature spectrum, area measure, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, Descartes tangency exactness, replacement stability, sibling-lattice routing, transport, replay, provenance, and local naming for BEDC.Derived.ApollonianGasketUp.

Chapter 8982

A Concrete Naming Certificate for $\mathsf{FiniteIntervalBisectionSelector}^{\uparrow}$

Following Bishop and Bridges on interval bisection and regular Cauchy construction, the FiniteIntervalBisectionSelect packet records the finite selector used when an L10 Real or Completion route must choose a displayed half of a finite interval cell. It sits after the endpoint-order lattice of chapter 6006, the dyadic interval cells of chapter 306, the stream schedules of chapter 126, the regular rational readback of chapter 301, and the terminal real-name seal of chapter 38. The selector supplies a finite bisection handoff; it is not an open-cover compactness principle, a quotient real equality row, an ambient completeness theorem, or a choice function over all intervals.

Definition 8982.1 (Finite interval bisection selector carrier)**.** *A* $\mathsf{FiniteIntervalBisectionSelector}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$F = (D, I, B, S, Q, R, H, C, P, N)$$

with the following rows:

1. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *endpoint-order row naming the lower endpoint, midpoint, and upper endpoint comparisons used by the bisection.*
2. *I is the* $\mathsf{DyadicInterval}^{\uparrow}$ *cell row naming the displayed parent interval and its two finite half-cells.*
3. *B is the selected-half row, recording whether the accepted continuation consumes the left half, the right half, or a refusal row when the half predicate is not displayed.*
4. *S is the* $\mathsf{StreamName}^{\uparrow}$ *schedule row for the finite endpoint and midpoint observations used by the selector.*
5. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the rational observations attached to the selected half.*
6. *R is the* $\mathsf{Real}^{\uparrow}$ *seal row exposed only after D, I, B, S, Q have remained visible.*
7. *H records componentwise* hsame *transport for endpoint order, interval cells, selected-half data, stream windows, readback, Real sealing, replay, provenance, and local naming.*
8. *C records displayed* Cont *replay from a parent interval request to the selected half and then to the regular-rational and Real-facing rows.*
9. *P is the* Pkg *provenance over* $\mathsf{FiniteIntervalBisectionSelector}^{\uparrow}$, $\mathsf{FiniteIntervalLattice}^{\uparrow}$, $\mathsf{DyadicInterval}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*

10. N is the local $\mathsf{NameCert}_{\mathsf{FiniteIntervalBisectionSelector}^{\uparrow}}$ *row.*
The carrier has no coordinate for a global interval choice function, a selected limit point, quotient equality of real names, open-cover compactness, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 8982.2 (Finite interval selected-half exactness)**.** *Let $F = (D, I, B, S, Q, R, H, C, P, N)$ be an accepted* $\mathsf{FiniteIntervalBisectionSelector}^{\uparrow}$ *carrier. Every selected-half read from B must expose the parent interval, midpoint split, and chosen half through the dyadic endpoint-order row D and the displayed cell row I before it can be consumed by a StreamName, RegSeqRat, or Real-facing continuation. The packet therefore selects only one of the two listed half-cells of I and exports no hidden representative, quotient real equality, open-cover compactness, or ambient completeness principle.*

Proof. Project the carrier of Definition 8982.1. The rows D and I display the lower endpoint, midpoint, upper endpoint, parent interval, and the two finite half-cells before the selector row is read.

Use the endpoint-order and Real-completion route of chapter 6006. That route already forces interval consumers to keep dyadic endpoint evidence and finite cell membership visible before analytic handoff.

The selected-half row B is then interpreted only relative to those displayed endpoint and cell rows. If the requested half is absent, the refusal row remains inside B; if it is present, the chosen half is one of the two cells listed by I.

Finally S, Q, R, H, C, P, N preserve the same displayed route by stream scheduling, regular rational readback, Real sealing, transport, replay, provenance, and local naming. None of those rows introduces a hidden representative, quotient real equality, open-cover compactness, or ambient completeness coordinate. □

Theorem 8982.3 (Finite interval bisection refinement induction)**.** *Let $F = (D, I, B, S, Q, R, H, C, P, N)$ be an accepted* $\mathsf{FiniteIntervalBisectionSelector}^{\uparrow}$ *carrier. For every displayed finite bisection depth, iterating the selector rebuilds a finite chain of dyadic half-cells whose endpoint comparisons remain in D, whose interval cells remain in I, whose selected-half rows remain in B, and whose analytic handoff remains the route*

$$S, Q, R, H, C, P, N.$$

Thus refinement induction supplies only a finite chain of displayed bisections and cannot introduce an infinite nested interval object, selected limit point, countable choice schedule, quotient real equality, or ambient completion theorem.

Proof. Induct on the displayed bisection depth. At depth zero the chain is the parent cell named by I, with endpoint order and analytic handoff already recorded by the carrier.

For the successor step, apply selected-half exactness, Definition 8982.2. The next half-cell is one of the two displayed halves of the current cell, and its lower endpoint, midpoint, and upper endpoint comparisons are still read through D.

The finite interval lattice refinement induction of Definition 6006.5 supplies the table-level refinement discipline for the surrounding cell lattice. The selector adds only the row recording which displayed half is consumed at the current step.

Finally the stream schedule, regular rational readback, Real seal, transport, replay, provenance, and local naming rows remain S, Q, R, H, C, P, N at every finite stage. The induction therefore builds a finite displayed chain and never supplies an infinite nested object, selected limit point, countable choice schedule, quotient real equality, or ambient completion theorem. □

Theorem 8982.4 (Finite interval bisection RegSeqRat handoff)**.** *Every RegSeqRat-facing consumer of an accepted* $\mathsf{FiniteIntervalBisectionSelector}^{\uparrow}$ *carrier factors through the displayed route*

$$\mathsf{FiniteIntervalLattice}^{\uparrow},\ \mathsf{DyadicInterval}^{\uparrow},\ \mathsf{DyadicRatCore}^{\uparrow},\ \mathsf{StreamName}^{\uparrow} \longrightarrow \mathsf{RegSeqRat}^{\uparrow}.$$

The selected-half row B may narrow the visible interval cell, but it does not create a rational sequence outside the displayed stream schedule or bypass the endpoint-order evidence.

Proof. Begin with the carrier of Definition 8982.1. The dyadic endpoint row D, interval-cell row I, selected-half row B, and stream schedule row S are upstream of the regular rational readback row Q.

Apply selected-half exactness. It forces B to choose only a displayed half-cell whose endpoint order is already visible through D and I.

Apply refinement induction. Every finite tail of repeated bisection remains a finite chain of displayed cells, so a RegSeqRat-facing readback sees the same endpoint and stream-window route at each finite stage.

Thus Q is reached only through the displayed finite interval lattice, dyadic interval, dyadic endpoint, and stream schedule rows. No quotient stream, selected representative, countable-choice subsequence, or ambient Real-completion route is imported by the handoff. □

Theorem 8982.5 (Finite interval bisection Real-seal nonescape)**.** *Let $F = (D, I, B, S, Q, R, H, C, P, N)$ be an accepted* $\mathsf{FiniteIntervalBisectionSelector}^{\uparrow}$ *carrier. A* $\mathsf{Real}^{\uparrow}$ *or* $\mathsf{Completion}^{\uparrow}$ *consumer reaches the terminal seal R only after the dyadic endpoint row D, displayed interval-cell row I, selected-half row B, stream schedule S, and RegSeqRat readback Q have been exposed. The Real-facing seal therefore records the same finite bisection route and not a chosen limit, quotient real equality, open-cover compactness principle, or ambient completeness witness.*

Proof. Use the RegSeqRat handoff of Definition 8982.4. It places every regular rational readback downstream of the finite interval lattice, dyadic interval, endpoint-order, selected-half, and stream schedule rows.

The Real-completion route of chapter 6006 keeps analytic consumers inside the displayed finite lattice route before a Real-facing seal is read.

Finally replay the structural rows H, C, P, N. Componentwise transport, continuation replay, provenance, and local naming preserve the same packet, so the terminal row R cannot add a chosen limit, quotient real equality, open-cover compactness principle, or ambient completeness witness. □

Closure status for $\mathsf{NameCert}_{\mathsf{FiniteIntervalBisectionSelector}^{\uparrow}}$.

Constructive story: A $\mathsf{FiniteIntervalBisectionSelector}^{\uparrow}$ packet is generated from dyadic endpoint-order rows, displayed interval cells, a selected-half row, finite stream windows, RegSeqRat readback, Real seal, componentwise hsame transport, continuation replay, package provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{FiniteIntervalBisectionSelector}^{\uparrow}}$, seed)

Scope closed: Definition 8982.1, selected-half exactness, refinement induction, RegSeqRat handoff, and Real-seal nonescape seed the finite bisection selector route for L10 Real and Completion consumers.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{FiniteIntervalBisectionSelector}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close global interval choice, infinite nested interval convergence, selected limits, quotient real equality, open-cover compactness, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, selected-half exactness, finite refinement induction, RegSeqRat handoff, Real-seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.FiniteIntervalBisectionSelecto

Chapter 8983

A Concrete Naming Certificate for $\mathsf{OmegaGenerationBoundaryPacket}^{\uparrow}$

The $\mathsf{OmegaGenerationBoundaryPacket}^{\uparrow}$ chapter realizes the omega generation structure interface of chapter 9361 as one finite NameCert carrier. The packet binds licensed interface objects, licensed morphisms, generation diagrams, legal stream displays, pairing rows, time rows, transport, replay, provenance, and local naming before any tower coordinate is read. It is an omega-boundary certificate, not a global tower object, not a quotient of generated bodies, and not an unlicensed selector for hidden coordinates.

Omega boundary reads consume the kernel acceptance boundary of chapter 6007 and the machine export boundary of chapter 5205 before exposing coordinate-facing rows. The acceptance boundary supplies the licensed public row, while the export boundary supplies the machine-facing read discipline for legal displays, pairing rows, and time rows.

Definition 8983.1 (Omega generation boundary packet carrier)**.** *An* $\mathsf{OmegaGenerationBoundaryPacket}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$O = (A, M, D, L, P, T, H, C, K, N)$$

with the following rows:

1. *A is the licensed interface-object row of Definition 9361.1, including carrier, public classifier, ledger, and displayed NameCert fields.*
2. *M is the licensed morphism row of Definition 9361.2, recording classifier, ledger, and continuation preservation.*
3. *D is the generation-diagram row of Definition 9361.4, including displayed readback morphisms and compatibility witnesses.*
4. *L is the legal stream display row of Definition 9361.5, including public stream classifier, stream ledger, and decode relation.*
5. *P is the pairing row, recording only typed involutive layers whose source interface licenses pairing behavior.*
6. *T is the time-row, recording generated one-step extension and continuation direction rather than an involution.*
7. *H records componentwise* hsame *transport for interface, morphism, generation diagram, legal display, pairing, time, replay, provenance, and local naming rows.*

8. *C records displayed* Cont *replay from a boundary read through the licensed interface, morphism, diagram, display, pairing, and time rows.*
9. *K is the* Pkg *provenance over* $\mathsf{OmegaGenerationBoundaryPacket}^{\uparrow}$*, licensed interface objects, licensed morphisms, generation diagrams, legal stream displays, pairing rows, time rows,* BHist*,* hsame*,* Cont*, and* NameCert *rows.*
10. *N is the local* $\mathsf{NameCert}_{\mathsf{OmegaGenerationBoundaryPacket}^{\uparrow}}$ *row.*

The carrier has no coordinate for an unlicensed tower element, hidden body equality, raw code stream, global inverse to time, host quotient of generated bodies, or external omega-completion principle.

Theorem 8983.2 (Omega generation boundary packet row exposure)**.** *Every accepted* OmegaGenerationBoundaryP *consumer that reads a tower coordinate must first display the licensed interface object row A, licensed morphism row M, generation-diagram row D, legal stream display row L, pairing row P, time row T, transport row H, replay row C, provenance row K, and local naming row N. Thus a coordinate read is accepted only through the finite boundary carrier and not through raw body equality, unlicensed code, hidden tower selection, or an ambient omega object.*

Proof. Project the carrier of Definition 8983.1. Its first six rows display the licensed object, morphism, diagram, legal stream, pairing, and time surfaces before any coordinate-facing conclusion is public.

Apply the no-unlicensed-coordinate principle of Definition 9361.3. It requires every visible omega coordinate to be represented by carrier, classifier, stability, ledger, and NameCert rows before tower language is accepted.

Use the omega generation structure package of Definition 9361.20. Encoded reflection, typed pairing, and generated time direction all live over the licensed carrier, classifier, ledger, and NameCert rows already exposed by A, M, D, L, P, T.

Finally replay H, C, K, N. Componentwise transport, displayed continuation replay, package provenance, and local naming preserve the same finite boundary packet and add no raw body equality, unlicensed code, hidden tower selector, or ambient omega object. □

Theorem 8983.3 (Omega generation boundary packet nonescape)**.** *An accepted* $\mathsf{OmegaGenerationBoundaryPacket}^{\uparrow}$ *read cannot replace the displayed legal stream row by a raw stream, cannot replace typed pairing by time direction, and cannot replace the time row by an involutive mirror. The only public route is the carrier*

$$A, M, D, L, P, T, H, C, K, N.$$

Proof. Use row exposure, Definition 8983.2. It puts the legal stream display, pairing row, and time row on the same finite boundary route.

The legal stream display of Definition 9361.5 is a certified public display with ledger-visible source rows, not a raw bit string. The pairing source discipline of Definition 9361.12 permits pairing only where an involution is licensed.

The time separation theorem Definition 9361.18 and the principle Definition 9361.19 keep generated extension direction separate from pairing. Therefore no accepted read can trade raw code, untyped pairing, or a global inverse-time map for the displayed boundary route. □

Falsifiable prediction: Every accepted $\mathsf{OmegaGenerationBoundaryPacket}^{\uparrow}$ consumer that reads a tower coordinate without first displaying licensed interface, morphism, generation-diagram, legal-stream, pairing, and time rows is outside the carrier surface.

Independence witness: finite-interface-spine, ask-sig-gap-route, kernel-category, finite-data-assembly, kernel-acceptance-boundary: none is bijective with the omega boundary packet because the packet binds all licensed-interface, display, pairing, and time rows in one carrier.

The Lean follow-up for this packet is the $\mathsf{OmegaGenerationBoundaryPacket}^{\uparrow}$ taste gate, whose public surface is expected to provide a nontriviality instance and a field-faithfulness instance for the boundary carrier.

Closure status for $\mathsf{NameCert}_{\mathsf{OmegaGenerationBoundaryPacket}^{\uparrow}}$.

Constructive story: An $\mathsf{OmegaGenerationBoundaryPacket}^{\uparrow}$ packet is generated from licensed interface-object rows, licensed morphism rows, generation-diagram rows, legal stream display rows, pairing rows, time rows, componentwise hsame transport, displayed Cont replay, package provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{OmegaGenerationBoundaryPacket}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8983.1, row exposure, nonescape, falsifiability, and independence rows seed the finite boundary carrier for omega generation coordinate reads.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{OmegaGenerationBoundaryPacket}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close a global omega tower, quotient body equality, raw stream coding, inverse-time symmetry, RH rigidity, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, licensed-interface exposure, legal-stream display, pairing-time separation, transport, replay, provenance, local naming, and taste-gate instances for BEDC.Derived.OmegaGenerationBoundaryPa

Chapter 8984

A Concrete Naming Certificate for $\mathsf{NetAdherence}^{\uparrow}$

Following Kelley and Bourbaki on nets and filters, the $\mathsf{NetAdherence}^{\uparrow}$ packet records the finite boundary at which a displayed net, a generated filterbase, and neighbourhood requests meet an adherence or cluster-point test. It sits downstream of the convergence interface of chapter 1667, the Cauchy-net window discipline of chapter 589, the filterbase carrier of chapter 1601, the neighbourhood language of chapter 88, and the completion-facing seal of chapter 95. The packet names finite hit evidence; it is not a selected subnet, a choice principle, a quotient completion, or ambient real completeness.

Definition 8984.1 (Net adherence carrier)**.** *A* $\mathsf{NetAdherence}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$A = (D, N, F, U, A, H, C, P, L)$$

with the following displayed rows:

1. *D is the directed-index row, naming the finite index window and the tail requests available to the net-side reader.*
2. *N is the net-sample row, recording the inspected values of the net on the displayed directed window.*
3. *F is the* $\mathsf{FilterBase}^{\uparrow}$ *row generated from the displayed tail family.*
4. *U is the neighbourhood-request row, read through the local* $\mathsf{Topology}^{\uparrow}$ *surface and only at the displayed candidate boundary.*
5. *A is the adherence-hit row, recording the finite evidence that a tail or filterbase member meets the requested neighbourhood.*
6. *H records componentwise* hsame *transport for directed indices, samples, filterbase rows, neighbourhood requests, hits, replay, provenance, and local naming.*
7. *C records displayed* Cont *replay for any consumer that asks for the same hit evidence.*
8. *P is the* Pkg *provenance over* $\mathsf{NetAdherence}^{\uparrow}$, $\mathsf{NetConvergence}^{\uparrow}$, $\mathsf{CauchyNet}^{\uparrow}$, $\mathsf{FilterBase}^{\uparrow}$, $\mathsf{Topology}^{\uparrow}$, $\mathsf{Completion}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
9. *L is the local* $\mathsf{NameCert}_{\mathsf{NetAdherence}^{\uparrow}}$ *row, whose source, pattern, classifier, stability, and ledger fields are read from D, N, F, U, A, H, C, P.*

The classifier compares accepted packets only through these rows. It has no coordinate for a selected subnet, cofinal choice over the directed set, quotient equality of filters, a completed ambient point, or $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 8984.2 (Net adherence FilterBase obligations)**.** *For every accepted* $\mathsf{NetAdherence}^{\uparrow}$ *carrier* $A = (D, N, F, U, A, H, C, P, L)$*, the local* $\mathsf{NameCert}_{\mathsf{NetAdherence}^{\uparrow}}$ *surface consists exactly of the following finite obligations:*

1. *carrier admission for the directed-index row, net-sample row, generated filterbase row, neighbourhood-request row, adherence-hit row, transport row, replay row, provenance row, and local naming row;*
2. *directed-tail discipline, requiring every hit read to expose the finite tail request in* D *before it inspects a sample in* N*;*
3. *filterbase generation, requiring the* $\mathsf{FilterBase}^{\uparrow}$ *row* F *to be read from the same displayed tail family and not from a host filter equality;*
4. *neighbourhood discipline, requiring the request row* U *to be interpreted through chapter 88;*
5. *hit stability, requiring the adherence-hit row to transport along the componentwise* hsame *row* H *and replay through* C*;*
6. *provenance and local naming through* P *and* L*.*

No obligation for selected subnet construction, choice over tails, quotient completion, or ambient $\mathsf{Real}^{\uparrow}$ *completeness is stored in this packet.*

Proof. Project the accepted carrier of Definition 8984.1. The source-side rows are D, N, F, U, A, and the structural rows are H, C, P, L.

The directed-tail evidence is displayed first. A hit read has to name the finite index window in D and the inspected net samples in N before any filterbase or neighbourhood row can be consumed.

The filterbase and topology rows then fix the analytic boundary. The row F is generated from the same displayed tails, while U records only the finite neighbourhood requests supplied by the topology-side surface. Thus the adherence hit is a finite meet between a displayed tail family and a displayed neighbourhood request.

Finally H, C, P, L transport, replay, source, and name the same packet. Since no coordinate stores a selected subnet, a choice operator, quotient filter equality, a completed ambient point, or real completeness, the listed rows exhaust the local $\mathsf{NameCert}_{\mathsf{NetAdherence}^{\uparrow}}$ obligations. □

Theorem 8984.3 (Net adherence Cauchy-net cluster route)**.** *Every completion-facing or cluster-point-facing consumer of an accepted* $\mathsf{NetAdherence}^{\uparrow}$ *carrier factors through*

$$D, N \longmapsto F, U \longmapsto A \longmapsto H, C, P, L.$$

The route may be read after the $\mathsf{NetConvergence}^{\uparrow}$ *and* $\mathsf{CauchyNet}^{\uparrow}$ *rows of chapter 1667 and chapter 589, may hand its filterbase row to chapter 1601, and may be consumed by completion arguments in chapter 95. It exports finite adherence evidence only; it does not select a subnet, choose a cluster point, identify quotient filters, or import ambient completeness.*

Proof. Begin with a completion-facing request. The carrier first exposes the directed-index and sample rows D, N, so the request sees a finite net window rather than a host net predicate.

The next boundary is the filterbase and neighbourhood interface. The generated row F gives the filterbase side, and U records the topology-side neighbourhood request. Their common display is exactly the finite surface needed by adherence and cluster arguments.

The hit row A is then read as evidence that the displayed tail or filterbase member meets the displayed neighbourhood request. The structural rows H, C, P, L preserve that evidence under transport, replay it for downstream consumers, record provenance, and bind the local name.

Thus a Cauchy-net or completion consumer receives only the finite route through $D, N, F, U, A, H, C, P, L$. The packet cannot add subnet selection, cluster-point choice, quotient-filter equality, or ambient $\mathsf{Real}^{\uparrow}$ completeness because none of those data appear among its rows. □

Falsifiable prediction: Every accepted $\mathsf{NetAdherence}^{\uparrow}$ consumer that reads adherence or cluster evidence without displaying the directed-index row, net-sample row, filterbase row, neighbourhood-request row, adherence-hit row, transport, replay, provenance, and local NameCert rows is outside the carrier surface.

Independence witness: net, filterbase, topology, completion: no single listed sibling is bijective with $\mathsf{NetAdherence}^{\uparrow}$ because this packet binds directed net samples, generated filterbase rows, neighbourhood requests, and finite hit evidence into one local NameCert boundary.

Closure status for $\mathsf{NameCert}_{\mathsf{NetAdherence}^{\uparrow}}$.

Constructive story: A $\mathsf{NetAdherence}^{\uparrow}$ packet is generated from a directed-index row, net-sample row, generated FilterBase row, topology-side neighbourhood-request row, adherence-hit row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{NetAdherence}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8984.1, Definition 8984.2, and Definition 8984.3 seed the finite net/filter adherence boundary used by completion and cluster-point arguments.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{NetAdherence}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close selected subnets, choice over directed tails, quotient filter equality, selected cluster points, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, directed-tail discipline, filterbase generation, neighbourhood discipline, hit stability, transport, replay, provenance, and local naming for BEDC.Derived.NetAdherenceUp.

Chapter 8985

A Concrete Naming Certificate for $\mathsf{KakeyaSet}^{\uparrow}$

Following Besicovitch and Kakeya on direction-rich plane sets, the $\mathsf{KakeyaSet}^{\uparrow}$ packet records only the finite BEDC geometry needed to name a displayed direction-window and segment-incidence carrier. It sits over the terminal real-name surface of chapter 38, the metric certificate of chapter 57, the dyadic interval rows of chapter 8927, and the incidence bookkeeping of chapter 8975. The packet is a finite naming certificate for direction-window geometry; it does not claim measure zero, the Kakeya conjecture, Besicovitch set existence, ambient planar completeness, or a host set-theoretic construction.

Definition 8985.1 (KakeyaSet carrier)**.** *A* $\mathsf{KakeyaSet}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (D, W, S, I, M, R, H, C, P, N)$$

with the following displayed rows:

1. *D is a finite direction-window row, listing named rational or dyadic direction samples and the tolerance cells that cover the inspected direction interval.*
2. *W is the window ledger, recording the finite observation windows in which the direction samples and segment endpoints are read.*
3. *S is the segment row, assigning to each displayed direction sample one finite segment name with endpoint rows over* $\mathsf{Real}^{\uparrow}$*.*
4. *I is the segment-incidence row, recording which sampled direction, endpoint pair, and window row belong to the same displayed segment.*
5. *M is the* $\mathsf{Met}^{\uparrow}$ *comparison row used to read endpoint distance and segment length only through displayed metric data.*
6. *R is the real-name handoff row, tying every endpoint coordinate and tolerance cell to the* $\mathsf{Real}^{\uparrow}$ *and* $\mathsf{DyadicRealInterval}^{\uparrow}$ *sibling surfaces.*
7. *H records componentwise* hsame *transport for direction windows, segment rows, incidence rows, metric comparisons, real-name handoff, replay, provenance, and local naming.*
8. *C records displayed* Cont *replay from a direction request through the finite window, segment-incidence row, metric row, and real-name handoff.*

9. *P is the* Pkg *provenance over* $\mathsf{KakeyaSet}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{DyadicRealInterval}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{KakeyaSet}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $D, W, S, I, M, R, H, C, P, N$. It has no coordinate for outer measure, null sets, arbitrary direction choice, infinite unions, host subsets of the plane, or any assertion that a Besicovitch set exists.

Theorem 8985.2 (KakeyaSet NameCert obligations)**.** *For every accepted* $\mathsf{KakeyaSet}^{\uparrow}$ *carrier*

$$K = (D, W, S, I, M, R, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{KakeyaSet}^{\uparrow}}$ *surface consists exactly of finite direction-window admission for D, finite observation-window display for W, segment-row admission for S, segment-incidence exactness for I, metric comparison display for M, real-name and dyadic-interval handoff for R, componentwise* hsame *transport through H, displayed* Cont *replay through C, sibling provenance through P, and local naming through N.*

No KakeyaSet obligation is stored outside these rows.

Proof. Project the accepted carrier. The finite direction-window row D and the observation ledger W are the only rows from which directions may be read, so the packet never introduces an arbitrary direction choice.

The segment data are then read through S and I. These rows bind each sampled direction to a displayed segment endpoint pair and to the window in which that pair is observed.

Finally the metric and real-name handoff rows M and R keep all endpoint and length comparisons inside the sibling Real, dyadic-interval, and metric surfaces. The structural rows H, C, P, N transport, replay, source, and name the same finite route, so the local certificate contains no measure-theoretic or host set-theoretic coordinate. □

Theorem 8985.3 (KakeyaSet direction-window route)**.** *Every consumer that reads a* $\mathsf{KakeyaSet}^{\uparrow}$ *packet as direction-rich geometry must first expose the finite route*

$$D, W, S, I, M, R, H, C, P, N.$$

The direction-window row and segment-incidence row are public before any geometric consumer may compare directions or endpoints. The route exports finite incidence geometry only; it does not assert measure zero, the Kakeya conjecture, Besicovitch set existence, arbitrary direction selection, or a completed host subset of the plane.

Proof. Start from the carrier of Definition 8985.1. The only direction data are the finite direction samples and tolerance cells stored in D, with their read windows stored in W.

Apply the NameCert obligations of Definition 8985.2. They require the segment row S and incidence row I before any consumer can attach a segment to a direction window.

The metric row M and real-name handoff row R then route endpoint and length reads through chapter 57, chapter 38, and chapter 8927. Transport, replay, provenance, and local naming preserve that same finite path, leaving no coordinate from which a measure-theoretic or completed-plane claim could be read. □

Closure status for $\mathsf{NameCert}_{\mathsf{KakeyaSet}^{\uparrow}}$**.**

Constructive story: A $\mathsf{KakeyaSet}^{\uparrow}$ packet is generated from finite direction-window rows, finite observation windows, segment rows, segment-incidence rows, metric comparison rows, Real and dyadic-interval handoff rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\mathsf{KakeyaSet}^{\uparrow}}$, seed)

Scope closed: Definition 8985.1, Definition 8985.2, and Definition 8985.3 seed the finite direction-window and segment-incidence carrier for KakeyaSet$^{\uparrow}$.

Formal verification: FormalStatus(NameCert$_{\mathsf{KakeyaSet}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close measure zero, the Kakeya conjecture, Besicovitch set existence, arbitrary direction choice, infinite unions, host subsets of the plane, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked direction-window admission, segment-incidence exactness, metric comparison display, Real and dyadic-interval handoff, transport stability, replay stability, and non-escape for BEDC.Derived.KakeyaSetUp.

Chapter 8986

A Concrete Naming Certificate for $\mathsf{StreamRegularLimitSeal}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{StreamRegularLimitSeal}^{\uparrow}$ packet records the finite cofinal diagonal representative used when a regular stream family is handed to Real and Completion consumers. It sits after the finite stream windows of chapter 126, the regular rational readback of chapter 301, the dyadic tolerance ledger of chapter 291, the terminal real-name seal of chapter 38, and the tail-control route of chapter 2220. The packet names one displayed diagonal-limit handoff; it does not select a host limit, quotient stream, choice schedule, trichotomy decision, or ambient completeness theorem.

Definition 8986.1 (Stream regular limit seal carrier)**.** *A* $\mathsf{StreamRegularLimitSeal}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (Q, W, R, D, I, E, H, C, P, N)$$

with the following displayed rows:

1. *Q is the finite request row, naming the inspected precision and the completion-facing consumer request.*
2. *W is the* $\mathsf{StreamName}^{\uparrow}$ *window row through which the requested member stream and the diagonal observation are read.*
3. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row, exposing the regular rational data obtained from the same finite windows.*
4. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row, carrying the dyadic budget used to compare the requested tail with the diagonal representative.*
5. *I is the cofinal diagonal index row, naming the finite index chosen by the displayed modulus route for this request.*
6. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row, available only after Q, W, R, D, I have been displayed.*
7. *H records componentwise* hsame *transport for the request, window, readback, tolerance, diagonal index, Real seal, provenance, and local naming rows.*
8. *C records the displayed* Cont *replay from the finite request through the stream window, regular readback, dyadic tolerance, cofinal diagonal index, and terminal seal.*
9. *P is the* Pkg *provenance over* $\mathsf{StreamRegularLimitSeal}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* NameCert.

10. N is the local $\mathsf{NameCert}_{\mathsf{StreamRegularLimitSeal}^{\uparrow}}$ *row.*
The classifier compares accepted packets only through $Q, W, R, D, I, E, H, C, P, N$. It has no coordinate for selected limits, quotient stream equality, countable choice, trichotomy, host real equality, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 8986.2 (Stream regular limit seal NameCert obligations)**.** *For every accepted* $\mathsf{StreamRegularLimitSeal}^{\uparrow}$ *carrier*

$$S = (Q, W, R, D, I, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{StreamRegularLimitSeal}^{\uparrow}}$ *surface consists exactly of carrier admission for the finite request,* $\mathsf{StreamName}^{\uparrow}$ *window exposure,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback exposure,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance exposure, cofinal diagonal index exposure,* $\mathsf{Real}^{\uparrow}$ *seal routing, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming.*

Proof. Project the carrier of Definition 8986.1. The packet first exposes the finite request Q, the stream window W, the regular rational readback R, the dyadic tolerance ledger D, and the cofinal diagonal index I.

Read the dependency route in order. The stream window confines the inspected rows to finite observations, the regular readback turns those observations into the regular rational surface, and the dyadic tolerance ledger supplies the displayed comparison budget used by the tail-control route of chapter 2220.

Only after those rows are visible may the packet expose the terminal Real seal E. The transport, replay, provenance, and local naming rows H, C, P, N preserve that same finite route, so the accepted surface is the displayed handoff through $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$.

Since the carrier has no row for a selected host limit, quotient stream equality, countable-choice schedule, trichotomy decision, host real equality, or ambient completeness proof, none of those objects can be exported by the local NameCert obligations. □

Closure status for $\mathsf{NameCert}_{\mathsf{StreamRegularLimitSeal}^{\uparrow}}$.

Constructive story: A $\mathsf{StreamRegularLimitSeal}^{\uparrow}$ packet is generated from a finite request row, StreamName window, RegSeqRat readback, DyadicRatCore tolerance ledger, cofinal diagonal index, RealUp seal, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{StreamRegularLimitSeal}^{\uparrow}}$, seed)

Scope closed: Definition 8986.1 and Definition 8986.2 seed the finite diagonal-limit seal route over request, window, readback, tolerance, cofinal index, Real-seal, transport, replay, provenance, and local naming rows.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{StreamRegularLimitSeal}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close selected limits, quotient stream equality, countable choice, trichotomy, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, finite request routing, StreamName window exposure, RegSeqRat readback, DyadicRatCore tolerance exposure, cofinal diagonal index routing, Real seal nonselection, transport, replay, provenance, and local naming for BEDC.Derived.StreamRegularLimitSealUp.

Chapter 8987

A Concrete Naming Certificate for EpsilonDeltaModulusSelector$^{\uparrow}$

Following Bishop and Bridges constructive analysis, an epsilon-delta proof of continuity is useful to later real analysis only when its local witness can be read as explicit finite modulus data. The EpsilonDeltaModulusSelector$^{\uparrow}$ packet records that read as a NameCert carrier between the displayed graph and local continuity rows of chapter 130, the modulus consumer interface of chapter 369, the dyadic tolerance ledger of chapter 291, the regular rational readback of chapter 301, and the terminal real seal of chapter 38. It names the finite route from a requested output tolerance to a displayed input-radius row, not a host choice of deltas, quotient equality of functions, or an ambient completeness principle.

Definition 8987.1 (Epsilon-delta modulus selector carrier)**.** *An* EpsilonDeltaModulusSelector$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (F, E, D, W, Q, U, R, H, C, P, N)$$

with the following displayed rows:

1. *F is the* ContinuousMap$^{\uparrow}$ *graph and local epsilon-delta continuity row whose source and target observations are already named;*
2. *E is the* DyadicRatCore$^{\uparrow}$ *output-tolerance request row;*
3. *D is the selected* DyadicRatCore$^{\uparrow}$ *input-radius row displayed for the same request;*
4. *W is the finite observation-window row naming the source and target samples inspected by the local proof;*
5. *Q is the* RegSeqRat$^{\uparrow}$ *readback row attached to the displayed source and target rational approximations;*
6. *U is the* UniformModulus$^{\uparrow}$ *consumer row that can be exported only after F, E, D, W, Q are visible;*
7. *R is the* Real$^{\uparrow}$ *seal row reached by the readback and modulus route, with no independent completeness coordinate;*
8. *H records componentwise* hsame *transport for the continuous-map, tolerance, radius, window, readback, uniform-modulus, Real seal, replay, provenance, and naming rows;*
9. *C records displayed* Cont *replay from an output tolerance through the local epsilon-delta row to the selected input radius and then to the uniform-modulus consumer;*

10. *P is the* Pkg *provenance over* $\mathsf{EpsilonDeltaModulusSelector}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{UniformModulus}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows;*
11. *N is the local* $\mathsf{NameCert}_{\mathsf{EpsilonDeltaModulusSelector}^{\uparrow}}$ *row.*

The carrier has no coordinate for a choice function over all tolerances, quotient equality of maps, a hidden global modulus, trichotomy over reals, or ambient completeness.

Theorem 8987.2 (Epsilon-delta modulus selector NameCert obligations)**.** *For every accepted* $\mathsf{EpsilonDeltaModulusSelector}^{\uparrow}$ *carrier* $S = (F, E, D, W, Q, U, R, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{EpsilonDeltaModulusSelecto}}$ *surface consists exactly of carrier admission for the displayed continuous-map row, output-tolerance row, selected input-radius row, finite window, regular-rational readback, uniform-modulus row, Real seal, transport, replay, provenance, and local naming rows. The selected radius D must be read from the same local epsilon-delta row F and the same tolerance request E before U is visible. Every consumer read of U or R preserves $F, E, D, W, Q, H, C, P, N$ and exports no host choice of radii, quotient map equality, hidden global modulus, trichotomy, or ambient completeness.*

Proof. Project the carrier of Definition 8987.1. The accepted packet exposes exactly the rows $F, E, D, W, Q, U, R, H, C, P, N$, so the naming surface is exhausted by those finite coordinates.

Read the analytic rows next. The tolerance request E is displayed as dyadic data, and the selected input radius D is accepted only as the row supplied by the same local epsilon-delta continuity proof F. The finite window W and readback Q record the observations on which the comparison is checked.

The structural rows then preserve the route. Transport H, replay C, provenance P, and the local name N cannot add a choice function, quotient equality, hidden modulus, trichotomy, or completeness coordinate because none is present in the carrier. Thus the NameCert obligations are exactly the displayed rows and their consumer order. □

Theorem 8987.3 (Epsilon-delta selector ContinuousMap route)**.** *Every* $\mathsf{UniformModulus}^{\uparrow}$ *consumer of an accepted* $\mathsf{EpsilonDeltaModulusSelector}^{\uparrow}$ *packet factors through the finite route*

$$\mathsf{ContinuousMap}^{\uparrow},\ \mathsf{DyadicRatCore}^{\uparrow},\ \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{UniformModulus}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}.$$

In carrier notation, the consumer must read the local continuous-map row F, the requested tolerance E, the selected radius D, the finite window W, and the readback row Q before it can consume the uniform-modulus row U or the Real seal R. The route is a displayed epsilon-delta modulus selection surface, not a host modulus function, quotient equality of functions, selected global delta table, trichotomy, or ambient real completeness.

Proof. Begin with the $\mathsf{ContinuousMap}^{\uparrow}$ row. It supplies the graph and local epsilon-delta continuity data as the displayed row F, while the dyadic request E names the target tolerance that the consumer wants to spend.

The selector row D is then read only through that same F, E pair. The finite window W and regular rational readback Q expose the source and target observations needed to check the local estimate before any modulus row is exported.

Finally read U and R through the structural rows. The uniform-modulus consumer receives the route preserved by H, C, P, N, and the Real seal is reached only after the readback and modulus rows are displayed. Since the packet has no coordinate for host modulus functions, quotient equality, global delta tables, trichotomy, or ambient completeness, none of those readings escapes the displayed route. □

Falsifiable prediction: An accepted $\mathsf{EpsilonDeltaModulusSelector}^{\uparrow}$ packet is refuted if a UniformModulus consumer reads the exported modulus without displaying the ContinuousMap row, dyadic tolerance request, selected dyadic radius, finite observation window, RegSeqRat readback, transport, replay, provenance, and local NameCert rows.

Independence witness: continuousmap, uniformmodulus, dyadicratcore, regseqrat, real: EpsilonDeltaModulusSel is not bijective to any listed sibling because it jointly stores the local epsilon-delta row, requested tolerance, selected input radius, finite readback window, uniform-modulus handoff, Real seal, and structural support in one packet.

Closure status for $\mathsf{NameCert}_{\mathsf{EpsilonDeltaModulusSelector}^{\uparrow}}$.

Constructive story: An $\mathsf{EpsilonDeltaModulusSelector}^{\uparrow}$ packet is generated from a ContinuousMap local epsilon-delta row, dyadic output-tolerance requests, selected dyadic input-radius rows, finite observation windows, RegSeqRat readback rows, a UniformModulus handoff, a Real seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{EpsilonDeltaModulusSelector}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8987.1, Definition 8987.2, and Definition 8987.3 seed the explicit epsilon-delta modulus selector over ContinuousMap, UniformModulus, DyadicRatCore, RegSeqRat, Real, transport, replay, provenance, and local naming rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{EpsilonDeltaModulusSelector}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host choice of radii, quotient equality of maps, selected global delta tables, trichotomy, ambient real completeness, Lean verification, or bridge checking.

Upgrade path: Formal verification requires a Lean carrier and checked NameCert obligations for BEDC.Derived.EpsilonDeltaModulusSelec

Chapter 8988

A Concrete Naming Certificate for $\mathsf{CarlesonBox}^{\uparrow}$

Following Carleson and the Hardy-space boundary geometry tradition, the $\mathsf{CarlesonBox}^{\uparrow}$ packet records the finite boundary arc and radial window data needed before a Hardy-boundary consumer can inspect a Carleson box. It sits after the Hardy-space carrier of chapter 5108, the dyadic tent-function window surface of chapter 8351, the finite content budget of chapter 3765, and the measure-facing carrier of chapter 92. The packet names only displayed arcs, dyadic radial intervals, tent windows, budget rows, Hardy handoff data, transport, replay, provenance, and local naming; it does not assert the Carleson embedding theorem, selected boundary limits, completed measure theory, quotient function equality, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 8988.1 (Carleson box carrier)**.** *A* $\mathsf{CarlesonBox}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (A, R, T, M, H, E, S, C, P, N)$$

with the following displayed rows:

1. *A is the boundary-arc row. It stores the named center, dyadic angular endpoints, orientation, and finite endpoint inspections of the boundary circle arc.*
2. *R is the radial dyadic-window row. It records the inner and outer radial cutoffs attached to the same arc, with all radial tolerances read through* $\mathsf{DyadicRatCore}^{\uparrow}$*.*
3. *T is the* $\mathsf{DyadicTentFunction}^{\uparrow}$ *window row whose tent footprint contains the displayed arc and radial window.*
4. *M is the finite measure or* $\mathsf{HausdorffContent}^{\uparrow}$ *budget row for the same window. It records only the displayed cover, mass, or content upper-bound data used by the boundary request.*
5. *H is the* $\mathsf{HardySpace}^{\uparrow}$ *handoff row. It stores the Hardy-boundary source whose local read is allowed to inspect the box after A, R, T, M are visible.*
6. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row for the radial, content, and Hardy-boundary scalar reads.*
7. *S records componentwise* hsame *transport for A, R, T, M, H, E.*
8. *C records displayed* Cont *replay from a boundary request through the arc, radial window, tent window, budget, Hardy handoff, and Real seal.*
9. *P is the* Pkg *provenance over* $\mathsf{CarlesonBox}^{\uparrow}$, $\mathsf{HardySpace}^{\uparrow}$, $\mathsf{DyadicTentFunction}^{\uparrow}$, $\mathsf{HausdorffContent}^{\uparrow}$, $\mathsf{Measure}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.

10. N is the local $\mathsf{NameCert}_{\mathsf{CarlesonBox}^\uparrow}$ *row.*
The classifier compares carriers only through $A, R, T, M, H, E, S, C, P, N$. It has no coordinate for a selected nontangential boundary limit, a host Carleson measure, a completed measure algebra, quotient function equality, a global embedding constant, countable choice, or ambient $\mathsf{Real}^\uparrow$ *completeness.*

Theorem 8988.2 (Carleson box NameCert obligations)**.** *For every accepted* $\mathsf{CarlesonBox}^\uparrow$ *carrier $B = (A, R, T, M, H, E, S, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{CarlesonBox}^\uparrow}$ *surface consists exactly of boundary-arc admission, radial dyadic-window admission, dyadic tent-window visibility, finite measure or Hausdorff-content budget visibility, Hardy-space handoff visibility, Real sealing, componentwise* hsame *transport, displayed* Cont *replay, package provenance, and local naming. A Hardy-boundary consumer may read the box only after A, R, T, M, H are all public in the same packet.*

Proof. Project the carrier of Definition 8988.1. The displayed tuple exposes exactly the boundary arc, radial window, tent window, budget row, Hardy handoff, Real seal, transport, replay, provenance, and local naming row.

Read the geometric rows first. The arc A and radial window R determine the finite boundary box, while T records the dyadic tent window that contains the same footprint.

The budget and Hardy rows are downstream of that footprint. The row M supplies only the displayed finite measure or content budget, and H supplies only the Hardy-space boundary source attached to that same window.

Finally the structural rows preserve the route. Since S, C, P, N add only transport, replay, provenance, and naming, the packet has no coordinate for selected boundary limits, host Carleson measures, completed measure algebras, quotient function equality, embedding constants, countable choice, or ambient completeness. □

Theorem 8988.3 (Carleson box Hardy-boundary route)**.** *Every* $\mathsf{HardySpace}^\uparrow$ *boundary read that consumes an accepted* $\mathsf{CarlesonBox}^\uparrow$ *packet factors through the finite route*

$$A, R \longmapsto \mathsf{DyadicTentFunction}^\uparrow \longmapsto \mathsf{HausdorffContent}^\uparrow/\mathsf{Measure}^\uparrow \longmapsto \mathsf{HardySpace}^\uparrow \longmapsto \mathsf{Real}^\uparrow.$$

In carrier notation, the consumer reads the boundary arc A, radial dyadic window R, tent window T, budget row M, Hardy handoff H, Real seal E, and the structural rows S, C, P, N. The route is a finite Hardy-boundary geometry handoff, not a Carleson embedding theorem, selected boundary limit, completed measure theory, quotient function equality, or ambient completeness claim.

Proof. Start with the geometric footprint. The boundary arc row A and radial window row R name the box as finite dyadic data, so the packet never begins with an ambient boundary set or completed measure object.

Next read the tent and budget rows. The $\mathsf{DyadicTentFunction}^\uparrow$ row T attaches the window to a finite tent footprint, and the row M supplies only the displayed $\mathsf{HausdorffContent}^\uparrow$ or $\mathsf{Measure}^\uparrow$ budget for that footprint.

The Hardy-facing read then passes through H and E. The Hardy handoff is visible only after the footprint and budget rows have been displayed, and the Real seal records the scalar endpoint of that same route.

Transport, replay, provenance, and local naming preserve the displayed packet. Because no carrier row stores a Carleson embedding theorem, selected boundary limit, completed measure theory, quotient equality, or ambient completeness principle, no Hardy-boundary consumer can read those endpoints from the box. □

Falsifiable prediction: An accepted $\mathsf{CarlesonBox}^{\uparrow}$ packet is refuted if a Hardy-boundary consumer reads a box without displaying the boundary arc, radial dyadic window, tent-function window, finite budget, Hardy handoff, Real seal, transport, replay, provenance, and local NameCert rows.

Independence witness: hardy-space, dyadic-tent-function, hausdorff-content, measure: $\mathsf{CarlesonBox}^{\uparrow}$ is not bijective to any listed sibling because it jointly stores the boundary arc, radial dyadic window, tent footprint, finite budget, Hardy handoff, Real seal, and structural support in one packet.

Closure status for $\mathsf{NameCert}_{\mathsf{CarlesonBox}^{\uparrow}}$.

Constructive story: A $\mathsf{CarlesonBox}^{\uparrow}$ packet is generated from a boundary arc, radial dyadic window, dyadic tent-function window, finite Hausdorff-content or measure budget, HardySpace handoff, Real seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CarlesonBox}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8988.1, Definition 8988.2, and Definition 8988.3 seed the finite Hardy-boundary geometry packet over boundary arcs, radial windows, tent windows, content or measure budgets, Hardy handoff, Real sealing, transport, replay, provenance, and local naming.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CarlesonBox}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close the Carleson embedding theorem, selected boundary limits, completed measure theory, quotient function equality, global embedding constants, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Formal verification requires a Lean carrier and checked NameCert obligations for BEDC.Derived.CarlesonBoxUp.

Chapter 8989

A Concrete Naming Certificate for $\mathsf{LocatedUpperLowerPair}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{LocatedUpperLowerPair}^{\uparrow}$ packet records a located real by paired lower and upper rational enclosures whose gap is visible at each requested tolerance. It sits between the dyadic tolerance ledger of chapter 291, the finite observation schedule of chapter 126, the regular rational readback of chapter 301, the terminal real seal of chapter 38, and the located real interface of chapter 1933. The packet supplies a finite L10 Real and Completion interface only; it does not assert quotient-cut equality, a chosen completed representative, trichotomy, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 8989.1 (Located upper-lower pair carrier)**.** *A* $\mathsf{LocatedUpperLowerPair}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (D, S, R, E, H, C, P, N)$$

with the following rows:

1. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *enclosure row, carrying the displayed lower endpoint, upper endpoint, dyadic tolerance, and gap comparison for the requested precision.*
2. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row through which the consumer requests and observes the enclosure stage.*
3. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row that turns the same finite window into regular rational lower and upper observations.*
4. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row, reached only after D, S, R have exposed the finite enclosure data.*
5. *H records componentwise* hsame *transport for enclosure, window, readback, seal, replay, provenance, and local naming rows.*
6. *C records displayed* Cont *replay from a requested tolerance to the matching enclosure window and then to the terminal seal.*
7. *P is the* Pkg *provenance over* $\mathsf{LocatedUpperLowerPair}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
8. *N is the local* $\mathsf{NameCert}_{\mathsf{LocatedUpperLowerPair}^{\uparrow}}$ *row.*

The carrier has no coordinate for a quotient cut, selected host real, omniscient comparison oracle, countable choice schedule, or ambient completeness principle.

Lean4 (statement) `BEDC.Derived.LocatedUpperLowerPairUp`

Theorem 8989.2 (Located upper-lower pair NameCert obligations)**.** *For every accepted* $\mathsf{LocatedUpperLowerPair}^{\uparrow}$ *carrier* $L = (D, S, R, E, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{LocatedUpperLowerPair}^{\uparrow}}$ *surface consists exactly of carrier admission, dyadic enclosure admission, StreamName window visibility, RegSeqRat lower-upper readback, Real seal nonescape, componentwise transport, displayed continuation replay, package provenance, and local naming. No NameCert obligation may replace these rows by quotient-cut equality, selected representative equality, trichotomy, countable choice, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the carrier of Definition 8989.1. The rows D, S, R, E expose the dyadic enclosure, finite window, regular rational readback, and terminal seal in that order, while H, C, P, N expose the transport, replay, provenance, and local naming rows.

The classifier is stable because every accepted comparison reads the same tolerance window through D and the same finite observation window through S. Componentwise hsame transport in H preserves the displayed lower endpoint, upper endpoint, tolerance, and gap comparison before the readback reaches R.

Finally, the terminal seal E is downstream of D, S, R. Thus the NameCert surface exports only the finite located enclosure route and cannot supply quotient-cut equality, selected host representatives, trichotomy, countable choice, or ambient completeness. □

Theorem 8989.3 (Located upper-lower pair completion handoff)**.** *Every completion-facing consumer of an accepted* $\mathsf{LocatedUpperLowerPair}^{\uparrow}$ *carrier must read*

$$\mathsf{DyadicRatCore}^{\uparrow} \longmapsto \mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}$$

through the displayed rows D, S, R, E *before treating the pair as a Real-facing located name.*

Proof. Start with the dyadic row D. It is the only row that displays the lower endpoint, upper endpoint, tolerance, and gap comparison for the request.

Open the finite observation row S and the regular rational readback row R. These rows bind the same request window to the lower-upper rational observations available to the consumer.

The Real-facing read then reaches E only after D, S, R have been displayed. Componentwise transport, continuation replay, package provenance, and local naming keep the handoff inside the accepted packet, so no quotient cut, selected representative, trichotomy, countable choice, or ambient completeness is introduced. □

Falsifiable prediction: An accepted $\mathsf{LocatedUpperLowerPair}^{\uparrow}$ consumer that reaches the terminal RealUp seal without reading a DyadicRatCore enclosure row, a StreamName finite window, and a RegSeqRat lower-upper readback row refutes the carrier surface.

Independence witness: dyadicratcore, streamname, regseqrat, real, located-real: no listed sibling is bijective with $\mathsf{LocatedUpperLowerPair}^{\uparrow}$ because this packet jointly binds lower and upper enclosure rows, tolerance windows, regular readback, a terminal Real seal, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{LocatedUpperLowerPair}^{\uparrow}}$**.**

Constructive story: A $\mathsf{LocatedUpperLowerPair}^{\uparrow}$ packet is generated from a DyadicRatCore lower-upper enclosure row, a StreamName finite-window row, a RegSeqRat readback row, a terminal RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{LocatedUpperLowerPair}^{\uparrow}}$, seed)

Scope closed: Definition 8989.1, the NameCert obligation sketch, completion handoff, falsifiability, and independence rows seed the finite Bishop-style located upper-lower pair route over DyadicRatCore, StreamName, RegSeqRat, Real, BHist, hsame, Cont, Pkg, and NameCert rows.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{LocatedUpperLowerPair}\uparrow}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close quotient-cut equality, selected representatives, trichotomy, countable choice, ambient RealUp completeness, theorem checking, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, enclosure exactness, window visibility, regular readback, Real seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.LocatedUpperLowerPairUp.

Chapter 8990

A Concrete Naming Certificate for $\mathsf{BoundedCauchyFilter}^{\uparrow}$

Following Kelley and Bishop–Bridges on Cauchy filters and bounded filters, the $\mathsf{BoundedCauchyFilter}^{\uparrow}$ packet records the bounded source surface used by the L10 completion corridor. It sits between the Cauchy-filter carrier of chapter 333, the bounded base face of chapter 1601, the dyadic tolerance ledger of chapter 291, the finite stream schedule of chapter 126, the regular rational readback of chapter 301, the terminal real-name seal of chapter 38, and the completion handoff of chapter 4054. The packet exposes bounded Cauchy-filter source data only as finite NameCert rows; it is not a selected limit, quotient filter equality, countable-choice selector, or ambient completeness principle.

Definition 8990.1 (Bounded Cauchy filter carrier)**.** *A* $\mathsf{BoundedCauchyFilter}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$X = (F, B, D, S, Q, R, H, C, P, N)$$

with the following displayed rows:

1. *F is the* $\mathsf{CauchyFilter}^{\uparrow}$ *source row whose requests and meets are read as displayed Cauchy-filter data.*
2. *B is the bounded* $\mathsf{FilterBase}^{\uparrow}$ *face naming the finite base requests and the bound certificate used by every source read.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row attached to bounded filter requests.*
4. *S is the finite* $\mathsf{StreamName}^{\uparrow}$ *window family opened from the bounded Cauchy-filter source.*
5. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row obtained from the stream windows and dyadic tolerances.*
6. *R is the* $\mathsf{Real}^{\uparrow}$ *seal row exposed only after F, B_0, D, S, Q have been displayed.*
7. *H records componentwise* hsame *transport for the Cauchy-filter source, bounded base face, dyadic tolerance, stream window, regular rational readback, Real seal, replay, provenance, and naming rows.*
8. *C records displayed* Cont *replay for the same bounded source route.*
9. *P is the* Pkg *provenance over* $\mathsf{BoundedCauchyFilter}^{\uparrow}$, $\mathsf{CauchyFilter}^{\uparrow}$, $\mathsf{FilterBase}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$ *rows.*
10. *N is the local* $\mathsf{NameCert}_{\mathsf{BoundedCauchyFilter}^{\uparrow}}$ *row.*

The carrier exports no coordinate for selected limits, quotient filter equality, countable choice, host real equality, or ambient completeness.

Lean4 (definition) `BEDC.Derived.BoundedCauchyFilterUp.TasteGate.BoundedCauchyFilterUp`

Theorem 8990.2 (Bounded Cauchy filter NameCert obligations)**.** *For an accepted carrier* $X = (F, B, D, S, Q, R, H, C, P, N)$ *of Definition 8990.1, the local* $\mathsf{NameCert}_{\mathsf{BoundedCauchyFilter}^{\uparrow}}$ *surface consists exactly of carrier admission,* $\mathsf{CauchyFilter}^{\uparrow}$ *source admission, bounded* $\mathsf{FilterBase}^{\uparrow}$ *face admission, dyadic tolerance accounting, finite* $\mathsf{StreamName}^{\uparrow}$ *window exposure,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback, terminal* $\mathsf{Real}^{\uparrow}$ *seal nonescape, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming.*

Lean4 ✓ `BEDC.Derived.BoundedCauchyFilterUp.BoundedCauchyFilterCarrier namecert obligations`

Proof. Project the accepted carrier. The Cauchy-filter source row is F, the bounded base face is B, and the dyadic tolerance ledger is D.

The route can open a finite window only after those source rows have been displayed. The window row S then determines the regular rational readback row Q available to Real-facing source consumers.

The seal row R is downstream of F, B_0, D, S, Q. Transport, replay, provenance, and local naming are exhausted by H, C, P, N, so the listed rows are precisely the local NameCert obligations. □

Theorem 8990.3 (Bounded Cauchy filter L10 handoff)**.** *Every L10 completion consumer of an accepted* $\mathsf{BoundedCauchyFilter}^{\uparrow}$ *carrier factors through the finite route*

$$\mathsf{CauchyFilter}^{\uparrow} \longmapsto \mathsf{FilterBase}^{\uparrow} \longmapsto \mathsf{DyadicRatCore}^{\uparrow} \longmapsto \mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow} \longmapsto \mathsf{BoundedCauch}$$

The handoff exports only the displayed source, bounded-base, tolerance, window, readback, seal, transport, replay, provenance, and naming rows.

Proof. Begin with an L10 completion consumer of X. By Definition 8990.2, the consumer cannot reach the completion-facing source route until it has read the Cauchy-filter source F, the bounded base face B, and the dyadic tolerance ledger D.

The finite readback is then forced through S, Q, R. These rows are the displayed stream schedule, regular rational readback, and Real seal, so the bounded completion packet receives only the bounded Cauchy-filter source route.

The structural rows H, C, P, N replay and name that same route. Since the carrier contains no selected limit, quotient-filter equality, host real equality, countable-choice selector, or ambient completeness witness, no other L10 handoff is available. □

Closure status for $\mathsf{NameCert}_{\mathsf{BoundedCauchyFilter}^{\uparrow}}$.

Constructive story: A $\mathsf{BoundedCauchyFilter}^{\uparrow}$ packet is generated from a CauchyFilter source row, bounded FilterBase face, DyadicRatCore tolerances, finite StreamName windows, RegSeqRat readback, a Real seal, componentwise transport, displayed replay, provenance, and local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{BoundedCauchyFilter}^{\uparrow}}$, seed)

Scope closed: Definition 8990.1, Definition 8990.2, and Definition 8990.3 seed the bounded Cauchy-filter source corridor for L10 completion consumers.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{BoundedCauchyFilter}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim selected limits, quotient filter equality, host real equality, countable choice, ambient completeness, Lean verification, or a standard bridge.

Upgrade path: Obligation closure requires checked carrier admission, bounded-source compatibility, dyadic tolerance accounting, finite-window exposure, regular readback, Real seal nonescape, package provenance, and local naming for the displayed packet.

Chapter 8991

A Concrete Naming Certificate for $\mathsf{ConstructiveLocatedIVT}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{ConstructiveLocatedIVT}^{\uparrow}$ packet records the finite located intermediate-value route for a continuous map on a located real interval whose endpoint reads display a sign change. It sits after the dyadic tolerance rows of chapter 291, the finite observation windows of chapter 126, the regular rational readback of chapter 301, the terminal real-name seal of chapter 38, the map carrier of chapter 130, the located interval boundary of chapter 1709, and the retained sign-change route of chapter 7008. The chapter names the Real and Completion boundary consumed by constructive IVT arguments; it does not assert classical completeness, trichotomy, quotient equality of real names, selected roots, countable choice, or an ambient host intermediate-value theorem.

Definition 8991.1 (ConstructiveLocatedIVT carrier)**.** *A* $\mathsf{ConstructiveLocatedIVT}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (I, F, S, B, D, W, R, E, H, C, P, N)$$

with the following displayed rows:

1. *I is the source* $\mathsf{LocatedRealInterval}^{\uparrow}$ *row, carrying the endpoint names, radius data, locator reads, locatedness moduli, and bracket boundary consumed by the interval argument.*
2. *F is the* $\mathsf{ContinuousMap}^{\uparrow}$ *row, recording the finite continuity and modulus surface through which endpoint and midpoint image reads are requested.*
3. *S is the sign-change ledger, recording only displayed endpoint and retained-window sign reads for the map row F over the interval row I.*
4. *B is the* $\mathsf{SignChangeBisection}^{\uparrow}$ *row, read through chapter 7008, which supplies the retained branch route from the displayed sign-change data.*
5. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *dyadic modulus and tolerance row for midpoint, endpoint, and image-window requests.*
6. *W is the* $\mathsf{StreamName}^{\uparrow}$ *finite observation-window row through which the bisection and image reads are inspected.*
7. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *regular rational readback row attached to the displayed windows and dyadic tolerance ledger.*
8. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row, available only after I, F, S, B, D, W, R have been displayed.*

9. *H records componentwise* hsame *transport for the interval, map, sign ledger, bisection, dyadic, window, readback, seal, replay, provenance, and local naming rows.*
10. *C records displayed* Cont *replay from a constructive located IVT request through the same rows.*
11. *P is the* Pkg *provenance over* $\mathsf{ConstructiveLocatedIVT}^{\uparrow}$, $\mathsf{LocatedRealInterval}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{SignChangeBisection}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
12. *N is the local* $\mathsf{NameCert}_{\mathsf{ConstructiveLocatedIVT}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $I, F, S, B, D, W, R, E, H, C, P, N$. It has no coordinate for host real trichotomy, quotient equality of real names, countable choice, selected zeroes, classical completeness, or an ambient intermediate-value theorem.

Theorem 8991.2 (ConstructiveLocatedIVT NameCert obligations)**.** *For every accepted* $\mathsf{ConstructiveLocatedIVT}^{\uparrow}$ *carrier $K = (I, F, S, B, D, W, R, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{ConstructiveLocatedIVT}^{\uparrow}}$ *surface consists exactly of located-interval admission, continuous-map admission, displayed sign-change ledger admission, sign-change bisection routing, dyadic tolerance and modulus admission, finite StreamName window admission, RegSeqRat readback, Real seal admission, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming for the displayed rows.*

Proof. Read the carrier of Definition 8991.1. Each accepted packet exposes exactly the rows $I, F, S, B, D, W, R, E, H, C, P, N$, and the classifier is declared over those rows only.

The cited sibling chapters supply the row meanings. Located intervals provide endpoint and bracket data, continuous maps provide the image-read surface, sign-change bisection provides the retained branch route, and the dyadic, StreamName, RegSeqRat, and Real chapters supply the finite tolerance, observation, rational readback, and terminal seal layers.

The structural rows then preserve the same surface under transport, replay, provenance, and local naming. Since the carrier excludes trichotomy, quotient real equality, countable choice, selected zeroes, classical completeness, and ambient IVT data, the listed rows exhaust the local NameCert obligations. □

Theorem 8991.3 (ConstructiveLocatedIVT sign-change route)**.** *Every accepted* $\mathsf{ConstructiveLocatedIVT}^{\uparrow}$ *packet routes an IVT-facing sign-change read through*

$$\mathsf{LocatedRealInterval}^{\uparrow} \longmapsto \mathsf{ContinuousMap}^{\uparrow} \longmapsto S \longmapsto \mathsf{SignChangeBisection}^{\uparrow} \longmapsto \mathsf{DyadicRatCore}^{\uparrow} \longmapsto \mathsf{StreamName}^{\uparrow} \mapsto$$

before any Real or Completion consumer may inspect the terminal seal. The route exports the finite displayed boundary of the constructive IVT argument, not a classical completeness principle or a selected root.

Proof. Start with the source rows I and F. The interval row fixes the located endpoint boundary, and the continuous-map row fixes the finite image-read surface over that boundary.

The sign ledger S is then consumed by the sign-change bisection row B. By chapter 7008, the retained branch is a displayed bisection route, not a selected root or a host theorem.

Finally the branch route reaches Real and Completion readers only through D, W, R, E. The dyadic tolerance ledger supplies the finite budgets, the StreamName row supplies visible windows, the RegSeqRat row supplies regular rational readback, and the Real row supplies the terminal seal. Transport, replay, provenance, and local naming do not add another path. □

Theorem 8991.4 (ConstructiveLocatedIVT Real-seal nonescape)**.** *Let $K = (I, F, S, B, D, W, R, E, H, C, P, N)$ be an accepted* $\mathsf{ConstructiveLocatedIVT}^{\uparrow}$ *carrier. A consumer that reaches the terminal* $\mathsf{Real}^{\uparrow}$ *seal E must have displayed the located interval I, continuous map F, sign ledger S, sign-change bisection row B, dyadic tolerance row D, StreamName window row W, RegSeqRat readback row R, and structural rows H, C, P, N. Hence the seal cannot be used as a shortcut to quotient real equality, trichotomy, countable choice, a selected zero, classical completeness, or an ambient IVT theorem.*

Proof. Project the Real seal coordinate from the carrier. The row E is declared terminal and is available only after the preceding interval, map, sign, bisection, dyadic, window, and readback rows have been displayed.

Use Definition 8991.3. It orders the only IVT-facing path to the seal through the located interval, continuous map, sign-change bisection, dyadic tolerance, finite window, and regular rational readback rows.

The transport, replay, provenance, and local naming rows preserve that route under accepted presentation changes. Because the classifier has no coordinate for quotient real equality, trichotomy, countable choice, selected zeroes, classical completeness, or ambient IVT data, the Real seal cannot escape the displayed carrier boundary. □

Falsifiable prediction: Every accepted $\mathsf{ConstructiveLocatedIVT}^{\uparrow}$ Real-facing read displays a located interval, continuous map, sign-change ledger, sign-change bisection route, dyadic tolerance row, StreamName window row, RegSeqRat readback row, RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert row.

Independence witness: located-real-interval, continuousmap, sign-change-bisection, dyadicratcore, streamname, regseqrat, real: none of these siblings contains the full located interval, continuousmap, sign-change, bisection, dyadic-modulus, stream-window, regular-readback, Real-seal, transport, replay, provenance, and local naming surface.

Closure status for $\mathsf{NameCert}_{\mathsf{ConstructiveLocatedIVT}^{\uparrow}}$.

Constructive story: A $\mathsf{ConstructiveLocatedIVT}^{\uparrow}$ packet is generated from a $\mathsf{LocatedRealInterval}^{\uparrow}$ source row, a $\mathsf{ContinuousMap}^{\uparrow}$ row, a sign-change ledger, a $\mathsf{SignChangeBisection}^{\uparrow}$ row, a $\mathsf{DyadicRatCore}^{\uparrow}$ dyadic modulus row, a $\mathsf{StreamName}^{\uparrow}$ finite-window row, a $\mathsf{RegSeqRat}^{\uparrow}$ readback row, a terminal $\mathsf{Real}^{\uparrow}$ seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{ConstructiveLocatedIVT}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8991.1, Definition 8991.2, Definition 8991.3, and Definition 8991.4 seed the constructive located IVT boundary over located intervals, continuous maps, sign-change bisection, dyadic tolerances, StreamName windows, RegSeqRat readback, Real seals, transport, replay, provenance, and local naming.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{ConstructiveLocatedIVT}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close classical completeness, trichotomy, quotient real equality, selected zeroes, countable choice, ambient IVT, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, NameCert obligations, sign-change routing, Real-seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.ConstructiveLocatedIVTUp.

Chapter 8992

A Concrete Naming Certificate for $\mathsf{UniformContractionRealCompletion}^{\uparrow}$

Following Banach, Picard, and Bishop–Bridges constructive completion, the $\mathsf{UniformContractionRealCompletion}^{\uparrow}$ packet records the finite route by which a uniformly contractive iteration over a displayed complete metric source is read as a regular rational completion handoff. It sits beside the Picard orbit of chapter 2359, the contraction source of chapter 1418, the Banach contraction sequence of chapter 8253, the interval contraction route of chapter 5867, the $\mathsf{StreamName}^{\uparrow}$ and $\mathsf{RegSeqRat}^{\uparrow}$ completion rows of chapter 126 and chapter 301, the $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance ledger of chapter 291, and the terminal $\mathsf{Real}^{\uparrow}$ seal of chapter 38. The packet names the finite completion-facing iteration surface; it does not assert ambient $\mathsf{Real}^{\uparrow}$ completeness, a selected fixed point, quotient stream equality, host contraction equality, or countable choice.

Definition 8992.1 (Uniform contraction real-completion carrier)**.** *A* $\mathsf{UniformContractionRealCompletion}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$U = (M, L, P, W, D, R, S, E, H, C, Q, N)$$

with the following displayed rows:

1. *M is the complete metric source row, exposing the source carrier, metric comparison, and endpoint-admission boundary.*
2. *L is the contraction modulus row, recording one uniform shrinkage bound for the displayed self-map.*
3. *P is the Picard window schedule row, naming the finite iterates inspected by the consumer.*
4. *W is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window read of those iterates.*
5. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger used to compare adjacent windows and requested error bounds.*
6. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback generated from P, W, D.*
7. *S is the* $\mathsf{Real}^{\uparrow}$ *seal boundary reached only after the regular rational readback is visible.*
8. *E is the endpoint handoff row for fixed-point consumers; it records the completion-facing route without selecting a fixed point.*
9. *H records componentwise* hsame *transport for M, L, P, W, D, R, S, E and the local certificate rows.*

10. *C records displayed* Cont *replay from the contraction source through the Picard schedule, dyadic tolerance ledger, stream window, regular readback, Real seal, and endpoint handoff.*
11. *Q is the* Pkg *provenance over* $\mathsf{UniformContractionRealCompletion}^{\uparrow}$, $\mathsf{CompleteMetric}^{\uparrow}$, $\mathsf{ContractionMapping}^{\uparrow}$, $\mathsf{PicardIteration}^{\uparrow}$, $\mathsf{BanachContractionSequence}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
12. *N is the local* $\mathsf{NameCert}_{\mathsf{UniformContractionRealCompletion}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these rows. It has no coordinate for an ambient real-completeness principle, selected limits, quotient stream equality, host fixed-point equality, function extensionality, or countable choice.

Lean4 (definition) `BEDC.Derived.UniformContractionRealCompletionUp.UniformContractionRealCompletionUp`

Theorem 8992.2 (Uniform contraction real-completion NameCert obligations)**.** *For every accepted* $\mathsf{UniformContractionRealCompletion}^{\uparrow}$ *carrier* $U = (M, L, P, W, D, R, S, E, H, C, Q, N)$*, the local* $\mathsf{NameCert}_{\mathsf{UniformContractionRealCompletion}^{\uparrow}}$ *surface consists exactly of complete metric source visibility, contraction modulus visibility, Picard window schedule visibility, dyadic tolerance exactness,* $\mathsf{StreamName}^{\uparrow}$ *window visibility,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback visibility,* $\mathsf{Real}^{\uparrow}$ *seal nonescape, endpoint handoff nonselection, componentwise transport, displayed replay, package provenance, and local naming for the finite packet of Definition 8992.1.*

Proof. Project the carrier. The source and iteration rows are M, L, P, the completion-facing rows are W, D, R, S, E, and the structural rows are H, C, Q, N.

Read M and L first. The complete metric source supplies the admissible endpoint boundary, while the contraction modulus row supplies the uniform shrinkage budget for every displayed Picard window.

Read P, W, D, R, S next. The schedule names only finite windows, the dyadic ledger supplies the tolerances, the stream row records the inspected iterates, the regular rational row reads those iterates as Cauchy data, and the Real seal is downstream of that readback.

Finally read E, H, C, Q, N. The endpoint handoff is a consumer boundary, and the structural rows preserve the same packet. Since none of the excluded ambient or choice objects is present in the carrier, the listed rows exhaust the local NameCert surface. □

Theorem 8992.3 (Uniform contraction real-completion Cauchy induction)**.** *Every Cauchy read of an accepted* $\mathsf{UniformContractionRealCompletion}^{\uparrow}$ *packet is obtained by induction on the displayed Picard window schedule P. The base window reads the complete metric source row M, the successor step spends the contraction modulus row L and dyadic tolerance row D, and the resulting finite windows pass through*

$$\mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}.$$

The induction exports regular rational completion data only; it does not export selected limits, quotient stream equality, countable choice, host fixed-point equality, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Use induction over the finite schedule row P. In the base case the source row M supplies the initial admitted metric point and the completion-facing boundary.

In the successor step, apply the contraction modulus row L to the displayed self-map read and spend the tolerance ledger D for the next window. This keeps every residual comparison attached to the same finite schedule rather than to a hidden infinite orbit.

The rows W and R then repack the finite windows as a stream name and regular rational readback. The Real seal S is reached only through that readback, so the induction supplies Cauchy data without adding any selected endpoint or ambient completeness coordinate. □

Theorem 8992.4 (Uniform contraction real-completion fixed-point handoff)**.** *Every fixed-point consumer reading an accepted* $\mathsf{UniformContractionRealCompletion}^{\uparrow}$ *packet must first expose the route*

$$M, L, P, W, D, R, S, H, C, Q, N.$$

Only after those rows are visible may the consumer use the endpoint handoff row E as input to a separate fixed-point certificate. The handoff supplies a finite contraction-iteration completion route; it is not itself a fixed-point theorem, a uniqueness theorem, a host function equality, a selected limit, quotient stream equality, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start from the obligation surface. It makes the complete metric source, contraction modulus, Picard schedule, dyadic tolerance ledger, stream windows, regular readback, and Real seal visible before any endpoint-facing consumer can inspect the packet.

Apply the Cauchy induction theorem. It shows that R and S are downstream of the finite schedule and tolerance rows, so the endpoint handoff cannot be detached from the displayed contraction route.

The structural rows H, C, Q, N preserve the same route for consumers. Thus E can be passed to a later fixed-point certificate, but it carries no fixed-point existence, uniqueness, selected-limit, quotient, choice, or ambient-completeness claim by itself. □

Falsifiable prediction: An accepted $\mathsf{UniformContractionRealCompletion}^{\uparrow}$ consumer is refuted if it reads a RegSeqRat handoff, Real seal, or fixed-point endpoint handoff without displaying the complete metric source, contraction modulus, Picard window schedule, StreamName windows, DyadicRatCore tolerance ledger, transport, replay, provenance, and local NameCert rows.

Independence witness: contractionmapping, picard-iteration, banach-contraction-sequence, bishop-interval-contraction, streamname, regseqrat, dyadicratcore, real: no listed sibling supplies the joint packet containing complete metric source, uniform contraction modulus, Picard window schedule, dyadic tolerance ledger, StreamName readback, RegSeqRat readback, Real seal, endpoint handoff, transport, replay, provenance, and local NameCert rows.

Closure status for $\mathsf{NameCert}_{\mathsf{UniformContractionRealCompletion}^{\uparrow}}$.

Constructive story: A $\mathsf{UniformContractionRealCompletion}^{\uparrow}$ packet is generated from a complete metric source row, a uniform contraction modulus row, a Picard window schedule, StreamName finite windows, a DyadicRatCore tolerance ledger, RegSeqRat readback, a Real seal, endpoint handoff, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{UniformContractionRealCompletion}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8992.1, Definition 8992.2, Definition 8992.3, and Definition 8992.4 seed the finite contraction-iteration completion route without asserting a completed fixed point.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{UniformContractionRealCompletion}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim ambient Real completeness, selected limits, quotient stream equality, host fixed-point equality, uniqueness, function extensionality, countable choice, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, contraction-modulus visibility, Picard-window induction, dyadic tolerance exactness, StreamName and RegSeqRat readback, Real seal nonescape, endpoint handoff nonselection, transport, replay, provenance, and local naming for BEDC.Derived.UniformContractionRealCompletionUp.

Chapter 8993

A Concrete Naming Certificate for $\mathsf{ArtinianModule}^{\uparrow}$

Following Bourbaki and Atiyah–Macdonald on Artinian modules, the $\mathsf{ArtinianModule}^{\uparrow}$ packet records descending submodule-chain stabilization over a displayed module source. It sits beside the module carrier of chapter 46, the scalar ring source of chapter 43, and the ascending-chain sibling $\mathsf{NoetherianModule}^{\uparrow}$ of chapter 3648. The packet supplies finite descending-chain evidence only; it does not assert a composition series, a length theorem, quotient-module classification, selected complements, or a host Artinian-module principle.

8993.1 Carrier definition

Definition 8993.1 (Artinian module carrier)**.** *An* $\mathsf{ArtinianModule}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$\mathsf{ArtMod}(M, R, D, S, H, C, P, N).$$

The row M is the $\mathsf{Module}^{\uparrow}$ *source surface. The row R is the scalar* $\mathsf{Ring}^{\uparrow}$ *source read from the module certificate. The row D is the descending-submodule-chain ledger: it lists the displayed submodule rows, their inclusion comparisons, and the finite read order in which a consumer may inspect them. The row S is the stabilization witness, assigning to every displayed descending chain in D a finite stage after which all later submodule endpoints classify with that stage. The row H is componentwise* hsame *transport for the module, scalar, descending-chain, and stabilization rows. The row C is displayed* Cont *replay for the descending-chain read and stabilization handoff. The row P is* Pkg *provenance over* $\mathsf{ArtinianModule}^{\uparrow}$*,* $\mathsf{Module}^{\uparrow}$*,* $\mathsf{Ring}^{\uparrow}$*,* BHist*,* hsame*,* Cont*, and local naming rows. The row N is the local* $\mathsf{NameCert}_{\mathsf{ArtinianModule}^{\uparrow}}$ *row.*

Theorem 8993.2 (Artinian module NameCert obligations)**.** *For every accepted* $\mathsf{ArtinianModule}^{\uparrow}$ *carrier* $\mathsf{ArtMod}(M, R, D, S, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{ArtinianModule}^{\uparrow}}$ *surface consists exactly of carrier admission for the eight displayed rows, source compatibility with the* $\mathsf{Module}^{\uparrow}$ *and* $\mathsf{Ring}^{\uparrow}$ *rows, descending-chain ledger admission through D, finite stabilization access through S, componentwise classifier transport through H, displayed continuation replay through C, provenance non-escape through P, and local naming through N.*

Proof. Project the eight rows of Definition 8993.1. The module row M fixes the additive carrier, scalar action, and module classifier before any descending submodule chain is inspected.

The scalar row R binds the chain to the same ring action already visible in the $\mathsf{Module}^{\uparrow}$ certificate. The descending ledger D then supplies only displayed submodule rows and inclusion comparisons, so the chain is not replaced by a quotient-module classifier or a selected complement.

Read the stabilization witness S over the displayed chain in D. Componentwise transport H moves the module, scalar, chain, and stabilization rows together through hsame, while C replays only the listed continuation data.

Finally, P and N repack the same finite inventory as the local naming certificate. Since no composition-series selector, length theorem, quotient classification, selected complement, or host Artinian principle occurs in the carrier, none can occur among the local obligations. □

Theorem 8993.3 (Artinian descending-chain route)**.** *Let* $\mathsf{ArtMod}(M, R, D, S, H, C, P, N)$ *be an accepted* $\mathsf{ArtinianModule}^{\uparrow}$ *carrier. Every downstream module consumer that reads descending-chain stabilization must first expose the* $\mathsf{Module}^{\uparrow}$ *source* M*, the scalar* $\mathsf{Ring}^{\uparrow}$ *row* R*, and the descending-submodule-chain ledger* D*, and only then may read the finite stabilization witness* S*. The route is the descending-chain analogue of the* $\mathsf{NoetherianModule}^{\uparrow}$ *ascending-chain packet, but it exports no ascending-chain theorem, composition-series theorem, selected quotient, or host Artinian-module result.*

Proof. Begin with the source rows M and R. They determine the module classifier and scalar action, so the later descending-chain read is attached to the same algebraic object used by chapter 46.

The ledger D is read next. It contains the finite list of displayed submodule rows and inclusion comparisons, and it is the only row from which a descending chain can be inspected.

Apply S to that displayed ledger. The resulting stage is finite and lives inside the same module classifier. Transport through H and replay through C preserve that ordered route, while P and N expose only the provenance and naming rows of the same packet.

Thus a consumer receives descending-chain stabilization as finite BHist data. The sibling comparison with chapter 3648 is structural only: the present packet uses descending chains, not the ascending-chain or finite-generator rows of $\mathsf{NoetherianModule}^{\uparrow}$. □

Closure status for $\mathsf{NameCert}_{\mathsf{ArtinianModule}^{\uparrow}}$.

Constructive story: An $\mathsf{ArtinianModule}^{\uparrow}$ packet is generated from a ModuleUp source, a scalar RingUp source, a descending-submodule-chain ledger, a finite stabilization witness, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{ArtinianModule}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8993.1, Definition 8993.2, and Definition 8993.3 seed the finite descending-submodule-chain route through ModuleUp, RingUp, hsame, Cont, Pkg, and local NameCert rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{ArtinianModule}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close composition series, length theory, quotient-module classification, selected complements, host Artinian-module theorems, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, source compatibility, descending-chain ledger admission, finite stabilization access, componentwise transport, provenance non-escape, and local NameCert exactness for BEDC.Derived.ArtinianModuleUp.

Chapter 8994

A Concrete Naming Certificate for $\mathsf{FinitePrefixCompactness}^{\uparrow}$

Following Bishop and Troelstra on fan-style compactness, the $\mathsf{FinitePrefixCompactness}^{\uparrow}$ packet records the finite prefix evidence used by compact-uniform-continuity consumers before any real-valued modulus is exported. It sits after the finite bar packet of chapter 5863, the binary tree surface of chapter 1475, the finite stream-window interface of chapter 126, the regular rational readback of chapter 301, and the terminal real seal of chapter 38. The packet names finite prefix compactness only; it does not assert open-cover compactness, choice-selected branches, quotient stream equality, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

8994.1 Carrier definition

Definition 8994.1 (Finite prefix compactness carrier)**.** *A* $\mathsf{FinitePrefixCompactness}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$\mathsf{FinPref}(F, K, S, Q, R, E, H, C, P, N).$$

The row F is the $\mathsf{FiniteFanTheorem}^{\uparrow}$ *bounded-bar source. The row K is the* $\mathsf{CantorSpace}^{\uparrow}$ *binary prefix tree read by the same fan window. The row S is the* $\mathsf{StreamName}^{\uparrow}$ *finite observation schedule. The row Q is the finite prefix-cover ledger: it lists the retained prefixes, their depths, and the cover decision read at each retained prefix. The row R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row used when the prefix packet is consumed by rational-modulus or regular-Cauchy routes. The row E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal for downstream compact-uniform-continuity consumers. The row H is componentwise* hsame *transport for the fan, Cantor, stream, prefix-cover, regular-rational, and real-seal rows. The row C is displayed* Cont *replay for finite prefix traversal, regular-rational readback, and real-seal handoff. The row P is* Pkg *provenance over* $\mathsf{FinitePrefixCompactness}^{\uparrow}$, $\mathsf{FiniteFanTheorem}^{\uparrow}$, $\mathsf{CantorSpace}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and local naming rows. The row N is the local* $\mathsf{NameCert}_{\mathsf{FinitePrefixCompactness}^{\uparrow}}$ *row.*

Theorem 8994.2 (Finite prefix compactness NameCert obligations)**.** *For every accepted* $\mathsf{FinitePrefixCompactness}^{\uparrow}$ *carrier* $\mathsf{FinPref}(F, K, S, Q, R, E, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{FinitePrefixCompactness}^{\uparrow}}$ *surface consists exactly of carrier admission for the ten displayed rows, source compatibility with* $\mathsf{FiniteFanTheorem}^{\uparrow}$, $\mathsf{CantorSpace}^{\uparrow}$, *and* $\mathsf{StreamName}^{\uparrow}$*, finite prefix-cover admission through Q, regular-rational readback through R, terminal real sealing through E, componentwise classifier transport through H, displayed continuation replay through C, provenance non-escape through P, and local naming through N.*

Proof. Project the ten rows of Definition 8994.1. The fan row F, Cantor row K, and stream row S determine the branch-facing finite prefix surface before any rational or real read is available.

The prefix-cover ledger Q is then read over those displayed prefixes. It stores only retained prefix names, their depths, and local cover decisions, so it cannot supply an arbitrary open cover or a choice-selected branch.

Rows R and E expose the analytic handoff. The regular-rational row R is read from the finite prefix packet, and the terminal $\mathsf{Real}^{\uparrow}$ row E is available only after that readback has been displayed.

Finally, H, C, P, N transport, replay, source, and name the same packet. Since no row stores open-cover compactness, a selected branch, quotient stream equality, or ambient real completeness, the listed rows exhaust the local NameCert surface. □

Theorem 8994.3 (Finite fan handoff)**.** *Let* $\mathsf{FinPref}(F, K, S, Q, R, E, H, C, P, N)$ *be an accepted* $\mathsf{FinitePrefixCompactness}^{\uparrow}$ *carrier. Every compact-uniform finite-prefix consumer must read the* $\mathsf{FiniteFanTheorem}^{\uparrow}$ *row* F*, the* $\mathsf{CantorSpace}^{\uparrow}$ *row* K*, and the* $\mathsf{StreamName}^{\uparrow}$ *row* S *before inspecting the finite prefix-cover ledger* Q*; it must then pass through* $\mathsf{RegSeqRat}^{\uparrow}$ *readback* R *before the* $\mathsf{Real}^{\uparrow}$ *seal* E *is exported. Thus the compact-uniform-continuity branch receives a finite prefix packet rather than an open-cover compactness theorem or a choice-selected branch.*

Proof. Start with the fan source F. It supplies bounded-bar evidence in the form accepted by chapter 5863, and it fixes the finite prefix discipline for the packet.

The Cantor and stream rows K and S make the actual prefix surface visible. The prefix-cover ledger Q is indexed by those displayed prefixes, so a consumer cannot inspect a cover decision outside the finite branch window.

The analytic handoff is ordered by R and E. Regular-rational readback in R records the finite rational data consumed by modulus routes, and the $\mathsf{Real}^{\uparrow}$ seal E is downstream of that readback.

Transport and replay through H and C preserve this order, while P and N expose only provenance and local naming. The handoff therefore factors through finite fan, Cantor, stream, RegSeqRat, and Real rows, with no open-cover or choice-selected branch coordinate. □

Closure status for $\mathsf{NameCert}_{\mathsf{FinitePrefixCompactness}^{\uparrow}}$.

Constructive story: A $\mathsf{FinitePrefixCompactness}^{\uparrow}$ packet is generated from FiniteFanTheorem, CantorSpace, StreamName, finite prefix-cover, RegSeqRat readback, RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{FinitePrefixCompactness}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8994.1, Definition 8994.2, and Definition 8994.3 seed the finite prefix compactness route through FiniteFanTheoremUp, CantorSpaceUp, StreamNameUp, RegSeqRatUp, RealUp, hsame, Cont, Pkg, and local NameCert rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{FinitePrefixCompactness}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close open-cover compactness, countable choice, selected branches, quotient stream equality, ambient RealUp completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, finite prefix-cover exactness, fan handoff order, RegSeqRat readback, RealUp seal non-escape, componentwise transport, provenance, and local NameCert exactness for BEDC.Derived.FinitePrefixCompactnessUp.

Chapter 8995

A Concrete Naming Certificate for $\mathsf{PrimeParityPhase}^{\uparrow}$

The $\mathsf{PrimeParityPhase}^{\uparrow}$ packet realizes the projection dictionary of section 9413.37 as one finite NameCert surface. It binds prime-charge rows, parity and unit-boundary rows, phase-routing rows, height-ledger rows, triadic closure-defect rows, transport, replay, provenance, and local naming before any phase or energy consumer reads the packet. The chapter names the finite dictionary surface; it does not prove RH, analytic continuation, Lee–Yang zeros, host complex equality, or an ambient spectral classification.

Definition 8995.1 (Prime parity phase carrier)**.** *A* $\mathsf{PrimeParityPhase}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$P = (Q, U, F, H, D, T, C, V, N)$$

with the following displayed rows:

1. *Q is the prime-charge row, displaying the finite prime register, height values, and charge ledger read from the source dictionary.*
2. *U is the parity and unit-boundary row, recording the sign boundary, unit-circle boundary, and the refusal of hidden positive real scale inside a compact phase fibre.*
3. *F is the phase-routing row, displaying the finite phase successor, winding, and solenoid-facing route used by the phase consumer.*
4. *H is the height-ledger row, tying the prime-charge heights to the routed phase and energy-facing reads.*
5. *D is the triadic closure-defect row, exposing only the finite defect data visible through the prime, parity, phase, and height rows.*
6. *T records componentwise* hsame *transport for prime charge, parity, unit boundary, phase route, height ledger, defect, replay, provenance, and local naming.*
7. *C records displayed* Cont *replay from the dictionary request through Q, U, F, H, D, T, V, N.*
8. *V is the* Pkg *provenance over* $\mathsf{PrimeParityPhase}^{\uparrow}$*, the prime-charge dictionary of section 9413.37, chapter 291, chapter 126,* BHist*,* hsame*,* Cont*, and* $\mathsf{NameCert}$*.*
9. *N is the local* $\mathsf{NameCert}_{\mathsf{PrimeParityPhase}^{\uparrow}}$ *row.*

The local classifier compares accepted packets only through $Q, U, F, H, D, T, C, V, N$. It has no coordinate for a completed zeta continuation, RH, Lee–Yang classification, host complex equality, noncompact hidden scale, selected infinite prime product, or global spectral theorem.

Theorem 8995.2 (PrimeParityPhase NameCert obligations)**.** *For an accepted* $\mathsf{PrimeParityPhase}^{\uparrow}$ *carrier*

$$P = (Q, U, F, H, D, T, C, V, N),$$

the local $\mathsf{NameCert}_{\mathsf{PrimeParityPhase}^{\uparrow}}$ *surface consists exactly of prime-charge exposure, parity and unit-boundary exposure, phase-routing exposure, height-ledger exposure, triadic closure-defect exposure, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. Any accepted phase or energy read must pass through*

$$Q, U, F, H, D \longmapsto T, C, V, N$$

before the read is exported.

Proof. Project the carrier of Definition 8995.1. Its visible dictionary rows are Q, U, F, H, D, and its structural rows are T, C, V, N.

The source dictionary of section 9413.37 separates prime charge, parity, phase routing, height ledger, and triadic closure defect. The carrier keeps those rows separate until the local NameCert read asks for a phase or energy-facing export.

Transport and replay are componentwise through T and C, while provenance and local naming are exhausted by V and N. Since no row records RH, analytic continuation, Lee–Yang classification, host complex equality, hidden noncompact scale, or a selected infinite prime product, the NameCert obligations are exactly the displayed finite dictionary rows. □

Theorem 8995.3 (PrimeParityPhase window readback)**.** *Every finite* $\mathsf{PrimeParityPhase}^{\uparrow}$ *phase window readback is anchored in the prime-charge row, parity and unit-boundary row, phase-routing row, height-ledger row, triadic closure-defect row, transport, replay, provenance, and local naming of the same accepted carrier.*

Proof. Let

$$P = (Q, U, F, H, D, T, C, V, N)$$

be an accepted carrier. By Definition 8995.2, a phase or energy consumer reads Q, U, F, H, D before any export.

The finite window is therefore not a host complex phase, a hidden real scale, or a selected infinite Euler product. It is the readback of the displayed route Q, U, F, H, D under the componentwise transport T, replay C, provenance V, and local naming N. □

Falsifiable prediction: Any accepted read of phase or energy without first displaying the prime-charge row, parity and unit-boundary row, phase-routing row, height-ledger row, transport row, replay row, provenance row, and local naming row refutes the $\mathsf{PrimeParityPhase}^{\uparrow}$ carrier.

Independence witness: prime-charge dictionary, zeta-continuation-socket, solenoid-lee-yang, dyadicratcore, streamname: the $\mathsf{PrimeParityPhase}^{\uparrow}$ packet is not bijective to any sibling because it jointly carries prime charge, parity, unit boundary, phase routing, height ledger, closure defect, transport, replay, provenance, and local naming. The dictionary supplies the source rows, the zeta and solenoid sockets remain outside the finite NameCert claim, and the dyadic and stream siblings supply readback discipline without absorbing the prime-parity-phase carrier.

Closure status for $\mathsf{NameCert}_{\mathsf{PrimeParityPhase}^{\uparrow}}$.

Constructive story: A $\mathsf{PrimeParityPhase}^{\uparrow}$ packet is generated from finite prime-charge, parity, unit-boundary, phase-routing, height-ledger, triadic closure-defect, transport, replay, provenance, and local NameCert rows.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{PrimeParityPhase}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8995.1, Definition 8995.2, and Definition 8995.3 seed the finite prime-charge, parity, phase, height-ledger, closure-defect, transport, replay, provenance, and naming dictionary.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{PrimeParityPhase}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close RH, analytic continuation, Lee–Yang classification, host complex equality, noncompact hidden scale, selected infinite prime products, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked Nontrivial and FieldFaithful TasteGate instances together with carrier, readback, transport, replay, provenance, and local naming rows for BEDC.Derived.PrimeParityPhaseUp.

Chapter 8996

A Concrete Naming Certificate for $\mathsf{LagrangeSpectrum}^{\uparrow}$

Following Perron and Cassels on the classical Lagrange spectrum of Diophantine approximation constants, the $\mathsf{LagrangeSpectrum}^{\uparrow}$ packet records a finite spectrum-window certificate over displayed real names and rational approximation data. It sits after the Hurwitz approximation packet of chapter 2111, the continued-fraction real packet of chapter 6738, the Farey and Stern–Brocot rows of chapter 1759 and chapter 1704, and the terminal StreamName, RegSeqRat, DyadicRatCore, and Real seals of chapter 126, chapter 301, chapter 291, and chapter 38. The packet names finite approximation windows; it does not classify the full Lagrange spectrum or select infinite continued fractions.

Definition 8996.1 (Lagrange spectrum finite-window carrier)**.** *A* $\mathsf{LagrangeSpectrum}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (X, A, K, H, F, S, D, W, Q, R, T, C, P, N)$$

with the following displayed rows:

1. *X is the displayed Real input row, naming the real source only through the available finite seal.*
2. *A is the finite continued-fraction prefix row read through* $\mathsf{ContinuedFractionReal}^{\uparrow}$*.*
3. *K is the approximation-constant row, listing the rational approximants and finite values used in the local spectrum window.*
4. *H is the Hurwitz comparison row, recording the finite Hurwitz-style threshold comparison visible in the window.*
5. *F is the Farey comparison row, recording the neighbouring rational interval data used to bound the approximants.*
6. *S is the Stern–Brocot comparison row, recording the finite tree route to the same rational window.*
7. *D is the DyadicRatCore tolerance row, displaying the dyadic tolerance and common-scale budget.*
8. *W is the StreamName window row, listing the finite observation schedule for the real source.*
9. *Q is the RegSeqRat readback row, giving the regular rational sequence read of the same window.*
10. *R is the Real seal row, recording the finite seal through which the spectrum-window data are exposed.*

11. *T records componentwise* hsame *transport for all displayed rows.*

12. *C records displayed* Cont *replay from the approximation-window request through $X, A, K, H, F, S, D, W, Q, R, T, P$*

13. *P is the* Pkg *provenance over* $\mathsf{LagrangeSpectrum}^{\uparrow}$*, the classical approximation siblings listed above,* BHist*,* hsame*,* Cont*, and* NameCert*.*

14. *N is the local* $\mathsf{NameCert}_{\mathsf{LagrangeSpectrum}^{\uparrow}}$ *row.*

The local classifier compares accepted packets only through $X, A, K, H, F, S, D, W, Q, R, T, C, P, N$. It has no coordinate for the completed Lagrange spectrum, an infinite continued-fraction choice, quotient real equality, trichotomy, countable choice, or ambient Real completeness.

Theorem 8996.2 (LagrangeSpectrum NameCert obligations)**.** *For an accepted* $\mathsf{LagrangeSpectrum}^{\uparrow}$ *carrier*

$$L = (X, A, K, H, F, S, D, W, Q, R, T, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{LagrangeSpectrum}^{\uparrow}}$ *surface consists exactly of displayed Real input exposure, finite continued-fraction prefix exposure, approximation-constant row exposure, Hurwitz comparison, Farey comparison, Stern–Brocot comparison, dyadic tolerance exposure, StreamName window exposure, RegSeqRat readback, Real seal handoff, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming.*

Proof. Project the carrier of Definition 8996.1. The rows $X, A, K, H, F, S, D, W, Q, R$ are the visible approximation-window data, and T, C, P, N are the transport, replay, provenance, and local naming rows.

The classical approximation rows remain finite. Hurwitz data are read through chapter 2111, Farey data through chapter 1759, and Stern–Brocot data through chapter 1704. The continued-fraction row is only the prefix A, not a selected infinite expansion.

The dyadic, StreamName, RegSeqRat, and Real rows expose the same finite request through D, W, Q, R. Since the carrier has no row for quotient real equality, trichotomy, countable choice, ambient Real completeness, or completed spectrum classification, the NameCert obligations are exhausted by the displayed finite-window route. □

Theorem 8996.3 (LagrangeSpectrum finite approximation route)**.** *Every accepted* $\mathsf{LagrangeSpectrum}^{\uparrow}$ *approximation-window read factors through the finite continued-fraction prefix, Hurwitz comparison, Farey comparison, Stern–Brocot comparison, dyadic tolerance, StreamName window, RegSeqRat readback, Real seal, transport, replay, provenance, and local naming rows of the same carrier.*

Proof. Let

$$L = (X, A, K, H, F, S, D, W, Q, R, T, C, P, N)$$

be an accepted carrier. By Definition 8996.2, the approximation-constant row K is read together with A, H, F, S, D, W, Q, R before export.

The route is therefore a finite comparison surface. The continued-fraction prefix supplies the displayed approximants, Hurwitz supplies the threshold comparison, Farey and Stern–Brocot supply rational-window checks, and the dyadic and stream rows bind the finite tolerance to the Real seal.

Transport, replay, provenance, and local naming are supplied by T, C, P, N. Thus the read has a finite BEDC route and does not require a completed spectrum, selected infinite continued fraction, quotient equality of reals, trichotomy, countable choice, or ambient completeness. □

Theorem 8996.4 (LagrangeSpectrum Real seal handoff)**.** *The* $\mathsf{LagrangeSpectrum}^{\uparrow}$ *finite-window route hands its displayed approximation data to* $\mathsf{Real}^{\uparrow}$ *only through the StreamName window, RegSeqRat readback, DyadicRatCore tolerance, Real seal row, transport, replay, provenance, and local naming rows already present in the carrier.*

Proof. Start with the accepted carrier of Definition 8996.1. The Real-facing rows are $X, D, W, Q, R, T, C, P, N$.

Apply Definition 8996.2. The Real seal R is downstream of the displayed real input, dyadic tolerance, StreamName window, and RegSeqRat readback; it is not an ambient completeness principle.

Therefore the handoff to $\mathsf{Real}^{\uparrow}$ is local to the finite packet. Any consumer that asks for a spectrum-window value must read the same tolerance, stream, regular-sequence, seal, transport, replay, provenance, and naming rows, and cannot replace them by quotient real equality or a global real-completeness claim. □

Closure status for $\mathsf{NameCert}_{\mathsf{LagrangeSpectrum}^{\uparrow}}$**.**

Constructive story: A $\mathsf{LagrangeSpectrum}^{\uparrow}$ packet is generated from displayed Real input, finite continued-fraction prefix, approximation-constant, Hurwitz, Farey, Stern–Brocot, DyadicRatCore tolerance, StreamName window, RegSeqRat readback, Real seal, transport, replay, provenance, and local NameCert rows.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{LagrangeSpectrum}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8996.1, Definition 8996.2, Definition 8996.3, and Definition 8996.4 seed the finite Diophantine-approximation spectrum-window route over real names and rational comparison rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{LagrangeSpectrum}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close completed Lagrange-spectrum classification, selected infinite continued fractions, quotient real equality, trichotomy, countable choice, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier, finite approximation route, Real seal handoff, transport, replay, provenance, and local naming rows for BEDC.Derived.LagrangeSpectrumUp.

Chapter 8997

A Concrete Naming Certificate for $\mathsf{BishopLocatedDiagonalSequence}^{\uparrow}$

Following Bishop and Bridges on diagonal arguments for regular Cauchy data, the $\mathsf{BishopLocatedDiagonalSequence}^{\uparrow}$ packet records the finite L10 route by which a located diagonal sequence is read before any completion-facing consumer reaches the real seal. It sits between the regular-sequence carrier of chapter 5965, the schedule surface of chapter 126, the rational readback surface of chapter 301, the dyadic tolerance core of chapter 291, the diagonal selector of chapter 372, and the terminal $\mathsf{Real}^{\uparrow}$ seal of chapter 38. The carrier stores the diagonal route as finite NameCert data, not as quotient streams, choice-selected representatives, or ambient completeness.

Definition 8997.1 (BishopLocatedDiagonalSequence carrier)**.** *A* $\mathsf{BishopLocatedDiagonalSequence}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (S, Q, D, L, R, H, C, P, N)$$

with the following displayed rows:

1. S *is the* $\mathsf{StreamName}^{\uparrow}$ *schedule row naming the inspected finite windows of the source family;*
2. Q *is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the regular rational values visible in those windows;*
3. D *is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row, exposing the dyadic budget used by the located diagonal read;*
4. L *is the* $\mathsf{RegularSequenceSpace}^{\uparrow}$ *source row whose accepted carrier supplies the family-level regular-sequence route;*
5. R *is the* $\mathsf{RegularCauchyDiagonal}^{\uparrow}$ *diagonal row, read only after* S, Q, D, L *have been exposed;*
6. H *records componentwise* hsame *transport for* S, Q, D, L, R, C, P, N*;*
7. C *records displayed* Cont *replay from the regular-sequence source to the stream window, regular rational readback, dyadic tolerance row, diagonal row, and real-facing seal route;*
8. P *is the* Pkg *provenance over* $\mathsf{BishopLocatedDiagonalSequence}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{RegularSequenceSpace}^{\uparrow}$*,* $\mathsf{RegularCauchyDiagonal}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*,* BHist*,* hsame*,* Cont*,* Pkg*, and* $\mathsf{NameCert}$ *rows;*
9. N *is the local* $\mathsf{NameCert}_{\mathsf{BishopLocatedDiagonalSequence}^{\uparrow}}$ *row.*

The local classifier compares accepted packets only through $S, Q, D, L, R, H, C, P, N$. It has no coordinate for quotient stream equality, selected diagonal representatives, countable-choice schedules, or an ambient completeness theorem for $\mathsf{Real}^{\uparrow}$.

Theorem 8997.2 (BishopLocatedDiagonalSequence NameCert obligations)**.** *For the carrier of Definition 8997.1, the local* $\mathsf{NameCert}_{\mathsf{BishopLocatedDiagonalSequence}^{\uparrow}}$ *surface consists exactly of the following five rows:*

1. *carrier admission for $B = (S, Q, D, L, R, H, C, P, N)$;*
2. *analytic exposure of the* $\mathsf{StreamName}^{\uparrow}$ *schedule S,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback Q,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row D,* $\mathsf{RegularSequenceSpace}^{\uparrow}$ *source row L, and* $\mathsf{RegularCauchyDiagonal}^{\uparrow}$ *diagonal row R;*
3. *structural stability through componentwise* hsame *transport H and displayed* Cont *replay C;*
4. *provenance and local naming through P and N;*
5. *nonescape for quotient streams, selected diagonal representatives, countable-choice schedules, and ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the carrier rows of Definition 8997.1. The analytic data are exactly S, Q, D, L, R, and the structural data are exactly H, C, P, N.

The schedule, readback, and tolerance rows expose the finite observation surface. The regular-sequence source row L keeps the family-level read inside $\mathsf{RegularSequenceSpace}^{\uparrow}$, while the diagonal row R is unavailable until those finite rows have been displayed.

Transport and replay preserve this route componentwise. Since the carrier has no row for quotient equality, choice of representatives, countable-choice schedules, or ambient completeness, the listed obligations exhaust the NameCert surface. □

Theorem 8997.3 (BishopLocatedDiagonalSequence L10 route)**.** *Every completion-facing read of an accepted* $\mathsf{BishopLocatedDiagonalSequence}^{\uparrow}$ *carrier passes through chapter 5965, chapter 126, chapter 301, chapter 291, and chapter 38 before the diagonal read is public. The route may cite the* $\mathsf{RegularCauchyDiagonal}^{\uparrow}$ *selector of chapter 372, but only as a consumer of the displayed regular-sequence, stream-window, rational-readback, and dyadic-tolerance rows.*

Proof. Start with the regular-sequence source row L. It binds the diagonal read to the accepted $\mathsf{RegularSequenceSpace}^{\uparrow}$ carrier before any completion-facing endpoint is visible.

Read the finite observation rows next. The $\mathsf{StreamName}^{\uparrow}$ schedule S fixes the inspected windows, the $\mathsf{RegSeqRat}^{\uparrow}$ row Q supplies the regular rational readback, and the $\mathsf{DyadicRatCore}^{\uparrow}$ row D records the displayed tolerance budget.

Only then consume the diagonal row R. The $\mathsf{RegularCauchyDiagonal}^{\uparrow}$ selector receives the finite window, readback, and tolerance data already exposed by the source route, so it cannot introduce quotient streams or selected representatives.

Finally replay H, C, P, N into the $\mathsf{Real}^{\uparrow}$ seal. The terminal real-facing read is therefore public only after the displayed L10 route has passed through the regular-sequence source, StreamName schedule, RegSeqRat readback, DyadicRatCore tolerance surface, and Real seal. □

Closure status for $\mathsf{NameCert}_{\mathsf{BishopLocatedDiagonalSequence}^{\uparrow}}$.

Constructive story: A $\mathsf{BishopLocatedDiagonalSequence}^{\uparrow}$ packet is generated from a StreamName schedule, RegSeqRat readback, DyadicRatCore tolerance row, RegularSequenceSpace source row, RegularCauchyDiagonal selector row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{BishopLocatedDiagonalSequence}^{\uparrow}}$, seed)

Scope closed: Definition 8997.1, Definition 8997.2, and Definition 8997.3 seed the finite located diagonal-sequence route from regular sequence spaces to the Real seal.

Formal verification: FormalStatus(NameCert$_{\mathsf{BishopLocatedDiagonalSequence}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not prove Lean verification, quotient stream equality, selected diagonal representatives, countable-choice schedules, or ambient Real$^{\uparrow}$ completeness.

Upgrade path: Formal closure requires a Lean carrier for BEDC.Derived.BishopLocatedDiagonalSequenceUp and checked NameCert obligations for the displayed L10 route.

Chapter 8998

A Concrete Naming Certificate for $\mathsf{UniformCauchyNetBridge}^{\uparrow}$

Following Bourbaki and Kelley on uniform spaces and Cauchy nets, the $\mathsf{UniformCauchyNetBridge}^{\uparrow}$ packet records the finite handoff by which directed Cauchy-net data, entourage-filter data, and regular-Cauchy readback are inspected before any completion-facing consumer may read a terminal seal. It sits between the regular Cauchy net surface of chapter 6338, the Cauchy entourage-filter route of chapter 1791, the uniform-space completion packet of chapter 3560, the regular rational readback of chapter 301, the finite stream windows of chapter 126, and the real-name seal of chapter 38. The packet names a constructive bridge object, not a quotient of nets, a selected limit, a countable-choice schedule, ambient $\mathsf{Real}^{\uparrow}$ completeness, or a checked Lean bridge.

Definition 8998.1 (Uniform Cauchy net bridge carrier)**.** *A* $\mathsf{UniformCauchyNetBridge}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (N, E, F, R, S, Z, H, C, P, L)$$

with the following displayed rows:

1. *N is the directed Cauchy-net source row, naming the directed index data, net observations, and displayed Cauchy-entourage requests.*
2. *E is the entourage row, recording finite uniform entourages and their monotone refinement route.*
3. *F is the filter row, recording the Cauchy filter data read from the entourage route and the compatibility witness with the net source.*
4. *R is the regular-Cauchy readback row, exposing the* $\mathsf{RegSeqRat}^{\uparrow}$ *regular rational name obtained from the displayed net/filter windows.*
5. *S is the* $\mathsf{StreamName}^{\uparrow}$ *window row, recording the finite observations by which the directed net and regular readback are inspected.*
6. *Z is the completion-seal row, recording the* $\mathsf{UniformSpaceCompletion}^{\uparrow}$ *handoff and the terminal* $\mathsf{Real}^{\uparrow}$ *zero-distance or classifier row available to completion consumers.*
7. *H records componentwise* hsame *transport for $N, E, F, R, S, Z, C, P, L$.*
8. *C records displayed* Cont *replay for directed-net inspection, entourage refinement, filter compatibility, regular-Cauchy readback, stream-window inspection, completion sealing, and zero-distance or classifier consumption.*

9. *P is the* Pkg *provenance over* UniformCauchyNetBridge$^{\uparrow}$, RegularCauchyNet$^{\uparrow}$, CauchyEntourageFilter$^{\uparrow}$, UniformSpaceCompletion$^{\uparrow}$, RegSeqRat$^{\uparrow}$, StreamName$^{\uparrow}$, Real$^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* NameCert *rows.*

10. *L is the local* NameCert$_{\text{UniformCauchyNetBridge}^{\uparrow}}$ *row.*

The carrier has no coordinate for quotienting nets, selecting a limit point, invoking countable choice, proving ambient completeness of Real$^{\uparrow}$*, or replacing the displayed bridge with a host uniform-completion theorem.*

Theorem 8998.2 (Uniform Cauchy net bridge NameCert obligations)**.** *For the carrier of Definition 8998.1, the local* NameCert$_{\text{UniformCauchyNetBridge}^{\uparrow}}$ *surface consists exactly of carrier admission for $K = (N, E, F, R, S, Z, H, C, P, L)$, directed-entourage stability through N, E, filter/net compatibility through F, regular readback through R, stream-window inspection through S, completion sealing and zero-distance or classifier exposure through Z, componentwise* hsame *transport through H, displayed* Cont *replay through C, provenance through P, and local naming through L.*

Proof. Project the carrier $K = (N, E, F, R, S, Z, H, C, P, L)$. Carrier admission supplies the directed net source before any entourage or filter row is consumed.

Read E and F together. The entourage row displays finite uniform refinements, while the filter row records that the same displayed route is compatible with the directed Cauchy-net source.

Next read R, S, Z. The regular-Cauchy readback is inspected through finite stream windows before the completion seal and the Real$^{\uparrow}$ zero-distance or classifier row can be consumed.

Finally use H, C, P, L. Transport, replay, provenance, and local naming preserve only the displayed packet, so the listed rows exhaust the NameCert surface and add no quotient net, selected limit, countable-choice schedule, ambient Real completeness theorem, or checked bridge. □

Falsifiable prediction: A completion consumer that reads a selected limit or quotient net from UniformCauchyNetBridge$^{\uparrow}$ without displaying $N, E, F, R, S, Z, H, C, P, L$ refutes this packet.

Independence witness: Nearest siblings: regular-cauchy-net, cauchy-entourage-filter, uniform-space-completion, regseqrat, streamname, real. None carries the combined bridge packet because each sibling exposes one route, while UniformCauchyNetBridge$^{\uparrow}$ stores directed-net source data, entourage/filter compatibility, regular-Cauchy readback, stream windows, completion seal, zero-distance or classifier exposure, transport, replay, provenance, and local naming in one finite carrier.

Closure status for NameCert$_{\text{UniformCauchyNetBridge}^{\uparrow}}$**.**

Constructive story: A UniformCauchyNetBridge$^{\uparrow}$ packet is generated by displaying a directed Cauchy-net source, finite entourage refinements, a compatible Cauchy-filter row, regular-Cauchy readback, stream windows, a completion seal, zero-distance or classifier exposure, componentwise transport, replay, provenance, and local naming in one finite BHist carrier.

Theory closure: TheoryGate(NameCert$_{\text{UniformCauchyNetBridge}^{\uparrow}}$, seed)

Scope closed: Definition 8998.1 and Definition 8998.2 bind the seed carrier and local NameCert obligations for the constructive net/filter/regular-Cauchy completion handoff.

Formal verification: FormalStatus(NameCert$_{\text{UniformCauchyNetBridge}^{\uparrow}}$, unformalized)

Bridge status: none

Origin: human

Not claimed: It does not claim quotient nets, selected limits, countable choice, ambient Real$^{\uparrow}$ completeness, or bridge checking.

Upgrade path: A scoped closure would require stable downstream theorems for directed-entourage compatibility, regular readback, completion sealing, and the displayed refusal boundary.

Chapter 8999

A Concrete Naming Certificate for $\mathsf{StrongChoquetSpace}^{\uparrow}$

Following Oxtoby and Kechris on Choquet-game topology, the $\mathsf{StrongChoquetSpace}^{\uparrow}$ packet records the finite rows by which a complete-metric or Baire-style space exposes a player-two response strategy without importing an ambient powerset of open sets. It sits beside the Baire-space carrier of chapter 334, the complete-metric surface of chapter 3687, the Polish-space carrier of chapter 1490, the stream-window discipline of chapter 126, and the topology source of chapter 88. The chapter names the finite Choquet-game certificate only; it does not assert choice-selected infinite plays, host open-set powersets, or ambient completeness.

8999.1 Strong Choquet Carrier

Definition 8999.1 (Strong Choquet space carrier)**.** *A* $\mathsf{StrongChoquetSpace}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$\mathsf{Chq}(T, B, O, R, S, W, H, C, P, N)$$

with the following displayed rows:

1. *T is the* $\mathsf{Topology}^{\uparrow}$ *source row, naming the finite open-neighborhood interface used by the game.*
2. *B is the Baire and Polish comparison row, recording the visible handoff to* $\mathsf{BaireSpace}^{\uparrow}$, $\mathsf{CompleteMetric}^{\uparrow}$, *and* $\mathsf{PolishSpace}^{\uparrow}$ *without asserting equality with any sibling carrier.*
3. *O is the open-move ledger, listing the finite initial-point, open-set, and refinement requests that the packet actually observes.*
4. *R is the response-strategy ledger, giving the displayed player-two response row for each listed open move.*
5. *S is the* $\mathsf{StreamName}^{\uparrow}$ *window row, recording the finite play prefix and the observation windows through which nested moves are read.*
6. *W is the winning-boundary row, naming the finite nonempty-intersection and legality checks exported by the packet.*
7. *H records componentwise* hsame *transport for topology source, comparison, open moves, responses, stream windows, winning boundary, replay, provenance, and local naming.*
8. *C records displayed* Cont *replay from a game request through $T, B, O, R, S, W, H, P, N$.*

9. *P is the* Pkg *provenance over* $\mathsf{StrongChoquetSpace}^{\uparrow}$, $\mathsf{Topology}^{\uparrow}$, $\mathsf{BaireSpace}^{\uparrow}$, $\mathsf{CompleteMetric}^{\uparrow}$, $\mathsf{PolishSpace}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{StrongChoquetSpace}^{\uparrow}}$ *row.*

The carrier contains no host collection of all open sets, no chosen infinite play, no ambient complete metric, and no rule that identifies the Choquet strategy with a Baire or Polish carrier.

Theorem 8999.2 (Strong Choquet NameCert obligations)**.** *For every accepted* $\mathsf{StrongChoquetSpace}^{\uparrow}$ *carrier* $\mathsf{Chq}(T, B, O, R, S, W, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{StrongChoquetSpace}^{\uparrow}}$ *surface consists exactly of topology-source admission, Baire and Polish comparison, finite open-move admission, response-strategy exposure, stream-window exposure, winning-boundary exposure, componentwise transport, displayed replay, provenance, and local naming. Any accepted Choquet-game consumer must read*

$$T, B, O, R, S, W \longmapsto H, C, P, N$$

before the strategy row is exported.

Proof. Project the carrier of Definition 8999.1. The game-facing surface is exactly T, B, O, R, S, W, and the structural surface is exactly H, C, P, N.

The open-move ledger O and response ledger R are finite rows. They expose only the moves and replies already listed in the packet, while the stream row S records the play prefix used by a consumer.

The winning-boundary row W is therefore read from displayed finite legality and intersection checks. Since the carrier contains no host open-set powerset, selected infinite play, or ambient complete metric, the listed rows exhaust the local NameCert obligations. □

Theorem 8999.3 (Strong Choquet winning strategy handoff)**.** *Every winning-strategy read of an accepted* $\mathsf{StrongChoquetSpace}^{\uparrow}$ *carrier factors through the topology source T, Baire and Polish comparison row B, open-move ledger O, response ledger R,* $\mathsf{StreamName}^{\uparrow}$ *window row S, winning boundary W, transport H, replay C, provenance P, and local naming N. The handoff exports a finite strategy surface and does not choose an infinite play, a host powerset of open sets, or a complete metric outside the displayed packet.*

Proof. Start with a consumer asking for a strategy. The topology source T supplies only the displayed open-neighborhood interface, and O lists the open moves that the packet accepts.

The response row R then gives the corresponding player-two replies, while S records the finite play windows and W records the boundary checks needed for a winning read. The comparison row B keeps the Baire, complete-metric, and Polish siblings available only as named dependency surfaces.

Finally H, C, P, N transport, replay, source, and name the same finite packet. Without a coordinate for choice-selected infinite plays, host open-set powersets, or ambient completeness, the exported handoff is exactly the displayed finite strategy surface. □

Closure status for $\mathsf{NameCert}_{\mathsf{StrongChoquetSpace}^{\uparrow}}$**.**

Constructive story: A $\mathsf{StrongChoquetSpace}^{\uparrow}$ packet is generated from topology-source, Baire and Polish comparison, finite open-move, response-strategy, StreamName window, winning-boundary, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert rows.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{StrongChoquetSpace}^{\uparrow}}$, seed)

Scope closed: Definition 8999.1, Definition 8999.2, and Definition 8999.3 seed the finite Choquet-game strategy surface over topology, Baire, complete-metric, Polish, StreamName, hsame, Cont, Pkg, and local NameCert rows.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{StrongChoquetSpace}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close choice-selected infinite plays, host open-set powersets, ambient completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, open-move exactness, response-strategy handoff, StreamName window stability, winning-boundary coverage, componentwise transport, provenance, and local naming for BEDC.Derived.StrongChoquetSpaceUp.

Chapter 9000

A Concrete Naming Certificate for $\mathsf{PrimeSpectralFingerprint}^{\uparrow}$

The $\mathsf{PrimeSpectralFingerprint}^{\uparrow}$ packet realizes the prime-fingerprint separation row of chapter 9248 as finite NameCert data. It binds prime-probe rows from chapter 64, zeta-channel projection rows from chapter 71, rational and dyadic response ledgers from chapter 37 and chapter 291, transport, replay, provenance, and local naming before any RH-facing fingerprint consumer reads a spectral separation witness. The chapter names the finite prime-local response packet only; it does not prove RH, analytic continuation, host complex equality, or an infinite Euler product.

9000.1 Prime Spectral Fingerprint Carrier

Definition 9000.1 (Prime spectral fingerprint carrier)**.** *A* $\mathsf{PrimeSpectralFingerprint}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$\mathsf{PSF}(P, Z, D, R, H, C, G, N)$$

with the following displayed rows:

1. *P is the prime-probe row, listing the finite prime names and local probe windows inspected by the packet.*
2. *Z is the zeta projection row, recording the visible prime-local channel response consumed from the zeta packet.*
3. *D is the dyadic response ledger, storing the finite* $\mathsf{DyadicRatCore}^{\uparrow}$ *approximants used by the response comparison.*
4. *R is the rational response ledger, storing the finite* $\mathsf{Rat}^{\uparrow}$ *readback rows used to compare probe amplitudes and phases.*
5. *H records componentwise* hsame *transport for prime probes, zeta projection, dyadic responses, rational responses, replay, provenance, and local naming.*
6. *C records displayed* Cont *replay from a fingerprint request through P, Z, D, R, H, G, N.*
7. *G is the* Pkg *provenance over* $\mathsf{PrimeSpectralFingerprint}^{\uparrow}$, $\mathsf{Prime}^{\uparrow}$, *zeta projection rows,* $\mathsf{Rat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
8. *N is the local* $\mathsf{NameCert}_{\mathsf{PrimeSpectralFingerprint}^{\uparrow}}$ *row.*

The carrier contains no host complex equality, no completed zeta continuation, no selected infinite prime product, no RH proof object, and no ambient spectral theorem.

Theorem 9000.2 (PrimeSpectralFingerprint NameCert obligations)**.** *For every accepted* $\mathsf{PrimeSpectralFingerprint}^{\uparrow}$ *carrier* $\mathsf{PSF}(P, Z, D, R, H, C, G, N)$*, the local* $\mathsf{NameCert}_{\mathsf{PrimeSpectralFingerprint}^{\uparrow}}$ *surface consists exactly of prime-probe exposure, zeta-projection exposure, dyadic response-ledger exposure, rational response-ledger exposure, componentwise transport, displayed replay, provenance, and local naming. Any accepted prime-local zeta response read must pass through*

$$P, Z, D, R \longmapsto H, C, G, N$$

before a separation consumer may inspect the fingerprint.

Proof. Project the carrier of Definition 9000.1. The fingerprint-facing rows are P, Z, D, R, and the structural rows are H, C, G, N.

The prime-probe row P supplies the finite probe names, while the zeta row Z supplies the corresponding visible channel responses. The dyadic and rational ledgers D and R record only finite approximants and readback rows used by that response comparison.

Transport, replay, provenance, and naming are exhausted by H, C, G, N. Since no row records host complex equality, a completed continuation, an infinite Euler product, or an RH proof object, the NameCert obligations are exactly the finite rows listed above. □

Theorem 9000.3 (PrimeSpectralFingerprint separation witness)**.** *Every separation witness exported by an accepted* $\mathsf{PrimeSpectralFingerprint}^{\uparrow}$ *carrier factors through the prime-probe row* P*, zeta projection row* Z*, dyadic ledger* D*, rational ledger* R*, transport* H*, replay* C*, provenance* G*, and local naming* N*. The witness may record that two displayed spectral histories differ at a prime-local response row, but it does not identify histories by host complex equality or by an unlisted infinite family of probes.*

Proof. Start with a consumer asking whether two displayed histories are separated by a prime-local response. The packet can inspect only the prime names in P and the zeta-channel response rows in Z.

The dyadic and rational ledgers D and R then provide the finite comparison surface for the response readback. They do not add a completed analytic continuation or a global Euler product; they only expose the approximants and rational rows already present in the packet.

Finally H, C, G, N transport, replay, source, and name the same finite witness. Therefore the exported separation row is prime-local and finite, with no host equality or unlisted infinite probe family. □

Falsifiable prediction: Any accepted prime-local zeta response read that exports a $\mathsf{PrimeSpectralFingerprint}^{\uparrow}$ separation without displaying the prime-probe row, zeta projection row, dyadic response ledger, rational response ledger, transport row, replay row, provenance row, and local naming row refutes the carrier.

Independence witness: prime, zeta, rat, dyadicratcore, namecert: the $\mathsf{PrimeSpectralFingerprint}^{\uparrow}$ packet is not bijective to any sibling because it jointly carries prime probes, zeta-channel projections, dyadic response approximants, rational readback rows, transport, replay, provenance, and local naming. Prime and zeta siblings supply source channels, rational and dyadic siblings supply response ledgers, and NameCert supplies the local naming discipline without absorbing the fingerprint carrier.

Closure status for $\mathsf{NameCert}_{\mathsf{PrimeSpectralFingerprint}^{\uparrow}}$.

Constructive story: A $\mathsf{PrimeSpectralFingerprint}^{\uparrow}$ packet is generated from prime-probe, zeta-projection, dyadic response-ledger, rational response-ledger, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert rows.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{PrimeSpectralFingerprint}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 9000.1, Definition 9000.2, and Definition 9000.3 seed the finite prime-local zeta response surface over PrimeUp, zeta projection, RatUp, DyadicRatCoreUp, hsame, Cont, Pkg, and local NameCert rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{PrimeSpectralFingerprint}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close RH, analytic continuation, host complex equality, selected infinite prime products, ambient spectral classification, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, prime-probe exactness, zeta-projection response coverage, dyadic and rational ledger stability, componentwise transport, provenance, and local naming for BEDC.Derived.PrimeSpectralFingerpr

Chapter 9001

A Concrete Naming Certificate for $\mathsf{DarbouxStieltjesIntegral}^{\uparrow}$

Following Darboux, Stieltjes, and Bishop-style constructive analysis, the $\mathsf{DarbouxStieltjesIntegral}^{\uparrow}$ packet records the finite upper-lower integration route for a bounded integrand read against a bounded-variation integrator. It sits beside the Darboux finite-partition surface of chapter 1460, the tagged Riemann–Stieltjes route of chapter 1637, the variation ledger of chapter 398, the regular rational readback of chapter 301, and the terminal real-name seal of chapter 38. The packet names the displayed finite Stieltjes mesh and gap route only; it does not import measure completion, choice-selected tags, quotient integrands, completed variation objects, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 9001.1 (Darboux–Stieltjes integral carrier)**.** *A* $\mathsf{DarbouxStieltjesIntegral}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (P, F, A, U, L, SU, SL, G, R, E, H, C, Pkg, N)$$

with the following displayed rows:

1. *P is the finite partition row, carrying the displayed interval endpoints, cell order, and common-refinement ledger used by all later rows.*
2. *F is the bounded integrand row, exposing bounded rational or real-value windows on the cells named by P.*
3. *A is the* $\mathsf{BoundedVariation}^{\uparrow}$ *integrator row, carrying endpoint changes, transported jump or oscillation rows, and the finite variation budget attached to the same partition.*
4. *U and L are upper and lower Darboux–Stieltjes envelope rows over a displayed common refinement of P.*
5. *SU and SL are the finite upper and lower Darboux–Stieltjes sum rows computed from U, L and the integrator changes in A.*
6. *G is the upper-lower gap and modulus row, binding the visible precision request to the finite difference between SU and SL.*
7. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row obtained from the gap/modulus ledger.*
8. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal, available only after $P, F, A, U, L, SU, SL, G, R$ have been displayed.*
9. *H records componentwise* hsame *transport for all carrier rows.*

10. *C records displayed* Cont *replay of refinements, variation reads, sum computations, gap comparisons, regular readback, and real sealing.*
11. *Pkg is the* Pkg *provenance over* DarbouxStieltjesIntegral$^{\uparrow}$, DarbouxIntegral$^{\uparrow}$, RiemannStieltjes$^{\uparrow}$, BoundedVariation$^{\uparrow}$, RegSeqRat$^{\uparrow}$, Real$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
12. *N is the local* NameCert$_{\text{DarbouxStieltjesIntegral}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $P, F, A, U, L, SU, SL, G, R, E, H, C, Pkg, N$. It has no coordinate for measure completion, choice-selected partition tags, host integrand equality, quotient functions, selected limiting partitions, completed variation objects, or ambient real completeness.

Theorem 9001.2 (Darboux–Stieltjes integral NameCert obligations)**.** *For every accepted* DarbouxStieltjesIntegral$^{\uparrow}$ *carrier $S = (P, F, A, U, L, SU, SL, G, R, E, H, C, Pkg, N)$, the local* NameCert$_{\text{DarbouxStieltjesIntegral}^{\uparrow}}$ *surface consists exactly of carrier admission for the displayed tuple, partition-refinement stability for P, U, L, bounded-integrand exposure through F, bounded-variation integrator control through A, finite upper/lower Darboux–Stieltjes sum exactness for SU, SL, gap/modulus exposure through G,* RegSeqRat$^{\uparrow}$ *and* Real$^{\uparrow}$ *sealing through R, E, componentwise* hsame *transport, displayed* Cont *replay, package provenance, local naming, and ledger refusal for measure completion, selected tags, quotient functions, selected limiting partitions, completed variation objects, and ambient* Real$^{\uparrow}$ *completeness.*

Proof. Carrier admission is projection from Definition 9001.1. The packet first displays the partition, integrand bounds, bounded-variation integrator row, upper and lower envelope rows, and finite sum rows before any gap or seal can be consumed.

Refinement stability is inherited from the Darboux and Riemann–Stieltjes sibling routes. The partition and envelope rows follow the finite Darboux common-refinement discipline, while the integrator changes are read only through the bounded-variation ledger attached to the same refined cells.

The sum and gap obligations are then finite ledger checks. The upper and lower Darboux–Stieltjes sums compute from the displayed envelopes and integrator changes, the gap row records the visible precision comparison, and R, E seal that comparison as a regular rational and real-name handoff. Since the excluded host objects are absent from the carrier coordinates, no continuation or transport row can export them. □

Theorem 9001.3 (Darboux–Stieltjes variation handoff)**.** *Every* DarbouxIntegral$^{\uparrow}$ *or* RiemannStieltjes$^{\uparrow}$ *consumer of an accepted* DarbouxStieltjesIntegral$^{\uparrow}$ *packet must read the finite partition row P, bounded integrand row F,* BoundedVariation$^{\uparrow}$ *integrator row A, upper and lower envelope rows U, L, finite sum rows SU, SL, gap/modulus row G,* RegSeqRat$^{\uparrow}$ *readback R,* Real$^{\uparrow}$ *seal E, componentwise* hsame *transport H, displayed* Cont *replay C,* Pkg *provenance Pkg, and local* NameCert *row N before treating the packet as an integral handoff. The consumer receives a finite variation-controlled Darboux route; it receives no measure completion, selected tags, quotient integrand equality, selected limiting partition, completed variation object, or ambient real-completeness proof.*

Proof. Start from the NameCert obligations of Definition 9001.2. They expose the carrier, partition refinement, bounded integrand, bounded-variation integrator, finite sum, gap, readback, seal, transport, replay, provenance, and local naming rows as the complete public surface.

For a DarbouxIntegral$^{\uparrow}$ consumer, forget only the Stieltjes-specific reading of A as an integrator ledger while keeping the partition, upper and lower envelope rows, finite sum rows, gap row, regular readback, and real seal visible. This is still a finite Darboux route because the sums and gap are computed from displayed cells.

For a $\mathsf{RiemannStieltjes}^{\uparrow}$ consumer, read A as the bounded-variation handoff and use the same finite mesh, sum, and seal order. The tagged route is not supplied by choice-selected tags; it is constrained by the displayed Stieltjes partition and variation ledger already present in the carrier.

The structural rows H, C, Pkg, N preserve this order and add no analytic coordinate. Thus every downstream integration handoff remains inside the finite variation-controlled packet and cannot export the refused host data. □

Falsifiable prediction: Every accepted $\mathsf{DarbouxStieltjesIntegral}^{\uparrow}$ read displays one finite partition row, one bounded integrand row, one BoundedVariationUp integrator row, upper and lower Darboux–Stieltjes envelope rows, upper and lower finite sum rows, one gap/modulus row, one RegSeqRatUp readback row, one RealUp seal, componentwise hsame transport, Cont replay, Pkg provenance, and local NameCert before any integral consumer reads the seal.

Independence witness: darboux-integral, riemann-stieltjes, bounded-variation, regseqrat, real: $\mathsf{DarbouxStieltjesIntegral}^{\uparrow}$ is not bijective to any listed sibling because it jointly binds finite upper/lower Darboux rows to bounded-variation integrator changes before the regular-rational and real-name seal, while refusing measure completion, selected tags, quotient function equality, selected limiting partitions, completed variation objects, and ambient real completeness.

Closure status for $\mathsf{NameCert}_{\mathsf{DarbouxStieltjesIntegral}^{\uparrow}}$.

Constructive story: A $\mathsf{DarbouxStieltjesIntegral}^{\uparrow}$ packet is generated from a finite partition row, bounded integrand row, BoundedVariationUp integrator row, upper and lower envelope rows, finite upper and lower Darboux–Stieltjes sum rows, a gap/modulus row, RegSeqRatUp readback, RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{DarbouxStieltjesIntegral}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 9001.1, Definition 9001.2, and Definition 9001.3 seed the finite variation-controlled Darboux–Stieltjes handoff through $\mathsf{DarbouxIntegral}^{\uparrow}$, $\mathsf{RiemannStieltjes}^{\uparrow}$, $\mathsf{BoundedVariation}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{DarbouxStieltjesIntegral}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim measure completion, selected tags, quotient integrand equality, selected limiting partitions, completed variation objects, ambient RealUp completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, finite sum exactness, bounded-variation handoff, gap/modulus nonescape, RegSeqRatUp readback, and RealUp seal ordering for BEDC.Derived.DarbouxStieltjesIntegralUp.

Chapter 9002

A Concrete Naming Certificate for $\mathsf{FiniteEnergyTower}^{\uparrow}$

The $\mathsf{FiniteEnergyTower}^{\uparrow}$ packet realizes the finite-to-infinite phase-energy tower of section 9413.55 as concrete NameCert data. It reads finite prime windows through the prime-window gluing surface of chapter 8765, prime rows through chapter 64, zeta-facing boundary data through chapter 71, complex coordinates through chapter 39, real readback through chapter 38, and dyadic tolerance rows through chapter 291. The packet names finite positive normal-energy evidence and monotone window extension; it does not claim RH, zero exclusion, an infinite spectral theorem, Euler-product completion, or analytic continuation beyond the displayed rows.

Definition 9002.1 (Finite energy tower carrier)**.** *A* $\mathsf{FiniteEnergyTower}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$T = (W, \Phi, E, M, Z, R, H, C, P, N)$$

with the following displayed rows:

1. *W is the finite prime-window row, carrying a nonempty displayed prime list, the finite inclusion order used for window extension, and the local prime provenance.*
2. *Φ is the phase-profile row, recording the finite phase rotations attached to the primes in W at the displayed complex coordinate.*
3. *E is the positive normal-energy row, computing the finite sum of nonnegative normal square terms and recording positivity when the displayed normal displacement is nonzero.*
4. *M is the monotone window-extension row, showing that passing from one displayed finite prime window to a larger displayed window only adds nonnegative normal-energy terms.*
5. *Z is the zeta-facing boundary row, recording the local zero-boundary request without asserting zero exclusion or a completed infinite tower.*
6. *R is the* $\mathsf{Real}^{\uparrow}/\mathsf{Complex}^{\uparrow}$ *readback row, exposing the real normal-energy value and the complex coordinate only after W, Φ, E, M, Z have been displayed.*
7. *H records componentwise* hsame *transport for finite windows, phase profiles, energy rows, monotone extension, zeta boundary, readback, provenance, and local naming.*
8. *C records displayed* Cont *replay from prime-window inspection through phase readback, positive energy, monotone extension, boundary request, and Real/Complex sealing.*

9. *P is the* Pkg *provenance over* $\mathsf{FiniteEnergyTower}^{\uparrow}$, $\mathsf{Prime}^{\uparrow}$, $\mathsf{FinitePrimeWindowGluing}^{\uparrow}$, $\mathsf{Zeta}^{\uparrow}$, $\mathsf{Complex}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{FiniteEnergyTower}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $W, \Phi, E, M, Z, R, H, C, P, N$. It has no coordinate for a completed infinite prime tower, a proof of RH*, global zeta recovery, infinite spectral completeness, Euler-product completion, selected limiting windows, or ambient analytic continuation.*

Theorem 9002.2 (Finite energy tower NameCert obligations)**.** *For every accepted* $\mathsf{FiniteEnergyTower}^{\uparrow}$ *carrier $T = (W, \Phi, E, M, Z, R, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{FiniteEnergyTower}^{\uparrow}}$ *surface consists exactly of finite prime-window admission, phase-profile exposure, positive normal-energy exposure, monotone finite-window extension, zeta-boundary request routing,* $\mathsf{Real}^{\uparrow}/\mathsf{Complex}^{\uparrow}$ *readback, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, local naming, and ledger refusal for completed infinite towers, RH proof claims, zero-exclusion claims, infinite spectral theorems, Euler-product completion, selected limiting windows, and ambient analytic continuation.*

Proof. Carrier admission is projection from Definition 9002.1. The packet first displays the finite prime window W, the phase profile Φ, the positive normal-energy row E, and the monotone extension row M.

The zeta-facing row Z is only a boundary request. It records where a zero-relevance consumer would inspect the finite energy data, while leaving the global zero law outside this packet.

The readback row R is downstream of those finite rows. It exposes Real and Complex data only after the prime window, phase profile, normal-energy, monotonicity, and boundary request are visible.

Finally H, C, P, N preserve, replay, source, and name the same route. Since no carrier coordinate stores an infinite tower, RH proof, zero exclusion theorem, spectral completion, Euler-product completion, limiting-window selector, or ambient analytic continuation principle, the listed rows exhaust the NameCert surface. □

Falsifiable prediction: A $\mathsf{FiniteEnergyTower}^{\uparrow}$ consumer reaching the energy obstruction without first displaying the finite prime window row W and positive normal-energy row E refutes the packet.

Independence witness: prime, zeta, complex, real, dyadicratcore: $\mathsf{FiniteEnergyTower}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries finite prime-window rows, phase-profile rows, positive normal-energy rows, monotone window extension, zeta-boundary request, Real/Complex readback, dyadic tolerance context, transport, replay, provenance, and local naming while refusing RH proof claims and infinite spectral closure.

Closure status for $\mathsf{NameCert}_{\mathsf{FiniteEnergyTower}^{\uparrow}}$**.**

Constructive story: A $\mathsf{FiniteEnergyTower}^{\uparrow}$ packet is generated from a finite prime-window row, phase-profile row, positive normal-energy row, monotone window-extension row, zeta-boundary request, RealUp and ComplexUp readback, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{FiniteEnergyTower}^{\uparrow}}$, seed)

Scope closed: Definition 9002.1 and Definition 9002.2 seed finite prime-window phase rows, positive normal-energy rows, monotone extension, Real/Complex readback, and nonescape ledgers as NameCert data.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{FiniteEnergyTower}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim RH, nontrivial zero exclusion, global zeta recovery, infinite spectral completeness, Euler-product completion, selected limiting windows, analytic continuation, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, finite prime-window exposure, phase-profile exposure, positive normal-energy exposure, monotone extension, Real/Complex readback, zeta-boundary nonescape, and local naming for BEDC.Derived.FiniteEnergyTowerUp.

Chapter 9003

A Concrete Naming Certificate for $\mathsf{PartialMetric}^{\uparrow}$

Following Matthews on partial metric spaces, the $\mathsf{PartialMetric}^{\uparrow}$ packet records the constructive distance surface in which self-distance is visible data rather than a suppressed diagonal law. It sits between the pre-distance carrier of chapter 5565, the zero-distance boundary of chapter 1614, the directed-distance surface of chapter 2158, the metric reader of chapter 57, and the terminal distance seal of chapter 38. The packet names only the finite NameCert rows needed to expose self-distance, partial triangle evidence, and completion-facing handoff; it does not identify points, quotient carriers, select limits, or import ambient completeness.

Definition 9003.1 (Partial metric carrier)**.** *A* $\mathsf{PartialMetric}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$P = (S, X, E, D, L, T, M, K, H, C, Q, N)$$

with the following displayed rows:

1. *S is the source carrier row. It records the traditional partial-metric source and the finite observation context in which point and distance requests are admitted.*
2. *X is the point row. It records admitted point names and their classifier without quotienting them by distance-zero evidence or by equality-like self-distance comparisons.*
3. *E is the self-distance row. For each admitted point row x, it displays the value $p(x, x)$ as a* $\mathsf{Real}^{\uparrow}$*-sealed distance witness.*
4. *D is the directed distance row. It records requested values $p(x, y)$ and keeps the reversed request $p(y, x)$ visible as a separate displayed read unless a later row supplies symmetry evidence.*
5. *L is the small-self-distance comparison row. It displays the comparisons $p(x, x) \leq p(x, y)$ and $p(y, y) \leq p(x, y)$ as finite ledger data, not as host-order laws.*
6. *T is the partial triangle ledger. It records the comparison of $p(x, z)$ with the finite route through $p(x, y)$, $p(y, z)$, and the displayed self-distance $p(y, y)$.*
7. *M is the metric-reflection handoff row. It names the boundary through which a later* $\mathsf{Met}^{\uparrow}$ *or* $\mathsf{Pseudometric}^{\uparrow}$ *reader may consume the displayed self-distance and triangle data.*
8. *K is the completion-facing row. It binds every completion-oriented request to S, X, E, D, L, T, M before any completed point, Cauchy limit, or quotient representative can be named.*

9. *H records componentwise* hsame *transport for source, point, self-distance, directed distance, small-self-distance, partial triangle, metric-reflection, completion, replay, provenance, and local naming rows.*
10. *C records displayed* Cont *replay from a consumer request through point admission, self-distance exposure, directed distance readback, small-self-distance comparison, partial triangle evidence, metric-reflection handoff, completion boundary, transport, provenance, and local naming.*
11. *Q is the* Pkg *provenance over* $\mathsf{PartialMetric}^{\uparrow}$, $\mathsf{Premetric}^{\uparrow}$, $\mathsf{Pseudometric}^{\uparrow}$, $\mathsf{QuasiMetric}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
12. *N is the local* $\mathsf{NameCert}_{\mathsf{PartialMetric}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $S, X, E, D, L, T, M, K, H, C, Q, N$. It has no coordinate for separatedness, metric completeness, open-cover compactness, quotient completion, selected representatives, selected limits, host metric equality, Lean verification, or bridge checking.

Theorem 9003.2 (Partial metric NameCert obligations)**.** *For every accepted* $\mathsf{PartialMetric}^{\uparrow}$ *carrier*

$$P = (S, X, E, D, L, T, M, K, H, C, Q, N),$$

the local $\mathsf{NameCert}_{\mathsf{PartialMetric}^{\uparrow}}$ *surface consists exactly of the following obligations:*

1. *carrier admission for the source row, point row, self-distance row, directed distance row, small-self-distance comparison row, partial triangle ledger, metric-reflection handoff, completion-facing row, componentwise transport, displayed replay, provenance, and local naming;*
2. *self-distance exposure, requiring every consumer that reads a point row to see the corresponding E row before treating diagonal distance as unavailable or zero;*
3. *partial triangle ledger, requiring each triangle comparison to read T through the displayed self-distance correction rather than through a host metric triangle axiom;*
4. *metric-reflection boundary, requiring every* $\mathsf{Met}^{\uparrow}$ *or* $\mathsf{Pseudometric}^{\uparrow}$ *consumer to pass through M after E, D, L, T have been displayed;*
5. *classifier transport, requiring accepted packets to move only by the componentwise* hsame *row H and the replay row C;*
6. *ledger nonescape, excluding separatedness, metric completeness, open-cover compactness, quotient completion, selected representatives, selected limits, host metric equality, Lean verification, and bridge checking.*

No partial-metric NameCert obligation is stored outside these rows.

Proof. Project the carrier of Definition 9003.1. The tuple lists exactly the source, point, self-distance, directed distance, small-self-distance comparison, partial triangle, metric-reflection, completion, transport, replay, provenance, and local naming rows.

Self-distance exposure is the row E. A consumer cannot erase diagonal distance before reading E, and the comparisons in L keep the small-self-distance boundary visible whenever an off-diagonal distance is inspected.

The partial triangle obligation is the row T. It routes each comparison through the displayed self-distance correction, so the triangle evidence is a finite ledger read rather than a detached metric axiom.

Metric and pseudometric consumers reach the packet only through M, while completion-facing consumers are stopped at K until the displayed source, distance, comparison, and triangle rows

have been consumed. The rows H, C, Q, N then transport, replay, source, and name the same finite surface.

The remaining exclusions follow from the carrier inventory. Since separatedness, metric completeness, open-cover compactness, quotient completion, selected representatives, selected limits, host metric equality, Lean verification, and bridge checking do not occur among the coordinates, none of those data can be exported by the local certificate. □

Theorem 9003.3 (Partial metric self-distance boundary)**.** *Let*

$$P = (S, X, E, D, L, T, M, K, H, C, Q, N)$$

be an accepted $\mathsf{PartialMetric}^{\uparrow}$ *carrier. Every* $\mathsf{Met}^{\uparrow}$ *or* $\mathsf{Pseudometric}^{\uparrow}$ *consumer may read equality-like separation only through the displayed self-distance boundary*

$$X, E, D, L, T \longmapsto M \longmapsto H, C, Q, N.$$

The packet itself never exports quotient point equality, selected representatives, host metric equality, chosen limits, ambient completeness, or a completed quotient carrier.

Proof. Start with an accepted carrier and read the point row X. The self-distance row E and directed distance row D remain visible before any equality-like separation request can be interpreted.

The comparison row L and triangle row T bind the self-distance data to the off-diagonal distance ledger. Thus a consumer sees the partial-metric boundary as displayed finite evidence, not as a quotient equality or a host metric equality.

Only after those rows are displayed does the metric-reflection handoff M become available. The support rows H, C, Q, N transport, replay, source, and name that same boundary for metric and pseudometric readers.

The completion row K does not add selected representatives, chosen limits, ambient completeness, or a completed quotient carrier. Those objects are absent from the coordinate list, so equality-like separation remains scoped to the displayed self-distance boundary. □

Closure status for $\mathsf{NameCert}_{\mathsf{PartialMetric}^{\uparrow}}$**.**

Constructive story: A $\mathsf{PartialMetric}^{\uparrow}$ packet is generated from a source row, a point row, a self-distance row, a directed distance row, a small-self-distance comparison row, a partial triangle ledger, a metric-reflection handoff, a completion-facing row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{PartialMetric}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 9003.1, Definition 9003.2, and Definition 9003.3 seed the constructive partial-metric boundary between premetric, pseudometric, quasi-metric, metric, Real-facing, and completion-facing consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{PartialMetric}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim separatedness, metric completeness, open-cover compactness, quotient completion, selected limits, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, self-distance exposure, partial triangle ledger, metric-reflection boundary, classifier transport, and ledger nonescape for BEDC.Derived.PartialMetricUp.

Chapter 9004

A Concrete Naming Certificate for RegularCauchyLocatedIntervalModulus$^{\uparrow}$

Following Bishop–Bridges regular real practice, the RegularCauchyLocatedIntervalModulus$^{\uparrow}$ packet records the finite route by which located interval endpoint data is read together with a regular Cauchy modulus before any Real-facing seal is consumed. It sits beside the locatedness source of chapter 2216, the modulus source of chapter 1423, the stability source of chapter 1927, the interval source of chapter 1709, the stream window surface of chapter 126, the regular rational readback of chapter 301, the dyadic radius core of chapter 291, and the terminal real-name seal of chapter 38. The packet names only displayed located interval and modulus rows; it does not assert quotient equality of real names, selected representatives, trichotomy, countable choice, or ambient Real$^{\uparrow}$ completeness.

Definition 9004.1 (RegularCauchyLocatedIntervalModulus carrier)**.** *A* RegularCauchyLocatedIntervalModulus$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (I, A, B, M, W, Q, D, E, H, C, P, N)$$

with the following displayed rows:

1. *I is the* LocatedRealInterval$^{\uparrow}$ *interval row, recording the located lower-endpoint and upper-endpoint incidence used by the interval consumer.*
2. *A and B are the endpoint rows, each read through* CauchyLocatedness$^{\uparrow}$ *and tied to the same located interval request.*
3. *M is the* RealCauchyModulus$^{\uparrow}$ *row, recording the finite regular Cauchy modulus budget consumed by the endpoint reads.*
4. *W is the* StreamName$^{\uparrow}$ *window row through which the endpoint names and modulus request are inspected.*
5. *Q is the* RegSeqRat$^{\uparrow}$ *readback row obtained from the displayed endpoint windows and modulus budget.*
6. *D is the* DyadicRatCore$^{\uparrow}$ *radius row, carrying the dyadic tolerance and interval-radius comparisons used by the locatedness test.*
7. *E is the terminal* Real$^{\uparrow}$ *seal row, available only after I, A, B, M, W, Q, D have been displayed.*

8. *H records componentwise* hsame *transport for interval rows, endpoint rows, modulus rows, windows, readback, dyadic radii, Real sealing, replay, provenance, and local naming.*
9. *C records displayed* Cont *replay from a located-interval modulus request through $I, A, B, M, W, Q, D, E, H$.*
10. *P is the* Pkg *provenance over* $\mathsf{RegularCauchyLocatedIntervalModulus}^{\uparrow}$, $\mathsf{CauchyLocatedness}^{\uparrow}$, $\mathsf{RealCauchyModulus}^{\uparrow}$, $\mathsf{RegularCauchyModulusStability}^{\uparrow}$, $\mathsf{LocatedRealInterval}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*
11. *N is the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyLocatedIntervalModulus}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $I, A, B, M, W, Q, D, E, H, C, P, N$. It has no coordinate for host endpoint equality, quotient equality of regular names, selected representatives, trichotomy, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 9004.2 (RegularCauchyLocatedIntervalModulus obligations)**.** *For every accepted* RegularCauchyLocated *carrier*

$$L = (I, A, B, M, W, Q, D, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{RegularCauchyLocatedIntervalModulus}^{\uparrow}}$ *surface consists exactly of carrier admission for the located interval row, the two* $\mathsf{CauchyLocatedness}^{\uparrow}$ *endpoint rows, the* $\mathsf{RealCauchyModulus}^{\uparrow}$ *regular modulus row, the* $\mathsf{RegularCauchyModulusStability}^{\uparrow}$ *stability dependency, the* $\mathsf{StreamName}^{\uparrow}$ *window row, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *radius row, the terminal* $\mathsf{Real}^{\uparrow}$ *seal row, componentwise transport, displayed replay, package provenance, and local naming. Any interval-modulus consumer must read those rows before citing the packet as a located regular Cauchy modulus witness.*

Proof. Project the carrier of Definition 9004.1. The interval and endpoint rows are I, A, B, and they supply the located interval surface through $\mathsf{LocatedRealInterval}^{\uparrow}$ and $\mathsf{CauchyLocatedness}^{\uparrow}$.

Read the modulus and radius rows next. Row M supplies the regular Cauchy budget, the stability dependency keeps that budget attached to the same regular read, and row D records the dyadic radius comparisons used by the locatedness test.

The window and readback rows W, Q turn the endpoint and modulus data into a finite regular rational read. The terminal seal E is downstream of that read and is not an ambient completeness theorem.

Finally replay H, C, P, N. Componentwise transport, displayed continuation, provenance, and local naming preserve the same finite packet. Since no row stores host endpoint equality, quotient equality, selected representatives, trichotomy, choice, or ambient Real completeness, the listed rows exhaust the local obligation surface. □

Falsifiable prediction: Every accepted $\mathsf{RegularCauchyLocatedIntervalModulus}^{\uparrow}$ read exposes located interval endpoint rows, a regular Cauchy modulus row, StreamName windows, RegSeqRat readback, DyadicRatCore radii, a terminal RealUp seal, componentwise hsame transport, Cont replay, Pkg provenance, and local NameCert data before any interval-modulus consumer can cite it.

Independence witness: cauchy-locatedness, realcauchymodulus, regular-cauchy-modulus-stability, located-real-interval, streamname, regseqrat, dyadicratcore, real: $\mathsf{RegularCauchyLocatedIntervalModulus}^{\uparrow}$ is not bijective to any listed sibling because it binds located interval endpoints, regular Cauchy modulus budget, stability dependency, finite windows, regular readback, dyadic radius comparisons, Real sealing, transport, replay, provenance, and local naming in one packet.

Closure status for $\mathsf{NameCert}_{\mathsf{RegularCauchyLocatedIntervalModulus}^{\uparrow}}$.

Constructive story: A RegularCauchyLocatedIntervalModulus$^{\uparrow}$ packet is generated from located interval endpoint rows, a regular Cauchy modulus row, a stability dependency, StreamName windows, RegSeqRat readback, DyadicRatCore radius comparisons, a RealUp seal, hsame transport, Cont replay, Pkg provenance, and local NameCert rows.

Theory closure: TheoryGate(NameCert$_{\text{RegularCauchyLocatedIntervalModulus}^{\uparrow}}$, seed)

Scope closed: Definition 9004.1, Definition 9004.2, the falsifiable prediction, and the independence witness seed the finite located-interval regular-modulus route over endpoint, modulus, window, readback, radius, seal, transport, replay, provenance, and local naming rows.

Formal verification: FormalStatus(NameCert$_{\text{RegularCauchyLocatedIntervalModulus}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close Real completeness, quotient equality of regular names, selected representatives, trichotomy, countable choice, host endpoint equality, Lean verification, axiom-clean audit, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, endpoint locatedness, regular Cauchy modulus stability, StreamName window admission, RegSeqRat readback, DyadicRatCore radius exactness, Real seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.RegularCauchyLocatedIntervalModulusUp.

Chapter 9005

A Concrete Naming Certificate for $\mathsf{BishopCauchyReblocking}^{\uparrow}$

Following Bishop and Bridges on regular Cauchy real names, the $\mathsf{BishopCauchyReblocking}^{\uparrow}$ packet records the finite L10 handoff by which a displayed regular rational Cauchy name is reblocked before a real-name consumer may inspect its endpoint. It sits beside the general reblocking carrier of chapter 7649, the finite stream windows of chapter 126, the regular rational readback of chapter 301, the dyadic tolerance ledger of chapter 291, and the terminal real-name seal of chapter 38. The packet names only the finite displayed rows of the Bishop-style reblocking route; it does not assert quotient equality of real names, selected limits, countable choice, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 9005.1 (BishopCauchyReblocking carrier)**.** *A* $\mathsf{BishopCauchyReblocking}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (R, W, K, T, D, L, H, C, P, N)$$

with the following displayed rows:

1. *R is the source* $\mathsf{RegSeqRat}^{\uparrow}$ *row whose regular Cauchy readings are being reblocked.*
2. *W is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row exposing the source observations consumed by the reblocking schedule.*
3. *K is the finite block schedule row, listing the displayed block endpoints and their monotone order.*
4. *T is the Bishop tail-control row, assigning each L10 tolerance request to a displayed block after which all later reads remain inside the required dyadic bound.*
5. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, recording the dyadic radii, comparisons, and arithmetic cells used by T.*
6. *L is the L10 handoff row, stating that a Real-facing consumer may read the reblocked name only after R, W, K, T, D are visible.*
7. *H records componentwise* hsame *transport for the source, window, schedule, tail-control, tolerance, handoff, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from a tolerance request through $R, W, K, T, D, L, H, P, N$.*
9. *P is the* Pkg *provenance over* $\mathsf{BishopCauchyReblocking}^{\uparrow}$, $\mathsf{CauchyReblocking}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

10. N is the local $\mathsf{NameCert}_{\mathsf{BishopCauchyReblocking}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $R, W, K, T, D, L, H, C, P, N$. No coordinate stores a completed real, a quotient representative, a selected limit, a countable-choice schedule, or ambient completeness of $\mathsf{Real}^{\uparrow}$.

Theorem 9005.2 (BishopCauchyReblocking NameCert obligations)**.** *For every accepted* $\mathsf{BishopCauchyReblocking}^{\uparrow}$ *carrier $B = (R, W, K, T, D, L, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{BishopCauchyReblocking}^{\uparrow}}$ *surface consists exactly of carrier admission, regular-source preservation, finite-window exposure, block-schedule exactness, Bishop tail-control exactness, dyadic tolerance readback, L10 handoff gating, transport, replay, provenance, and local naming. A downstream* $\mathsf{Real}^{\uparrow}$ *consumer may inspect the reblocked name only through those rows and receives no quotient equality, selected endpoint, countable choice, trichotomy branch, or ambient real completeness principle.*

Lean4 ✓ `BEDC.Derived.BishopCauchyReblockingUp.BishopCauchyReblockingCarrier namecert obligations`

Proof. Project the carrier of Definition 9005.1. The rows $R, W, K, T, D, L, H, C, P, N$ display the source regular sequence, finite stream window, block schedule, tail control, dyadic tolerance ledger, L10 handoff, transport, replay, provenance, and local naming.

Regular-source preservation and finite-window exposure are forced by R and W. The reblocking schedule cannot be read until the same source observations have been displayed through the stream-name row.

Block-schedule exactness and Bishop tail-control exactness are supplied by K and T. The dyadic row D records the tolerance cells used by the tail control, and the handoff row L requires those displayed rows before any Real-facing read.

The remaining rows transport, replay, cite, and name the same route. Since the carrier has no coordinate for a completed endpoint, quotient representative, selected limit, choice schedule, trichotomy branch, or ambient completeness theorem, the listed rows exhaust the local NameCert obligations. □

Theorem 9005.3 (BishopCauchyReblocking L10 handoff)**.** *Every L10-facing read exported by an accepted* $\mathsf{BishopCauchyReblocking}^{\uparrow}$ *carrier factors through*

$$R, W, K, T, D, L, H, C, P, N.$$

Thus the handoff to $\mathsf{Real}^{\uparrow}$ *is a finite Bishop-style reblocking of the source* $\mathsf{RegSeqRat}^{\uparrow}$ *row through a displayed* $\mathsf{StreamName}^{\uparrow}$ *window, finite block schedule, dyadic tolerance ledger, componentwise transport, replay, provenance, and local naming. It is not a separate completion, selected host limit, quotient equality of Cauchy names, or countable-choice principle.*

Proof. Start with an accepted carrier $B = (R, W, K, T, D, L, H, C, P, N)$. The only source of rational Cauchy data is R, and the only displayed observations of that source are exposed by W.

The block schedule K and tail-control row T choose the finite reblocking route for each L10 tolerance request. The dyadic tolerance row D records the comparisons consumed by that route, and the handoff row L blocks a Real-facing read until the route is visible.

Transport and replay through H and C preserve the same rows, while P and N record provenance and local naming. Therefore every L10-facing read factors through the stated finite packet and cannot acquire an independent completion or selected endpoint. □

Falsifiable prediction: An accepted $\mathsf{BishopCauchyReblocking}^{\uparrow}$ read is refuted if it reaches a $\mathsf{Real}^{\uparrow}$ seal without displaying the $\mathsf{RegSeqRat}^{\uparrow}$ source row, $\mathsf{StreamName}^{\uparrow}$ finite window, finite block schedule, Bishop tail-control row, $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance ledger, L10 handoff row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert evidence.

Independence witness: cauchy-reblocking, streamname, regseqrat, dyadicratcore, real: BishopCauchyReblocking is not bijective to any listed sibling because it binds a regular rational source, finite stream window, block schedule, Bishop tail-control row, dyadic tolerance ledger, and L10 handoff gate into one Real-facing NameCert packet.

Closure status for $\mathsf{NameCert}_{\mathsf{BishopCauchyReblocking}^{\uparrow}}$.

Constructive story: A $\mathsf{BishopCauchyReblocking}^{\uparrow}$ packet is generated from a RegSeqRat source row, StreamName finite window, finite block schedule, Bishop tail-control row, DyadicRatCore tolerance ledger, L10 handoff row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BishopCauchyReblocking}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 9005.1, Definition 9005.2, and Definition 9005.3 seed the finite Bishop-style Cauchy reblocking handoff before any Real seal is consumed.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BishopCauchyReblocking}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient equality of Cauchy names, selected limits, countable choice, trichotomy, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, regular-source preservation, finite-window exposure, block-schedule exactness, Bishop tail-control exactness, dyadic tolerance readback, L10 handoff gating, transport, replay, provenance, and local naming for BEDC.Derived.BishopCauchyReblockingUp.

Chapter 9006

A Concrete Naming Certificate for $\mathsf{PrimeSkewDefectLedger}^{\uparrow}$

The $\mathsf{PrimeSkewDefectLedger}^{\uparrow}$ packet realizes the prime-skew boundary-defect route of chapter 9249 as finite NameCert data. It records an accepted off-line zero packet, a displayed prime-visible skew row, boundary-defect readback, zero-defect incompatibility, refusal, transport, replay, provenance, and local naming. The packet consumes the prime-spectral fingerprint carrier of chapter 9000 through row Q before exposing the boundary-defect ledger. The packet is a falsifiable carrier for the route; it does not prove RH, construct zeta zeros, import complex analysis beyond displayed rows, or identify a global prime-spectral object.

The ledger consumes the prime-skew boundary packet of chapter 8848, the prime spectral fingerprint of chapter 9000, and the prime carrier of chapter 64 before its off-line-zero refusal row is public.

Definition 9006.1 (PrimeSkewDefectLedger carrier)**.** *A* $\mathsf{PrimeSkewDefectLedger}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$D = (Z, P, B, I, F, H, C, Q, R, N)$$

with the following displayed rows:

1. *Z is the accepted off-line zero packet row, carrying the displayed* $\mathsf{OffLineZero}$ *source data.*
2. *P is the prime-visible skew row, recording the displayed* $\mathsf{PrimeSkew}$ *evidence attached to the zero packet.*
3. *B is the boundary-defect ledger row, listing the local boundary layers on which the prime-visible skew is read.*
4. *I is the zero-defect incompatibility row, recording that an accepted non-trivial zero atom cannot coexist with the displayed boundary defect.*
5. *F is the falsifiable refusal row, declaring that an accepted off-line zero packet with no displayed prime-skew row refutes this carrier.*
6. *H records componentwise* hsame *transport for the zero, skew, boundary-defect, incompatibility, refusal, replay, provenance, and local naming rows.*
7. *C records displayed* Cont *replay from the off-line zero packet through the prime-skew row, boundary-defect row, incompatibility row, refusal row, transport row, provenance row, and local naming row.*

8. *Q is the prime-spectral fingerprint row, naming the displayed fingerprint consumed by the ledger without claiming a complete spectral reconstruction.*
9. *R is the* Pkg *provenance over* $\mathsf{PrimeSkewDefectLedger}^{\uparrow}$, $\mathsf{PrimeSpectralFingerprint}^{\uparrow}$, $\mathsf{Prime}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{PrimeSkewDefectLedger}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $Z, P, B, I, F, H, C, Q, R, N$. It has no coordinate for an unshown zero, a hidden prime-skew witness, a chosen complex-analytic model, a critical-line oracle, or an ambient proof of RH.

Lean4 (statement) `BEDC.Derived.PrimeSkewDefectLedgerUp`

Theorem 9006.2 (PrimeSkewDefectLedger NameCert obligations)**.** *For every accepted* $\mathsf{PrimeSkewDefectLedger}^{\uparrow}$ *carrier $D = (Z, P, B, I, F, H, C, Q, R, N)$, the local* $\mathsf{NameCert}_{\mathsf{PrimeSkewDefectLedger}^{\uparrow}}$ *surface consists exactly of off-line zero admission, prime-skew display, boundary-defect ledger exposure, zero-defect incompatibility, falsifiable refusal, componentwise transport, displayed replay, prime-spectral fingerprint citation, provenance, and local naming. The chapter therefore packages the off-line zero, prime-visible skew, and local-global defect incompatibility rows as one finite ledger without claiming the Riemann Hypothesis.*

Proof. Project the carrier of Definition 9006.1. Its rows display the off-line zero packet, prime-visible skew, boundary-defect ledger, zero-defect incompatibility, falsifiable refusal, transport, replay, fingerprint, provenance, and local naming.

The zero row Z cannot be accepted alone. The prime-skew row P and boundary-defect row B expose the local-global defect route, while I records the incompatibility used by the refutation interface.

The refusal row F makes the carrier falsifiable: if an accepted off-line zero packet omits a displayed prime-skew row, the packet is outside the ledger. The rows H, C, Q, R, N transport, replay, cite, source, and name the same finite evidence.

Since no coordinate stores a hidden zero, chosen analytic model, critical-line oracle, or proof of RH, the listed rows exhaust the local NameCert obligations. □

Theorem 9006.3 (PrimeSkewDefectLedger falsifiable boundary)**.** *Any accepted off-line zero packet that lacks a displayed prime-skew row refutes the* $\mathsf{PrimeSkewDefectLedger}^{\uparrow}$ *carrier. Equivalently, every accepted ledger route from Z to the boundary-defect row must pass through*

$$Z, P, B, I, F, H, C, Q, R, N$$

before the local NameCert surface may be read.

Proof. Read an accepted carrier $D = (Z, P, B, I, F, H, C, Q, R, N)$. The source zero packet is Z, but the carrier admits it only as part of the ten-row ledger.

The prime-skew row P is the required displayed witness connecting the off-line zero packet to the boundary-defect ledger B. The incompatibility row I and refusal row F then state the boundary at which the ledger can be falsified.

Transport, replay, fingerprint citation, provenance, and local naming pass through H, C, Q, R, N. Therefore a zero packet without P cannot be an accepted $\mathsf{PrimeSkewDefectLedger}^{\uparrow}$ packet; it refutes the carrier surface rather than supplying a hidden route. □

Falsifiable prediction: Any accepted off-line zero packet with no displayed PrimeSkew row refutes the $\mathsf{PrimeSkewDefectLedger}^{\uparrow}$ chapter.

Independence witness: prime, zeta, complex, critical-line-witness, prime-spectral-fingerprint: $\mathsf{PrimeSkewDefectLedger}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries off-line zero admission, prime-skew display, boundary-defect ledger exposure, zero-defect incompatibility, falsifiable refusal, transport, replay, prime-spectral fingerprint citation, provenance, and local naming as one finite packet.

The Lean follow-up for this chapter must provide `Nontrivial` and `FieldFaithful` instances in `lean4/BEDC/Derived/PrimeSkewDefectLedgerUp/TasteGate.lean`; the present marker records the carrier name that the TasteGate file will inhabit.

Closure status for $\mathsf{NameCert}_{\mathsf{PrimeSkewDefectLedger}^{\uparrow}}$.

Constructive story: A $\mathsf{PrimeSkewDefectLedger}^{\uparrow}$ packet is generated from off-line zero admission, prime-skew display, boundary-defect ledger exposure, zero-defect incompatibility, falsifiable refusal, componentwise hsame transport, displayed Cont replay, prime-spectral fingerprint citation, Pkg provenance, and local NameCert rows.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{PrimeSkewDefectLedger}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 9006.1, Definition 9006.2, and Definition 9006.3 seed the finite carrier for the off-line zero, prime-visible skew, and defect-incompatibility route.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{PrimeSkewDefectLedger}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not prove RH, construct zeta zeros, close complex analysis, provide critical-line witnesses, complete the prime-spectral fingerprint, claim Lean TasteGate coverage, or bridge check the route.

Upgrade path: Obligation closure requires checked off-line zero admission, prime-skew display, boundary-defect ledger exposure, zero-defect incompatibility, falsifiable refusal, transport, replay, fingerprint citation, provenance, local naming, and the required Nontrivial and FieldFaithful TasteGate instances for BEDC.Derived.PrimeSkewDefectLedgerUp.

Chapter 9007

A Concrete Naming Certificate for $\mathsf{RegularSequenceSubsequence}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{RegularSequenceSubsequence}^{\uparrow}$ packet records the finite route by which a regular sequence remains regular after a displayed increasing subsequence schedule is read. It sits over the regular-sequence source of chapter 5965, the finite observation windows of chapter 126, the rational readback surface of chapter 301, the dyadic tolerance ledger of chapter 291, and the terminal real-name boundary of chapter 38. The packet names only the subsequence-stability route; it does not choose a host subsequence, identify quotient sequence names, import countable choice, or assert ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 9007.1 (RegularSequenceSubsequence carrier)**.** *A* $\mathsf{RegularSequenceSubsequence}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$R = (S, W, K, D, Q, E, H, C, P, N)$$

with the following displayed rows:

1. *S is the* $\mathsf{RegularSequenceSpace}^{\uparrow}$ *source row, retaining the source regular-sequence classifier and its admitted observation windows.*
2. *W is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row, recording the source observations from which the subsequence is read.*
3. *K is the increasing subsequence schedule row. It records finite monotone index windows and does not select an infinite host function outside the packet.*
4. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row, carrying the dyadic budget used to compare source and subsequence windows.*
5. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row, exposing the regular rational observations of the selected windows.*
6. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row consumed by Real-facing or Completion-facing readers after S, W, K, D, Q have been displayed.*
7. *H records componentwise* hsame *transport for source, stream-window, subsequence schedule, dyadic tolerance, rational readback, Real seal, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from a subsequence request through S, W, K, D, Q, E, H.*

9. *P is the* Pkg *provenance over* $\mathsf{RegularSequenceSubsequence}^{\uparrow}$, $\mathsf{RegularSequenceSpace}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{RegularSequenceSubsequence}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $S, W, K, D, Q, E, H, C, P, N$. It has no coordinate for a host subsequence selector, quotient sequence equality, selected limit, countable choice, or ambient completeness.

Theorem 9007.2 (RegularSequenceSubsequence NameCert obligations)**.** *For every accepted* RegularSequenceSubse *carrier*

$$R = (S, W, K, D, Q, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{RegularSequenceSubsequence}^{\uparrow}}$ *surface consists exactly of source regular-sequence admission, finite StreamName window exposure, increasing subsequence schedule display, dyadic tolerance readback, RegSeqRat rational readback, terminal Real seal nonescape, componentwise* hsame *transport, displayed* Cont *replay, package provenance, and local naming. Each obligation is read through the finite route*

$$\mathsf{RegularSequenceSpace}^{\uparrow} \longmapsto \mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{DyadicRatCore}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}.$$

Proof. Project the carrier of Definition 9007.1. The source row S and finite-window row W are the only rows from which a subsequence request may begin.

The schedule row K records monotone finite index windows, while D supplies the dyadic comparison budget for those windows. Thus a subsequence consumer receives a displayed finite route rather than a host-selected infinite map.

The rational readback row Q is downstream of S, W, K, D, and the Real seal row E is downstream of Q. Componentwise transport through H and replay through C preserve that order, while P, N record provenance and local naming.

Since the tuple contains no coordinate for quotient sequence equality, selected limits, countable choice, host subsequence selectors, or ambient completeness, no NameCert obligation can be discharged outside the displayed packet rows. □

Theorem 9007.3 (RegularSequenceSubsequence regularity preservation)**.** *Let $R = (S, W, K, D, Q, E, H, C, P, N)$ be an accepted* $\mathsf{RegularSequenceSubsequence}^{\uparrow}$ *carrier. Every* $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, *or completion-facing consumer that reads the subsequence as regular must first expose the* $\mathsf{RegularSequenceSpace}^{\uparrow}$ *source row S, the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row W, the increasing schedule row K, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row D, and the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row Q. Therefore regularity preservation is a finite readback route from the source regular sequence to the subsequence seal, not a host theorem about arbitrary subsequences.*

Proof. Start with the obligation surface of Definition 9007.2. It places S, W, K, D, Q before every Real-facing or completion-facing read of the subsequence.

The source regularity is read from $\mathsf{RegularSequenceSpace}^{\uparrow}$ through S, and the observed subsequence windows are read through $\mathsf{StreamName}^{\uparrow}$ and K. The dyadic row D supplies the tolerance budget that makes the selected windows compatible with the regular rational readback.

Finally the $\mathsf{RegSeqRat}^{\uparrow}$ row Q exposes the rational regularity data before the terminal $\mathsf{Real}^{\uparrow}$ seal E can be consumed. The support rows H, C, P, N transport, replay, package, and name that same finite route, so they cannot add a host subsequence selector, quotient equality, selected limit, countable choice, or ambient completeness principle. □

Closure status for $\mathsf{NameCert}_{\mathsf{RegularSequenceSubsequence}^{\uparrow}}$.

Constructive story: A $\mathsf{RegularSequenceSubsequence}^{\uparrow}$ packet is generated from a RegularSequenceSpace source row, StreamName finite windows, an increasing subsequence schedule, DyadicRatCore tolerances, RegSeqRat readback, a Real seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RegularSequenceSubsequence}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 9007.1, Definition 9007.2, and Definition 9007.3 seed the finite subsequence-stability route over RegularSequenceSpaceUp, StreamNameUp, RegSeqRatUp, DyadicRatCoreUp, RealUp, BHist, hsame, Cont, Pkg, and NameCert rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RegularSequenceSubsequence}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim a host subsequence selector, quotient sequence equality, selected limits, countable choice, Lean verification, bridge checking, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Upgrade path: Obligation closure requires checked source admission, finite-window exposure, subsequence-schedule display, dyadic tolerance readback, RegSeqRat rational readback, Real-seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.RegularSequenceSubsequenceUp.

Chapter 9008

A Concrete Naming Certificate for $\mathsf{EventualMap}^{\uparrow}$

Following Kelley and Bourbaki on eventual maps of directed sets and filters, the $\mathsf{EventualMap}^{\uparrow}$ packet records the finite route by which a tail-indexed source surface is transported into a target tail surface. It sits over the directed-index substrate of chapter 1607, the Moore–Smith subnet route of chapter 5098, the Frechet filter boundary of chapter 1564, the filter-base surface of chapter 1601, the finite stream windows of chapter 126, and the regular rational readback of chapter 301. The chapter names eventuality only as displayed cofinal-tail data; it does not import host functions, quotient filters, selected representatives, or countable choice.

Definition 9008.1 (EventualMapUp carrier)**.** *An* $\mathsf{EventualMap}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$E = (S, T, M, C, W, R, H, K, P, N)$$

with the following displayed rows:

1. *S is the source tail row, naming the inspected directed-set, filter-base, or stream-index tail requests on the domain side.*
2. *T is the target tail row, naming the inspected directed-set, filter-base, or stream-index tail requests on the codomain side.*
3. *M is the monotone eventual-map row, recording only the displayed comparisons showing that target-tail refinement pulls source-tail requests forward.*
4. *C is the cofinal ledger, assigning to each displayed target tail a source tail whose image is eventually inside it.*
5. *W is the finite-window pullback row, recording the pulled-back StreamName and RegSeqRat windows used by Real and Completion consumers.*
6. *R is the readback row, exposing the target-side observation only after S, T, M, C, W have been displayed.*
7. *H records componentwise* hsame *transport for source tails, target tails, monotone-eventual comparisons, cofinal ledgers, finite-window pullbacks, readbacks, replay, provenance, and local naming.*
8. *K records displayed* Cont *replay from every eventual-map request through $S, T, M, C, W, R, H, P, N$.*

9. *P is the* Pkg *provenance over* $\mathsf{EventualMap}^{\uparrow}$, $\mathsf{DirectedSet}^{\uparrow}$, $\mathsf{MooreSmithSubnet}^{\uparrow}$, $\mathsf{FrechetFilter}^{\uparrow}$, $\mathsf{FilterBase}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{EventualMap}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these ten rows. It has no coordinate for equality of host functions, selected representatives of filters or nets, quotient filters, choice-indexed cofinal maps, or an ambient eventual-equality relation outside the displayed BHist *packet.*

Theorem 9008.2 (EventualMapUp NameCert obligations)**.** *For every accepted* $\mathsf{EventualMap}^{\uparrow}$ *carrier*

$$E = (S, T, M, C, W, R, H, K, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{EventualMap}^{\uparrow}}$ *surface consists exactly of these finite obligations:*

1. *carrier admission for source-tail data, target-tail data, monotone eventual-map comparisons, the cofinal ledger, finite-window pullbacks, readback, transport, replay, provenance, and local naming;*
2. *monotone exactness, requiring every exported refinement comparison to be a displayed row of M between addresses already named by S and T;*
3. *cofinal exactness, requiring each target-tail request to read its source-tail witness through the ledger C before any downstream consumer can use it;*
4. *tail-window pullback stability, requiring the window row W to preserve the same StreamName and RegSeqRat request under the displayed tail pullback;*
5. *readback handoff, requiring R to expose the target-side observation only after S, T, M, C, W are visible;*
6. *transport and replay stability under H and K, with no hidden row added by structural replay;*
7. *provenance exhaustion through P, N, so the packet is sourced and locally named exactly as an* $\mathsf{EventualMap}^{\uparrow}$ *carrier;*
8. *refusal of host function equality, selected representatives, quotient filters, countable choice, and ambient eventual-equality predicates.*

Proof. Project the carrier of Definition 9008.1. The source and target tail rows are S and T, while the monotone eventual-map comparisons and cofinal witnesses are M and C.

The window and readback rows are downstream. The row W records finite pullbacks of the displayed StreamName and RegSeqRat windows, and R reads the target observation only after the pulled-back tail data have been exposed.

The structural rows H, K, P, N preserve this route componentwise. They transport, replay, source, and name the same finite packet, so they cannot add host function equality, selected representatives, quotient filters, a choice-indexed cofinal map, or an ambient eventual-equality predicate. □

Theorem 9008.3 (EventualMapUp composition handoff)**.** *Let*

$$E_{01} = (S_0, S_1, M_{01}, C_{01}, W_{01}, R_{01}, H_{01}, K_{01}, P_{01}, N_{01})$$

and

$$E_{12} = (S_1', S_2, M_{12}, C_{12}, W_{12}, R_{12}, H_{12}, K_{12}, P_{12}, N_{12})$$

be accepted EventualMap$^{\uparrow}$ *packets whose middle tail rows agree through a displayed* hsame *transport. Their composite is exported only by reading the shared finite cofinal ledgers* C_{01}, C_{12} *and the visible tail-window pullbacks* W_{01}, W_{12}*. No composition step may replace those rows by host function composition, quotient-filter equality, a selected subnet representative, or countable choice.*

Proof. First expose the middle-tail agreement. The only bridge between the target row of E_{01} and the source row of E_{12} is the displayed hsame transport on the middle tail surface.

Next read the cofinal data in order. A final target-tail request is pulled back through C_{12} to a middle-tail request and then through C_{01} to a source-tail request. The monotone rows M_{12} and M_{01} supply only the displayed refinement comparisons needed for this two-step pullback.

Finally compose the finite windows. The rows W_{12} and W_{01} carry the visible StreamName and RegSeqRat pullbacks, and the readback rows R_{12} and R_{01} remain downstream of those windows. Transport, replay, provenance, and local naming preserve the same finite ledgers, so no host-level composition or choice principle is available. □

Closure status for $\mathsf{NameCert}_{\mathsf{EventualMap}^{\uparrow}}$**.**

Constructive story: An EventualMap$^{\uparrow}$ packet is generated from source and target tail rows, monotone eventual-map comparisons, a cofinal ledger, finite-window pullbacks, readback, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{EventualMap}^{\uparrow}}$, seed)

Scope closed: Definition 9008.1, Definition 9008.2, and Definition 9008.3 seed the finite eventual-map interface for directed tails, filters, StreamName windows, and RegSeqRat readbacks.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{EventualMap}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close host function equality, selected subnet or filter representatives, quotient filters, countable choice, ambient eventual equality, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, monotone exactness, cofinal exactness, tail-window pullback stability, readback handoff, transport, replay, provenance, and local naming for BEDC.Derived.EventualMapUp.

Chapter 9009

A Concrete Naming Certificate for $\mathsf{OrliczSpace}^{\uparrow}$

Following Orlicz and the classical presentations of Krasnoselskii–Rutickii and Rao–Ren, the $\mathsf{OrliczSpace}^{\uparrow}$ packet records the Luxemburg-gauge construction of an Orlicz function space as displayed BEDC NameCert data. It sits after the functional-analysis carrier of chapter 94, the norm ledger of chapter 89, the measure carrier of chapter 92, the terminal real-name seal of chapter 38, and the vector-space surface of chapter 47. The packet names only the finite rows by which a Young-function ledger, measurable-function row, modular readback, Luxemburg gauge, vector operations, transport, replay, provenance, and local NameCert are exposed; it does not import a host Banach-space object, quotient representatives, selected almost-everywhere classes, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 9009.1 (Orlicz space carrier)**.** *An* $\mathsf{OrliczSpace}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$O = (A, \Phi, M, F, I, L, V, R, H, C, P, N)$$

with the following displayed rows:

1. *A is the measure-domain row. It records the measurable source and its* $\mathsf{Measure}^{\uparrow}$ *NameCert route.*
2. *Φ is the Young-function row. It displays the convex growth ledger, null-at-zero read, and finite real-valued comparison data used by the modular.*
3. *M is the measurable-function admission row. It records the function names inspected by the packet and keeps their measurable status visible before any norm read.*
4. *F is the finite real-readback row. It routes every scalar comparison through* $\mathsf{Real}^{\uparrow}$ *and the local functional-analysis surface.*
5. *I is the modular row. It records the displayed integral-read of $\Phi(|f|)$ as a measure-facing ledger, not as a host integral over quotient classes.*
6. *L is the Luxemburg-gauge row. It records the finite scale test for the value*

$$\inf\{\lambda > 0 : I(f/\lambda) \leq 1\}$$

only through displayed positive-scale and modular rows.

7. *V is the vector-space row. It records addition and scalar multiplication requests as* $\mathsf{VecSpace}^{\uparrow}$ *reads that preserve* A, Φ, M, F, I, L.
8. *R is the norm-readback row. It names the* $\mathsf{Norm}^{\uparrow}$ *consumer route through the Luxemburg gauge and exposes no external Banach-space completion.*
9. *H records componentwise* hsame *transport for domain, Young-function, measurable-function, real-readback, modular, Luxemburg-gauge, vector-space, norm-readback, replay, provenance, and local naming rows.*
10. *C records displayed* Cont *replay from a consumer request through* $A, \Phi, M, F, I, L, V, R, H, P, N$.
11. *P is the* Pkg *provenance over* $\mathsf{OrliczSpace}^{\uparrow}$, $\mathsf{FunctionalAnalysis}^{\uparrow}$, $\mathsf{Norm}^{\uparrow}$, $\mathsf{Measure}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{VecSpace}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
12. *N is the local* $\mathsf{NameCert}_{\mathsf{OrliczSpace}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $A, \Phi, M, F, I, L, V, R, H, C, P, N$. *It has no coordinate for quotient measurable-function classes, selected representatives, countable choice, host almost-everywhere equality, Banach-space completeness, Lean verification, or bridge checking.*

Theorem 9009.2 (Orlicz space NameCert obligations)**.** *For every accepted* $\mathsf{OrliczSpace}^{\uparrow}$ *carrier*

$$O = (A, \Phi, M, F, I, L, V, R, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{OrliczSpace}^{\uparrow}}$ *surface consists exactly of the following obligations:*

1. *carrier admission for the measure-domain row, Young-function row, measurable-function row, finite real-readback row, modular row, Luxemburg-gauge row, vector-space row, norm-readback row, componentwise transport, displayed replay, provenance, and local naming;*
2. *modular exposure, requiring each consumer of a Luxemburg value to first read* A, Φ, M, F, I;
3. *positive-scale visibility, requiring the row L to display the finite positive-scale tests used by the Luxemburg gauge before any* $\mathsf{Norm}^{\uparrow}$ *readback is exported;*
4. *vector-operation stability, requiring V to keep addition and scalar multiplication inside the same* A, Φ, M, F, I, L *route;*
5. *norm-reader boundary, requiring every* $\mathsf{Norm}^{\uparrow}$ *or functional-analysis consumer to pass through R after the modular and vector rows have been displayed;*
6. *ledger nonescape, excluding quotient measurable-function classes, selected representatives, countable choice, host almost-everywhere equality, Banach-space completeness, Lean verification, and bridge checking.*

No Orlicz-space NameCert obligation is stored outside these rows.

Proof. Project the carrier of Definition 9009.1. The tuple lists exactly the domain, Young-function, measurable-function, real-readback, modular, Luxemburg-gauge, vector-space, norm-readback, transport, replay, provenance, and local naming rows.

The modular obligation is the row I. It can be read only after A, Φ, M, F are displayed, so the integral expression remains a measure-facing ledger over named functions and real comparisons.

The Luxemburg obligation is the row L. Its positive-scale tests are displayed finite reads of the modular row, hence a norm consumer cannot replace them by a host infimum over quotient representatives.

The vector and norm-reader obligations are the rows V and R. They keep addition, scalar multiplication, and $\mathsf{Norm}^{\uparrow}$ readback attached to the same modular route, while H, C, P, N transport, replay, source, and name that route.

The remaining exclusions follow from the carrier inventory. Since quotient measurable-function classes, selected representatives, countable choice, host almost-everywhere equality, Banach-space completeness, Lean verification, and bridge checking do not occur among the coordinates, none of those data can be exported by the local certificate. □

Theorem 9009.3 (Orlicz space Luxemburg route)**.** *Every* $\mathsf{Norm}^{\uparrow}$, $\mathsf{FunctionalAnalysis}^{\uparrow}$, *or vector-space consumer of an accepted* $\mathsf{OrliczSpace}^{\uparrow}$ *packet must read the Luxemburg gauge through the displayed route*

$$A, \Phi, M, F, I \longmapsto L \longmapsto V, R, H, C, P, N.$$

Thus the norm-facing value is a local NameCert route through measure data, Young-function data, finite real readback, modular exposure, and positive-scale tests. It is not a host quotient-space norm, selected almost-everywhere representative, countable-choice family of scales, ambient Banach-space completion, or external $\mathsf{Real}^{\uparrow}$ *completeness theorem.*

Proof. Start with an accepted carrier and expose A, Φ, M, F, I. These rows display the measure source, Young-function ledger, admitted measurable functions, real comparisons, and modular read before a Luxemburg request is available.

Read the Luxemburg row L. It records the positive-scale test surface over the modular row, so the gauge remains a finite route through the displayed carrier rather than an external norm formula.

The vector row V and norm-readback row R are downstream of L. They let vector-space and norm consumers inspect the same route, while H, C, P, N preserve componentwise transport, replay, provenance, and local naming.

The refused endpoints are absent from the carrier. Therefore a consumer can receive only the displayed Luxemburg route and cannot extract quotient representatives, selected almost-everywhere classes, countable-choice scales, Banach-space completion, or ambient $\mathsf{Real}^{\uparrow}$ completeness. □

Closure status for $\mathsf{NameCert}_{\mathsf{OrliczSpace}^{\uparrow}}$.

Constructive story: An $\mathsf{OrliczSpace}^{\uparrow}$ packet is generated from a measure-domain row, a Young-function row, a measurable-function row, finite real readback, a modular row, a Luxemburg-gauge row, a vector-space row, a norm-readback row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{OrliczSpace}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 9009.1, Definition 9009.2, and Definition 9009.3 seed the Orlicz-space route from measure and Young-function data to Luxemburg-gauge norm readback.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{OrliczSpace}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim quotient measurable-function classes, selected representatives, countable choice, host almost-everywhere equality, Banach-space completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, modular exposure, positive-scale visibility, vector-operation stability, norm-reader boundary, transport, replay, provenance, and local naming for BEDC.Derived.OrliczSpaceUp.

Chapter 9010

A Concrete Naming Certificate for DyadicMeshRefinement$^{\uparrow}$

Following Bishop and Bridges on constructive interval refinements, the DyadicMeshRefinement$^{\uparrow}$ packet records the finite route by which one dyadic mesh is refined before any regular-Cauchy or Real-facing consumer reads the resulting windows. It sits over the dyadic arithmetic core of chapter 291, the finite stream-window discipline of chapter 126, the regular rational readback surface of chapter 301, and the terminal real-name seal of chapter 38. The packet names only finite mesh-refinement data; it does not assert quotient interval equality, select a limiting point, prove Real completeness, supply open-cover compactness, or exhibit a standard bridge.

Definition 9010.1 (Dyadic mesh refinement carrier)**.** *A* DyadicMeshRefinement$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M = (G, R, E, K, B, D, H, C, P, N)$$

with the following displayed rows:

1. *G is the parent dyadic grid row, read through* DyadicRatCore$^{\uparrow}$ *endpoints and mesh widths.*
2. *R is the refinement grid row, whose cells are again dyadic and whose indexing is exposed by finite* StreamName$^{\uparrow}$ *windows.*
3. *E is the endpoint-preservation row, recording that the first and last endpoints of the refinement are the displayed parent endpoints.*
4. *K is the cell-containment row, assigning each refinement cell to a displayed parent cell without quotienting intervals by host equality.*
5. *B is the mesh-bound comparison row, comparing the refinement mesh width with the parent bound through dyadic arithmetic.*
6. *D is the dyadic tolerance readback row, carrying the requested tolerance to the* RegSeqRat$^{\uparrow}$ *and* Real$^{\uparrow}$ *consumers that inspect refined windows.*
7. *H records componentwise* hsame *transport for the parent grid, refinement grid, endpoint, containment, mesh-bound, tolerance, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from a consumer request through parent-grid inspection, refinement-grid inspection, endpoint preservation, cell containment, mesh-bound comparison, and dyadic tolerance readback.*

9. *P is the* Pkg *provenance over* $\mathsf{DyadicMeshRefinement}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{DyadicMeshRefinement}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $G, R, E, K, B, D, H, C, P, N$. It has no coordinate for quotient interval equality, selected limiting data, ambient real completeness, open-cover compactness, or bridge checking.

Theorem 9010.2 (Dyadic mesh refinement NameCert obligations)**.** *For every accepted* $\mathsf{DyadicMeshRefinement}^{\uparrow}$ *carrier $M = (G, R, E, K, B, D, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{DyadicMeshRefinement}^{\uparrow}}$ *surface consists exactly of carrier admission, parent dyadic-grid exposure, refinement-grid exposure, endpoint preservation, refinement-cell containment in parent cells, mesh-bound comparison, dyadic tolerance readback, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming.*

Every regular-Cauchy or Real-facing consumer must read the finite route from $\mathsf{DyadicRatCore}^{\uparrow}$ *through* $\mathsf{StreamName}^{\uparrow}$ *windows and* $\mathsf{RegSeqRat}^{\uparrow}$ *readback before it reaches the terminal* $\mathsf{Real}^{\uparrow}$ *seal. The route exports no quotient interval equality, selected limit, Real completeness, open-cover compactness, or standard bridge.*

Proof. Project the accepted carrier. The tuple displays exactly the parent grid G, refinement grid R, endpoint row E, containment row K, mesh-bound row B, dyadic tolerance row D, transport row H, replay row C, provenance row P, and local naming row N.

Endpoint preservation and cell containment are read from E and K. These rows compare displayed dyadic endpoints and finite cells, so the refinement is witnessed by $\mathsf{DyadicRatCore}^{\uparrow}$ arithmetic rather than by host interval equality.

The mesh-bound and tolerance rows B, D are the only route to a regular rational or Real-facing read. A consumer therefore passes through the finite $\mathsf{StreamName}^{\uparrow}$ windows and $\mathsf{RegSeqRat}^{\uparrow}$ readback before using the $\mathsf{Real}^{\uparrow}$ seal.

The support rows H, C, P, N transport, replay, package, and name that same finite route. Since no row carries quotient intervals, selected limiting data, Real completeness, open-cover compactness, or bridge evidence, none of those data are exported by the local certificate. □

Theorem 9010.3 (Dyadic mesh refinement sibling route)**.** *Every accepted* $\mathsf{DyadicMeshRefinement}^{\uparrow}$ *read used by interval, regular-Cauchy, compact-net, or Real-facing arguments factors through the sibling chain*

$$\mathsf{DyadicRatCore}^{\uparrow} \longmapsto \mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}.$$

The parent and refinement grids are dyadic rows, the inspected windows are $\mathsf{StreamName}^{\uparrow}$ *rows, the rational observations are* $\mathsf{RegSeqRat}^{\uparrow}$ *rows, and the terminal seal is a* $\mathsf{Real}^{\uparrow}$ *row. No consumer may bypass this chain by importing quotient interval equality, a selected limit, ambient real completeness, open-cover compactness, or a standard bridge.*

Proof. Start with the carrier of Definition 9010.1. The parent grid, refinement grid, endpoint preservation, containment, and mesh-bound comparison are all dyadic rows, so the first sibling dependency is chapter 291.

The refinement is read through finite windows before regular rational observations are consumed. Thus the next two dependencies are the $\mathsf{StreamName}^{\uparrow}$ surface of chapter 126 and the $\mathsf{RegSeqRat}^{\uparrow}$ readback surface of chapter 301.

Finally the Real-facing consumer reads only the terminal seal named by chapter 38. The obligation surface of Definition 9010.2 keeps all support rows inside H, C, P, N, so the sibling route

cannot export quotient intervals, selected limits, Real completeness, open-cover compactness, or bridge evidence. □

Closure status for $\mathsf{NameCert}_{\mathsf{DyadicMeshRefinement}^{\uparrow}}$.

Constructive story: A $\mathsf{DyadicMeshRefinement}^{\uparrow}$ packet is generated from a parent dyadic grid, a refinement grid, endpoint preservation, refinement-cell containment, mesh-bound comparison, dyadic tolerance readback, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{DyadicMeshRefinement}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 9010.1, Definition 9010.2, and Definition 9010.3 seed the finite dyadic refinement route over DyadicRatCoreUp, StreamNameUp, RegSeqRatUp, RealUp, BHist, hsame, Cont, Pkg, and NameCert rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{DyadicMeshRefinement}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim quotient interval equality, selected limits, Real completeness, open-cover compactness, Lean verification, bridge checking, or a standard bridge.

Upgrade path: Obligation closure requires checked carrier admission, endpoint preservation, cell containment, mesh-bound comparison, dyadic tolerance readback, transport/replay/provenance stability, and sibling-route non-escape for BEDC.Derived.DyadicMeshRefinementUp.

Chapter 9011

A Concrete Naming Certificate for $\mathsf{TraceClassOperator}^{\uparrow}$

Following Reed and Simon, the $\mathsf{TraceClassOperator}^{\uparrow}$ packet records the standard trace-class operator surface as finite BEDC naming data. It sits over the Hilbert-space carrier of chapter 91, the bounded-linear-operator row of chapter 1644, the operator-ideal route of chapter 213, the spectral-measure window of chapter 298, the terminal Real row of chapter 38, and the regular rational readback of chapter 301. The packet names only the displayed trace-class route through Hilbert, bounded-operator, ideal, spectral, Real, and rational rows; it does not assert compact-operator completeness, Schatten duality, arbitrary spectral integration, choice of an eigenbasis, host Hilbert-space separability, or ambient operator-algebra completeness.

Definition 9011.1 (TraceClassOperator carrier)**.** *A* $\mathsf{TraceClassOperator}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$T = (H, B, I, S, R, Q, A, X, C, P, N)$$

with the following displayed rows:

1. *H is the* $\mathsf{Hilbert}^{\uparrow}$ *source row, retaining the inner-product, norm, completion, and local naming data visible to the packet.*
2. *B is the* $\mathsf{BoundedLinearOperator}^{\uparrow}$ *row, exposing a bounded operator over the same Hilbert source.*
3. *I is the* $\mathsf{OperatorIdeal}^{\uparrow}$ *row, recording the ideal-membership route through which the bounded operator is inspected.*
4. *S is the* $\mathsf{SpectralMeasure}^{\uparrow}$ *window row, available only as a finite spectral readback surface and not as unrestricted functional calculus.*
5. *R is the* $\mathsf{Real}^{\uparrow}$ *trace-value row, carrying the terminal real-number seal for trace reads.*
6. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *rational approximation row used to display finite trace windows before the Real seal is consumed.*
7. *A records the finite trace-window admission row tying B, I, S, Q, R to one inspected trace-class request.*
8. *X records componentwise* hsame *transport for $H, B, I, S, R, Q, A, C, P, N$.*
9. *C records displayed* Cont *replay from a trace-class query through the Hilbert, bounded-operator, ideal, spectral, rational, Real, and admission rows.*

10. *P is the* Pkg *provenance over* TraceClassOperator$^\uparrow$, Hilbert$^\uparrow$, BoundedLinearOperator$^\uparrow$, OperatorIdeal$^\uparrow$, SpectralMeasure$^\uparrow$, Real$^\uparrow$, RegSeqRat$^\uparrow$, BHist, hsame, Cont, *and* NameCert *rows.*
11. *N is the local* NameCert$_{\text{TraceClassOperator}^\uparrow}$ *row.*

The classifier compares accepted packets only through $H, B, I, S, R, Q, A, X, C, P, N$. It has no coordinate for arbitrary eigenbasis choice, full compact-operator theory, unrestricted spectral integration, Schatten duality, host trace-norm completion, or ambient operator-algebra completeness.

Lean4 (statement) `BEDC.Derived.TraceClassOperatorUp`

Theorem 9011.2 (TraceClassOperator NameCert obligations)**.** *For every accepted* TraceClassOperator$^\uparrow$ *carrier*

$$T = (H, B, I, S, R, Q, A, X, C, P, N),$$

the local NameCert$_{\text{TraceClassOperator}^\uparrow}$ *surface consists exactly of Hilbert-source admission, bounded-operator admission, operator-ideal membership, finite spectral-window readback, rational trace approximation, terminal Real seal, finite trace-window admission, componentwise* hsame *transport, displayed* Cont *replay, package provenance, and local naming.*

Proof. Project the carrier of Definition 9011.1. The Hilbert row H is the source for the inner-product and norm data, while B is the only bounded-operator row exposed by the packet.

The ideal row I and spectral row S are read before any trace value is consumed. They place the inspected operator inside the finite operator-ideal and spectral-window routes rather than inside an ambient compact-operator algebra.

The rational trace row Q supplies the finite approximation surface, and the Real row R is visible only after Q and the trace-window admission row A have been displayed. Thus the trace read is a finite route through H, B, I, S, Q, R, A.

Finally X, C, P, N transport, replay, source, and name the same route. Since the tuple contains no coordinate for eigenbasis choice, unrestricted spectral integration, Schatten duality, trace-norm completion, or ambient operator-algebra completeness, the listed rows exhaust the local NameCert obligations. □

Theorem 9011.3 (TraceClassOperator finite trace window)**.** *Every Real-valued trace read exported by an accepted* TraceClassOperator$^\uparrow$ *packet first exposes the* Hilbert$^\uparrow$ *source row, the* BoundedLinearOperator$^\uparrow$ *boundedness row, the* OperatorIdeal$^\uparrow$ *membership row, the* SpectralMeasure$^\uparrow$ *finite-window row, and the* RegSeqRat$^\uparrow$ *rational trace approximation row. The exported trace is therefore a finite NameCert window into a trace-class request, not a host theorem about arbitrary compact operators, spectral decompositions, or operator-algebra completions.*

Proof. Start with the NameCert obligations of Definition 9011.2. They place the Hilbert, bounded-operator, ideal, spectral, rational, Real, and admission rows before any public trace read.

The finite trace-window row A binds the bounded operator B to the ideal route I and the spectral readback S. The rational row Q then exposes the finite trace approximation consumed by the Real row R.

Componentwise transport and replay preserve that same row order. A downstream spectral, quantum-state, or operator-ideal consumer therefore receives only $H, B, I, S, Q, R, A, X, C, P, N$ and cannot read arbitrary eigenbasis choice, unrestricted spectral integration, Schatten duality, trace-norm completion, or compact-operator completeness from the packet. □

Closure status for NameCert$_{\text{TraceClassOperator}^\uparrow}$.

Constructive story: A TraceClassOperator$^{\uparrow}$ packet is generated from Hilbert, bounded-linear-operator, operator-ideal, spectral-measure, Real, RegSeqRat, finite trace-window, transport, replay, provenance, and local NameCert rows.

Theory closure: TheoryGate(NameCert$_{\mathsf{TraceClassOperator}\uparrow}$, seed)

Scope closed: Definition 9011.1, Definition 9011.2, and Definition 9011.3 seed the finite trace-class operator route over HilbertUp, BoundedLinearOperatorUp, OperatorIdealUp, SpectralMeasureUp, RealUp, RegSeqRatUp, BHist, hsame, Cont, Pkg, and NameCert rows.

Formal verification: FormalStatus(NameCert$_{\mathsf{TraceClassOperator}\uparrow}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim compact-operator completeness, Schatten duality, arbitrary spectral integration, eigenbasis choice, host Hilbert-space separability, Lean verification, bridge checking, or ambient operator-algebra completeness.

Upgrade path: Obligation closure requires checked Hilbert-source admission, bounded-operator admission, operator-ideal membership, finite spectral-window readback, rational trace approximation, Real-seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.TraceClassOperatorUp.

Chapter 9012

A Concrete Naming Certificate for $\mathsf{RegularVariation}^{\uparrow}$

Following Karamata and Bingham–Goldie–Teugels, the $\mathsf{RegularVariation}^{\uparrow}$ packet records regular variation as finite asymptotic-comparison data rather than as a completed function space. It sits after the $\mathsf{Real}^{\uparrow}$ seal of chapter 38, the regular rational readback of chapter 301, the slowly varying sibling row of chapter 6724, and the dyadic tolerance discipline of chapter 291. The packet gives later asymptotic comparison chapters a named BEDC carrier while refusing ambient real completeness, quotient equality of real-valued streams, and host-selected limits.

Definition 9012.1 (Regular variation carrier)**.** *A* $\mathsf{RegularVariation}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Q = (S, L, R, M, O, H, C, P, N)$$

with the following displayed rows:

1. *S is the positive* $\mathsf{Real}^{\uparrow}$ *scale stream whose inspected windows are exposed before any ratio comparison is read;*
2. *L is the slowly varying sibling row inherited from* $\mathsf{NameCert}_{\mathsf{SlowlyVaryingSequence}^{\uparrow}}$*;*
3. *R is the ratio-window readback row comparing the displayed values of S against the slowly varying component over the same finite window;*
4. *M records multiplication and division provenance through the visible* $\mathsf{Real}^{\uparrow}$ *algebra rows and the regular-rational readback supplied by* $\mathsf{RegSeqRat}^{\uparrow}$*;*
5. *O is the eventual order and tolerance comparison row, measured through dyadic and rational windows rather than by an ambient order oracle;*
6. *H records componentwise* hsame *transport for scale, slowly varying, ratio, algebra, order, replay, provenance, and local naming rows;*
7. *C records displayed* Cont *replay from the scale stream through the ratio and order windows;*
8. *P is the* Pkg *provenance over* $\mathsf{RegularVariation}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{SlowlyVaryingSequence}^{\uparrow}$*,* $\mathsf{Rat}^{\uparrow}$*,* $\mathsf{Order}^{\uparrow}$*,* BHist*,* hsame*,* Cont*,* Pkg*, and* $\mathsf{NameCert}$*;*
9. *N is the local* $\mathsf{NameCert}_{\mathsf{RegularVariation}^{\uparrow}}$ *row.*

The local classifier compares accepted packets only through $S, L, R, M, O, H, C, P, N$.

Theorem 9012.2 (Regular variation NameCert obligations)**.** *The local* $\mathsf{NameCert}_{\mathsf{RegularVariation}^{\uparrow}}$ *surface consists exactly of carrier admission for* $Q = (S, L, R, M, O, H, C, P, N)$*, positive* $\mathsf{Real}^{\uparrow}$ *scale exposure through* S*, slowly varying sibling exposure through* L*, ratio-window readback through* R*, visible real algebra provenance through* M*, eventual order and tolerance comparison through* O*, componentwise* hsame *transport through* H*, displayed* Cont *replay through* C*,* Pkg *provenance through* P*, and local naming through* N*.*

Every Real or regular-sequence consumer must read the sibling routes of chapter 6724, chapter 301, and chapter 38 before it treats the packet as a regular-variation comparison. The certificate exports no host function space, no quotient stream equality, no selected real limit, no countable-choice selection of eventual bounds, and no ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the accepted packet. The scale stream, slowly varying row, ratio readback, algebra provenance, order comparison, transport, replay, provenance, and local name are the only visible coordinates.

Read the dependency rows in order. The slowly varying component is supplied by the sibling certificate, the regular rational windows provide finite readback, and the terminal $\mathsf{Real}^{\uparrow}$ seal is reached only after those displayed rows and the algebra provenance have been exposed.

Since the carrier has no coordinate for host functions, quotient stream equality, selected limits, countable choice, or ambient Real completeness, the listed rows exhaust the local NameCert obligation surface. □

Falsifiable prediction: A purported $\mathsf{RegularVariation}^{\uparrow}$ consumer is refuted if it reads a regular-variation ratio without displaying the positive RealUp scale stream, slowly varying row, ratio-window readback, real-algebra provenance, eventual order comparison, transport, replay, provenance, and local NameCert rows.

Independence witness: slowly-varying-sequence, regseqrat, real, dyadicratcore: the slowly varying sibling lacks the positive scale and ratio-window rows, RegSeqRatUp supplies regular rational readback without the asymptotic classifier, RealUp supplies the terminal seal without eventual comparison data, and DyadicRatCoreUp supplies tolerance rows without the regular-variation carrier. None is bijective to $\mathsf{RegularVariation}^{\uparrow}$.

Closure status for $\mathsf{NameCert}_{\mathsf{RegularVariation}^{\uparrow}}$**.**

Constructive story: A $\mathsf{RegularVariation}^{\uparrow}$ packet is generated from a positive RealUp scale stream, a slowly varying sibling row, ratio-window readback, real-algebra provenance, eventual order and tolerance comparison, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{RegularVariation}^{\uparrow}}$, seed)

Scope closed: Definition 9012.1 and Definition 9012.2 seed the finite regular-variation NameCert surface over RealUp, RegSeqRatUp, SlowlyVaryingSequenceUp, RatUp, OrderUp, BHist, hsame, Cont, Pkg, and NameCert rows.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{RegularVariation}^{\uparrow}}$, unformalized)

Bridge status: none

Origin: human

Not claimed: This chapter does not close Lean verification, ambient RealUp completeness, quotient equality of real-valued streams, selected host limits, countable-choice eventual bounds, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, ratio-window exactness, real-algebra provenance, eventual order comparison, transport, replay, provenance, and local naming for BEDC.Derived.RegularVariationUp.

Chapter 9013

A Concrete Naming Certificate for HyperbolicSectorOverlapLedger$^{\uparrow}$

The HyperbolicSectorOverlapLedger$^{\uparrow}$ packet realizes the sector-overlap branch of chapter 9463 as finite observer-expansion data. It sits beside the sector envelope of chapter 8546, the sector expansion packet of chapter 8685, the boundary-shadow transport route of chapter 6678, and the four-point metric discipline of chapter 6862. The carrier names overlap only through displayed sector, shadow, radius, observer-window, transport, replay, provenance, and local NameCert rows.

Definition 9013.1 (Hyperbolic sector-overlap ledger carrier)**.** *A* HyperbolicSectorOverlapLedger$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Q = (A, B, V, W, O, U, H, C, P, N)$$

with the following displayed rows:

1. *A is the sector aperture row inherited from the sector-envelope and sector-expansion siblings;*
2. *B is the boundary-shadow row that records the boundary face inspected by the overlap comparison;*
3. *V is the visual-radius row measured through the existing hyperbolic visual and Gromov-metric readback routes;*
4. *W is the observer-window provenance row, naming the finite observer-expansion window in which the sector is read;*
5. *O is the overlap witness row, displaying the two sector windows and the finite boundary-shadow intersection data;*
6. *U is the TasteGate-facing row requiring Lean* Nontrivial HyperbolicSectorOverlapLedger$^{\uparrow}$ *and* FieldFaithful HyperbolicSectorOverlapLedger$^{\uparrow}$ *instances for the same displayed carrier fields;*
7. *H records componentwise* hsame *transport for aperture, boundary shadow, visual radius, overlap witness, observer window, TasteGate-facing evidence, replay, provenance, and local naming rows;*
8. *C records displayed* Cont *replay from sector aperture through boundary shadow, visual radius, observer window, and overlap witness;*

9. *P is the* Pkg *provenance over* $\mathsf{HyperbolicSectorOverlapLedger}^{\uparrow}$, $\mathsf{HyperbolicSectorEnvelope}^{\uparrow}$, $\mathsf{HyperbolicSectorExpar}$ $\mathsf{HyperbolicBoundaryShadowTransport}^{\uparrow}$, $\mathsf{GromovHyperbolicMetric}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* NameCert*;*

10. *N is the local* $\mathsf{NameCert}_{\mathsf{HyperbolicSectorOverlapLedger}^{\uparrow}}$ *row.*

The local classifier compares accepted packets only through $A, B, V, W, O, U, H, C, P, N$.

Theorem 9013.2 (Hyperbolic sector-overlap ledger NameCert obligations)**.** *The local* $\mathsf{NameCert}_{\mathsf{HyperbolicSectorOverlap}}$ *surface consists exactly of carrier admission for $Q = (A, B, V, W, O, U, H, C, P, N)$, sector-aperture exposure through A, boundary-shadow exposure through B, visual-radius readback through V, observer-window provenance through W, overlap-witness exposure through O, TasteGate-facing nontriviality and field-faithfulness obligations through U, componentwise* hsame *transport through H, displayed* Cont *replay through C,* Pkg *provenance through P, and local naming through N.*

Every observer-expansion consumer must read the sibling routes of chapter 8546, chapter 8685, chapter 6678, and chapter 6862 before it treats an overlap row as accepted. The packet exports no completed hyperbolic boundary, no selected global sector, no host geometric intersection theorem, no physical observer law, and no ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the accepted packet. The aperture, boundary shadow, visual radius, observer window, overlap witness, TasteGate-facing row, transport, replay, provenance, and local name are exactly the visible coordinates.

Read the sibling routes in order. The sector envelope supplies the aperture surface, sector expansion supplies the expansion comparison, boundary-shadow transport supplies the transported shadow row, and the Gromov hyperbolic metric supplies the finite metric discipline for visual-radius readback.

The TasteGate-facing row records the Lean obligation to provide Nontrivial and FieldFaithful instances preserving the same fields. Since no carrier coordinate stores a completed boundary, selected global sector, host intersection theorem, physical observer law, or ambient Real completeness principle, the displayed rows exhaust the NameCert surface. □

Falsifiable prediction: An accepted $\mathsf{HyperbolicSectorOverlapLedger}^{\uparrow}$ read is refuted if an observer-expansion consumer obtains a sector-overlap witness without displaying sector aperture, boundary shadow, visual radius, observer-window provenance, overlap witness, TasteGate-facing nontriviality and field-faithfulness rows, hsame transport, Cont replay, Pkg provenance, and local NameCert data.

Independence witness: hyperbolic-sector-envelope, hyperbolic-sector-expansion, hyperbolic-boundary-shadow-transport, gromov-hyperbolic-metric: the envelope sibling lacks an overlap witness, the expansion sibling lacks the two-sector ledger, the boundary-shadow transport sibling lacks sector aperture comparison, and the Gromov metric sibling supplies metric discipline without observer-sector overlap provenance. None is bijective to $\mathsf{HyperbolicSectorOverlapLedger}^{\uparrow}$.

Closure status for $\mathsf{NameCert}_{\mathsf{HyperbolicSectorOverlapLedger}^{\uparrow}}$**.**

Constructive story: A $\mathsf{HyperbolicSectorOverlapLedger}^{\uparrow}$ packet is generated from sector aperture, boundary-shadow, visual-radius, observer-window provenance, overlap-witness, TasteGate-facing nontriviality and field-faithfulness, hsame transport, Cont replay, Pkg provenance, and local naming rows.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{HyperbolicSectorOverlapLedger}^{\uparrow}}$, seed)

Scope closed: Definition 9013.1 and Definition 9013.2 seed the finite sector-overlap ledger over the hyperbolic sector envelope, sector expansion, boundary-shadow transport, Gromov metric, BHist, hsame, Cont, Pkg, and NameCert rows.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{HyperbolicSectorOverlapLedger}^{\uparrow}}$, unformalized)

Bridge status: none

Origin: ai

Not claimed: This chapter does not close Lean verification, a completed hyperbolic boundary, selected global sectors, host geometric intersection, physical observer dynamics, ambient RealUp completeness, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, sector-aperture exposure, boundary-shadow and visual-radius readback, overlap-witness exactness, observer-window provenance, TasteGate Nontrivial and FieldFaithful instances, transport, replay, provenance, and local naming for BEDC.Derived.HyperbolicSectorOverlapLedgerUp.

Chapter 9014

A Concrete Naming Certificate for $\mathsf{BishopSequenceSpace}^{\uparrow}$

Following Bishop and Bridges on sequence spaces over constructive real names, the $\mathsf{BishopSequenceSpace}^{\uparrow}$ packet records the finite L10 route by which a displayed stream-indexed family of regular rational names is read as a sequence-space object before any completion or Real-facing consumer inspects the terminal seal. It sits over the finite schedule of chapter 126, the regular rational readback of chapter 301, the dyadic tolerance ledger of chapter 291, the source route of chapter 5965, and the terminal real-name seal of chapter 38. The packet names only displayed sequence-space rows; it does not assert quotient equality of real sequences, selected pointwise representatives, countable choice, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 9014.1 (BishopSequenceSpace carrier)**.** *A* $\mathsf{BishopSequenceSpace}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (S, R, D, Q, E, H, C, P, N)$$

with the following displayed rows:

1. *S is the* $\mathsf{StreamName}^{\uparrow}$ *schedule row, listing the finite sequence indices, precision requests, and observation windows opened by the consumer.*
2. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row, assigning each displayed window the regular rational data read from the scheduled sequence entry.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, recording the dyadic radii, comparisons, and finite arithmetic cells used to compare the scheduled reads.*
4. *Q is the* $\mathsf{RegularSequenceSpace}^{\uparrow}$ *source route, exposing the sequence-space admission row consumed by the Bishop packet.*
5. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row, available only after S, R, D, Q have been displayed.*
6. *H records componentwise* hsame *transport for the schedule, readback, tolerance, source-route, seal, replay, provenance, and local naming rows.*
7. *C records displayed* Cont *replay from a sequence-space request through S, R, D, Q, E, H.*
8. *P is the* Pkg *provenance over* $\mathsf{BishopSequenceSpace}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegularSequenceSpace}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
9. *N is the local* $\mathsf{NameCert}_{\mathsf{BishopSequenceSpace}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $S, R, D, Q, E, H, C, P, N$. It has no coordinate for quotient equality of real sequences, selected pointwise representatives, countable-choice schedules, trichotomy branches, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 9014.2 (BishopSequenceSpace NameCert obligations)**.** *For every accepted* $\mathsf{BishopSequenceSpace}^{\uparrow}$ *carrier*

$$B = (S, R, D, Q, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{BishopSequenceSpace}^{\uparrow}}$ *surface consists exactly of finite StreamName scheduling through S, RegSeqRat readback through R, DyadicRatCore tolerance accounting through D, RegularSequenceSpace source admission through Q, terminal Real sealing through E, componentwise* hsame *transport through H, displayed* Cont *replay through C,* Pkg *provenance through P, and local naming through N.*

Proof. Project the carrier of Definition 9014.1. The schedule row S, readback row R, tolerance row D, source-route row Q, and seal row E are visible before the structural rows are consumed.

Read the sequence-space route in order. The $\mathsf{StreamName}^{\uparrow}$ row opens only the finite windows requested by the consumer, $\mathsf{RegSeqRat}^{\uparrow}$ reads those windows as regular rational data, and $\mathsf{DyadicRatCore}^{\uparrow}$ records the displayed tolerance comparisons.

The $\mathsf{RegularSequenceSpace}^{\uparrow}$ row supplies the source sequence-space admission, and the terminal $\mathsf{Real}^{\uparrow}$ seal is downstream of that finite route. The structural rows H, C, P, N transport, replay, source, and name the same packet.

Since the carrier contains no quotient sequence equality, selected representative, choice schedule, trichotomy branch, or ambient completeness coordinate, the listed rows exhaust the local NameCert surface. □

Theorem 9014.3 (BishopSequenceSpace Stream-RegSeq-Real scope)**.** *Every completion-facing or Real-facing read of an accepted* $\mathsf{BishopSequenceSpace}^{\uparrow}$ *carrier must pass through the finite route*

$$S \longmapsto R \longmapsto D \longmapsto Q \longmapsto E \longmapsto H, C, P, N.$$

Thus the consumer receives a StreamName schedule, RegSeqRat readback, DyadicRatCore tolerance ledger, RegularSequenceSpace source route, terminal Real seal, componentwise transport, replay, provenance, and local naming. It receives no quotient stream, selected pointwise representative, countable choice, trichotomy branch, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start with an accepted carrier $B = (S, R, D, Q, E, H, C, P, N)$. A completion-facing read can inspect only the displayed schedule, readback, tolerance, source-route, seal, transport, replay, provenance, and local naming rows.

Apply the NameCert obligation theorem of Definition 9014.2. It forces the read through S, R, D, Q, E before the structural rows can export the packet to a downstream consumer.

The structural rows do not add new analytic content. Componentwise hsame transport, displayed Cont replay, Pkg provenance, and local $\mathsf{NameCert}$ naming preserve the same finite route from StreamName windows to the Real seal.

Therefore every public read is scoped to the StreamName, RegSeqRat, DyadicRatCore, RegularSequenceSpace, and Real rows named in the statement, and the excluded quotient, representative, choice, trichotomy, and completeness surfaces are unavailable. □

Falsifiable prediction: Every accepted $\mathsf{BishopSequenceSpace}^{\uparrow}$ completion-facing read exposes a StreamName schedule, RegSeqRat readback, DyadicRatCore tolerance ledger, RegularSequenceSpace source route, RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert data before a downstream consumer reads the terminal seal.

Independence witness: streamname, regseqrat, dyadicratcore, regular-sequence-space, real: $\mathsf{BishopSequenceSpace}^{\uparrow}$ is not bijective to any listed sibling because it binds schedule windows, regular rational readback, tolerance arithmetic, sequence-space source admission, Real sealing, transport, replay, provenance, and local naming in one finite packet.

Closure status for $\mathsf{NameCert}_{\mathsf{BishopSequenceSpace}^{\uparrow}}$.

Constructive story: A $\mathsf{BishopSequenceSpace}^{\uparrow}$ packet is generated from a StreamName schedule, RegSeqRat readback, DyadicRatCore tolerance ledger, RegularSequenceSpace source route, RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BishopSequenceSpace}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 9014.1, Definition 9014.2, and Definition 9014.3 seed the finite Bishop sequence-space route from displayed stream windows through regular rational readback and dyadic tolerance accounting to the Real seal.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BishopSequenceSpace}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient equality of real sequences, selected pointwise representatives, countable choice, trichotomy, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, axiom-clean audit, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, StreamName scheduling, RegSeqRat readback, DyadicRatCore tolerance exactness, RegularSequenceSpace source routing, Real-seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.BishopSequenceSpaceUp.

Chapter 9015

A Concrete Naming Certificate for $\mathsf{BishopRegularCompletionObserver}^{\uparrow}$

Following Bishop and Bridges on constructive real completion, the $\mathsf{BishopRegularCompletionObserver}^{\uparrow}$ packet records the finite observer surface by which a regular Cauchy rational name is read through a displayed modulus, dyadic tolerance, sequence-space row, and terminal Real seal. It sits over the finite window discipline of chapter 126, the rational readback of chapter 301, the dyadic tolerance core of chapter 291, the sequence-space route of chapter 5965, and the value-facing boundary of chapter 38. The observer names only displayed regular-completion rows; it does not add quotient stream equality, selected representatives, countable choice, trichotomy, host completion, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 9015.1 (Bishop regular completion observer carrier)**.** *A* $\mathsf{BishopRegularCompletionObserver}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$O = (S, R, D, M, W, E, H, C, P, N)$$

with the following displayed rows:

1. *S is the* $\mathsf{StreamName}^{\uparrow}$ *observation-window row, listing the finite windows opened by the observer.*
2. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row served from those windows.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row naming the requested precision scale.*
4. *M is the regular-modulus row, recording the displayed window bound that witnesses the regular Cauchy condition at tolerance D.*
5. *W is the* $\mathsf{RegularSequenceSpace}^{\uparrow}$ *membership row tying the observed readback to the sequence-space carrier.*
6. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal reached only after S, R, D, M, W remain visible together.*
7. *H records componentwise* hsame *transport for observation windows, regular readback, dyadic tolerance, modulus, sequence-space membership, Real seal, replay, provenance, and local naming.*
8. *C records displayed* Cont *replay from an observer request through the same finite rows.*
9. *P is the* Pkg *provenance over* $\mathsf{BishopRegularCompletionObserver}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegularSequenceSpace}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{BishopRegularCompletionObserver}^{\uparrow}}$ *row.*

The carrier has no coordinate for quotient stream equality, selected representative streams, countable choice, hidden tail selection, trichotomy, host completion equality, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 9015.2 (Bishop regular completion observer NameCert obligations)**.** *For every accepted* $\mathsf{BishopRegularCompletionObserver}^{\uparrow}$ *carrier*

$$O = (S, R, D, M, W, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{BishopRegularCompletionObserver}^{\uparrow}}$ *surface consists exactly of carrier admission for the displayed packet, finite* $\mathsf{StreamName}^{\uparrow}$ *observation windows,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance, regular-modulus evidence,* $\mathsf{RegularSequenceSpace}^{\uparrow}$ *membership, terminal* $\mathsf{Real}^{\uparrow}$ *sealing, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. No obligation row may replace this observer surface by quotient stream equality, selected representatives, countable choice, trichotomy, host completion, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the carrier of Definition 9015.1. The rows S, R, D, M, W, E are the observer-facing data, while H, C, P, N preserve transport, replay, provenance, and local naming.

The finite observation row S opens the windows that make R visible as regular rational readback. The dyadic row D fixes the tolerance request, and the modulus row M records the displayed regular Cauchy bound for that request.

The sequence-space row W and terminal seal E keep the readback route attached to $\mathsf{RegularSequenceSpace}^{\uparrow}$ before any Real-facing consumer reads it. The structural rows H, C, P, N can only transport, replay, source, and name this same packet.

Since no carrier coordinate stores quotient equality, selected representatives, countable choice, hidden tail selection, trichotomy, host completion equality, or ambient completeness, the listed rows exhaust the NameCert obligations. □

Theorem 9015.3 (Bishop regular completion observer regularity window)**.** *Every Real-facing consumer of an accepted* $\mathsf{BishopRegularCompletionObserver}^{\uparrow}$ *carrier must expose the observation row* S*, regular rational readback* R*, dyadic tolerance row* D*, regular-modulus row* M*, sequence-space row* W*, and Real seal* E *before reading the value-facing boundary. Thus the observer's completion read is a finite regularity-window route through StreamName, RegSeqRat, DyadicRatCore, RegularSequenceSpace, and Real rows, not a quotient or host-completion principle.*

Proof. Start with an accepted observer packet. The Real-facing boundary is E, but E is downstream of the finite rows S, R, D, M, W in the carrier.

The window row S and regular readback row R display the inspected rational name. The dyadic tolerance row D and modulus row M display the regularity budget at the requested precision scale.

The sequence-space row W attaches this budgeted readback to $\mathsf{RegularSequenceSpace}^{\uparrow}$ before the terminal $\mathsf{Real}^{\uparrow}$ seal is consumed. Transport, replay, provenance, and local naming preserve that same finite route through H, C, P, N.

Therefore any consumer that skips S, R, D, M, W is outside the accepted carrier. The observer exports a regularity-window certificate and no quotient equality, representative selector, choice schedule, hidden tail, trichotomy, host completion, or ambient completeness. □

Falsifiable prediction: Any accepted $\mathsf{BishopRegularCompletionObserver}^{\uparrow}$ Real-facing read that reaches the terminal seal without displaying a StreamName window, RegSeqRat readback, DyadicRatCore tolerance, regular-modulus row, and RegularSequenceSpace membership refutes the carrier.

Independence witness: streamname, regseqrat, dyadicratcore, regularsequencespace, real: BishopRegularComple is not bijective to any listed sibling because it jointly carries observation windows, regular rational readback, dyadic tolerance, modulus evidence, sequence-space membership, Real sealing, transport, replay, provenance, and local naming as one observer packet.

Closure status for $\mathsf{NameCert}_{\mathsf{BishopRegularCompletionObserver}^{\uparrow}}$.

Constructive story: A $\mathsf{BishopRegularCompletionObserver}^{\uparrow}$ packet is generated from finite StreamName observation windows, RegSeqRat readback, DyadicRatCore tolerance, regular-modulus evidence, RegularSequenceSpace membership, Real sealing, hsame transport, Cont replay, Pkg provenance, and local NameCert rows.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BishopRegularCompletionObserver}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 9015.1, Definition 9015.2, Definition 9015.3, the falsifiable prediction, and the independence witness seed the finite regular-completion observer surface.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BishopRegularCompletionObserver}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close Lean verification, quotient stream equality, selected representatives, countable choice, hidden tail choice, trichotomy, host completion equality, ambient $\mathsf{Real}^{\uparrow}$ completeness, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, observation-window exactness, regular rational readback, dyadic tolerance stability, modulus determinacy, sequence-space membership, Real-seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.BishopRegularCompletionObserverUp.

Chapter 9016

A Concrete Naming Certificate for $\mathsf{DedekindSplitTowerLiftBoundary}^{\uparrow}$

The $\mathsf{DedekindSplitTowerLiftBoundary}^{\uparrow}$ packet realizes the boundary side of section 9413.67 as finite NameCert data. It records only displayed q-split Dedekind lift rows, local split-prime energy, tower provenance, zeta and number-field sources, refusal, transport, replay, and local naming. It sits beside the zeta carrier of chapter 71, the prime carrier of chapter 64, the number-field carrier of chapter 168, the Dedekind carrier of chapter 172, and the prime-spectral fingerprint of chapter 9000. The packet is a boundary certificate for visible lift rows; it does not construct Dedekind cuts, form quotient completions, prove RH, assert analytic continuation, or internalize an infinite tower.

Definition 9016.1 (Dedekind split-tower lift boundary carrier)**.** *A* $\mathsf{DedekindSplitTowerLiftBoundary}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (Z, P, K, D, E, F, Q, H, C, G, N)$$

with the following displayed rows:

1. *Z is the* $\mathsf{ZetaBasic}^{\uparrow}$ *source row naming the visible Riemann zeta read being routed into the lift boundary.*
2. *P is the* $\mathsf{Prime}^{\uparrow}$ *split-prime row naming the displayed rational prime q and the finite split-prime windows inspected by the packet.*
3. *K is the* $\mathsf{NumField}^{\uparrow}$ *tower-source row naming the displayed number-field levels and Galois-route data consumed by the boundary.*
4. *D is the* $\mathsf{Dedekind}^{\uparrow}$ *read row naming the displayed Dedekind zeta read at the inspected tower levels.*
5. *E is the split-prime energy row, recording only displayed normal-energy terms for the listed prime-ideal rows.*
6. *F is the refusal row: an off-route Dedekind lift row with no displayed split-prime energy is rejected by the carrier.*
7. *Q is the* $\mathsf{PrimeSpectralFingerprint}^{\uparrow}$ *handoff row, naming the prime-local response fingerprint consumed by the boundary without claiming a spectral classification.*

8. *H records componentwise* hsame *transport for zeta, prime, number-field, Dedekind, energy, refusal, fingerprint, replay, provenance, and local naming rows.*
9. *C records displayed* Cont *replay through the same finite route.*
10. *G is the* Pkg *provenance over* $\mathsf{DedekindSplitTowerLiftBoundary}^{\uparrow}$, $\mathsf{ZetaBasic}^{\uparrow}$, $\mathsf{Prime}^{\uparrow}$, $\mathsf{NumField}^{\uparrow}$, $\mathsf{Dedekind}^{\uparrow}$, $\mathsf{PrimeSpectralFingerprint}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{DedekindSplitTowerLiftBoundary}^{\uparrow}}$ *row.*

The carrier has no coordinate for a Dedekind-cut real, quotient completion, selected tower limit, analytic-continuation proof, RH proof object, hidden prime-ideal family, or ambient spectral theorem.

Theorem 9016.2 (Dedekind split-tower lift boundary NameCert obligations)**.** *For every accepted* $\mathsf{DedekindSplitTowerLiftBoundary}^{\uparrow}$ *carrier*

$$B = (Z, P, K, D, E, F, Q, H, C, G, N),$$

the local $\mathsf{NameCert}_{\mathsf{DedekindSplitTowerLiftBoundary}^{\uparrow}}$ *surface consists exactly of zeta-source admission, split-prime admission, number-field tower-source admission, Dedekind-read exposure, split-prime energy exposure, off-route refusal, prime-spectral fingerprint handoff, componentwise transport, displayed replay, provenance, and local naming. The packet therefore records a finite boundary route for q-split Dedekind lift rows without constructing Dedekind cuts, quotient completions, hidden tower limits, analytic-continuation proofs, RH proof objects, or ambient spectral classifications.*

Proof. Project the carrier of Definition 9016.1. The rows Z, P, K, D, E, F, Q are the boundary-facing data, and H, C, G, N are the structural rows.

The source route starts with the zeta row Z, split-prime row P, number-field tower row K, and Dedekind read row D. These rows display the finite tower and split-prime data that the boundary is allowed to inspect.

The energy row E and refusal row F make the boundary falsifiable. A lift row that is not accompanied by displayed split-prime energy cannot enter the accepted packet, and the fingerprint row Q supplies only a finite prime-local handoff.

Transport, replay, provenance, and local naming preserve the same displayed rows through H, C, G, N. Since the carrier contains no Dedekind cut, quotient completion, selected tower limit, analytic-continuation proof, RH proof object, hidden prime-ideal family, or ambient spectral theorem, the listed rows exhaust the NameCert obligations. □

Theorem 9016.3 (Dedekind split-tower lift boundary nonescape)**.** *Every accepted* DedekindSplitTowerLiftBoundary *read must pass through*

$$Z, P, K, D, E, F, Q, H, C, G, N$$

before any boundary consumer may inspect the lift route. In particular, an off-route Dedekind lift row with no displayed split-prime energy row E refutes the carrier rather than supplying a hidden tower escape.

Proof. Start with an accepted carrier $B = (Z, P, K, D, E, F, Q, H, C, G, N)$. The zeta, prime, number-field, and Dedekind rows display the only source route that the boundary recognizes.

The split-prime energy row E is required before the lift is read as boundary data. The refusal row F declares that a Dedekind lift row lacking such displayed energy is outside the accepted carrier.

The fingerprint row Q and structural rows H, C, G, N then carry only finite prime-local response, transport, replay, provenance, and local naming. They cannot introduce a hidden tower limit or RH-facing proof object because no such coordinate appears in the carrier.

Thus any boundary consumer must traverse the displayed rows in the stated order, and an off-route lift row without E refutes the carrier surface. □

Falsifiable prediction: Any off-route Dedekind lift row accepted without displayed split-prime energy refutes the $\mathsf{DedekindSplitTowerLiftBoundary}^{\uparrow}$ carrier.

Independence witness: zeta-basic, prime, numfield, dedekind, prime-spectral-fingerprint: DedekindSplitTowerLif is not bijective to any listed sibling because it jointly carries zeta-source admission, split-prime display, number-field tower source, Dedekind read, split-prime energy, off-route refusal, prime-spectral fingerprint handoff, transport, replay, provenance, and local naming as one finite boundary packet.

The Lean follow-up for this chapter must provide `Nontrivial` and `FieldFaithful` TasteGate instances for the displayed zeta, prime, number-field, Dedekind, split-energy, refusal, fingerprint, transport, replay, provenance, and naming carrier.

Closure status for $\mathsf{NameCert}_{\mathsf{DedekindSplitTowerLiftBoundary}^{\uparrow}}$.

Constructive story: A $\mathsf{DedekindSplitTowerLiftBoundary}^{\uparrow}$ packet is generated from zeta-source, split-prime, number-field tower, Dedekind read, split-prime energy, refusal, prime-spectral fingerprint, hsame transport, Cont replay, Pkg provenance, and local NameCert rows.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{DedekindSplitTowerLiftBoundary}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 9016.1, Definition 9016.2, Definition 9016.3, the falsifiable prediction, and the independence witness seed the finite boundary packet for displayed q-split Dedekind lift rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{DedekindSplitTowerLiftBoundary}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close Dedekind-cut construction, quotient completion, selected tower limits, analytic continuation, RH, ambient spectral classification, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, zeta-source admission, split-prime display, number-field tower-source admission, Dedekind-read exposure, split-prime energy exactness, off-route refusal, fingerprint handoff, transport, replay, provenance, local naming, and the required Nontrivial and FieldFaithful TasteGate instances for BEDC.Derived.DedekindSplitTowerLiftBoundaryUp.

Chapter 9017

A Concrete Naming Certificate for $\mathsf{FiniteOpenCoverInterval}^{\uparrow}$

Following Bishop and Bridges on constructive compactness of closed intervals, the $\mathsf{FiniteOpenCoverInterval}^{\uparrow}$ packet records a finite open-cover certificate by displaying endpoints, cover rows, and dyadic refinements rather than importing compactness as a primitive. It sits beside the real-name seal of chapter 38, the dyadic arithmetic core of chapter 291, the finite dyadic interval-net route of chapter 5966, and the dyadic mesh refinement route of chapter 9010. The packet names only finite interval-cover data; it does not assert arbitrary Heine–Borel compactness, choose a Lebesgue number, select a limiting point, or provide ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 9017.1 (Finite open-cover interval carrier)**.** *A* $\mathsf{FiniteOpenCoverInterval}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$O = (E, U, M, W, H, C, P, N)$$

with the following displayed rows:

1. *E is the interval endpoint row, recording the left and right endpoint reads through* $\mathsf{Real}^{\uparrow}$ *together with their dyadic boundary approximations through* $\mathsf{DyadicRatCore}^{\uparrow}$*.*
2. *U is the finite* ProbeBundle *open-cover row, listing the displayed open probes, their interval-hit predicates, and the finite cover ledger inspected by the packet.*
3. *M is the dyadic mesh refinement row, read through* $\mathsf{DyadicMeshRefinement}^{\uparrow}$ *and the finite dyadic interval-net route of chapter 5966.*
4. *W is the membership-witness row assigning every displayed mesh cell to a cover probe whose openness witness contains that cell.*
5. *H records componentwise* hsame *transport for endpoint rows, cover probes, mesh refinements, membership witnesses, replay, provenance, and local naming rows.*
6. *C records displayed* Cont *replay from an interval-cover request through endpoint inspection, finite cover inspection, dyadic mesh refinement, and membership witnessing.*
7. *P is the* Pkg *provenance over* $\mathsf{FiniteOpenCoverInterval}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*,* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{DyadicMeshRefinement}^{\uparrow}$*,* ProbeBundle*,* BHist*,* hsame*,* Cont*, and* NameCert*.*
8. *N is the local* $\mathsf{NameCert}_{\mathsf{FiniteOpenCoverInterval}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through E, U, M, W, H, C, P, N. It has no coordinate for an arbitrary open cover over an unbounded domain, a chosen Lebesgue number, a selected interval point, a quotient real representative, or ambient compactness.

Theorem 9017.2 (FiniteOpenCoverInterval NameCert obligations)**.** *For every accepted* $\mathsf{FiniteOpenCoverInterval}^{\uparrow}$ *carrier* $O = (E, U, M, W, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{FiniteOpenCoverInterval}^{\uparrow}}$ *surface consists exactly of five certificate rows:*

1. *carrier admission for the displayed endpoint and finite-cover packet;*
2. *endpoint exposure through E along the* $\mathsf{Real}^{\uparrow}$ *and* $\mathsf{DyadicRatCore}^{\uparrow}$ *sibling routes;*
3. *finite open-cover exposure through the* ProbeBundle *row U;*
4. *dyadic mesh refinement and membership witnessing through M and W;*
5. *structural stability through componentwise* hsame *transport H, displayed* Cont *replay C,* Pkg *provenance P, and local naming N.*

Every downstream compact-uniform, density-net, or interval consumer must read those five rows before treating the packet as a finite interval-cover certificate. The route exports no arbitrary compactness principle, no selected Lebesgue number, no point selector, no quotient real representative, and no ambient $\mathsf{Real}^{\uparrow}$ *completeness theorem.*

Proof. Project the accepted packet of Definition 9017.1. The endpoint row E, finite cover row U, mesh row M, membership row W, transport row H, replay row C, provenance row P, and local name row N are exactly the displayed coordinates.

Read the sibling routes in order. The real-name seal supplies the endpoint read, the dyadic arithmetic core supplies finite boundary approximations, the dyadic interval-net route supplies the finite cell surface, and the dyadic mesh refinement route supplies the refinement ledger.

The cover row is finite because it is a displayed ProbeBundle row, and the membership row assigns each displayed mesh cell to one displayed open probe. Thus the certificate is consumed through finite rows rather than through an unrecorded compactness theorem.

Finally replay the structural rows. Componentwise hsame transport, Cont replay, Pkg provenance, and local naming preserve the same route and add no coordinate for an arbitrary compactness principle, a selected Lebesgue number, a point selector, quotient real representatives, or ambient Real completeness. □

Falsifiable prediction: An accepted $\mathsf{FiniteOpenCoverInterval}^{\uparrow}$ read is refuted if a compact-uniform, density-net, or interval consumer obtains a finite interval-cover certificate without displaying endpoint rows, finite ProbeBundle cover rows, dyadic mesh refinement rows, membership-witness rows, hsame transport, Cont replay, Pkg provenance, and local NameCert data.

Independence witness: real, dyadicratcore, dyadic-interval-net, dyadic-mesh-refinement: the real-name sibling supplies endpoint seals without finite cover data, the dyadic arithmetic core supplies endpoint arithmetic without open probes, the dyadic interval-net sibling supplies cells without cover membership, and the mesh-refinement sibling supplies refinement rows without the finite ProbeBundle cover. None is bijective to $\mathsf{FiniteOpenCoverInterval}^{\uparrow}$.

Closure status for $\mathsf{NameCert}_{\mathsf{FiniteOpenCoverInterval}^{\uparrow}}$**.**

Constructive story: A $\mathsf{FiniteOpenCoverInterval}^{\uparrow}$ packet is generated from interval endpoint rows, finite ProbeBundle cover rows, dyadic mesh refinement rows, membership-witness rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{FiniteOpenCoverInterval}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 9017.1 and Definition 9017.2 seed the finite open-cover interval certificate over RealUp, DyadicRatCoreUp, DyadicMeshRefinementUp, ProbeBundle, BHist, hsame, Cont, Pkg, and NameCert rows.

Formal verification: FormalStatus(NameCert$_{\mathsf{FiniteOpenCoverInterval}\uparrow}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim arbitrary Heine–Borel compactness, a selected Lebesgue number, point selection, quotient real representatives, RealUp completeness, Lean verification, bridge checking, or a standard bridge.

Upgrade path: Obligation closure requires checked carrier admission, endpoint exposure, finite ProbeBundle cover exposure, dyadic mesh refinement, membership-witness exactness, transport, replay, provenance, and local naming for BEDC.Derived.FiniteOpenCoverIntervalUp.

Chapter 9018

A Concrete Naming Certificate for $\mathsf{HyperbolicSectorRefinement}^{\uparrow}$

The $\mathsf{HyperbolicSectorRefinement}^{\uparrow}$ packet realizes the sector-refinement branch of chapter 9463 as finite NameCert data. It sits after the sector envelope of chapter 8546, the sector expansion packet of chapter 8685, the sector overlap ledger of chapter 9013, and the observer-expansion packet of chapter 4167. The packet names a finite refinement of an observer-facing sector; it is not a completed hyperbolic boundary, a selected global sector, a host geometric subdivision theorem, or a physical observer law.

Definition 9018.1 (Hyperbolic sector-refinement carrier)**.** *A* $\mathsf{HyperbolicSectorRefinement}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$R = (A, B, V, O, L, T, H, C, P, N)$$

with the following displayed rows:

1. *A is the aperture row inherited from the sector-expansion packet.*
2. *B is the boundary-shadow row inherited from the sector-envelope and boundary-facing sector packets.*
3. *V is the visual-radius row that keeps the refined sector visible at finite observer scale.*
4. *O is the observer-window row, naming the finite focus through which the refinement is read.*
5. *L is the overlap ledger row, exposing the sector-overlap constraints before any refined sector is accepted.*
6. *T is the transport row for moving aperture, boundary-shadow, radius, observer-window, and overlap evidence together.*
7. *H records componentwise* hsame *transport for $A, B, V, O, L, T, C, P, N$.*
8. *C records displayed* Cont *replay through aperture, boundary shadow, visual radius, observer window, overlap, transport, provenance, and local naming.*
9. *P is the* Pkg *provenance over* $\mathsf{HyperbolicSectorEnvelope}^{\uparrow}$*,* $\mathsf{HyperbolicSectorExpansion}^{\uparrow}$*,* $\mathsf{HyperbolicSectorOverlapLe}$ $\mathsf{HyperbolicObserverExpansion}^{\uparrow}$*,* BHist*,* hsame*,* Cont*, and* $\mathsf{NameCert}$ *rows.*
10. *N is the local* $\mathsf{NameCert}_{\mathsf{HyperbolicSectorRefinement}^{\uparrow}}$ *row.*

The classifier compares two refinement packets only through these rows. It has no coordinate for ambient hyperbolic-sector equality, selected ideal endpoints, completed boundary regions, or a host subdivision algorithm.

Theorem 9018.2 (Hyperbolic sector-refinement NameCert obligations)**.** *For every accepted* HyperbolicSectorRefine *carrier*

$$R = (A, B, V, O, L, T, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{HyperbolicSectorRefinement}^{\uparrow}}$ *surface consists exactly of aperture admission through* A*, boundary-shadow admission through* B*, visual-radius admission through* V*, observer-window admission through* O*, overlap-ledger admission through* L*, transport through* T, H*, displayed replay through* C*, package provenance through* P*, and local naming through* N*.*

Every observer-expansion consumer must read the sector envelope, sector expansion, and overlap-ledger sibling routes before treating the refinement as accepted. The packet exports no completed hyperbolic boundary, selected global sector, host geometric subdivision theorem, physical observer law, or ambient $\mathsf{Real}^{\uparrow}$ *completeness claim.*

Proof. Project the carrier of Definition 9018.1. The aperture row, boundary-shadow row, visual-radius row, observer-window row, and overlap ledger are the only rows from which a refinement can be read.

Read the sibling anchors in order. The sector envelope supplies the boundary-facing shell, the sector expansion packet supplies aperture and growth comparison, and the sector overlap ledger supplies the finite compatibility rows.

The transport and replay rows keep these dependencies together for each consumer request. Provenance and local naming then record the same finite route as a NameCert surface.

Since the carrier has no coordinate for completed boundary regions, selected endpoints, host subdivision laws, or physical observer dynamics, the listed rows exhaust the accepted refinement packet. □

Falsifiable prediction: An accepted $\mathsf{HyperbolicSectorRefinement}^{\uparrow}$ read fails if the overlap ledger is removed while the aperture, boundary-shadow, visual-radius, and observer-window rows remain.

Independence witness: hyperbolic-sector-envelope, hyperbolic-sector-expansion, hyperbolic-sector-overlap-ledger, hyperbolic-observer-expansion: no listed sibling is bijective to $\mathsf{HyperbolicSectorRefinement}^{\uparrow}$ because this packet jointly carries aperture, boundary-shadow, visual-radius, observer-window, overlap, transport, replay, provenance, and local naming rows as one refinement surface.

Closure status for $\mathsf{NameCert}_{\mathsf{HyperbolicSectorRefinement}^{\uparrow}}$**.**

Constructive story: A $\mathsf{HyperbolicSectorRefinement}^{\uparrow}$ packet is generated from aperture, boundary-shadow, visual-radius, observer-window, overlap, transport, componentwise hsame, displayed Cont replay, Pkg provenance, and local NameCert rows.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{HyperbolicSectorRefinement}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 9018.1 and Definition 9018.2 seed the finite sector-refinement packet over HyperbolicSectorEnvelopeUp, HyperbolicSectorExpansionUp, HyperbolicSectorOverlapLedgerUp, HyperbolicObserverExpansionUp, BHist, hsame, Cont, Pkg, and NameCert rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{HyperbolicSectorRefinement}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close Lean verification, bridge checking, completed hyperbolic boundary sectors, selected ideal endpoints, host subdivision theorems, physical observer laws, or ambient Real completeness.

Upgrade path: Obligation closure requires checked aperture admission, boundary-shadow admission, visual-radius admission, observer-window admission, overlap-ledger exactness, transport, replay, provenance, and local naming for BEDC.Derived.HyperbolicSectorRefinementUp.

Chapter 9019

A Concrete Naming Certificate for $\mathsf{ChomskyHierarchy}^{\uparrow}$

Following Chomsky and Hopcroft–Ullman, the $\mathsf{ChomskyHierarchy}^{\uparrow}$ packet records the standard formal-language strata as one finite BEDC carrier. It links the regular-language surface of chapter 351, the context-free language surface of chapter 7733, the context-sensitive language surface of chapter 7749, the linear-bounded automaton surface of chapter 8100, and the Turing-machine surface of chapter 280. The packet names the hierarchy classifier before any consumer may treat the strata as host powersets of languages or as an unrestricted semantic inclusion theorem.

Definition 9019.1 (Chomsky hierarchy carrier)**.** *A* $\mathsf{ChomskyHierarchy}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (R, F, S, L, T, H, C, P, N)$$

with the following displayed rows:

1. *R is the regular-language stratum, anchored by the finite automaton carrier and accepted-word classifier of chapter 351.*
2. *F is the context-free language stratum, anchored by the grammar, derivation, yield, and pushdown-handoff rows of chapter 7733.*
3. *S is the context-sensitive language stratum, anchored by the noncontracting grammar and linear-bounded acceptance rows of chapter 7749.*
4. *L is the linear-bounded automaton stratum, anchored by the bounded-tape computation rows of chapter 8100.*
5. *T is the unrestricted Turing-machine stratum, anchored by the finite trace, source-classifier, ledger-exactness, and public certificate rows of chapter 280.*
6. *H records componentwise* hsame *transport for the five strata and the local hierarchy name.*
7. *C records displayed* Cont *replay from a hierarchy query through R, F, S, L, T, H, P, N.*
8. *P is the* Pkg *provenance over* $\mathsf{RegularLanguage}^{\uparrow}$, $\mathsf{ContextFreeLanguage}^{\uparrow}$, $\mathsf{ContextSensitiveLanguage}^{\uparrow}$, $\mathsf{LinearBoundedAutomaton}^{\uparrow}$, $\mathsf{TuringMachine}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$ *rows.*
9. *N is the local* $\mathsf{NameCert}_{\mathsf{ChomskyHierarchy}^{\uparrow}}$ *row.*

The classifier reads the hierarchy only through the ordered stratum packet R, F, S, L, T. It has no coordinate for a host language powerset, quotient grammar equality, selected universal machine, complement closure, strictness theorem, or ambient decidability principle.

Theorem 9019.2 (Chomsky hierarchy NameCert obligations)**.** *For every accepted* $\mathsf{ChomskyHierarchy}^{\uparrow}$ *carrier*

$$K = (R, F, S, L, T, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{ChomskyHierarchy}^{\uparrow}}$ *surface consists exactly of regular-stratum admission through* R*, context-free admission through* F*, context-sensitive admission through* S*, linear-bounded admission through* L*, Turing-machine admission through* T*, componentwise* hsame *transport through* H*, displayed* Cont *replay through* C*,* Pkg *provenance through* P*, and local naming through* N*.*

The sibling anchors are the regular-language obligation surface of Definition 351.6, the context-free language obligation surface of Definition 7733.2, the context-sensitive language obligation surface of Definition 7749.2, the linear-bounded automaton obligation surface of Definition 8100.2, and the Turing-machine obligation surface of Definition 280.12. The hierarchy exports this finite ordered carrier, not a host-language inclusion theorem or a strictness classification.

Proof. Project the carrier of Definition 9019.1. The rows R, F, S, L, T are the only stratum rows, and each row points to an existing finite NameCert surface.

Read the sibling obligations. The regular row is grounded by deterministic finite-run data, the context-free row by grammar and derivation data, the context-sensitive row by noncontracting grammar and bounded acceptance data, the linear-bounded row by bounded-tape computation data, and the Turing-machine row by finite trace and public certificate data.

The transport and continuation rows keep hierarchy queries inside the same ordered packet. Provenance and local naming then record exactly this dependency surface.

Since no row stores host powersets, quotient grammar equality, a selected universal machine, complement closure, strictness, or global decidability, the local NameCert obligations close only the finite hierarchy carrier. □

Falsifiable prediction: Removing any one of the five stratum rows R, F, S, L, T makes the $\mathsf{ChomskyHierarchy}^{\uparrow}$ carrier unable to answer the corresponding hierarchy query without importing an external language semantics.

Independence witness: regularlanguage, context-free-language, context-sensitive-language, linear-bounded-automaton, turingmachine: none is bijective to $\mathsf{ChomskyHierarchy}^{\uparrow}$ because the hierarchy packet jointly carries the five ordered stratum anchors, transport, replay, provenance, and local naming as one finite classifier surface.

Closure status for $\mathsf{NameCert}_{\mathsf{ChomskyHierarchy}^{\uparrow}}$**.**

Constructive story: A $\mathsf{ChomskyHierarchy}^{\uparrow}$ packet is generated from regular, context-free, context-sensitive, linear-bounded automaton, and Turing-machine stratum rows together with componentwise hsame, displayed Cont replay, Pkg provenance, and local NameCert rows.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{ChomskyHierarchy}^{\uparrow}}$, seed)

Scope closed: Definition 9019.1 and Definition 9019.2 seed the finite hierarchy carrier over RegularLanguageUp, ContextFreeLanguageUp, ContextSensitiveLanguageUp, LinearBoundedAutomatonUp, TuringMachineUp, BHist, hsame, Cont, Pkg, and NameCert rows.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{ChomskyHierarchy}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close Lean verification, bridge checking, strictness of the hierarchy, host language-set inclusion, complement closure, universal-machine selection, grammar quotient equality, or global decidability.

Upgrade path: Obligation closure requires checked stratum admission, ordered-classifier stability, route exactness, package provenance, local naming, and non-escape from the finite hierarchy packet for BEDC.Derived.ChomskyHierarchyUp.

Chapter 9020

A Concrete Naming Certificate for $\mathsf{KuratowskiFiniteAxioms}^{\uparrow}$

Following Kuratowski's closure axioms and the finite-set practice used in elementary topology, the $\mathsf{KuratowskiFiniteAxioms}^{\uparrow}$ packet records the displayed finite ledger by which a closure operator proves preservation of the empty set, extensivity, idempotence, and binary-union stability without importing a host powerset closure as primitive. It sits beside the closure-operator surface of chapter 6154, the topology row of chapter 88, the membership classifier of chapter 3668, and the finite-set packet of chapter 7157.

Definition 9020.1 (Kuratowski finite axioms carrier)**.** *A* $\mathsf{KuratowskiFiniteAxioms}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (X, T, S, E, A, I, U, H, C, P, N)$$

with the following displayed rows:

1. *X is the underlying displayed-object row whose subset requests are read through* $\mathsf{SetLike}^{\uparrow}$*;*
2. *T is the* $\mathsf{Topology}^{\uparrow}$ *row exposing the finite open and closed tests available to the packet;*
3. *S is the* $\mathsf{SetLike}^{\uparrow}$ *membership classifier row for every subset name mentioned by the ledger;*
4. *E is the empty-set closure row;*
5. *A is the extensivity row, recording that each displayed member of a named subset remains visible after closure;*
6. *I is the idempotence row, recording that a second closure read adds no new displayed subset request;*
7. *U is the binary-union row, recording that closure of a displayed union is read by the two component closure rows and the union classifier;*
8. *H records componentwise* hsame *transport for $X, T, S, E, A, I, U, C, P, N$;*
9. *C records displayed* Cont *replay for the empty, inclusion, idempotence, and binary-union reads;*
10. *P is the* Pkg *provenance over* $\mathsf{KuratowskiFiniteAxioms}^{\uparrow}$*,* $\mathsf{KuratowskiClosureAxiom}^{\uparrow}$*,* $\mathsf{Topology}^{\uparrow}$*,* $\mathsf{SetLike}^{\uparrow}$*,* $\mathsf{KuratowskiFiniteSet}^{\uparrow}$*,* BHist*,* hsame*,* Cont*, and* $\mathsf{NameCert}$*;*
11. *N is the local* $\mathsf{NameCert}_{\mathsf{KuratowskiFiniteAxioms}^{\uparrow}}$ *row.*

The carrier has no coordinate for a host powerset, arbitrary indexed union, quotient equality of subsets, selected closed hull, classical separation principle, compactness theorem, or ambient set-theoretic closure operator.

Theorem 9020.2 (Kuratowski finite axiom NameCert obligations)**.** *For an accepted* $\mathsf{KuratowskiFiniteAxioms}^{\uparrow}$ *carrier* $K = (X, T, S, E, A, I, U, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{KuratowskiFiniteAxioms}^{\uparrow}}$ *surface consists exactly of carrier admission for the displayed object, topology row, SetLike membership classifier, empty-set closure row, extensivity row, idempotence row, binary-union row, componentwise transport, continuation replay, provenance, and local naming. Every topology or closure-operator consumer must read the sibling* $\mathsf{KuratowskiClosureAxiom}^{\uparrow}$*,* $\mathsf{Topology}^{\uparrow}$*,* $\mathsf{SetLike}^{\uparrow}$*, and* $\mathsf{KuratowskiFiniteSet}^{\uparrow}$ *rows before it treats the finite closure ledger as a Kuratowski axiom packet.*

Proof. Project the carrier of Definition 9020.1. The rows X, T, S supply the displayed object, topology surface, and membership classifier before any closure axiom is inspected.

Read the finite axiom ledger next. The empty row E, extensivity row A, idempotence row I, and binary-union row U are the only closure-axiom rows in the packet, and each is tied to the SetLike classifier rather than to an ambient powerset operation.

Finally apply transport, replay, provenance, and local naming through H, C, P, N. These rows keep the four finite axiom checks attached to the Kuratowski closure, topology, SetLike, and finite-set sibling sources, so the certificate exports no arbitrary-union closure, quotient subset equality, selected hull, separation theorem, compactness principle, or host closure operator. □

Theorem 9020.3 (Kuratowski finite axiom topology route)**.** *Every accepted* $\mathsf{KuratowskiFiniteAxioms}^{\uparrow}$ *read consumed by a topology-facing chapter factors through*

$$\mathsf{KuratowskiClosureAxiom}^{\uparrow}, \quad \mathsf{Topology}^{\uparrow}, \quad \mathsf{SetLike}^{\uparrow}, \quad \mathsf{KuratowskiFiniteSet}^{\uparrow}.$$

The route exposes only the finite empty, extensivity, idempotence, and binary-union checks displayed in E, A, I, U*. It cannot be used as an arbitrary indexed-union closure principle, a selected closed-hull construction, a quotient equality of subsets, or a compactness argument.*

Proof. Begin with the sibling dependency route named in the carrier. The Kuratowski closure row supplies the closure-operator context, the topology row supplies open and closed tests, the SetLike row classifies displayed subset membership, and the finite-set row bounds the inspected ledger.

The consumer then reads E, A, I, U as four finite checks. Since these rows are displayed entries of the same packet, a topology-facing consumer cannot replace them by an unbounded family of subset claims or by an ambient closure operation.

The structural rows H, C, P, N preserve the same route under transport and replay. Thus the exported surface remains a finite NameCert ledger over the four sibling chapters and does not acquire host powerset, selected-hull, quotient, or compactness data. □

Closure status for $\mathsf{NameCert}_{\mathsf{KuratowskiFiniteAxioms}^{\uparrow}}$**.**

Constructive story: A $\mathsf{KuratowskiFiniteAxioms}^{\uparrow}$ packet is generated from a displayed object row, topology row, SetLike membership classifier, finite empty-set closure row, extensivity row, idempotence row, binary-union row, componentwise hsame, displayed Cont, Pkg, and local NameCert rows.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{KuratowskiFiniteAxioms}^{\uparrow}}$, seed)

Scope closed: Definition 9020.1, Definition 9020.2, and Definition 9020.3 seed the finite Kuratowski closure-axiom ledger over topology, SetLike, and finite-set rows.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{KuratowskiFiniteAxioms}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close Lean verification, bridge checking, arbitrary indexed-union closure, quotient subset equality, selected closed hulls, compactness, separation axioms, or an ambient host powerset closure operator.

Upgrade path: Obligation closure requires checked carrier admission, empty-set closure, extensivity, idempotence, binary-union stability, topology routing, SetLike classifier routing, finite-set bounding, transport, replay, provenance, and local naming for BEDC.Derived.KuratowskiFiniteAxiomsUp.

Chapter 9021

A Concrete Naming Certificate for $\mathsf{CompletionInjectiveExtension}^{\uparrow}$

Following Bishop and Bridges on constructive completions and Kelley on separated completions, the $\mathsf{CompletionInjectiveExtension}^{\uparrow}$ packet records the finite surface by which a densely defined map into a separated target has at most one completion extension. It sits after the dense-extension surface of chapter 6382, the extension-uniqueness surface of **??**, the metric-completion dense embedding of chapter 3351, and the dense embedding carrier of chapter 3617. The packet names injective extension determinacy only as finite NameCert data; it does not identify quotient completions, host functions, selected representatives, countable-choice schedules, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 9021.1 (CompletionInjectiveExtension carrier)**.** *A* $\mathsf{CompletionInjectiveExtension}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$J = (D, E, I, U, S, R, H, C, P, N)$$

with the following visible rows:

1. *D is the dense source row, reading the* $\mathsf{DenseEmbedding}^{\uparrow}$ *and* $\mathsf{MetricCompletionDenseEmbedding}^{\uparrow}$ *data used to place the source inside its completion.*
2. *E is the completion dense-extension row supplied by* $\mathsf{CompletionDenseExtension}^{\uparrow}$*.*
3. *I is the injective image-reflection row, recording that two extension reads with the same dense-source image have the same target-facing image row.*
4. *U is the completion-extension uniqueness row supplied by* $\mathsf{CompletionExtensionUniqueness}^{\uparrow}$ *and the universal-property boundary of* $\mathsf{CompletionUniversalProperty}^{\uparrow}$*.*
5. *S is the separated target row, read through* $\mathsf{CompleteMetric}^{\uparrow}$ *only as the classifier needed to turn zero-distance target reads into a unique target-facing comparison.*
6. *R is the StreamName, RegSeqRat, DyadicRatCore, and Real readback row used to expose the finite completion-facing comparison before the separated classifier consumes it.*
7. *H records componentwise* hsame *transport for dense-source, dense-extension, injective-reflection, uniqueness, separated-target, readback, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from dense-source reads through the completion extension, image reflection, uniqueness route, separated classifier, and readback rows.*

9. *P records* Pkg *provenance over* CompletionInjectiveExtension$^{\uparrow}$, CompletionDenseExtension$^{\uparrow}$, CompletionExtensionU MetricCompletionDenseEmbedding$^{\uparrow}$, DenseEmbedding$^{\uparrow}$, CompletionUniversalProperty$^{\uparrow}$, CompleteMetric$^{\uparrow}$, StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, Real$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* NameCert$_{\text{CompletionInjectiveExtension}^{\uparrow}}$ *row.*

The carrier accepts exactly those finite packets whose injective-extension read can be replayed through $D, E, I, U, S, R, H, C, P, N$.

Theorem 9021.2 (CompletionInjectiveExtension NameCert obligations)**.** *For every accepted* CompletionInjectiveE *carrier*

$$J = (D, E, I, U, S, R, H, C, P, N),$$

the local NameCert$_{\text{CompletionInjectiveExtension}^{\uparrow}}$ *surface consists exactly of dense-source admission for D, completion dense-extension admission for E, injective image-reflection exactness for I, completion-extension uniqueness for U, separated target classification for S, StreamName/RegSeqRat/DyadicRatCore/Real readback for R, componentwise* hsame *transport through H, displayed* Cont *replay through C, package provenance through P, and local naming through N.*

Proof. Project the accepted carrier. The dense source row and dense-extension row give the only input surface from which an extension read can start.

Read the image-reflection and uniqueness rows next. The reflection row I keeps image comparison internal to the displayed dense source, while U supplies the completion-extension uniqueness boundary already named by the sibling chapter.

The target-facing comparison then passes through R and S. The readback row exposes the finite completion comparison, and the separated target row is the only classifier allowed to turn it into a uniqueness read.

Finally H, C, P, N transport, replay, source, and name the same packet. No quotient completion equality, host function equality, selected representative, countable-choice schedule, or ambient Real completeness row occurs among these coordinates. □

Theorem 9021.3 (CompletionInjectiveExtension uniqueness route)**.** *Every accepted injective-extension comparison exported by a* CompletionInjectiveExtension$^{\uparrow}$ *packet factors through the dense source row D, the completion dense-extension row E, the injective image-reflection row I, the completion-extension uniqueness row U, the StreamName/RegSeqRat/DyadicRatCore/Real readback row R, the separated target row S, and the structural rows H, C, P, N. The route is therefore a finite completion-facing determinacy path, not an equality of host functions or quotient completion representatives.*

Proof. Start with the carrier of Definition 9021.1. It lists $D, E, I, U, S, R, H, C, P, N$ as the only accepted coordinates.

Apply the NameCert obligations of Definition 9021.2. They force the comparison through the dense source, dense extension, image reflection, completion-extension uniqueness, readback, and separated-target rows before a consumer can read injective-extension determinacy.

The structural rows preserve that route. Since no host function row, quotient equality row, representative selector, choice schedule, or ambient completeness principle is present in the carrier, no downstream read can obtain one from the packet. □

Closure status for NameCert$_{\text{CompletionInjectiveExtension}^{\uparrow}}$**.**

Constructive story: A CompletionInjectiveExtension$^{\uparrow}$ packet is generated from a dense source row, a completion dense-extension row, an injective image-reflection row, a completion-extension uniqueness row, a separated target classifier,

StreamName/RegSeqRat/DyadicRatCore/Real readback, componentwise hsame transport, displayed Cont replay, package provenance, and local naming.

Theory closure: TheoryGate(NameCert$_{\mathsf{CompletionInjectiveExtension}^{\uparrow}}$, seed)

Scope closed: Definition 9021.1, Definition 9021.2, and Definition 9021.3 bind the finite injective-extension carrier, its local NameCert obligations, and its uniqueness route.

Formal verification: FormalStatus(NameCert$_{\mathsf{CompletionInjectiveExtension}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close quotient completion equality, host function equality, countable choice, selected representatives, or ambient Real$^{\uparrow}$ completeness.

Upgrade path: Obligation closure requires checked carrier admission, injective image-reflection exactness, completion-extension uniqueness routing, separated target classification, readback provenance, transport, replay, and local naming for the same finite packet.

Chapter 9022

A Concrete Naming Certificate for $\mathsf{RegularCauchySelectorStability}^{\uparrow}$

Bishop–Bridges constructive analysis treats a regular Cauchy real by displayed moduli and finite rational windows, not by a hidden completed endpoint. The $\mathsf{RegularCauchySelectorStability}^{\uparrow}$ packet records the finite stability route by which a selected modulus window remains the same Real-facing row after displayed transport. It sits after the selector surface of chapter 1576, the finite windows of chapter 126, the dyadic tolerance ledger of chapter 291, the regular rational readback of chapter 301, and the terminal real-name seal of chapter 38. The packet names selector stability only as finite BEDC data; it does not assert quotient equality of real names, a chosen limit, countable choice, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 9022.1 (Regular Cauchy selector stability carrier)**.** *A* $\mathsf{RegularCauchySelectorStability}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$T = (M, S, D, R, E, U, H, C, P, N)$$

with the following displayed rows:

1. *M is the* $\mathsf{RealCauchyModulusSelector}^{\uparrow}$ *selector row, naming the accepted modulus threshold used by the regular Cauchy route.*
2. *S is the* $\mathsf{StreamName}^{\uparrow}$ *window row through which the selected source observations are inspected.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row, carrying the finite dyadic budget attached to the selected modulus threshold.*
4. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row obtained from the displayed selector window and tolerance budget.*
5. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row, available only after M, S, D, R have been displayed.*
6. *U is the selector-stability row, recording that displayed componentwise transport preserves the same selector, window, tolerance, readback, and seal route.*
7. *H records componentwise* hsame *transport for selector rows, stream windows, tolerance rows, readback rows, Real seals, the stability row, replay, provenance, and local naming.*
8. *C records displayed* Cont *replay from a regular Cauchy selector request through M, S, D, R, E, U, H.*
9. *P is the* Pkg *provenance over* $\mathsf{RegularCauchySelectorStability}^{\uparrow}$, $\mathsf{RealCauchyModulusSelector}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*

10. N is the local $\mathsf{NameCert}_{\mathsf{RegularCauchySelectorStability}^{\uparrow}}$ *row.*
The classifier compares accepted packets only through $M, S, D, R, E, U, H, C, P, N$. It has no coordinate for quotient equality of real names, selected representatives, countable choice, trichotomy, host real equality, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 9022.2 (Regular Cauchy selector stability NameCert obligations)**.** *For every accepted* $\mathsf{RegularCauchySelectorStability}^{\uparrow}$ *carrier*

$$T = (M, S, D, R, E, U, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{RegularCauchySelectorStability}^{\uparrow}}$ *surface consists exactly of carrier admission for the* $\mathsf{RealCauchyModulusSelector}^{\uparrow}$ *selector row,* $\mathsf{StreamName}^{\uparrow}$ *window exposure,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance exposure,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback exposure, terminal* $\mathsf{Real}^{\uparrow}$ *seal routing, selector-stability routing through U, componentwise transport, displayed replay, package provenance, and local naming. A Real or Completion consumer may cite selector stability only after those rows have been displayed.*

Proof. Project the carrier of Definition 9022.1. The selector-facing route first exposes M, S, D, R, E, so the selected modulus threshold, finite window, tolerance budget, regular rational readback, and Real seal are visible before any stability conclusion is read.

Read the stability row U next. It records preservation of the same displayed selector route under componentwise transport; it is not an independent selector, quotient representative, or completed endpoint.

The structural rows H, C, P, N transport, replay, source, and name the same finite packet. Since no row stores quotient real equality, selected representatives, countable choice, trichotomy, host real equality, or ambient completeness, the listed rows exhaust the local NameCert surface. □

Falsifiable prediction: An accepted $\mathsf{RegularCauchySelectorStability}^{\uparrow}$ read is refuted if it cites selector stability without displaying the $\mathsf{RealCauchyModulusSelector}^{\uparrow}$ selector row, $\mathsf{StreamName}^{\uparrow}$ finite window, $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance row, $\mathsf{RegSeqRat}^{\uparrow}$ readback, $\mathsf{Real}^{\uparrow}$ seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert row.

Independence witness: realcauchymodulusselector, streamname, dyadicratcore, regseqrat, real: $\mathsf{RegularCauchySelectorStability}^{\uparrow}$ is not bijective to any listed sibling because it jointly binds selector admission, finite windows, dyadic tolerance, regular readback, Real sealing, selector-stability transport, replay, provenance, and local naming in one packet.

Closure status for $\mathsf{NameCert}_{\mathsf{RegularCauchySelectorStability}^{\uparrow}}$.

Constructive story: A $\mathsf{RegularCauchySelectorStability}^{\uparrow}$ packet is generated from a RealCauchyModulusSelector row, a StreamName finite window, a DyadicRatCore tolerance row, RegSeqRat readback, a RealUp seal, selector-stability routing, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{RegularCauchySelectorStability}^{\uparrow}}$, seed)

Scope closed: Definition 9022.1, Definition 9022.2, the falsifiable prediction, and the independence witness seed the finite regular Cauchy selector-stability route over selector, window, tolerance, readback, seal, transport, replay, provenance, and local naming rows.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{RegularCauchySelectorStability}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close quotient equality of real names, selected limits, countable choice, trichotomy, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, axiom-clean audit, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, selector preservation, StreamName window exposure, DyadicRatCore tolerance exactness, RegSeqRat readback, Real seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.RegularCauchySelectorStabilityUp.

Chapter 9023

A Concrete Naming Certificate for $\mathsf{SpectralSpace}^{\uparrow}$

Following Hochster and the scheme-topology tradition, the $\mathsf{SpectralSpace}^{\uparrow}$ packet records the finite BEDC surface of quasi-compact open bases, finite intersections, and sober prime-facing observation rows. It sits between the topology carrier of chapter 88, the point-free open ledger of chapter 5153, the clopen compact boundary of chapter 7424, and the affine-site consumer surface of chapter 153. The packet names the compact-open certificate data available to later scheme, locale, and Stone routes; it does not import host prime spectra, selected prime ideals, quotient topology equality, spatiality for every locale, or an open-cover compactness theorem outside the displayed rows.

Definition 9023.1 (Spectral space carrier)**.** *A* $\mathsf{SpectralSpace}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (T, B, K, I, L, A, H, C, P, N)$$

with the following displayed rows:

1. *T is the ambient* $\mathsf{Topology}^{\uparrow}$ *indexed-open row.*
2. *B is the compact-open basis row, recording displayed basis indices and membership reads.*
3. *K is the quasi-compactness witness row for each displayed basis open, read only as finite cover-refinement data.*
4. *I is the finite-intersection row, requiring the intersection of two displayed compact-open basis rows to be routed through another displayed basis row.*
5. *L is the* $\mathsf{LocaleSpace}^{\uparrow}$ *handoff row, exposing the same compact-open data as a point-free finite meet and cover-refinement ledger.*
6. *A is the* $\mathsf{Scheme}^{\uparrow}$ *affine-site row, used only when scheme consumers read distinguished-open or affine-cover data through the compact-open basis surface.*
7. *H records componentwise* hsame *transport for the topology, basis, compactness, intersection, locale, scheme, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay for the route*

$$T, B, K, I \longmapsto L, A, H, P, N.$$

9. *P is the* Pkg *provenance over* $\mathsf{SpectralSpace}^{\uparrow}$*,* $\mathsf{Topology}^{\uparrow}$*,* $\mathsf{LocaleSpace}^{\uparrow}$*,* $\mathsf{StoneSpace}^{\uparrow}$*,* $\mathsf{Scheme}^{\uparrow}$*,* BHist*,* hsame*,* Cont*, and* $\mathsf{NameCert}$ *rows.*

10. N is the local $\mathsf{NameCert}_{\mathsf{SpectralSpace}^{\uparrow}}$ *row.*
The classifier compares accepted packets only through $T, B, K, I, L, A, H, C, P, N$. It has no coordinate for a host set of points, selected prime ideals, arbitrary open-cover compactness, quotient topology equality, or a global spatiality theorem.

Theorem 9023.2 (Spectral space NameCert obligations)**.** *For every accepted* $\mathsf{SpectralSpace}^{\uparrow}$ *carrier $S = (T, B, K, I, L, A, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{SpectralSpace}^{\uparrow}}$ *surface consists exactly of topology-source exposure through T, compact-open basis exposure through B, finite cover-refinement compactness through K, compact-open finite-intersection stability through I, locale handoff through L, affine-site scheme handoff through A, componentwise* hsame *transport through H, displayed* Cont *replay through C,* Pkg *provenance through P, and local naming through N. A* $\mathsf{StoneSpace}^{\uparrow}$*,* $\mathsf{LocaleSpace}^{\uparrow}$*,* $\mathsf{Scheme}^{\uparrow}$*, or* $\mathsf{Topology}^{\uparrow}$ *consumer may read only those rows from the packet.*

Proof. Carrier admission is projection from Definition 9023.1. The accepted packet displays exactly the topology row, compact-open basis row, compactness row, finite-intersection row, locale handoff, scheme handoff, transport, replay, provenance, and local naming row.

The basis row B is read before compactness or intersection data. The row K then records only finite cover-refinement witnesses for displayed basis opens, while I records only finite intersections that remain inside the displayed compact-open basis.

The locale handoff L and scheme handoff A consume that same basis route. The locale consumer receives finite meet and cover-refinement data, and the scheme consumer receives affine-site compact-open reads, but neither receives a detached host point set or a chosen family of prime ideals.

Finally H, C, P, N transport, replay, source, and name the same rows. Since the carrier contains no coordinate for arbitrary open covers, quotient topology equality, selected prime ideals, or a global spatiality theorem, the listed rows exhaust the local NameCert obligation surface. □

Theorem 9023.3 (Spectral space compact-open stability)**.** *Every compact-open read exported by an accepted* $\mathsf{SpectralSpace}^{\uparrow}$ *packet factors through*

$$\mathsf{Topology}^{\uparrow} \longmapsto B, K, I \longmapsto \mathsf{LocaleSpace}^{\uparrow}, \mathsf{Scheme}^{\uparrow}, \mathsf{StoneSpace}^{\uparrow} \longmapsto H, C, P, N.$$

Thus a downstream scheme, locale, Stone, or topology consumer sees a compact-open basis row together with finite cover-refinement and finite-intersection stability. The read exports no selected prime point, host powerset of opens, quotient topology equality, arbitrary open-cover compactness, or bridge-checked spatial representation.

Proof. Start with the topology row T and compact-open basis row B. A compact-open read is admitted only after the basis index and membership observation have been displayed.

The compactness and stability data are then K and I. The compactness row is finite cover-refinement data for the displayed basis open, and the intersection row keeps binary meets inside the same compact-open basis ledger.

The locale, scheme, and Stone consumers can only inspect those displayed rows. Locale reads use the point-free meet and cover route, scheme reads use the affine-site compact-open handoff, and Stone reads compare the clopen compact boundary as a sibling compact-open fragment.

Transport, replay, provenance, and local naming preserve the same finite route. Since no accepted carrier stores selected prime points, host powersets, quotient topologies, arbitrary open-cover compactness, or a checked bridge, those objects cannot be exported by the compact-open read. □

Falsifiable prediction: Every accepted $\mathsf{SpectralSpace}^{\uparrow}$ read exposes a TopologyUp indexed-open row, compact-open basis row, finite cover-refinement compactness row, finite-intersection row, LocaleSpaceUp handoff, SchemeUp affine-site handoff, StoneSpaceUp sibling comparison, componentwise hsame transport, Cont replay, Pkg provenance, and local NameCert row before a compact-open consumer may use the packet.

Independence witness: topology, locale-space, stone-space, scheme: $\mathsf{SpectralSpace}^{\uparrow}$ is not bijective to any listed sibling because it jointly binds compact-open basis data, finite cover-refinement compactness, finite-intersection stability, locale handoff, scheme affine-site handoff, Stone sibling comparison, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{SpectralSpace}^{\uparrow}}$.

Constructive story: A $\mathsf{SpectralSpace}^{\uparrow}$ packet is generated from a TopologyUp indexed-open row, compact-open basis row, finite cover-refinement compactness row, finite-intersection row, LocaleSpaceUp handoff, SchemeUp affine-site handoff, StoneSpaceUp sibling comparison, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{SpectralSpace}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 9023.1, Definition 9023.2, and Definition 9023.3 seed the compact-open spectral-space surface over topology, locale, Stone, scheme, transport, replay, provenance, and local naming rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{SpectralSpace}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close selected prime points, host powersets of opens, quotient topology equality, arbitrary open-cover compactness, spatiality for every locale, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, compact-open basis exposure, finite cover-refinement compactness, finite-intersection stability, locale and scheme handoffs, Stone sibling comparison, transport, replay, provenance, and local naming for BEDC.Derived.SpectralSpaceUp.

Chapter 9024

A Concrete Naming Certificate for FiniteModulusRegularCauchyCompletion$^{\uparrow}$

Following Bishop and Bridges, the FiniteModulusRegularCauchyCompletion$^{\uparrow}$ packet records the finite modulus surface by which a regular rational Cauchy name is read into the Real and Completion route without claiming ambient completeness. It sits after the dyadic arithmetic core of chapter 291, the finite stream schedule of chapter 126, the regular rational readback of chapter 301, and the terminal real-name seal of chapter 38. The packet packages the displayed modulus ledger only; it does not quotient regular streams, select a completed limit, assert host real equality, import countable choice, or promote Real$^{\uparrow}$ to an ambient completeness theorem.

Definition 9024.1 (Finite modulus regular Cauchy completion carrier)**.** *A* FiniteModulusRegularCauchyCompletion *carrier is a finite* BHist *packet*

$$F = (D, S, R, M, E, H, C, P, N)$$

with the following displayed rows:

1. *D is the* DyadicRatCore$^{\uparrow}$ *window row, carrying the dyadic precision scale, comparison budget, and tolerance ledger used by the completion-facing read.*
2. *S is the* StreamName$^{\uparrow}$ *schedule row, listing the finite observations inspected before a modulus claim is exposed.*
3. *R is the* RegSeqRat$^{\uparrow}$ *regularity row, recording the rational-name regularity predicate on the displayed schedule.*
4. *M is the tail-modulus row, binding each requested dyadic precision to a displayed tail window in S and a regularity witness in R.*
5. *E is the terminal* Real$^{\uparrow}$ *seal row, available only after D, S, R, M have been displayed.*
6. *H records componentwise* hsame *transport for the dyadic window, stream schedule, regularity, tail modulus, real seal, replay, provenance, and local naming rows.*
7. *C records displayed* Cont *replay from the dyadic precision request through the stream schedule, regular rational readback, tail modulus, real seal, transport, provenance, and local naming rows.*
8. *P is the* Pkg *provenance over* FiniteModulusRegularCauchyCompletion$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, Real$^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* NameCert *rows.*

9. N is the local $\mathsf{NameCert}_{\mathsf{FiniteModulusRegularCauchyCompletion}^{\uparrow}}$ *row.*
The classifier compares accepted packets only through $D, S, R, M, E, H, C, P, N$. It has no coordinate for quotient stream equality, selected limits, hidden convergence witnesses, host real equality, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 9024.2 (Finite modulus regular Cauchy completion NameCert obligations)**.** *For every accepted* $\mathsf{FiniteModulusRegularCauchyCompletion}^{\uparrow}$ *carrier $F = (D, S, R, M, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{FiniteModulusRegularCauchyCompletion}^{\uparrow}}$ *surface consists exactly of dyadic-window admission, finite stream scheduling, regular rational readback, tail-modulus exposure, terminal Real seal, componentwise transport, displayed replay, package provenance, and local naming. Every completion-facing consumer must read the* $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$ *sibling surfaces through those displayed rows before citing the finite modulus route.*

Proof. Project the carrier of Definition 9024.1. The rows D, S, R, M expose the dyadic precision window, the inspected stream schedule, the regular rational readback, and the tail-modulus ledger.

The terminal seal E is downstream from those rows. It can be read only after the displayed regular Cauchy route has opened the dyadic budget and finite schedule, so the seal is not a selected host limit or a quotient of streams.

The structural rows H, C, P, N preserve, replay, source, and name the same finite evidence. Since the carrier has no coordinate for hidden convergence, countable choice, quotient equality, host real equality, or ambient completeness, the listed rows exhaust the local NameCert obligations. □

Theorem 9024.3 (Finite modulus completion route boundary)**.** *Any* $\mathsf{Real}^{\uparrow}$*-facing read of an accepted* $\mathsf{FiniteModulusRegularCauchyCompletion}^{\uparrow}$ *packet factors through the dyadic window row D, stream schedule row S, regularity row R, tail-modulus row M, terminal seal row E, transport row H, replay row C, provenance row P, and local naming row N. A consumer that reaches a real seal without the displayed finite modulus leaves the packet.*

Proof. Apply the obligations theorem. It lists $D, S, R, M, E, H, C, P, N$ as the complete local surface, with the $\mathsf{Real}^{\uparrow}$ seal downstream from dyadic, stream, regularity, and modulus rows.

If a consumer omits M, then the requested precision has no displayed tail window. If it omits D, S, or R, then the modulus is detached from the dyadic budget, finite observations, or regular rational readback.

Transport, replay, provenance, and local naming do not create missing analytic data. Therefore every accepted completion read must pass through the full finite route, and a detached seal is outside the carrier. □

Falsifiable prediction: A Real or Completion consumer that cites a terminal RealUp seal without a displayed dyadic window, stream schedule, regular rational readback, and tail-modulus row refutes the FiniteModulusRegularCauchyCompletionUp carrier.

Independence witness: dyadicratcore, streamname, regseqrat, real: $\mathsf{FiniteModulusRegularCauchyCompletion}^{\uparrow}$ is not bijective to any listed sibling because it binds dyadic tolerance, finite observation schedule, regular rational readback, tail modulus, terminal seal, transport, replay, provenance, and local naming as one completion-facing packet.

Closure status for $\mathsf{NameCert}_{\mathsf{FiniteModulusRegularCauchyCompletion}^{\uparrow}}$.

Constructive story: A $\mathsf{FiniteModulusRegularCauchyCompletion}^{\uparrow}$ packet is generated from a DyadicRatCore precision window, StreamName observation schedule, RegSeqRat regularity row, tail-modulus ledger, Real seal, componentwise hsame transport, Cont replay, Pkg provenance, and local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{FiniteModulusRegularCauchyCompletion}^{\uparrow}}$, seed)

Scope closed: Definition 9024.1, Definition 9024.2, and Definition 9024.3 seed the finite regular-Cauchy completion route over DyadicRatCore, StreamName, RegSeqRat, Real, BHist, hsame, Cont, Pkg, and NameCert rows.

Formal verification: FormalStatus(NameCert$_{\text{FiniteModulusRegularCauchyCompletion}\uparrow}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close quotient stream equality, selected limits, host real equality, countable choice, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked dyadic-window admission, stream scheduling, regularity readback, tail-modulus exposure, Real seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.FiniteModulusRegularCauchyCo

Chapter 9025

A Concrete Naming Certificate for DyadicTruncationLPRefutationWindow$^{\uparrow}$

The DyadicTruncationLPRefutationWindow$^{\uparrow}$ packet realizes the sharp dyadic truncation route obstruction of chapter 9338 as finite NameCert data. It sits beside the zeta-zero surface of chapter 73, the critical-strip boundary of chapter 72, the zero-count ledger of chapter 573, the contour-operation route of chapter 521, and the finite ordered-field comparison discipline of chapter 235. The packet names the obstruction to the all-cutoff Laguerre–Polya premise; it does not prove or disprove RH, classify all truncations, assert a smooth-deformation route, or import analytic continuation beyond displayed rows.

Definition 9025.1 (Dyadic truncation LP refutation window carrier)**.** *A* DyadicTruncationLPRefutationWindow$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$W = (K, T, Z, Q, F, H, C, P, N)$$

with the following displayed rows:

1. *K is the dyadic cutoff row, recording the sharp finite cutoff and the dyadic precision budget used to inspect the truncated integral.*
2. *T is the truncation-evaluation row, recording the displayed finite approximation of the sharp cutoff function on the inspected contour windows.*
3. *Z is the zero-count row, carrying the argument-principle or equivalent winding-count evidence that the inspected truncation has a non-real zero pair.*
4. *Q is the Laguerre–Polya premise row, naming the all-real-zero condition that the sharp cutoff route would require at the inspected cutoff.*
5. *F is the refusal row, recording that the displayed non-real zero-count row refutes the all-cutoff premise at this finite window.*
6. *H records componentwise* hsame *transport for cutoff, truncation, zero-count, premise, refusal, replay, provenance, and local naming rows.*
7. *C records displayed* Cont *replay from the cutoff and truncation rows through zero-count evidence, premise refusal, transport, provenance, and local naming.*
8. *P is the* Pkg *provenance over* DyadicTruncationLPRefutationWindow$^{\uparrow}$*,* ZetaZeros$^{\uparrow}$*,* CritStrip$^{\uparrow}$*,* LPDuality$^{\uparrow}$*,* BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *rows.*

9. N is the local $\mathsf{NameCert}_{\mathsf{DyadicTruncationLPRefutationWindow}^{\uparrow}}$ *row.*
The classifier compares accepted packets only through $K, T, Z, Q, F, H, C, P, N$. It has no coordinate for a proof of RH*, a disproof of* RH*, a global zero classifier, a hidden analytic-continuation theorem, a smoothed heat-flow replacement, or an all-cutoff real-rootedness oracle.*

Theorem 9025.2 (Dyadic truncation LP refutation window NameCert obligations)**.** *For every accepted* $\mathsf{DyadicTruncationLPRefutationWindow}^{\uparrow}$ *carrier $W = (K, T, Z, Q, F, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{DyadicTruncationLPRefutationWindow}^{\uparrow}}$ *surface consists exactly of cutoff admission, truncation-evaluation exposure, zero-count evidence, Laguerre–Polya premise naming, finite refusal, componentwise transport, displayed replay, package provenance, and local naming. The packet makes the sharp-cutoff route obstruction inspectable as one finite window while leaving all global RH readings outside the carrier.*

Proof. Project the carrier of Definition 9025.1. The cutoff row K and truncation row T identify the inspected sharp finite window, while Z supplies the displayed zero-count evidence.

The premise row Q names the all-real-zero condition required by the route. The refusal row F is then finite: the displayed non-real zero-count evidence at the same window blocks that premise for the sharp-cutoff family.

The rows H, C, P, N transport, replay, source, and name the same evidence. Since no coordinate stores an RH proof, an RH refutation, a global zero classifier, or a smoothed deformation route, the listed rows exhaust the local NameCert obligations. □

Theorem 9025.3 (Dyadic truncation LP route nonclaim boundary)**.** *Every accepted* DyadicTruncationLPRefutation *read exposes only the finite route*

$$K, T, Z, Q, F, H, C, P, N$$

before a consumer may cite the Laguerre–Polya premise obstruction. The read cannot be reinterpreted as a proof of RH*, a disproof of* RH*, a statement about every cutoff family, or a smooth de Bruijn–Newman deformation certificate.*

Proof. Use the obligations theorem. The packet's positive content is the finite cutoff, truncation-evaluation, zero-count, premise, and refusal surface.

The obstruction is local to the displayed sharp cutoff row. Transport and replay preserve that local evidence; they do not quantify over all cutoffs and do not replace the sharp cutoff by a smooth heat-flow deformation.

Thus the consumer receives a finite route refutation window only. Any RH conclusion, global zero classification, or smooth-deformation certificate would require coordinates absent from the carrier. □

Falsifiable prediction: An accepted sharp dyadic truncation window with displayed non-real zero-count evidence refutes the all-cutoff Laguerre–Polya premise for that sharp-cutoff route.

Independence witness: zeta-zeros, critical-strip, riemann-zero-count-ledger, contourintegral-operation, lpduality: $\mathsf{DyadicTruncationLPRefutationWindow}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries cutoff, truncation, zero-count, premise, refusal, transport, replay, provenance, and local naming rows while refusing all global RH readings.

Closure status for $\mathsf{NameCert}_{\mathsf{DyadicTruncationLPRefutationWindow}^{\uparrow}}$**.**

Constructive story: A $\mathsf{DyadicTruncationLPRefutationWindow}^{\uparrow}$ packet is generated from a dyadic cutoff row, truncation-evaluation row, zero-count evidence row, Laguerre–Polya premise row, refusal row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert row.

Theory closure: TheoryGate(NameCert$_{\text{DyadicTruncationLPRefutationWindow}\uparrow}$, seed)

Scope closed: Definition 9025.1, Definition 9025.2, and Definition 9025.3 seed the finite sharp-cutoff route obstruction over zeta-zero, critical-strip, zero-count, contour, LP-duality, BHist, hsame, Cont, Pkg, and NameCert rows.

Formal verification: FormalStatus(NameCert$_{\text{DyadicTruncationLPRefutationWindow}\uparrow}$, unformalized)

Bridge status: none

Not claimed: This chapter does not prove RH, disprove RH, classify all truncations, close analytic continuation, replace sharp cutoffs by a smooth deformation, provide Lean verification, or bridge check the route.

Upgrade path: Obligation closure requires checked cutoff admission, truncation evaluation, zero-count evidence, Laguerre–Polya premise naming, finite refusal, transport, replay, provenance, and local naming for BEDC.Derived.DyadicTruncationLPRefutatio

Chapter 9026

Bishop Separated Real Completion NameCert Construction

Following Bishop–Bridges constructive-completion practice, the $\mathsf{BishopSeparatedRealCompletion}^{\uparrow}$ packet records the finite route by which regular rational stream data is read as a separated real completion object. It refines the regular Cauchy route of chapter 1639, the metric completion carrier of chapter 1506, and the separation reflector of chapter 1790. The packet exposes completion data through $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{MetricCompletion}^{\uparrow}$, and $\mathsf{SeparatedMetricReflection}^{\uparrow}$; it does not add quotient real equality, countable choice, a host limit selector, or ambient completeness of $\mathsf{Real}^{\uparrow}$.

Definition 9026.1 (Bishop separated real completion carrier)**.** *A* $\mathsf{BishopSeparatedRealCompletion}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (S, R, M, Q, E, H, C, P, N)$$

with the following displayed rows:

1. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-observation row, exposing only the stream windows requested by the completion consumer.*
2. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *regular rational row read from those stream windows.*
3. *M is the* $\mathsf{MetricCompletion}^{\uparrow}$ *completion row, recording the completion-facing metric handoff before separation is applied.*
4. *Q is the* $\mathsf{SeparatedMetricReflection}^{\uparrow}$ *separation row, restricting comparison to displayed indistinguishability data instead of quotient equality.*
5. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row, available only after S, R, M, Q have been displayed.*
6. *H records componentwise* hsame *transport for the stream, regularity, metric-completion, separation, real-seal, replay, provenance, and local naming rows.*
7. *C records displayed* Cont *replay from a Real or Completion request through S, R, M, Q, E.*
8. *P is the* Pkg *provenance over* $\mathsf{BishopSeparatedRealCompletion}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{MetricCompletion}^{\uparrow}$*,* $\mathsf{SeparatedMetricReflection}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*,* BHist*,* hsame*,* Cont*, and* $\mathsf{NameCert}$*.*
9. *N is the local* $\mathsf{NameCert}_{\mathsf{BishopSeparatedRealCompletion}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $S, R, M, Q, E, H, C, P, N$. It has no coordinate for quotient stream equality, host real equality, selected limits, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 (statement) `BEDC.Derived.BishopSeparatedRealCompletionUp`

Theorem 9026.2 (Bishop separated real completion classifier surface)**.** *For every accepted* BishopSeparatedRealCor *carrier $B = (S, R, M, Q, E, H, C, P, N)$, the local classifier is exhausted by the stream row S, regular rational row R, metric-completion row M, separated-reflection row Q, Real seal E, componentwise transport H, replay C, provenance P, and local naming row N. Every comparison between accepted carriers must first expose the same finite stream window and regular rational readback before it may inspect the separated metric reflection row. No classifier branch may introduce quotient equality of streams, host real equality, a selected limit, countable choice, or ambient completeness of* $\mathsf{Real}^{\uparrow}$.

Proof. Project the carrier in Definition 9026.1. The only data available to the classifier are the displayed rows $S, R, M, Q, E, H, C, P, N$.

The completion-facing part of the route reads finite observations through S, regular rational data through R, and the metric completion handoff through M. The separated reflection row Q is downstream of those rows, so it can compare only the displayed metric-completion data already present in the packet.

Transport and replay are row-local. Componentwise hsame in H preserves the same rows, and Cont replay in C repeats the route S, R, M, Q, E for each request.

Since neither the carrier nor its structural rows contain an excluded coordinate, the classifier surface cannot supply quotient stream equality, host real equality, selected limits, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness. □

Theorem 9026.3 (Bishop separated real completion stability route)**.** *Let $B = (S, R, M, Q, E, H, C, P, N)$ and $B' = (S', R', M', Q', E', H', C', P', N')$ be accepted* $\mathsf{BishopSeparatedRealCompletion}^{\uparrow}$ *carriers. If the displayed transport rows identify corresponding components by* hsame*, then any Real-facing consumer reads B and B' through the same ordered route*

$$\mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{MetricCompletion}^{\uparrow} \longmapsto \mathsf{SeparatedMetricReflection}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}.$$

The stability route preserves the finite carrier surface and exports no quotient equality, host-selected representative, countable-choice schedule, detached real equality, or ambient Real completeness.

Proof. Start with the classifier surface of Definition 9026.2. It restricts both accepted carriers to the rows $S, R, M, Q, E, H, C, P, N$ and their transported companions.

The hsame rows identify corresponding displayed components only. Thus a transported read of B' follows the same finite stream window, the same regular rational handoff shape, the same metric-completion exposure, and the same separated-reflection boundary as the read of B.

Finally, the Cont rows replay the ordered route before the terminal $\mathsf{Real}^{\uparrow}$ seal can be inspected. The replay keeps the separated metric reflection downstream of the metric completion row and upstream of the Real seal, so no external quotient or selected representative is introduced. □

Theorem 9026.4 (Bishop separated real completion embedding handoff)**.** *Every standard real-embedding read from an accepted* $\mathsf{BishopSeparatedRealCompletion}^{\uparrow}$ *packet factors through the displayed carrier rows*

$$S, R, M, Q, E, H, C, P, N.$$

The embedding may use the regular rational stream data as a completion-facing name and may pass through the separated metric reflection boundary, but it receives the $\mathsf{Real}^{\uparrow}$ *seal only as the terminal displayed row. It cannot claim ambient* $\mathsf{Real}^{\uparrow}$ *completeness, quotient stream equality, countable choice, host real equality, or a selected representative outside the packet.*

Proof. Use the carrier definition to expose the finite rows. A read that asks for an embedding first consumes the $\mathsf{StreamName}^{\uparrow}$ row S and the $\mathsf{RegSeqRat}^{\uparrow}$ row R, because these rows are the only source of regular rational stream data in the packet.

The metric-completion row M then records the completion-facing handoff, while Q records the separated reflection boundary. The terminal Real seal E is downstream of both rows and cannot be read independently of them.

The structural rows H, C, P, N transport, replay, record provenance, and name the same carrier surface. They add no coordinate for an external representative, quotient equality, countable choice, host equality, or ambient completeness. □

Theorem 9026.5 (Bishop separated real completion uniqueness boundary)**.** *If two accepted* BishopSeparatedRealCo *packets have the same displayed* $\mathsf{StreamName}^{\uparrow}$ *windows, the same* $\mathsf{RegSeqRat}^{\uparrow}$ *readback rows, and the same* $\mathsf{SeparatedMetricReflection}^{\uparrow}$ *comparison row, then every completion-facing comparison between them is determined inside the shared finite carrier surface. The comparison is a separated-reflection boundary over displayed rows, not a quotient of streams, a host real equality, a selected limit, a countable-choice witness, or an ambient completeness theorem.*

Proof. Read the two packets through the stability route of Definition 9026.3. Both completion-facing comparisons must expose stream windows and regular rational readbacks before either metric-completion or Real-seal data is available.

The shared separated reflection row is the only comparison boundary admitted by the carrier. Once that row is fixed, the remaining Real-facing read is replayed through the same displayed metric completion handoff and terminal seal.

Thus uniqueness is scoped to the finite carrier surface. The packet supplies no further equality principle and no way to choose representatives outside the displayed rows. □

Theorem 9026.6 (Bishop separated real completion ledger rows)**.** *The local* $\mathsf{NameCert}_{\mathsf{BishopSeparatedRealCompletion}^{\uparrow}}$ *ledger contains exactly these rows: carrier admission for* $S, R, M, Q, E, H, C, P, N$*; classifier exposure for the same rows; stability under componentwise* hsame *transport; embedding handoff through* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{MetricCompletion}^{\uparrow}$*,* $\mathsf{SeparatedMetricReflection}^{\uparrow}$*, and* $\mathsf{Real}^{\uparrow}$*; uniqueness boundary inside the separated reflection row; provenance through* Pkg*; and local naming through* N*. It records no quotient equality, countable choice, host-selected limit, detached real equality, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness row.*

Proof. Carrier admission is Definition 9026.1. Classifier exposure is Definition 9026.2.

Stability is supplied by Definition 9026.3, which keeps every transported read inside the same ordered row surface. The embedding handoff is Definition 9026.4.

The uniqueness boundary is Definition 9026.5. Provenance and local naming are the displayed rows P and N, and neither row adds data beyond the carrier. □

Closure status for $\mathsf{NameCert}_{\mathsf{BishopSeparatedRealCompletion}^{\uparrow}}$**.**

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{BishopSeparatedRealCompletion}^{\uparrow}}$, seed)

Scope closed: The chapter records the seed carrier, classifier, stability, embedding, uniqueness, and ledger rows for the Bishop separated real completion packet.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{BishopSeparatedRealCompletion}^{\uparrow}}$, formalTarget)

Lean target: `BEDC.Derived.BishopSeparatedRealCompletionUp`

Bridge status: none

Not claimed: This chapter does not close quotient equality of streams, host real equality, selected limits, countable choice, ambient Real$^{\uparrow}$ completeness, theorem-level Lean verification, or bridge checking.

Upgrade path: To reach scoped closure, formalize the listed carrier rows and prove classifier, stability, embedding, uniqueness, and ledger exactness in Lean.

Constructive story: A BishopSeparatedRealCompletion$^{\uparrow}$ packet is generated from StreamName finite windows, RegSeqRat readback, MetricCompletion handoff, SeparatedMetricReflection comparison, a terminal Real seal, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Chapter 9027

A Concrete Naming Certificate for $\mathsf{LoewnerOrder}^{\uparrow}$

Following Loewner's order on self-adjoint matrices and the Boyd–Vandenberghe semidefinite-programming presentation, the $\mathsf{LoewnerOrder}^{\uparrow}$ packet records the finite BEDC surface for the comparison $A \preceq B$ as semidefinite-cone membership of the displayed difference $B - A$. It sits after the Hermitian matrix carrier of chapter 6403, the semidefinite-cone packet of chapter 310, and the affine feasible-region route of chapter 5960. The packet names an order interface over finite Hermitian matrix rows; it does not assert spectral decomposition, eigenvalue monotonicity, analytic closure, selected diagonalization, or a host positive-semidefinite predicate.

Definition 9027.1 (Loewner order carrier)**.** *A* $\mathsf{LoewnerOrder}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$(A, B, H, D, K, V, O, T, C, P, N)$$

with the following displayed rows:

1. *A is the left* $\mathsf{HermitianMatrix}^{\uparrow}$ *row.*
2. *B is the right* $\mathsf{HermitianMatrix}^{\uparrow}$ *row over the same square dimension, scalar source, and vector-space boundary as A.*
3. *H is the shared Hermitian comparison window, recording the common dimension, complex scalar rows, vector-space source, and self-adjointness readbacks used by A and B.*
4. *D is the displayed difference-matrix row for $B - A$, read through the same* $\mathsf{Mat}^{\uparrow}$ *and* $\mathsf{VecSpace}^{\uparrow}$ *provenance as the two endpoint rows.*
5. *K is the* $\mathsf{SemidefiniteCone}^{\uparrow}$ *membership row for the difference matrix $B - A$.*
6. *V is the joint* $\mathsf{VecSpace}^{\uparrow}$ *and* $\mathsf{Mat}^{\uparrow}$ *provenance row tying A, B, H, and D to one finite coordinate surface.*
7. *O is the* $\mathsf{Order}^{\uparrow}$ *nonnegativity readback exported by K for displayed vector tests against $B - A$.*
8. *T records componentwise* hsame *transport for the endpoint, Hermitian, difference, cone-membership, order, replay, provenance, and local naming rows.*
9. *C records displayed* Cont *replay from endpoint inspection through difference formation and semidefinite-cone readback.*

10. *P is the* Pkg *provenance over* $\mathsf{LoewnerOrder}^{\uparrow}$, $\mathsf{HermitianMatrix}^{\uparrow}$, $\mathsf{SemidefiniteCone}^{\uparrow}$, $\mathsf{Mat}^{\uparrow}$, $\mathsf{VecSpace}^{\uparrow}$, $\mathsf{Order}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{LoewnerOrder}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through the eleven displayed rows. It has no coordinate for spectral theorem data, eigenvalue comparison, quotient matrix equality, analytic closure, selected basis data, or host-level positive semidefiniteness.

Theorem 9027.2 (Loewner order NameCert obligations)**.** *For every accepted* $\mathsf{LoewnerOrder}^{\uparrow}$ *carrier*

$$L = (A, B, H, D, K, V, O, T, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{LoewnerOrder}^{\uparrow}}$ *surface consists exactly of carrier admission, left and right Hermitian endpoint exposure, shared Hermitian comparison-window exposure, displayed difference-matrix formation, semidefinite-cone membership of $B - A$, vector-space and matrix provenance,* $\mathsf{Order}^{\uparrow}$ *nonnegativity readback, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming.*

Proof. Carrier admission is projection from Definition 9027.1. The endpoint rows A and B are visible only through the Hermitian matrix carrier, and the shared window H keeps their dimension, scalar source, vector-space source, and self-adjointness reads aligned.

The difference obligation is finite. The row D is the displayed matrix row for $B - A$, formed from the same matrix and vector-space provenance row V that types the two endpoint packets.

The positivity obligation is the semidefinite-cone row K. Its order-facing output is the nonnegativity readback O, so a consumer sees the comparison only after passing through the sibling semidefinite-cone certificate.

Finally T, C, P, N close the transport, replay, provenance, and local naming surface. Since no listed row stores spectral data, eigenvalue comparison, selected bases, quotient matrix equality, analytic closure, or a host positivity predicate, the displayed rows exhaust the local NameCert obligations. □

Theorem 9027.3 (Loewner order semidefinite route)**.** *Every optimization or convex-feasibility consumer that reads an accepted* $\mathsf{LoewnerOrder}^{\uparrow}$ *packet as $A \preceq B$ must factor through the displayed route*

$$(A, B, H, V) \longmapsto D = B - A \longmapsto K : \mathsf{SemidefiniteCone}^{\uparrow}(D) \longmapsto O : \mathsf{Order}^{\uparrow}.$$

The route may be cited by spectrahedral consumers, but it exports only the finite difference row, semidefinite-cone membership row, order readback, transport, replay, and provenance rows already present in the packet.

Proof. Read the accepted packet through Definition 9027.1. The left and right endpoints are Hermitian rows over the shared comparison window, so a matrix inequality read has no source other than A, B, H, and V.

Next form the displayed difference row D. This is the only row that turns endpoint data into a cone-facing matrix, and it remains tied to the same $\mathsf{Mat}^{\uparrow}$ and $\mathsf{VecSpace}^{\uparrow}$ provenance.

Then read the semidefinite-cone membership row K and its order output O. By chapter 310, the cone read is a finite BEDC membership surface rather than an imported positive-semidefinite predicate.

A spectrahedral consumer may use the resulting route as an affine-matrix inequality boundary, as in chapter 5960. The consumer still receives only D, K, O, T, C, P, N, so the Loewner comparison remains a finite semidefinite route. □

Theorem 9027.4 (Loewner order Hermitian nonescape)**.** *Every accepted* $\mathsf{LoewnerOrder}^{\uparrow}$ *packet keeps both endpoints and the displayed difference inside the finite Hermitian matrix surface: the rows* A *and* B *are* $\mathsf{HermitianMatrix}^{\uparrow}$ *carriers, the shared row* H *supplies the common self-adjoint comparison window, and the difference row* D *is admitted only as the matrix row consumed by the semidefinite-cone membership* K *over that same Hermitian boundary.*

Thus a Loewner comparison cannot escape to non-Hermitian matrices, quotient matrix equality, host equality of arrays, selected eigenbasis data, or spectral positivity.

Proof. Project the endpoint rows A and B from the carrier. Both are explicit $\mathsf{HermitianMatrix}^{\uparrow}$ rows, so their matrix entries, conjugate-transpose reads, and self-adjointness comparisons are governed by chapter 6403.

The row H keeps the two endpoint packets over one comparison window. Transport through T is componentwise over that same window, and replay through C inspects only the displayed endpoint, difference, cone, and order rows.

The difference row D is not a separate ambient matrix object. It is the finite matrix row consumed by K, and K is the semidefinite-cone membership row whose order readback is O.

Since the carrier has no additional coordinate, a consumer cannot read non-Hermitian matrix data, quotient equality, host array equality, selected eigenbasis data, or spectral positivity from an accepted $\mathsf{LoewnerOrder}^{\uparrow}$ packet. □

Closure status for $\mathsf{NameCert}_{\mathsf{LoewnerOrder}^{\uparrow}}$**.**

Constructive story: A $\mathsf{LoewnerOrder}^{\uparrow}$ packet is generated from two $\mathsf{HermitianMatrix}^{\uparrow}$ endpoint rows over a shared comparison window, a displayed difference-matrix row, a $\mathsf{SemidefiniteCone}^{\uparrow}$ membership row for $B - A$, an $\mathsf{Order}^{\uparrow}$ nonnegativity readback, hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{LoewnerOrder}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 9027.1, Definition 9027.2, Definition 9027.3, and Definition 9027.4 seed the finite Loewner-order packet over displayed $\mathsf{HermitianMatrix}^{\uparrow}$, $\mathsf{SemidefiniteCone}^{\uparrow}$, $\mathsf{Mat}^{\uparrow}$, $\mathsf{VecSpace}^{\uparrow}$, $\mathsf{Order}^{\uparrow}$, BHist, hsame, Cont, Pkg, and NameCert rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{LoewnerOrder}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close spectral decomposition, eigenvalue monotonicity, analytic closure, selected diagonalization, host positive-semidefinite predicates, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, endpoint Hermitian visibility, difference-row exactness, semidefinite-cone membership, order readback, transport, replay, provenance, and local naming for the same finite packet.

Chapter 9028

A Concrete Naming Certificate for $\mathsf{ConstructiveMetricSpace}^{\uparrow}$

Following Bishop and Bridges on constructive metric spaces, the $\mathsf{ConstructiveMetricSpace}^{\uparrow}$ packet records the finite interface needed before an L10 completion consumer may ask for points, located distances, separatedness evidence, or completion ledgers. It is read downstream of the metric naming surface in chapter 57, the finite window service of chapter 126, the regular rational-name route of chapter 301, the terminal real-name seal of chapter 38, and the completion boundary of chapter 128. The packet supplies countable constructive naming data; it does not import host equality, quotients, choice, selected limits, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 9028.1 (Constructive metric-space carrier)**.** *A* $\mathsf{ConstructiveMetricSpace}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M = (X, E, d, L, S, R, C, Q, P, N)$$

with the following displayed rows:

1. *X is the point-name carrier, read only through finite* $\mathsf{StreamName}^{\uparrow}$ *windows.*
2. *E is the point classifier, transported by displayed* hsame *rows and never by host equality of points.*
3. *d is the located-distance service, returning finite* $\mathsf{RegSeqRat}^{\uparrow}$ *evidence for requested point pairs and requested tolerances.*
4. *L is the separatedness-reflection row: a positive located distance is the only exported witness that two point names are apart.*
5. *S is the* $\mathsf{StreamName}^{\uparrow}$ *window ledger used by point and distance reads.*
6. *R is the* $\mathsf{Real}^{\uparrow}$ *seal row for completed distance names, available only after the located-distance and regular-rational rows have been displayed.*
7. *C is the completion ledger tying the point, classifier, located-distance, separatedness, stream, regular-rational, and real-seal rows to downstream* $\mathsf{CompleteMetric}^{\uparrow}$ *consumers.*
8. *Q stores componentwise* hsame *transport for the displayed rows.*
9. *P is the* Pkg *provenance over* $\mathsf{ConstructiveMetricSpace}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{CompleteMetric}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{ConstructiveMetricSpace}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $X, E, d, L, S, R, C, Q, P, N$. It has no coordinate for quotient completion, countable choice, selected representatives, host point equality, or ambient completeness.

Theorem 9028.2 (Constructive metric-space NameCert obligations)**.** *For every accepted* $\mathsf{ConstructiveMetricSpace}^{\uparrow}$ *carrier* $M = (X, E, d, L, S, R, C, Q, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{ConstructiveMetricSpace}^{\uparrow}}$ *surface consists of five finite obligation rows:*

1. *point carrier: X admits only finitely requested point-name windows through S;*
2. *classifier: E compares point names through displayed* hsame *and* Cont *routes, not through host equality;*
3. *located distance: d supplies* $\mathsf{RegSeqRat}^{\uparrow}$ *evidence for each requested pair and tolerance before the* $\mathsf{Real}^{\uparrow}$ *seal R is available;*
4. *separatedness reflection: L exports apartness only from a displayed positive located-distance row;*
5. *completion ledger: C records how $X, E, d, L, S, R, Q, P, N$ may be consumed by a later* $\mathsf{CompleteMetric}^{\uparrow}$ *packet.*

No obligation row exports quotient points, selected Cauchy representatives, choice functions, host equality of names, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the carrier of Definition 9028.1. The point carrier, classifier, located-distance row, separatedness-reflection row, stream ledger, real seal, completion ledger, transports, provenance, and local naming row are all visible coordinates of the same finite packet.

The located-distance obligation reads a requested point pair through X, E, S before it reaches the regular-rational evidence in d. The real-facing row R is a seal for that displayed distance name, not a completion principle.

The completion ledger C then records the downstream handoff to $\mathsf{CompleteMetric}^{\uparrow}$ consumers. Since the carrier has no quotient row, selected representative row, choice schedule, host equality row, or ambient completeness row, the NameCert surface is exhausted by the five displayed obligations. □

Theorem 9028.3 (Constructive metric-space separated completion route)**.** *Every downstream completion read of an accepted* $\mathsf{ConstructiveMetricSpace}^{\uparrow}$ *carrier must pass through the displayed route*

$$X, E, d, L, S, R, C, Q, P, N.$$

The route may hand a $\mathsf{CompleteMetric}^{\uparrow}$ *consumer point names, classifier evidence, located distances, separatedness reflection, finite StreamName windows, RegSeqRat distance names, Real seals, transport rows, package provenance, and local naming. It may not hand over quotient-completion equality, a selected limit, countable choice, host point equality, or a theorem that* $\mathsf{Real}^{\uparrow}$ *is complete.*

Proof. Start with the completion ledger C. Its only inputs are the visible rows of the carrier, so every completion-facing read is downstream of the point carrier, classifier, located-distance service, separatedness row, window ledger, real seal, transports, provenance, and local NameCert row.

Separatedness is supplied by L only after a positive located-distance row has been displayed. Thus a completion consumer may cite separatedness as a finite reflection of the located metric data, not as host equality or quotient equality.

The terminal handoff to $\mathsf{CompleteMetric}^{\uparrow}$ is therefore a route through countable constructive naming data. It supplies the interface needed by completion work while leaving quotient construction, selected limits, choice, and ambient $\mathsf{Real}^{\uparrow}$ completeness outside this chapter. □

Falsifiable prediction: Every $\mathsf{ConstructiveMetricSpace}^{\uparrow}$ completion-facing read factors through one point carrier, one point classifier, one located-distance service, one separatedness-reflection row, one finite StreamName ledger, one RegSeqRat distance-name route, one RealUp seal, one completion ledger, componentwise hsame transport, package provenance, and local naming.

Independence witness: metric, streamname, regseqrat, real, completemetric: $\mathsf{ConstructiveMetricSpace}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries point naming, classifier stability, located-distance service, separatedness reflection, finite windows, regular rational distance names, Real seals, completion ledger rows, transport, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{ConstructiveMetricSpace}^{\uparrow}}$.

Constructive story: A $\mathsf{ConstructiveMetricSpace}^{\uparrow}$ packet is generated from point names, a displayed point classifier, located-distance rows, separatedness reflection, StreamName windows, RegSeqRat distance names, a RealUp seal, a CompleteMetricUp ledger, componentwise hsame transport, package provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{ConstructiveMetricSpace}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 9028.1, Definition 9028.2, and Definition 9028.3 seed the finite constructive metric-space interface consumed by separated completion routes.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{ConstructiveMetricSpace}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient completions, selected limits, countable choice, host equality of points, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked point-carrier admission, classifier stability, located-distance exactness, separatedness reflection, completion-ledger replay, transport, provenance, and local naming for BEDC.Derived.ConstructiveMetricSpaceUp

Chapter 9029

A Concrete Naming Certificate for $\mathsf{CantorSpaceCompletion}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{CantorSpaceCompletion}^{\uparrow}$ packet records the completion of Cantor space by finite prefix Cauchy names. It sits after the binary-prefix carrier of chapter 1475, the finite prefix stream certificate of chapter 7253, the regular rational readback of chapter 301, the dyadic tolerance ledger of chapter 291, the terminal real-name seal of chapter 38, the Cantor-intersection route of chapter 1421, and the interval coding surface of chapter 7588. The packet names constructive prefix completion as displayed BEDC rows; it is not quotient stream equality, not open-cover compactness, not trichotomy, and not ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 9029.1 (CantorSpaceCompletion carrier)**.** *A* $\mathsf{CantorSpaceCompletion}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (A, W, D, R, E, L, H, C, P, N)$$

with the following displayed rows:

1. *A is the* $\mathsf{CantorSpace}^{\uparrow}$ *prefix row, naming the inspected binary cylinders and their extension order.*
2. *W is the* $\mathsf{StreamName}^{\uparrow}$ *finite window row, displaying the prefix observations available at the requested depths.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, recording the dyadic diameter bound attached to each displayed cylinder.*
4. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row obtained from the same prefix windows and dyadic bounds.*
5. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row, available only after A, W, D, R have been displayed.*
6. *L is the prefix Cauchy ledger, recording that later prefix windows extend the earlier cylinders and shrink their displayed dyadic diameters.*
7. *H records componentwise* hsame *transport for prefix rows, windows, dyadic ledgers, regular readbacks, terminal seals, the prefix Cauchy ledger, replay, provenance, and local naming.*
8. *C records displayed* Cont *replay of the same finite prefix Cauchy route.*
9. *P is the* Pkg *provenance over* $\mathsf{CantorSpaceCompletion}^{\uparrow}$, $\mathsf{CantorSpace}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{CantorIntersection}^{\uparrow}$, $\mathsf{BishopIntervalCantor}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*

10. N is the local $\mathsf{NameCert}_{\mathsf{CantorSpaceCompletion}^{\uparrow}}$ *row.*
The classifier compares accepted packets only through $A, W, D, R, E, L, H, C, P, N$. It has no coordinate for quotient stream equality, selected infinite representatives, trichotomy, open-cover compactness, countable choice, host real equality, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 9029.2 (CantorSpaceCompletion NameCert obligations)**.** *For every accepted* $\mathsf{CantorSpaceCompletion}^{\uparrow}$ *carrier*

$$K = (A, W, D, R, E, L, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{CantorSpaceCompletion}^{\uparrow}}$ *surface consists exactly of carrier admission for the* $\mathsf{CantorSpace}^{\uparrow}$ *prefix row,* $\mathsf{StreamName}^{\uparrow}$ *finite-window exposure,* $\mathsf{DyadicRatCore}^{\uparrow}$ *diameter accounting,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback exposure, terminal* $\mathsf{Real}^{\uparrow}$ *seal routing, prefix Cauchy ledger exposure, componentwise transport, displayed replay, package provenance, and local naming. A Real or Completion consumer may cite completed Cantor-space data only after those rows have been displayed.*

Proof. Project the carrier of Definition 9029.1. The visible completion-facing rows are exactly the binary prefix row A, finite windows W, dyadic diameter ledger D, regular readback R, terminal seal E, and prefix Cauchy ledger L.

Read the prefix Cauchy ledger L after the source rows. It says only that later displayed windows extend earlier binary cylinders and tighten the dyadic diameter bounds already recorded in D.

The structural rows H, C, P, N transport, replay, source, and name the same finite route. Since none of the rows stores quotient stream equality, a selected representative stream, trichotomy, open-cover compactness, countable choice, host real equality, or ambient completeness, the listed rows exhaust the local NameCert surface. □

Theorem 9029.3 (CantorSpaceCompletion prefix limit route)**.** *Every Real or Completion-facing consumer of an accepted* $\mathsf{CantorSpaceCompletion}^{\uparrow}$ *carrier must factor its read through the displayed route*

$$\mathsf{CantorSpace}^{\uparrow} \longmapsto \mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{DyadicRatCore}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}$$

together with the prefix Cauchy ledger L and the structural rows H, C, P, N. The route may be compared with $\mathsf{CantorIntersection}^{\uparrow}$ *and* $\mathsf{BishopIntervalCantor}^{\uparrow}$ *sibling packets as a finite prefix handoff, but it cannot be replaced by quotient stream equality, a selected infinite branch, trichotomy, open-cover compactness, countable choice, host real equality, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Begin with the NameCert obligations of Definition 9029.2. They force any accepted consumer to read A, W, D, R, E, L before using the completion-facing surface.

The Cantor-space source row A supplies only displayed binary cylinders. The StreamName row W exposes finite observations of those cylinders, the DyadicRatCore row D records the displayed diameter bounds, and the RegSeqRat row R reads the same finite data as regular rational completion input before the terminal Real seal E is available.

Now use the sibling routes. $\mathsf{CantorIntersection}^{\uparrow}$ and $\mathsf{BishopIntervalCantor}^{\uparrow}$ may consume the same displayed prefix Cauchy ledger as a finite handoff, but neither sibling adds a quotient stream row, selected infinite branch, trichotomy row, open-cover compactness witness, countable-choice schedule, host real equality, or ambient completeness theorem.

Finally, H, C, P, N preserve only the displayed route under transport, replay, provenance, and local naming. Thus every prefix-limit read remains inside the finite Cantor-space completion packet named in the statement. □

Falsifiable prediction: An accepted $\mathsf{CantorSpaceCompletion}^{\uparrow}$ read is refuted if it reaches Real or Completion data without displaying the CantorSpace prefix row, StreamName finite windows, DyadicRatCore diameter ledger, RegSeqRat readback, RealUp seal, prefix Cauchy ledger, componentwise hsame transport, Cont replay, Pkg provenance, and local NameCert row.

Independence witness: cantorspace, streamname, regseqrat, dyadicratcore, real, cantorintersection, bishopintervalcantor: $\mathsf{CantorSpaceCompletion}^{\uparrow}$ is not bijective to any listed sibling because it jointly binds binary prefix cylinders, finite windows, dyadic diameter bounds, regular readback, terminal sealing, prefix Cauchy extension, transport, replay, provenance, and local naming in one packet.

Closure status for $\mathsf{NameCert}_{\mathsf{CantorSpaceCompletion}^{\uparrow}}$.

Constructive story: A $\mathsf{CantorSpaceCompletion}^{\uparrow}$ packet is generated from a CantorSpace prefix row, StreamName finite windows, a DyadicRatCore diameter ledger, RegSeqRat readback, a RealUp seal, a prefix Cauchy ledger, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CantorSpaceCompletion}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 9029.1, Definition 9029.2, Definition 9029.3, the falsifiable prediction, and the independence witness seed the finite prefix Cauchy completion route over CantorSpace, StreamName, DyadicRatCore, RegSeqRat, Real, CantorIntersection, BishopIntervalCantor, transport, replay, provenance, and local naming rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CantorSpaceCompletion}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient stream equality, selected infinite representatives, trichotomy, open-cover compactness, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, axiom-clean audit, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, prefix Cauchy ledger exactness, StreamName window exposure, DyadicRatCore diameter accounting, RegSeqRat readback, Real seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.CantorSpaceCompletionUp.

Chapter 9030

A Concrete Naming Certificate for $\mathsf{RegularCauchyModulusWitness}^{\uparrow}$

Following Bishop and Bridges' regular Cauchy treatment of constructive real numbers, the RegularCauchyModulusW packet isolates the finite tail-modulus witness needed before a regular rational stream is sealed as a real object. It sits on the dyadic tolerance rows of chapter 291, the finite stream-window interface of chapter 126, the regular rational sequence route of chapter 301, and the terminal real-name seal of chapter 38. The packet records the witnessed tail window as finite NameCert data; it is not a selected limit, a quotient stream, a countable-choice principle, or an ambient completeness theorem.

Definition 9030.1 (Regular Cauchy modulus-witness carrier)**.** *A* $\mathsf{RegularCauchyModulusWitness}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$W = (S, R, T, D, Q, E, H, C, P, N)$$

with the following displayed rows:

1. *S is the* $\mathsf{StreamName}^{\uparrow}$ *source-window row, naming the finite observations of the rational stream that are available to the witness.*
2. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *regularity row, recording that the source stream is read through the regular rational sequence carrier rather than through a host sequence.*
3. *T is the tail-window row, naming a finite index budget after which the displayed comparison is served.*
4. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row consumed by the tail-window request.*
5. *Q is the tail readback row, recording that every displayed comparison inside the window reads the same S, R, T, D route.*
6. *E is the* $\mathsf{Real}^{\uparrow}$ *consumer-facing seal row, recording that a later real-name read may consume the witnessed route without receiving a selected limit or quotient equality.*
7. *H records componentwise* hsame *transport for S, R, T, D, Q, E and the local naming row.*
8. *C records displayed* Cont *replay through stream readback, regularity readback, tail-window service, dyadic tolerance lookup, seal handoff, provenance, and local naming.*
9. *P is the* Pkg *provenance over* $\mathsf{RegularCauchyModulusWitness}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* NameCert *rows.*

10. N is the local $\mathsf{NameCert}_{\mathsf{RegularCauchyModulusWitness}^{\uparrow}}$ *row.*
The carrier exports only the displayed witness route. It contains no hidden selector, no second tolerance ledger, no quotient stream, no host real equality, no selected limit, no countable-choice row, and no ambient completeness coordinate.

Theorem 9030.2 (Regular Cauchy modulus-witness NameCert obligations)**.** *For the carrier of Definition 9030.1, the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyModulusWitness}^{\uparrow}}$ *surface consists exactly of carrier admission for*

$$W = (S, R, T, D, Q, E, H, C, P, N),$$

finite stream-window exposure through S, regular rational sequence exposure through R, tail-window exposure through T, dyadic tolerance exposure through D, readback exactness through Q, consumer-facing $\mathsf{Real}^{\uparrow}$ *seal exposure through E, componentwise* hsame *transport through H, displayed* Cont *replay through C,* Pkg *provenance through P, and local naming through N.*

Proof. Project the accepted carrier. Its displayed rows are exactly the stream window, regular rational sequence row, tail-window budget, dyadic tolerance, readback route, real-seal handoff, transport, replay, provenance, and local naming.

The four sibling dependencies are consumed in order. The $\mathsf{StreamName}^{\uparrow}$ row supplies the finite observations, the $\mathsf{RegSeqRat}^{\uparrow}$ row supplies the regular-sequence discipline, the $\mathsf{DyadicRatCore}^{\uparrow}$ row supplies the tolerance being served, and the $\mathsf{Real}^{\uparrow}$ row is only a downstream seal consumer.

Finally read H, C, P, N. These rows transport, replay, package, and name the same finite packet, and no carrier coordinate can be projected as a selected limit, quotient stream, countable choice, host real equality, or ambient completeness theorem. □

Closure status for $\mathsf{NameCert}_{\mathsf{RegularCauchyModulusWitness}^{\uparrow}}$.

Constructive story: A $\mathsf{RegularCauchyModulusWitness}^{\uparrow}$ packet is generated from a finite stream window, a regular rational sequence row, a displayed tail-window budget, a dyadic tolerance row, a readback route, a Real-facing seal handoff, componentwise transports, displayed replay, provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{RegularCauchyModulusWitness}^{\uparrow}}$, obligation)

Scope closed: Definition 9030.1 and Definition 9030.2 bind the finite tail-modulus witness surface over $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{RegularCauchyModulusWitness}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close Lean verification, bridge checking, selected limits, quotient streams, countable choice, host real equality, or ambient completeness for $\mathsf{RegularCauchyModulusWitness}^{\uparrow}$.

Upgrade path: Lean closure requires an encoding of the carrier, tail-window readback exactness, classifier transport, displayed replay, provenance, and local naming for the same finite packet.

Chapter 9031

A Concrete Naming Certificate for $\mathsf{MatroidGreedy}^{\uparrow}$

Following Edmonds' matroid greedy theorem, the $\mathsf{MatroidGreedy}^{\uparrow}$ packet records the finite exchange route by which a displayed weight-ordered scan produces a maximum-weight independent set in a finite matroid. It reads the independence and exchange rows of chapter 202, the augmenting-incidence discipline of chapter 234, the finite residual comparison surface of chapter 233, and the ordered-field weak-duality rows of chapter 235. The packet names the greedy certificate as finite BEDC data; it does not import a host optimizer, quotient equality of bases, selected maximal bases outside the ledger, or an ambient linear-programming oracle.

Definition 9031.1 (Matroid greedy carrier)**.** *A* $\mathsf{MatroidGreedy}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$G = (E, M, W, O, A, X, V, H, C, P, N)$$

with the following displayed rows:

1. *E is the finite ground row shared with the source* $\mathsf{Matroid}^{\uparrow}$ *packet.*
2. *M is the source* $\mathsf{Matroid}^{\uparrow}$ *row, including independent-set admission, hereditary restriction, and exchange data.*
3. *W is the finite weight row, assigning an ordered value to every displayed ground element.*
4. *O is the weight-order scan row, recording the finite descending inspection order and tie ledger.*
5. *A is the accepted greedy prefix row, recording each admitted independent prefix.*
6. *X is the exchange witness row, pairing any competing independent row with the first displayed exchange point at which the greedy prefix dominates.*
7. *V is the value comparison row, read through finite sums and the* $\mathsf{LPDuality}^{\uparrow}$ *weak-duality discipline.*
8. *H records componentwise* hsame *transport for ground, source matroid, weights, order, accepted prefixes, exchange witnesses, value comparison, replay, provenance, and local naming rows.*
9. *C records displayed* Cont *replay for every consumer that reopens the scan or exchange route.*
10. *P is the* Pkg *provenance over* $\mathsf{MatroidGreedy}^{\uparrow}$, $\mathsf{Matroid}^{\uparrow}$, $\mathsf{Matching}^{\uparrow}$, $\mathsf{NetworkFlow}^{\uparrow}$, $\mathsf{LPDuality}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*

11. *N is the local* $\mathsf{NameCert}_{\mathsf{MatroidGreedy}^\uparrow}$ *row.*
The carrier has no coordinate for a host greedy algorithm, quotient ground equality, selected bases outside the displayed scan, an unrestricted optimizer, or ambient linear-programming strong duality.

Theorem 9031.2 (Matroid greedy NameCert obligations)**.** *For every accepted* $\mathsf{MatroidGreedy}^\uparrow$ *carrier*

$$G = (E, M, W, O, A, X, V, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{MatroidGreedy}^\uparrow}$ *surface consists exactly of carrier admission for G, source* $\mathsf{Matroid}^\uparrow$ *exposure through M, weight and scan exposure through W, O, greedy-prefix exposure through A, exchange-witness exposure through X, value-comparison exposure through V, componentwise* hsame *transport through H, displayed* Cont *replay through C,* Pkg *provenance through P, and local naming through N.*

Proof. Project the carrier of Definition 9031.1. The rows E, M, W, O, A, X, V are the complete finite optimization inventory: source ground and matroid, ordered weights, accepted scan prefixes, exchange witnesses, and value comparison.

Read M through chapter 202. Hereditary restriction licenses rejected scan steps, while the exchange row is the only source for replacing a competing independent element by the earliest greedy element.

The matching and network-flow siblings supply finite incidence and residual-comparison discipline for the exchange ledger, and the $\mathsf{LPDuality}^\uparrow$ sibling supplies the ordered value-comparison surface. The rows H, C, P, N transport, replay, source, and name exactly the same data.

Since no carrier coordinate stores a host optimizer, quotient ground equality, selected basis family, unrestricted search, or ambient strong-duality theorem, none of those objects can discharge a local $\mathsf{NameCert}_{\mathsf{MatroidGreedy}^\uparrow}$ obligation. □

Theorem 9031.3 (Matroid greedy exchange certificate)**.** *Every accepted* $\mathsf{MatroidGreedy}^\uparrow$ *packet exports a finite exchange certificate: for any displayed competing independent row over the same* $\mathsf{Matroid}^\uparrow$ *source, the row X supplies a finite sequence of exchange steps that replaces the competitor by the greedy prefix without lowering the displayed value row V. The exchange route factors through the same ground row E, source matroid row M, weight row W, scan row O, accepted-prefix row A, componentwise* hsame *transport,* Cont *replay,* Pkg *provenance, and local* NameCert *row.*

The certificate is finite and public. It is not a host optimality theorem, not quotient equality of bases, not a selected external maximum, not an unbounded augmenting search, and not an ambient linear-programming oracle.

Proof. Start with a displayed competitor over the same source matroid. The carrier in Definition 9031.1 makes the source ground E, independence row M, weights W, and scan order O visible before any exchange step is read.

Use the source exchange row from $\mathsf{Matroid}^\uparrow$. At the first scan position where the competitor differs from the greedy prefix, the exchange witness row X names a displayed replacement that preserves independence and does not move to a lower weight position.

Iterating this finite exchange ledger rewrites the competitor into the greedy prefix. The matching and network-flow sibling rows keep the incidence and residual bookkeeping finite, while the $\mathsf{LPDuality}^\uparrow$ value row V records that the displayed value comparison is monotone along the ledger.

The support rows H, C, P, N transport, replay, source, and name the same exchange certificate. Because the packet contains no host optimizer, quotient-basis equality, selected maximum,

unbounded search, or ambient LP oracle, the exported certificate is exactly the finite exchange route. □

Falsifiable prediction: A consumer that cites $\mathsf{MatroidGreedy}^{\uparrow}$ without displaying the source matroid, weight-order scan, accepted prefixes, exchange witness ledger, value comparison, hsame, Cont, Pkg, and local NameCert rows is not reading the carrier.

Independence witness: matroid, matching, networkflow, lpduality: $\mathsf{Matroid}^{\uparrow}$ supplies the exchange source, $\mathsf{Matching}^{\uparrow}$ supplies incidence pairing, $\mathsf{NetworkFlow}^{\uparrow}$ supplies residual comparison discipline, and $\mathsf{LPDuality}^{\uparrow}$ supplies finite ordered value comparison, but none carries the greedy scan plus exchange-certificate packet as a local NameCert row.

Closure status for $\mathsf{NameCert}_{\mathsf{MatroidGreedy}^{\uparrow}}$**.**

Constructive story: A $\mathsf{MatroidGreedy}^{\uparrow}$ packet is generated from a finite ground row, source MatroidUp row, finite weight row, weight-order scan row, accepted greedy prefix row, exchange witness row, value comparison row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert naming.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{MatroidGreedy}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 9031.1, Definition 9031.2, and Definition 9031.3 seed the finite greedy exchange certificate over MatroidUp, MatchingUp, NetworkFlowUp, LPDualityUp, BHist, hsame, Cont, Pkg, and NameCert rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{MatroidGreedy}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host matroid optimization, quotient ground equality, selected global bases, unrestricted search, ambient linear-programming strong duality, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, scan-prefix exactness, exchange-witness exactness, value comparison, transport, replay, provenance, and local naming for BEDC.Derived.MatroidGreedyUp.

Chapter 9032

A Concrete Naming Certificate for $\mathsf{RegularCauchyApartnessCriterion}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{RegularCauchyApartnessCriterion}^{\uparrow}$ packet records the finite-window criterion by which two regular Cauchy rational names exhibit positive apartness before any quotient real equality, trichotomy principle, or host real order is consulted. It sits between the regular rational names of chapter 301, the observation schedule of chapter 126, the positive dyadic gap evidence of chapter 291, the real-name seal of chapter 38, and the finite separation interface of chapter 304.

Definition 9032.1 (Regular Cauchy apartness criterion carrier)**.** *A* $\mathsf{RegularCauchyApartnessCriterion}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Q = (L, R, W, D, A, H, C, P, N)$$

with the following displayed rows:

1. *L and R are the left and right* $\mathsf{RegSeqRat}^{\uparrow}$ *rows, including their displayed rational-value reads and regular Cauchy modulus rows.*
2. *W is a common finite* $\mathsf{StreamName}^{\uparrow}$ *window that names exactly the finitely many indices inspected on both rows.*
3. *D is the positive* $\mathsf{DyadicRatCore}^{\uparrow}$ *gap evidence read from the windowed endpoint approximations.*
4. *A is the* $\mathsf{ApartnessReal}^{\uparrow}$ *finite-window separation row produced after the* $\mathsf{Real}^{\uparrow}$ *seal reads the two regular Cauchy rows as real names.*
5. *H records componentwise* hsame *transport for L, R, W, D, A, C, P, N and for the two windowed endpoint readbacks.*
6. *C records displayed* Cont *replay from an apartness request through the two regular Cauchy rows, the common window, the positive dyadic gap, the real seal, and the separation row.*
7. *P is the* Pkg *provenance over* $\mathsf{RegularCauchyApartnessCriterion}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*,* $\mathsf{ApartnessReal}^{\uparrow}$*,* BHist*,* hsame*,* Cont*, and* $\mathsf{NameCert}$ *rows.*
8. *N is the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyApartnessCriterion}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $L, R, W, D, A, H, C, P, N$. It has no coordinate for quotient equality of reals, a total order, trichotomy, excluded middle, a selected limit, a host metric, or a completion theorem.

Theorem 9032.2 (Regular Cauchy apartness criterion NameCert obligations)**.** *For every accepted* $\mathsf{RegularCauchyApartnessCriterion}^{\uparrow}$ *carrier*

$$Q = (L, R, W, D, A, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{RegularCauchyApartnessCriterion}^{\uparrow}}$ *surface consists exactly of left and right* $\mathsf{RegSeqRat}^{\uparrow}$ *admission, common finite* $\mathsf{StreamName}^{\uparrow}$ *window exposure, positive* $\mathsf{DyadicRatCore}^{\uparrow}$ *gap evidence,* $\mathsf{Real}^{\uparrow}$ *seal compatibility,* $\mathsf{ApartnessReal}^{\uparrow}$ *separation-row handoff, componentwise* hsame *transport, displayed* Cont *replay, provenance, and local naming.*

Proof. Project the carrier of Definition 9032.1. The rows L and R supply the two regular rational names, while W restricts the inspection to a common finite window.

Read the dyadic gap row D. Because D is positive evidence over the displayed windowed endpoint readbacks, the criterion uses a finite witness rather than a total comparison of completed reals.

The row A is then obtained by replaying the $\mathsf{Real}^{\uparrow}$ seal and the $\mathsf{ApartnessReal}^{\uparrow}$ finite-window separation interface on the same displayed data. The structural rows H, C, P, N transport, replay, source, and name only these finite rows, so the listed obligations exhaust the local NameCert surface. □

Theorem 9032.3 (Regular Cauchy apartness criterion Real seal handoff)**.** *Let*

$$Q = (L, R, W, D, A, H, C, P, N)$$

be an accepted $\mathsf{RegularCauchyApartnessCriterion}^{\uparrow}$ *carrier. Any* $\mathsf{Real}^{\uparrow}$ *or* $\mathsf{ApartnessReal}^{\uparrow}$ *consumer that reads the positive apartness of the two regular Cauchy names must first expose* L, R, W, D *and the structural rows* H, C, P, N*. The handoff is the finite route*

$$\mathsf{RegSeqRat}^{\uparrow}, \mathsf{StreamName}^{\uparrow}, \mathsf{DyadicRatCore}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}, \mathsf{ApartnessReal}^{\uparrow},$$

not quotient equality of completed reals, a host real order, trichotomy, a selected limit, or a choice principle over tails.

Proof. Start from the two $\mathsf{RegSeqRat}^{\uparrow}$ rows and the common window. The finite window W identifies which rational approximants are inspected, so the handoff has an explicit observation schedule before the real-name seal is consumed.

Replay the positive dyadic gap D through the displayed endpoint readbacks. This produces the separation data required by the $\mathsf{ApartnessReal}^{\uparrow}$ finite-window row after the $\mathsf{Real}^{\uparrow}$ seal reads the same regular Cauchy names.

Finally use H, C, P, N to transport, replay, source, and locally name the handoff. Since every consumer must pass through these rows, the public output is positive apartness evidence only, with no quotient equality, trichotomy, host order, selected limit, or tail-choice principle added. □

Closure status for $\mathsf{NameCert}_{\mathsf{RegularCauchyApartnessCriterion}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RegularCauchyApartnessCriterion}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 9032.1, Definition 9032.2, and Definition 9032.3 seed the finite-window apartness criterion over regular Cauchy rational rows, common stream windows, positive dyadic gaps, real seals, apartness handoff, transport, replay, provenance, and local naming.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RegularCauchyApartnessCriterion}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close Lean verification, bridge checking, quotient equality of reals, trichotomy, total real order, host metric apartness, selected limits, completion, or choice over tails.

Upgrade path: Obligation closure requires checked carrier admission, window exactness, positive dyadic-gap stability, real-seal handoff, apartness-row handoff, transport, replay, provenance, and local naming for BEDC.Derived.RegularCauchyApartnessCriterionU

Constructive story: A RegularCauchyApartnessCriterion$^{\uparrow}$ packet is generated from two RegSeqRatUp rows, a common finite StreamNameUp window, positive DyadicRatCoreUp gap evidence, RealUp seal compatibility, an ApartnessRealUp separation row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert.

Chapter 9033

A Concrete Naming Certificate for $\mathsf{BishopRealIntervalHalving}^{\uparrow}$

Following Bishop and Bridges, interval halving is a finite located-interval operation used to keep a constructive real search inside explicit rational bounds. The $\mathsf{BishopRealIntervalHalving}^{\uparrow}$ packet isolates that operation as L10 NameCert data after the dyadic carrier of chapter 291, the stream naming surface of chapter 126, the regular rational sequence packet of chapter 301, the constructive real packet of chapter 38, and the located-real surface of **??**.

Definition 9033.1 (BishopRealIntervalHalving carrier)**.** *A* $\mathsf{BishopRealIntervalHalving}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (L, U, M, S, D, R, E, H, C, P, N)$$

with the following displayed rows:

1. *L is the lower dyadic endpoint row;*
2. *U is the upper dyadic endpoint row;*
3. *M is the dyadic midpoint row, read as the exact average of L and U inside the dyadic carrier of chapter 291;*
4. *S is the selected-half row, choosing either the lower half $[L, M]$ or the upper half $[M, U]$ from displayed located evidence;*
5. *D is the dyadic tolerance row recording the radius before and after one halving step;*
6. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the selected endpoint sequence;*
7. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row, asserting that the selected half remains inside the same constructive-real envelope;*
8. *H records componentwise* hsame *transport for endpoint, midpoint, selected-half, tolerance, readback, seal, replay, provenance, and local certificate rows;*
9. *C records displayed* Cont *routes for endpoint inspection, midpoint replay, selected-half handoff, tolerance decrease, regular-sequence readback, real-seal replay, and consumer use;*
10. *P is the provenance row over the cited dyadic, stream-name, regular-sequence, real, and located-real siblings;*
11. *N is the local* $\mathsf{NameCert}_{\mathsf{BishopRealIntervalHalving}^{\uparrow}}$ *row.*

The carrier has no coordinate for trichotomy, Heine–Borel compactness, quotient-real equality, global choice of nested intervals, or countable choice. It records one finite bisection step with all endpoints, tolerance, readback, seal, transport, replay, provenance, and naming rows visible.

Theorem 9033.2 (BishopRealIntervalHalving NameCert obligations)**.** *For the carrier of Definition 9033.1, the local* $\mathsf{NameCert}_{\mathsf{BishopRealIntervalHalving}^{\uparrow}}$ *surface consists of five finite obligations:*

1. *midpoint exactness: M is displayed as the dyadic midpoint of the endpoint rows L and U;*
2. *selected-half containment: the selected row S names either $[L, M]$ or $[M, U]$ and remains contained in the original located interval;*
3. *dyadic radius decrease: the tolerance row D records the halved radius of the selected interval;*
4. *Real seal nonescape: the seal row E keeps the selected half inside the same* $\mathsf{Real}^{\uparrow}$ *envelope read through R;*
5. *provenance exhaustion: the rows H, C, P, N replay only the dyadic endpoint, StreamName, RegSeqRat, Real, LocatedReal, transport, continuation, package, and local NameCert sources displayed in K.*

The obligations produce a finite bisection certificate, not an interval-completeness theorem, trichotomy principle, Heine–Borel theorem, quotient-real construction, uniform search over arbitrary predicates, or countable-choice principle.

Proof. The midpoint obligation is read directly from the M row together with the dyadic endpoint rows L and U. Since all three rows are part of the finite packet, no external real-number quotient or hidden completion operation is required to name the midpoint.

The selected-half and radius obligations are the rows S and D. The selected half is one of the two displayed dyadic subintervals, and the tolerance row records that this subinterval has the halved radius.

The readback and seal obligations are the rows R and E. The regular rational sequence readback supplies the finite endpoint data consumed by the constructive-real seal, while the seal records nonescape inside the same real envelope.

Finally, H, C, P, N exhaust the transport, replay, provenance, and naming rows. They cite only the dyadic, stream-name, regular-sequence, real, located-real, BHist, hsame, Cont, Pkg, and NameCert surfaces already displayed in the packet, so the certificate exports a single finite halving step and none of the refused global principles. □

Closure status for $\mathsf{NameCert}_{\mathsf{BishopRealIntervalHalving}^{\uparrow}}$.

Constructive story: A $\mathsf{BishopRealIntervalHalving}^{\uparrow}$ packet is generated from dyadic endpoints, an exact midpoint, a selected half, a dyadic tolerance row, RegSeqRat readback, a Real seal, transport, replay, provenance, and local NameCert rows.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{BishopRealIntervalHalving}^{\uparrow}}$, seed)

Scope closed: Definition 9033.1 and Definition 9033.2 bind the finite interval-halving carrier and its midpoint, containment, radius, seal, and provenance obligations.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{BishopRealIntervalHalving}^{\uparrow}}$, unformalized)

Bridge status: none

Origin: human

Not claimed: This chapter does not close interval completeness, trichotomy, Heine–Borel compactness, quotient-real equality, uniform predicate search, Lean verification, audit cleanliness, or bridge checking.

Upgrade path: Formalization requires a future Lean carrier and theorem under BEDC.Derived.BishopRealIntervalHalvingUp for midpoint exactness, selected-half containment, dyadic radius decrease, Real seal nonescape, and provenance exhaustion.

Chapter 9034

A Concrete Naming Certificate for $\mathsf{CauchyFilterCompletionUniversal}^{\uparrow}$

Following Bishop and Bridges on completion by Cauchy data, the $\mathsf{CauchyFilterCompletionUniversal}^{\uparrow}$ packet names the finite universal-factorization surface for a Cauchy-filter completion. It sits over the Cauchy-filter carrier of chapter 333, the completion boundary of chapter 1569, the abstract completion interface of chapter 95, the metric source of chapter 57, the continuous-map handoff of chapter 130, and the terminal real-name seal of chapter 38. The packet records the universal property as displayed rows only; it does not quotient filters, select limits, invoke choice, use host function extensionality, or assert ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 9034.1 (Cauchy-filter completion universal carrier)**.** *A* $\mathsf{CauchyFilterCompletionUniversal}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$U = (F, D, Y, u, f, g, U_0, H, C, P, N)$$

with the following rows:

1. *F is the source* $\mathsf{CauchyFilter}^{\uparrow}$ *row, exposing only displayed filter bases and finite Cauchy-window requests.*
2. *D is the dense embedding row from the metric source into the completion boundary.*
3. *Y is the completion target row, read through* $\mathsf{Completion}^{\uparrow}$ *and the Cauchy-filter completion surface.*
4. *u is the uniformly continuous source map row, routed through the* $\mathsf{ContinuousMap}^{\uparrow}$ *sibling.*
5. *f is the factor map row from the completion target to the receiving metric object.*
6. *g is the uniqueness ledger row comparing two displayed factor rows only after F, D, Y, u, f are visible.*
7. *U_0 is the universal-factorization transport row, recording that u is replayed through D and then through f.*
8. *H records componentwise* hsame *transport for the source Cauchy filters, dense embedding, completion target, source map, factor map, uniqueness ledger, universal row, replay, provenance, and local naming rows.*
9. *C records displayed* Cont *replay of the factorization route.*

10. *P is the* Pkg *provenance over* $\mathsf{CauchyFilterCompletionUniversal}^{\uparrow}$, $\mathsf{CauchyFilter}^{\uparrow}$, $\mathsf{Completion}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{CauchyFilterCompletionUniversal}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $F, D, Y, u, f, g, U_0, H, C, P, N$. It has no coordinate for quotient filters, selected completion points, countable choice, host function extensionality, or ambient completeness.

Lean4 (statement) `BEDC.Derived.CauchyFilterCompletionUniversalUp`

Theorem 9034.2 (Cauchy-filter completion universal NameCert obligations)**.** *For every accepted* $\mathsf{CauchyFilterCompletionUniversal}^{\uparrow}$ *carrier $U = (F, D, Y, u, f, g, U_0, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{CauchyFilterCompletion}}$ *surface consists exactly of carrier admission for the source Cauchy-filter row, dense embedding row, completion target row, uniformly continuous source-map row, factor-map row, uniqueness ledger, universal-factorization transport, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. No obligation may replace these rows by quotient classes of Cauchy filters, selected limits, countable choice, host-level function extensionality, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the carrier of Definition 9034.1. The only available coordinates are $F, D, Y, u, f, g, U_0, H, C, P, N$.

The source side is finite. The Cauchy-filter row F supplies displayed filter-base and Cauchy-window data, while the dense embedding row D and target row Y place that data inside the completion boundary named by the sibling completion chapters.

The mapping side is also row-local. The source map u is consumed through the continuous-map handoff, the factor row f is visible only after F, D, Y, u have been displayed, and the uniqueness ledger g compares factor rows inside that same packet.

Transport, replay, provenance, and local naming are the rows H, C, P, N. Since no carrier coordinate records quotient filters, selected limits, choice schedules, host function extensionality, or ambient completeness, no NameCert obligation can read such data. □

Theorem 9034.3 (Cauchy-filter completion universal factorization)**.** *Every accepted* CauchyFilterCompletionUniver *packet factors a displayed uniformly continuous source map through the displayed completion target by the finite route*

$$F, D, Y, u \longmapsto f \longmapsto g \longmapsto U_0$$

and then through H, C, P, N. The route is universal only over the displayed Cauchy-filter, dense-embedding, completion-target, continuous-map, factor-map, uniqueness, transport, replay, provenance, and local naming rows. It does not assert quotient-filter completion, selected completed points, countable choice, host-level function extensionality, or an ambient completeness theorem for $\mathsf{Real}^{\uparrow}$.

Proof. Read the source Cauchy filters through F and the dense embedding through D. The completion target Y is available only as the displayed completion boundary supplied by the sibling completion surfaces.

Use the source-map row u as the only uniformly continuous input. The factor row f is attached after F, D, Y, u have been exposed, and the uniqueness ledger g compares factor rows inside that same displayed route.

Finally read the universal-factorization row U_0 and the structural rows H, C, P, N. Componentwise transport and replay preserve the same route, while provenance and local naming certify only this finite packet. The excluded host-side objects have no row in the carrier, so no consumer can extract them from the factorization. □

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyFilterCompletionUniversal}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CauchyFilterCompletionUniversal}^{\uparrow}}, \mathsf{seed})$

Scope closed: The chapter records the seed carrier, NameCert obligations, and displayed universal-factorization route for Cauchy-filter completion.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CauchyFilterCompletionUniversal}^{\uparrow}}, \mathsf{formalTarget})$

Lean target: `BEDC.Derived.CauchyFilterCompletionUniversalUp`

Bridge status: none

Not claimed: This chapter does not close quotient-filter completion, selected completed points, countable choice, host function extensionality, ambient $\mathsf{Real}^{\uparrow}$ completeness, theorem-level Lean verification, or bridge checking.

Upgrade path: To reach scoped closure, formalize the carrier rows and prove the NameCert-obligation and factorization routes in Lean.

Constructive story: A $\mathsf{CauchyFilterCompletionUniversal}^{\uparrow}$ packet is generated from source Cauchy filters, dense embedding, completion target, uniformly continuous source map, factor map, uniqueness ledger, universal transport, replay, provenance, and a local NameCert row.

Chapter 9035

A Concrete Naming Certificate for SeparatedCompletionUniversalArrow$^{\uparrow}$

Following Bishop–Bridges constructive completion and Kelley's separated uniform-space language, the SeparatedCompletionUniversalArrow$^{\uparrow}$ packet records the finite universal-arrow surface for a separated completion without quotienting Cauchy names or selecting representatives. It sits after the separated-reflection route of chapter 4151, the metric-completion carrier of chapter 1506, the Cauchy-completion universal arrow of chapter 3997, the finite StreamName windows of chapter 126, the RegSeqRat readback of chapter 301, and the terminal Real seal of chapter 38. The packet exposes only the displayed separated universal-arrow route consumed by Real and Completion readers.

Definition 9035.1 (Separated completion universal-arrow carrier)**.** *A* SeparatedCompletionUniversalArrow$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$U = (S, M, A, W, Q, E, F, H, C, P, N)$$

with the following displayed rows:

1. *S is the* SeparatedReflection$^{\uparrow}$ *row exposing the separated classifier and zero-distance identity boundary.*
2. *M is the* MetricCompletion$^{\uparrow}$ *completion row admitted only after the separated reflection has been displayed.*
3. *A is the* CauchyCompletionUniversalArrow$^{\uparrow}$ *row carrying the unit and universal-arrow handoff.*
4. *W is the* StreamName$^{\uparrow}$ *finite-window row read by the completion consumer.*
5. *Q is the* RegSeqRat$^{\uparrow}$ *regular rational readback row attached to the same windows.*
6. *E is the terminal* Real$^{\uparrow}$ *seal row.*
7. *F records the factorization route from a separated source map through S, M, A, W, Q, E.*
8. *H records componentwise* hsame *transport for the separated reflection, completion, universal arrow, finite windows, readback, seal, factorization, replay, provenance, and local name.*
9. *C records displayed* Cont *replay of the same route.*
10. *P is the* Pkg *provenance over* SeparatedCompletionUniversalArrow$^{\uparrow}$, SeparatedReflection$^{\uparrow}$, MetricCompletion$^{\uparrow}$, CauchyCompletionUniversalArrow$^{\uparrow}$, StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, Real$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

11. *N is the local* $\mathsf{NameCert}_{\mathsf{SeparatedCompletionUniversalArrow}^{\uparrow}}$ *row.*
The carrier has no coordinate for quotient completion equality, selected Cauchy representatives, countable choice, host function equality, trichotomy, or ambient Real completeness.

Theorem 9035.2 (Separated completion universal-arrow NameCert obligations)**.** *For an accepted* $\mathsf{SeparatedCompletionUniversalArrow}^{\uparrow}$ *carrier* $U = (S, M, A, W, Q, E, F, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{SeparatedCompletionUniversalArrow}^{\uparrow}}$ *surface consists exactly of separated-reflection exposure through S, metric-completion exposure through M, Cauchy universal-arrow exposure through A, finite StreamName window exposure through W, RegSeqRat readback through Q, Real sealing through E, factorization through F, componentwise transport through H, displayed replay through C, provenance through P, and local naming through N.*

Proof. Project the carrier of Definition 9035.1. Its rows display the separated reflection, completion object, universal arrow, finite window, regular rational readback, Real seal, factorization, transport, replay, provenance, and local name.

The separatedness obligation is held in S before completion is consumed. The completion row M and universal-arrow row A are downstream of that separated boundary, so a consumer cannot read a non-separated quotient representative as the source of the factorization.

The Real-facing part is held in W, Q, E. These rows expose finite windows, regular rational readback, and the terminal seal before any completion-facing consumer cites the packet.

Finally F, H, C, P, N factor, transport, replay, source, and name only those displayed rows. Since no excluded principle appears in the carrier, the local NameCert surface is exhausted by the finite route above. □

Theorem 9035.3 (Separated completion universal-arrow factorization route)**.** *Every accepted* $\mathsf{SeparatedCompletionUniversalArrow}^{\uparrow}$ *universal-arrow read factors through*

$$S \longmapsto M \longmapsto A \longmapsto W \longmapsto Q \longmapsto E \longmapsto (F, H, C, P, N).$$

In particular, the completion-facing consumer reaches the terminal $\mathsf{Real}^{\uparrow}$ *seal only after the* $\mathsf{SeparatedReflection}^{\uparrow}$, $\mathsf{MetricCompletion}^{\uparrow}$, $\mathsf{CauchyCompletionUniversalArrow}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, *and* $\mathsf{RegSeqRat}^{\uparrow}$ *rows have all been displayed.*

Proof. Apply the NameCert obligations of Definition 9035.2. They force the separated reflection row S, the metric-completion row M, and the Cauchy universal-arrow row A to be visible before the factorization row F can be consumed.

Next read the finite observation segment W, Q, E. The StreamName and RegSeqRat rows expose the inspected finite windows and rational readback before the terminal Real seal is named.

The rows H, C, P, N preserve the same route under componentwise transport, continuation replay, provenance, and local naming. Because the carrier stores no quotient completion equality, selected representative, countable-choice schedule, host function equality, trichotomy, or ambient Real completeness row, the displayed factorization route is the only accepted route to the seal. □

Closure status for $\mathsf{NameCert}_{\mathsf{SeparatedCompletionUniversalArrow}^{\uparrow}}$.

Constructive story: A $\mathsf{SeparatedCompletionUniversalArrow}^{\uparrow}$ packet is generated from a separated-reflection row, metric-completion row, Cauchy universal-arrow row, finite StreamName windows, RegSeqRat readback, a RealUp seal, factorization row, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{SeparatedCompletionUniversalArrow}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 9035.1, Definition 9035.2, and Definition 9035.3 seed the separated completion universal-arrow route over SeparatedReflection, MetricCompletion, CauchyCompletionUniversalArrow, StreamName, RegSeqRat, and Real rows.

Formal verification: FormalStatus(NameCert$_{\mathsf{SeparatedCompletionUniversalArrow}\uparrow}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close quotient completion equality, selected representatives, countable choice, host function equality, trichotomy, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, separatedness exactness, completion-object exposure, universal-arrow factorization, finite-window readback, Real seal factorization, transport, replay, provenance, and local naming for BEDC.Derived.SeparatedCompletionUniversalArrowUp.

Chapter 9036

A Concrete Naming Certificate for $\mathsf{SeparatedCauchyFilter}^{\uparrow}$

Following Bishop and Bridges and Bourbaki, the $\mathsf{SeparatedCauchyFilter}^{\uparrow}$ packet records the finite route by which a Cauchy-filter completion read is first reflected through separated metric data before any Real-facing consumer may inspect the terminal seal. It sits between the filter surface of chapter 333, the completion route of chapter 1506, the separated reflection surface of chapter 1790, the finite stream observation surface of chapter 126, the regular rational readback of chapter 301, and the terminal Real boundary of chapter 38. The packet names only displayed filter-base, separated-reflection, finite-window, regular-readback, and Real-seal rows; it does not identify quotient filters, choose representatives, invoke countable choice, import host limits, or assume ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 9036.1 (Separated Cauchy filter carrier)**.** *A* $\mathsf{SeparatedCauchyFilter}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (F, M, Q, T, R, E, H, C, P, N)$$

with the following displayed rows:

1. F *is the* $\mathsf{CauchyFilter}^{\uparrow}$ *source row, exposing only a finite filter-base request and its displayed refinement data.*
2. M *is the* $\mathsf{MetricCompletion}^{\uparrow}$ *route row, naming the completion-facing carrier through which the filter request is read.*
3. Q *is the* $\mathsf{SeparatedMetricReflection}^{\uparrow}$ *row, recording the separated reflection boundary before any equality-facing completion read is available.*
4. T *is the* $\mathsf{StreamName}^{\uparrow}$ *finite observation row used to inspect the reflected filter route.*
5. R *is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row extracted from the displayed observation windows.*
6. E *is the terminal* $\mathsf{Real}^{\uparrow}$ *seal, available only after* F, M, Q, T, R *remain visible together.*
7. H *records componentwise* hsame *transport for the filter source, completion route, separated reflection, stream observation, regular readback, Real seal, replay, provenance, and local naming rows.*
8. C *records displayed* Cont *replay from a completion request through the same finite rows.*
9. P *is the* Pkg *provenance over* $\mathsf{SeparatedCauchyFilter}^{\uparrow}$, $\mathsf{CauchyFilter}^{\uparrow}$, $\mathsf{MetricCompletion}^{\uparrow}$, $\mathsf{SeparatedMetricReflectio}$ $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.

10. N is the local $\mathsf{NameCert}_{\mathsf{SeparatedCauchyFilter}^{\uparrow}}$ *row.*
The carrier has no coordinate for quotient filter equality, selected representatives, countable choice, hidden limit selection, host limits, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 9036.2 (Separated Cauchy filter NameCert obligations)**.** *For every accepted* $\mathsf{SeparatedCauchyFilter}^{\uparrow}$ *carrier*

$$S = (F, M, Q, T, R, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{SeparatedCauchyFilter}^{\uparrow}}$ *surface consists exactly of Cauchy-filter source admission, metric-completion route admission, separated-reflection exposure, finite stream observation, regular rational readback, terminal Real sealing, componentwise transport, displayed continuation replay, provenance, and local naming. No obligation row may replace these displayed rows by quotient filter equality, a selected representative, countable choice, host limit selection, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the carrier of Definition 9036.1. The analytic route is carried by F, M, Q, T, R, E, and the structural route is carried by H, C, P, N.

The source row F exposes a finite Cauchy-filter base request. The completion row M records the metric-completion route for that request, while Q inserts the separated reflection boundary before any equality-facing read can occur.

The finite observation and readback rows then make the route inspectable. The stream row T displays the observation windows, and R records the regular rational readback extracted from those windows before the terminal Real seal E is consumed.

Transport, replay, provenance, and naming preserve the same rows through H, C, P, N. Since no carrier coordinate stores quotient filter equality, selected representatives, countable choice, host limit selection, or ambient completeness, the listed rows exhaust the local NameCert obligations. □

Theorem 9036.3 (Separated Cauchy filter reflection soundness)**.** *Every Real-facing read of an accepted* $\mathsf{SeparatedCauchyFilter}^{\uparrow}$ *packet factors through the finite route*

$$\mathsf{CauchyFilter}^{\uparrow} \longmapsto \mathsf{MetricCompletion}^{\uparrow} \longmapsto \mathsf{SeparatedMetricReflection}^{\uparrow} \longmapsto \mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}.$$

Consequently the packet exports a separated completion-facing filter read without exporting quotient filter equality, selected representatives, countable choice, host limits, or ambient Real completeness.

Proof. Start with an accepted packet $S = (F, M, Q, T, R, E, H, C, P, N)$. The only source row is F, and the only completion route row is M.

The separated reflection row Q is placed between the completion route and the observation rows. Thus a consumer cannot read the terminal seal as an unreflected filter quotient or as an equality of representative filters.

The finite observation row T and regular readback row R supply the displayed data used by the terminal seal E. The structural rows H, C, P, N transport, replay, source, and name this same route rather than adding a host limit operation or choice schedule.

Therefore every accepted Real-facing read follows the displayed route, and any consumer that skips the separated-reflection, finite-window, or regular-readback rows is outside the carrier. □

Falsifiable prediction: An accepted $\mathsf{SeparatedCauchyFilter}^{\uparrow}$ Real-facing read that reaches the terminal seal without displaying a CauchyFilter source row, MetricCompletion route row, SeparatedMetricReflection boundary row, StreamName observation row, and RegSeqRat readback row refutes the carrier.

Independence witness: cauchyfilter, metriccompletion, separatedmetricreflection, streamname, regseqrat, real: $\mathsf{SeparatedCauchyFilter}^{\uparrow}$ is not bijective to any listed sibling because it jointly binds filter source, completion route, separated reflection, finite observation, regular readback, Real sealing, transport, replay, provenance, and local naming in one carrier.

Closure status for $\mathsf{NameCert}_{\mathsf{SeparatedCauchyFilter}^{\uparrow}}$.

Constructive story: A $\mathsf{SeparatedCauchyFilter}^{\uparrow}$ packet is generated from CauchyFilter source, MetricCompletion route, SeparatedMetricReflection boundary, StreamName observation, RegSeqRat readback, Real seal, hsame transport, Cont replay, Pkg provenance, and local NameCert rows.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{SeparatedCauchyFilter}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 9036.1, Definition 9036.2, Definition 9036.3, the falsifiable prediction, and the independence witness seed the separated Cauchy-filter completion route.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{SeparatedCauchyFilter}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close Lean verification, quotient filter equality, selected representatives, countable choice, host limits, ambient $\mathsf{Real}^{\uparrow}$ completeness, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, filter-base exposure, completion-route admission, separated-reflection soundness, finite observation, regular readback, Real-seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.SeparatedCauchyFilterUp.

Chapter 9037

A Concrete Naming Certificate for $\mathsf{OreLocalization}^{\uparrow}$

Following Ore localization of noncommutative rings, the $\mathsf{OreLocalization}^{\uparrow}$ packet records the finite denominator calculus needed to read fractions $s^{-1}r$ or rs^{-1} without treating localization as generic parameter transport. It sits after the multiplicative monoid surface of chapter 40, the ring operation rows of chapter 43, and the ideal-facing absorption surface of chapter 81. The packet names an admissible denominator set, left and right Ore squares, cancellation witnesses, fraction rows, transport, replay, provenance, and local naming; it does not import a host quotient ring, a selected common denominator outside the ledger, commutativity, or a classical total ring of fractions.

Definition 9037.1 (OreLocalization carrier)**.** *An* $\mathsf{OreLocalization}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (R, S, O, C, F, D, H, T, P, N)$$

with the following displayed rows:

1. *R is the ambient* $\mathsf{Ring}^{\uparrow}$ *row, including the additive, multiplicative, and distributive operation data read through chapter 43;*
2. *S is the denominator* $\mathsf{Monoid}^{\uparrow}$ *row, naming the multiplicatively closed set used by the localization route;*
3. *O is the Ore-square ledger, listing the displayed left and right common-multiple squares used to move a numerator past a denominator;*
4. *C is the cancellation ledger, recording the denominator-side cancellation witnesses allowed by the same Ore surface;*
5. *F is the finite fraction row, whose entries are displayed numerator-denominator pairs and not host quotient classes;*
6. *D is the denominator ledger, recording which denominator row is consumed by each fraction, Ore square, cancellation step, and multiplication handoff;*
7. *H records componentwise* hsame *transport for the ring, denominator, Ore-square, cancellation, fraction, denominator-ledger, replay, provenance, and local naming rows;*
8. *T records displayed* Cont *replay for denominator admission, Ore-square formation, fraction multiplication, cancellation, and consumer readback;*

9. *P is the* Pkg *provenance over* OreLocalization$^{\uparrow}$, Ring$^{\uparrow}$, Monoid$^{\uparrow}$, Ideal$^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* NameCert *rows;*
10. *N is the local* NameCert$_{\text{OreLocalization}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $R, S, O, C, F, D, H, T, P, N$.

Lean4 (definition) `BEDC.Derived.OreLocalizationUp.OreLocalizationUp`
Lean4 ✓ `BEDC.Derived.OreLocalizationUp.OreLocalizationTasteGate single carrier alignment`

Theorem 9037.2 (OreLocalization NameCert obligations)**.** *For the carrier of Definition 9037.1, the local* NameCert$_{\text{OreLocalization}^{\uparrow}}$ *surface consists exactly of ambient ring admission, denominator-monoid admission, left and right Ore-square exposure, denominator-side cancellation exposure, finite fraction-row admission, denominator-ledger readback, componentwise transport, displayed continuation replay, provenance, and local naming. Every accepted localization read must pass through these rows before a fraction multiplication or denominator handoff is public.*

Proof. Project the carrier $L = (R, S, O, C, F, D, H, T, P, N)$. The ring and denominator rows are visible first, so every numerator and denominator read is grounded in the displayed Ring$^{\uparrow}$ and Monoid$^{\uparrow}$ certificates.

The Ore-square and cancellation rows are O and C. They provide the finite common-multiple and cancellation witnesses used to compare displayed fraction rows; no commutative shortcut or host quotient equality is available.

The fraction and denominator ledgers are F and D. They record which denominator is consumed at each multiplication, comparison, and handoff step.

Finally, H, T, P, N transport, replay, source, and name the same finite data. Since the packet has no coordinate for a host localization object, selected representatives outside the ledger, total quotient rings, or ambient ideal equality, these rows exhaust the local NameCert obligations. □

Theorem 9037.3 (OreLocalization denominator ledger)**.** *In an accepted* OreLocalization$^{\uparrow}$ *carrier $L = (R, S, O, C, F, D, H, T, P, N)$, every public fraction row in F has its denominator named in D, every Ore-square witness in O consumes denominator rows from D, and every cancellation witness in C returns to the same denominator ledger. A consumer cannot cite a localized product, comparison, or handoff unless the relevant denominator route is displayed in D.*

Proof. Read the fraction row F together with the denominator ledger D. The carrier admits fractions only as displayed numerator-denominator pairs, so each fraction coordinate has a corresponding denominator entry.

Use the Ore-square ledger O. A common-multiple square is accepted only when the denominator rows it moves across are already listed in D.

Use the cancellation ledger C for the final handoff. Cancellation may shorten or compare displayed fraction rows, but it does not create a denominator outside the ledger. The transport, replay, provenance, and naming rows H, T, P, N preserve the same denominator route for downstream consumers. □

Closure status for NameCert$_{\text{OreLocalization}^{\uparrow}}$.

Constructive story: An OreLocalization$^{\uparrow}$ packet is generated from an ambient RingUp row, a denominator MonoidUp row, Ore-square witnesses, cancellation witnesses, finite fraction rows, a denominator ledger, transport, replay, provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\text{OreLocalization}^{\uparrow}}$, seed)

Scope closed: Definition 9037.1, Definition 9037.2, and Definition 9037.3 seed the finite denominator-localization carrier and its NameCert and denominator-ledger obligations.

Formal verification: FormalStatus(NameCert$_{\mathsf{OreLocalization}\uparrow}$, unformalized)
Bridge status: none
Origin: human
Not claimed: This chapter does not construct a host quotient ring, prove universal localization, assume commutativity, select common denominators outside the ledger, close ideal equality, provide Lean verification, or bridge check the route.
Upgrade path: Obligation closure requires checked ring admission, denominator-monoid admission, Ore-square exposure, cancellation exposure, fraction-row admission, denominator-ledger readback, transport, replay, provenance, and local naming for BEDC.Derived.OreLocalizationUp.

Chapter 9038

A Concrete Naming Certificate for $\mathsf{RightBlockFluxReservoirCoefficient}^{\uparrow}$

The $\mathsf{RightBlockFluxReservoirCoefficient}^{\uparrow}$ packet realizes the right-block flux-reservoir coefficient of Definition 9346.49 as finite NameCert data. It records the right-block boundary count, the cube-degree normalization, the resulting local ratio, the static cut source, transport, replay, provenance, and local naming rows before any impedance or coupling reader can cite the coefficient. The packet sits beside the Zeckendorf phase shell of chapter 8811, the static Green boundary-flux row of chapter 8769, the flux-operator geometry surface of chapter 8821, and the beta-sign selection packet of chapter 8846.

Definition 9038.1 (RightBlockFluxReservoirCoefficient carrier)**.** *A* $\mathsf{RightBlockFluxReservoirCoefficient}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (B, E, G, R, S, T, H, C, P, N)$$

with the following displayed rows:

1. *B is the right-block row, naming the six-element right edge-flux block inside the Window-six cube;*
2. *E is the boundary-count row, recording the displayed boundary size* 32*;*
3. *G is the cube-degree row, recording the degree* 6 *used by the local directed-edge normalization;*
4. *R is the normalized-ratio row, displaying the coefficient* $32/(6 \cdot 6) = 8/9$*;*
5. *S is the static-cut row, tying the coefficient to the right-boundary cut-flux source rather than to the dynamic Green-relaxation readout;*
6. *T is the transport row from the coefficient packet to impedance or coupling consumers;*
7. *H records componentwise* hsame *transport for block, boundary, degree, ratio, static-cut, consumer, replay, provenance, and local naming rows;*
8. *C records displayed* Cont *replay for block admission, boundary counting, degree normalization, ratio readback, static-cut handoff, and consumer use;*
9. *P is the* Pkg *provenance over* $\mathsf{RightBlockFluxReservoirCoefficient}^{\uparrow}$*,* $\mathsf{ZeckendorfPhaseShell}^{\uparrow}$*,* StaticGreenBoundaryFl FluxOperatorGeometry$^{\uparrow}$*,* $\mathsf{BetaSignSelection}^{\uparrow}$*,* BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *rows;*
10. *N is the local* $\mathsf{NameCert}_{\mathsf{RightBlockFluxReservoirCoefficient}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $B, E, G, R, S, T, H, C, P, N$.

Theorem 9038.2 (RightBlockFluxReservoirCoefficient NameCert obligations)**.** *For the carrier of Definition 9038.1, the local* $\mathsf{NameCert}_{\mathsf{RightBlockFluxReservoirCoefficient}^{\uparrow}}$ *surface consists exactly of right-block admission, boundary-count exposure, cube-degree exposure, normalized-ratio readback, static-cut source exposure, consumer transport, componentwise* hsame *transport, displayed* Cont *replay, provenance, and local naming. The packet therefore turns the coefficient* $8/9$ *into a finite boundary-count and normalization certificate, not a free-floating numerical parameter.*

Proof. Project the carrier $K = (B, E, G, R, S, T, H, C, P, N)$. The block, boundary, degree, ratio, static-cut, and consumer rows are all visible coordinates of one finite packet.

The boundary-count and degree rows determine the normalized ratio row. The coefficient is read as $32/(6 \cdot 6) = 8/9$ through E, G, R, so it cannot be replaced by an untracked scalar or by the global cut-flux density.

The static-cut and transport rows are S and T. They route the coefficient to impedance or coupling consumers while keeping it separate from the dynamic Green-relaxation layer.

Finally, H, C, P, N preserve the same finite rows under transport, replay, provenance, and local naming. No additional coordinate supplies a physical continuum model, a dynamic relaxation coefficient, or a hidden normalization convention. □

Theorem 9038.3 (RightBlockFluxReservoirCoefficient boundary ratio)**.** *In an accepted* RightBlockFluxReservoirCo *carrier $K = (B, E, G, R, S, T, H, C, P, N)$, the public coefficient row R is available only after the right-block row B, boundary-count row E, cube-degree row G, and static-cut row S have been displayed. The ratio readback is the local boundary escape value* $8/9$*, and it does not claim the global cut-flux density, the one-way mismatch mean, or a dynamic Green-relaxation coefficient.*

Proof. Read the displayed block row B and boundary-count row E. They identify the finite right edge-flux block and its boundary size before any ratio is public.

Use the cube-degree row G to normalize the boundary count locally. The ratio row R is therefore tied to the directed-edge budget of the block, not to the full cube budget.

The static-cut row S fixes the readout mode. It keeps the coefficient in the static right-boundary source layer, while T, H, C, P, N transport, replay, source, and name the same finite readback for downstream consumers. □

Falsifiable prediction: If an accepted RightBlockFluxReservoirCoefficientUp packet exposes the coefficient without the right-block row, boundary-count row, cube-degree row, and static-cut row, then the packet is refuted as a NameCert carrier for the right-block flux-reservoir coefficient.

Independence witness: zeckendorf-phase-shell, static-green-boundary-flux, flux-operator-geometry, beta-sign-selection: none is bijective to $\mathsf{RightBlockFluxReservoirCoefficient}^{\uparrow}$ because those siblings respectively bind phase-shell, Green-exact cut-source, operator-geometry, or sign-selection rows, while this packet binds the right-block boundary count, cube-degree normalization, local ratio, static-cut source, transport, replay, provenance, and local NameCert rows.

The Lean follow-up file `lean4/BEDC/Derived/RightBlockFluxReservoirCoefficientUp/TasteGate.lean` must provide explicit Nontrivial $\mathsf{RightBlockFluxReservoirCoefficient}^{\uparrow}$ and FieldFaithful RightBlockFluxReservoirCoeffici instances. The nontriviality witness must distinguish an accepted coefficient packet from a packet with a missing boundary-count or cube-degree row, and the field-faithfulness witness must preserve $B, E, G, R, S, T, H, C, P, N$ as separate rows.

Closure status for $\mathsf{NameCert}_{\mathsf{RightBlockFluxReservoirCoefficient}^{\uparrow}}$.

Constructive story: A RightBlockFluxReservoirCoefficient$^{\uparrow}$ packet is generated from a right-block row, boundary-count row, cube-degree row, normalized-ratio row, static-cut row, consumer transport row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert rows.

Theory closure: TheoryGate(NameCert$_{\text{RightBlockFluxReservoirCoefficient}^{\uparrow}}$, seed)

Scope closed: Definition 9038.1, Definition 9038.2, and Definition 9038.3 seed the finite boundary-count, cube-degree, ratio, static-cut, transport, replay, provenance, and naming surface.

Formal verification: FormalStatus(NameCert$_{\text{RightBlockFluxReservoirCoefficient}^{\uparrow}}$, unformalized)

Bridge status: none

Origin: ai

Not claimed: This chapter does not claim a physical continuum model, dynamic Green-relaxation coefficient, global cut-flux density, one-way mismatch theorem, Lean verification, audit cleanliness, or bridge checking.

Upgrade path: Obligation closure requires checked right-block admission, boundary-count exposure, cube-degree exposure, normalized-ratio readback, static-cut exposure, transport, replay, provenance, local naming, and the required Nontrivial and FieldFaithful instances for BEDC.Derived.RightBlockFluxReservoirCoefficientUp.

Chapter 9039

A Concrete Naming Certificate for $\mathsf{ConvexFunction}^{\uparrow}$

Following Rockafellar's convex analysis and Boyd–Vandenberghe's convex optimization presentation, the $\mathsf{ConvexFunction}^{\uparrow}$ packet records the finite route by which a displayed convex domain, vector source, real codomain, rational affine weights, and comparison rows name a convex-function surface. It sits over the convex carrier of chapter 208, the real comparison boundary of chapter 38, the vector source of chapter 47, and the rational coefficient source of chapter 37. The packet supplies the source row consumed by chapter 2235 and chapter 321; it is a finite NameCert surface, not a host function space or an ambient completeness principle.

Definition 9039.1 (ConvexFunction carrier)**.** *A* $\mathsf{ConvexFunction}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$F = (D, V, R, A, M, E, H, C, P, N)$$

with the following displayed rows:

1. *D is the convex-domain row, recording the accepted* $\mathsf{ConvexSet}^{\uparrow}$ *carrier whose elements may be queried.*
2. *V is the vector-source row, recording the displayed* $\mathsf{VecSpace}^{\uparrow}$ *operations used to form affine expressions.*
3. *R is the* $\mathsf{Real}^{\uparrow}$ *codomain and readback row, recording the real-valued output names and comparison interface.*
4. *A is the affine-weight route, recording finite rational weights through* $\mathsf{Rat}^{\uparrow}$*, nonnegative checks, and the displayed finite-sum-to-one row.*
5. *M is the midpoint or finite affine-combination ledger, recording the source points, weighted vector expression, and the proof row that the result remains inside D.*
6. *E is the epigraph and comparison row, recording the displayed inequality between the function value at the affine point and the corresponding affine combination of output reads.*
7. *H records componentwise* hsame *transport for D, V, R, A, M, E and the local naming row.*
8. *C records displayed* Cont *replay from the domain, vector, rational-weight, real-comparison, transport, provenance, and local name rows.*
9. *P is the* Pkg *provenance over* $\mathsf{ConvexFunction}^{\uparrow}$*,* $\mathsf{ConvexSet}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*,* $\mathsf{VecSpace}^{\uparrow}$*,* $\mathsf{Rat}^{\uparrow}$*,* BHist*,* hsame*,* Cont*,* Pkg*, and* $\mathsf{NameCert}$ *rows.*

10. *N is the local* $\mathsf{NameCert}_{\mathsf{ConvexFunction}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $D, V, R, A, M, E, H, C, P, N$. It has no coordinate for a host convex function, quotient equality of functions or real names, selected extrema, trichotomy, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 9039.2 (ConvexFunction NameCert obligations)**.** *For every accepted* $\mathsf{ConvexFunction}^{\uparrow}$ *carrier $F = (D, V, R, A, M, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{ConvexFunction}^{\uparrow}}$ *surface consists exactly of the following five obligations:*

1. *carrier admission for the displayed convex domain, vector source, real codomain and readback row, affine-weight route, midpoint or finite affine-combination ledger, epigraph and comparison row, transport, replay, provenance, and local naming;*
2. *affine-combination accountability, requiring every weight and finite affine expression read by a consumer to pass through A and M;*
3. *convexity comparison exactness, requiring every displayed convexity inequality to be the row recorded in E over the* $\mathsf{Real}^{\uparrow}$ *readback interface R;*
4. *transport and replay stability, requiring componentwise* hsame *transport and* Cont *replay to preserve the same domain, vector, rational-weight, real-comparison, provenance, and local naming route;*
5. *ledger nonescape from host functions, quotient real equality, selected extrema, trichotomy, countable choice, and ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the accepted packet $F = (D, V, R, A, M, E, H, C, P, N)$. The carrier definition exposes exactly the convex domain, vector source, real codomain, affine-weight, affine-combination, comparison, transport, replay, provenance, and naming rows.

The affine data are read before the comparison row. Thus A supplies the rational weights and finite-sum row, while M supplies the displayed midpoint or finite affine expression and its return to the convex domain.

The convexity comparison is then read only through E and R. Transport and replay are componentwise through H and C, and provenance and naming are carried by P and N. Since none of the excluded host objects is a carrier coordinate, the five listed clauses exhaust the local NameCert surface. □

Theorem 9039.3 (ConvexFunction midpoint route)**.** *Every midpoint or finite affine read of an accepted* $\mathsf{ConvexFunction}^{\uparrow}$ *carrier routes through*

$$D, V, A, M \longmapsto R, E \longmapsto H, C, P, N.$$

Consequently Jensen and Fenchel consumers may inspect a convex-function source only after the displayed domain, rational weights, $\mathsf{VecSpace}^{\uparrow}$ *affine route,* $\mathsf{Real}^{\uparrow}$ *comparison row, componentwise transport, replay, provenance, and local name have all been read.*

Proof. Start with a consumer read of a midpoint or finite affine expression. By Definition 9039.1, the only source rows for such a read are the domain row D, vector row V, affine-weight row A, and affine-combination ledger M.

The real-valued convexity statement is downstream of those rows. The codomain row R supplies the displayed real reads, and E supplies the comparison row tying the value at the affine point to the affine combination of output reads.

Finally H, C, P, N transport, replay, source, and name the same route. Since the packet contains no separate host-function or quotient-equality coordinate, Jensen and Fenchel consumers cannot bypass this displayed path. □

Falsifiable prediction: Every $\mathsf{ConvexFunction}^{\uparrow}$ consumer reads a ConvexSet domain row, VecSpace affine route, Rat weight row, Real codomain and comparison row, midpoint or finite affine-combination ledger, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming before the convex-function source is public.

Independence witness: convexset, vecspace, rat, real: $\mathsf{ConvexFunction}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries a convex-domain row, vector-source row, rational affine-weight row, real codomain and comparison row, epigraph ledger, transport, replay, provenance, and local NameCert data as one finite function packet.

Closure status for $\mathsf{NameCert}_{\mathsf{ConvexFunction}^{\uparrow}}$ **.**

Constructive story: A $\mathsf{ConvexFunction}^{\uparrow}$ packet is generated from a displayed ConvexSet domain row, VecSpace source row, Real codomain and readback row, Rat affine-weight route, midpoint or finite affine-combination ledger, epigraph and comparison row, componentwise hsame transport, Cont replay, Pkg provenance, and local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{ConvexFunction}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 9039.1, Definition 9039.2, and Definition 9039.3 seed the finite convex-function route over ConvexSet, VecSpace, Rat, Real, affine-combination, epigraph, transport, replay, provenance, and local naming rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{ConvexFunction}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host convex functions, quotient equality of functions or real names, selected extrema, trichotomy, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, affine-combination accountability, convexity comparison exactness, transport and replay stability, ledger nonescape, provenance, and local naming for BEDC.Derived.ConvexFunctionUp.

Chapter 9040

A Concrete Naming Certificate for $\mathsf{FaulhaberFormula}^{\uparrow}$

Following Faulhaber and the finite-difference treatment of sums of powers, the $\mathsf{FaulhaberFormula}^{\uparrow}$ packet records the finite BEDC route by which a unary exponent row, a polynomial coefficient ledger, and a finite-difference telescoping row name the closed-form power-sum formula. It sits over the natural-number carrier of chapter 28, the additive and multiplicative arithmetic rows of chapter 29 and chapter 30, the polynomial coefficient surface of chapter 50, and the finite-difference row of chapter 5135. The packet is a finite summation consumer: it does not import an ambient analytic series, a host polynomial identity library, quotient real equality, countable choice, or a selected infinite limit.

Definition 9040.1 (Faulhaber formula carrier)**.** *A* $\mathsf{FaulhaberFormula}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$F = (N, A, M, P, D, S, H, C, Q, L)$$

with the following displayed rows:

1. *N is the* $\mathsf{Nat}^{\uparrow}$ *exponent and summation-length row.*
2. *A is the* $\mathsf{Add}^{\uparrow}$ *accumulation row for finite partial sums.*
3. *M is the* $\mathsf{Mul}^{\uparrow}$ *multiplication row used to form powers and polynomial products.*
4. *P is the* $\mathsf{Poly}^{\uparrow}$ *coefficient ledger whose displayed polynomial is the closed power-sum candidate.*
5. *D is the* $\mathsf{FiniteDifference}^{\uparrow}$ *row asserting that the forward difference of the displayed polynomial is the inspected power row.*
6. *S is the finite summation row comparing the accumulated power values with the polynomial endpoint difference.*
7. *H records componentwise* hsame *transport for exponent, arithmetic, polynomial, finite-difference, summation, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from a unary bound through N, A, M, P, D, S, H.*
9. *Q is the* Pkg *provenance over* $\mathsf{FaulhaberFormula}^{\uparrow}$*,* $\mathsf{Nat}^{\uparrow}$*,* $\mathsf{Add}^{\uparrow}$*,* $\mathsf{Mul}^{\uparrow}$*,* $\mathsf{Poly}^{\uparrow}$*,* $\mathsf{FiniteDifference}^{\uparrow}$*,* BHist*,* hsame*,* Cont*, and* $\mathsf{NameCert}$*.*
10. *L is the local* $\mathsf{NameCert}_{\mathsf{FaulhaberFormula}^{\uparrow}}$ *row.*

The classifier accepts a Faulhaber read only through these rows. It has no coordinate for an analytic generating function, Bernoulli-number completion outside the displayed coefficient ledger, quotient equality of polynomials, ambient ordered-field automation, or an infinite summation principle.

Theorem 9040.2 (Faulhaber formula NameCert obligations)**.** *For every accepted* $\mathsf{FaulhaberFormula}^{\uparrow}$ *carrier* $F = (N, A, M, P, D, S, H, C, Q, L)$*, the local* $\mathsf{NameCert}_{\mathsf{FaulhaberFormula}^{\uparrow}}$ *surface consists exactly of carrier admission for the natural-number exponent and bound, additive accumulation, multiplicative power formation, polynomial coefficient ledger, finite-difference certificate, finite summation comparison, componentwise transport, displayed replay, provenance, and local naming rows. No accepted consumer may read the closed power-sum formula before those rows are displayed.*

Proof. Project the carrier of Definition 9040.1. The rows $N, A, M, P, D, S, H, C, Q, L$ are the only displayed data available to a local certificate.

The arithmetic rows A and M expose finite addition and multiplication before any power row is summed. The polynomial row P supplies the closed candidate as a finite coefficient ledger, not as an ambient host polynomial identity.

The finite-difference row D is then the exactness row: it relates the displayed polynomial ledger to the inspected power row. The summation row S consumes that exactness by finite telescoping over the unary bound named by N.

Finally H, C, Q, L transport, replay, source, and name the same finite route. Since no excluded object is a carrier coordinate, the local NameCert obligations are exactly the listed rows. □

Theorem 9040.3 (Faulhaber finite-difference route)**.** *Every accepted* $\mathsf{FaulhaberFormula}^{\uparrow}$ *consumer factors the closed power-sum read through the finite route*

$$\mathsf{Nat}^{\uparrow}, \mathsf{Add}^{\uparrow}, \mathsf{Mul}^{\uparrow} \longmapsto \mathsf{Poly}^{\uparrow} \longmapsto \mathsf{FiniteDifference}^{\uparrow} \longmapsto \mathsf{BHist}, \mathsf{hsame}, \mathsf{Cont}, \mathsf{Pkg}, \mathsf{NameCert}.$$

The route reads the polynomial coefficient ledger and its displayed finite difference before it exports the summation comparison, and it cannot be replaced by an analytic series, a host Bernoulli-coefficient table, quotient equality of polynomials, countable choice, or an infinite limit.

Proof. Use the NameCert obligations of Definition 9040.2. They force every accepted read to expose the natural-number, additive, multiplicative, polynomial, finite-difference, and summation rows before provenance and local naming are consumed.

The finite-difference row is the bridge from the coefficient ledger to the power row. Once the displayed forward difference is read, the finite summation row performs only the bounded telescoping comparison over the unary length from N.

The non-escape clause follows from the carrier definition. None of analytic series data, host Bernoulli tables outside P, quotient polynomial equality, countable choice, or infinite limits is present in F, so none can serve as an intermediate factor in an accepted Faulhaber read. □

Falsifiable prediction: A $\mathsf{FaulhaberFormula}^{\uparrow}$ consumer that exports a power-sum formula while omitting the polynomial coefficient ledger P or the finite-difference row D is not reading an accepted packet of this chapter.

Independence witness: nat, add, mul, polynomial, finite-difference: $\mathsf{FaulhaberFormula}^{\uparrow}$ is not bijective with any listed sibling because it jointly carries arithmetic power formation, a polynomial coefficient ledger, a finite-difference exactness row, a summation comparison, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{FaulhaberFormula}^{\uparrow}}$**.**

Constructive story: A FaulhaberFormula$^{\uparrow}$ packet is generated from NatUp exponent and bound rows, AddUp accumulation, MulUp power formation, a PolynomialUp coefficient ledger, a FiniteDifferenceUp exactness row, a finite summation comparison, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\text{FaulhaberFormula}^{\uparrow}}$, seed)

Scope closed: Definition 9040.1, Definition 9040.2, and Definition 9040.3 seed the finite power-sum certificate route over arithmetic, polynomial, finite-difference, transport, replay, provenance, and naming rows.

Formal verification: FormalStatus(NameCert$_{\text{FaulhaberFormula}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim Lean verification, bridge checking, analytic generating functions, Bernoulli-number completion outside the displayed coefficient ledger, quotient polynomial equality, countable choice, or infinite summation.

Upgrade path: Obligation closure requires checked carrier admission, arithmetic power formation, polynomial coefficient readiness, finite-difference exactness, finite summation telescoping, transport, replay, provenance, and local naming for BEDC.Derived.FaulhaberFormulaUp.

Chapter 9041

A Concrete Naming Certificate for $\mathsf{SeparatedCauchySequence}^{\uparrow}$

Following Bishop–Bridges style separated metric and Cauchy-sequence grounding, the $\mathsf{SeparatedCauchySequence}^{\uparrow}$ packet records the finite route by which a displayed regular rational sequence is read as a separated completion-facing name before a Real consumer may inspect the terminal seal. It sits after the $\mathsf{StreamName}^{\uparrow}$ finite-window surface of chapter 126, the $\mathsf{RegSeqRat}^{\uparrow}$ readback surface of chapter 301, the $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance ledger of chapter 291, the cofinal restriction route of chapter 1592, and the terminal $\mathsf{Real}^{\uparrow}$ seal of chapter 38. The packet names separated Cauchy-sequence data as finite NameCert rows, not as quotient sequence equality, a selected limit, host real equality, countable choice, or ambient Real completeness.

Definition 9041.1 (Separated Cauchy sequence carrier)**.** *A* $\mathsf{SeparatedCauchySequence}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (W, R, D, K, Q, E, H, C, P, N)$$

with the following displayed rows:

1. *W is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row exposing the observed prefix and tail windows of the sequence.*
2. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row attached to those windows.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger recording the separated tail comparisons used by the Cauchy test.*
4. *K is the* $\mathsf{CauchySubnet}^{\uparrow}$ *cofinal-tail route used when the consumer restricts the read to a displayed subnet of tail requests.*
5. *Q is the separated-comparison row, recording that zero-distance comparison is read only through displayed tail and tolerance rows.*
6. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal, available only after W, R, D, K, Q remain visible together.*
7. *H records componentwise* hsame *transport for the window, readback, tolerance, cofinal route, separated-comparison, seal, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from a precision request through W, R, D, K, Q, E in that order.*
9. *P is the* Pkg *provenance over* $\mathsf{SeparatedCauchySequence}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{CauchySubnet}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

10. N is the local $\mathsf{NameCert}_{\mathsf{SeparatedCauchySequence}^{\uparrow}}$ *row.*
The carrier has no coordinate for quotient sequence equality, selected limits, countable choice, host real equality, trichotomy, or ambient Real completeness.

Theorem 9041.2 (Separated Cauchy sequence NameCert obligations)**.** *For every accepted* SeparatedCauchySequen *carrier $S = (W, R, D, K, Q, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{SeparatedCauchySequence}^{\uparrow}}$ *surface consists exactly of finite-window admission, regular rational readback, dyadic tolerance exposure, cofinal-tail route exposure, separated-comparison exposure, terminal Real sealing, componentwise transport, displayed replay, provenance, and local naming.*

Every obligation is anchored in the displayed BHist, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{CauchySubnet}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, hsame, Cont, Pkg, *and* $\mathsf{NameCert}$ *rows. No obligation row may replace the finite packet by quotient sequence equality, a selected limit, countable choice, host real equality, trichotomy, or ambient completeness.*

Proof. Project the carrier of Definition 9041.1. The analytic data are W, R, D, K, Q, E, and the structural support is H, C, P, N.

Read the route in order. The StreamName window W exposes the inspected finite tail data, the RegSeqRat row R records the regular rational readback, and the DyadicRatCore row D supplies the tolerance ledger for separated tail comparison.

The cofinal-tail row K is the only subnet restriction route, and the separated-comparison row Q is downstream of W, R, D, K. The terminal Real seal E is downstream of all five displayed data rows.

Transport, replay, provenance, and local naming preserve the same rows through H, C, P, N. Since no carrier coordinate stores quotient sequence equality, selected limits, countable choice, host real equality, trichotomy, or ambient completeness, the listed rows exhaust the NameCert obligations. □

Theorem 9041.3 (Separated Cauchy sequence real-completion handoff)**.** *Every Real or completion-facing consumer of an accepted* $\mathsf{SeparatedCauchySequence}^{\uparrow}$ *packet factors through the finite route*

$$\mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{DyadicRatCore}^{\uparrow} \longmapsto \mathsf{CauchySubnet}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}$$

together with the separated-comparison, BHist, *componentwise* hsame, *displayed* Cont, Pkg, *and local* $\mathsf{NameCert}_{\mathsf{SeparatedCauchySequence}^{\uparrow}}$ *rows. The consumer receives a displayed separated Cauchy-sequence handoff and not quotient sequence equality, a selected limit, host real equality, countable choice, trichotomy, or ambient Real completeness.*

Proof. Start with an accepted carrier $S = (W, R, D, K, Q, E, H, C, P, N)$. The terminal seal E is not a free Real value; it is downstream of the window, readback, tolerance, cofinal route, and separated-comparison rows.

Use Definition 9041.2 to exhaust the local surface. A consumer must expose $W, R, D, K, Q, E, H, C, P, N$ before the packet can be consumed by a Real or completion-facing route.

The cited sibling chapters supply the allowed components: StreamName windows, RegSeqRat readback, DyadicRatCore tolerances, CauchySubnet cofinal-tail routing, and the terminal Real seal. Since the carrier refuses the excluded coordinates, the handoff is a finite NameCert route rather than an ambient completeness theorem or selected host limit. □

Falsifiable prediction: An accepted $\mathsf{SeparatedCauchySequence}^{\uparrow}$ read is refuted by any Real-facing consumer that reaches the terminal seal without first displaying the StreamName finite

window, RegSeqRat readback, DyadicRatCore tolerance ledger, CauchySubnet cofinal route, and separated-comparison row.

Independence witness: streamname, regseqrat, dyadicratcore, real, cauchysubnet: $\mathsf{SeparatedCauchySequence}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries finite windows, regular rational readback, dyadic separated-tail tolerance, cofinal-tail routing, terminal Real sealing, transport, replay, provenance, and local naming in one packet.

Closure status for $\mathsf{NameCert}_{\mathsf{SeparatedCauchySequence}^{\uparrow}}$.

Constructive story: A $\mathsf{SeparatedCauchySequence}^{\uparrow}$ packet is generated from StreamName finite windows, RegSeqRat readback, a DyadicRatCore separated-tail tolerance ledger, a CauchySubnet cofinal route, a separated-comparison row, a terminal Real seal, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{SeparatedCauchySequence}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 9041.1, Definition 9041.2, and Definition 9041.3 seed the separated Cauchy-sequence route through StreamName, RegSeqRat, DyadicRatCore, CauchySubnet, and Real rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{SeparatedCauchySequence}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient sequence equality, selected limits, countable choice, host real equality, trichotomy, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, separated-tail tolerance exposure, cofinal-tail routing, Real seal handoff, transport, replay, provenance, and local naming for BEDC.Derived.SeparatedCauchySequenceUp.

Chapter 9042

A Concrete Naming Certificate for $\mathsf{RealPrefixDiagonal}^{\uparrow}$

The $\mathsf{RealPrefixDiagonal}^{\uparrow}$ packet realizes the finite prefix-window diagonal route of chapter 9238 as NameCert data. It consumes the finite observation discipline of chapter 126, the regular rational readback surface of chapter 301, the dyadic tolerance ledger of chapter 291, the diagonal-limit route of chapter 6002, and the terminal seal of chapter 38. The packet is paper-side TasteGate aware: a future gate must preserve nontrivial prefix variation and field-faithful visibility for the displayed rows before any positive discovery claim can be made.

Falsifiable prediction: An accepted $\mathsf{RealPrefixDiagonal}^{\uparrow}$ read is refuted by any diagonal-limit consumer that reaches the terminal RealUp seal without displaying a finite prefix window, RegSeqRat readback, DyadicRatCore tolerance ledger, diagonal selector row, transport row, replay row, provenance row, and local NameCert row.

Independence witness: streamname, regseqrat, dyadicratcore, regular-cauchy-diagonal-limit, real: $\mathsf{RealPrefixDiagonal}^{\uparrow}$ is not bijective to any listed sibling because it jointly binds the finite prefix-window diagonal selector, regular rational readback, dyadic tolerance ledger, terminal Real seal, transport, replay, provenance, and local naming as one packet.

Definition 9042.1 (Real prefix diagonal carrier)**.** *A* $\mathsf{RealPrefixDiagonal}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$P = (B, W, R, D, G, E, H, C, K, N)$$

with the following displayed rows:

1. *B is the finite prefix-budget row naming the admitted observation depth for the diagonal read.*
2. *W is the* $\mathsf{StreamName}^{\uparrow}$ *window row exposed under that prefix budget.*
3. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row attached to the displayed window.*
4. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger recording the diagonal error budget.*
5. *G is the diagonal selector row, recording which displayed prefix coordinate is read at the current precision.*
6. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal, available only after B, W, R, D, G have been displayed together.*
7. *H records componentwise* hsame *transport for the budget, window, readback, tolerance, selector, seal, replay, provenance, and local naming rows.*

8. *C records displayed* Cont *replay from a precision request through B, W, R, D, G, E.*
9. *K is the* Pkg *provenance over* $\mathsf{RealPrefixDiagonal}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{RealPrefixDiagonal}^{\uparrow}}$ *row.*

The carrier exports only finite prefix-window diagonal data. It has no coordinate for a host-selected subsequence, quotient stream equality, ambient Real completeness, countable choice, or a bridge schema.

Theorem 9042.2 (Real prefix diagonal NameCert obligations)**.** *For every accepted* $\mathsf{RealPrefixDiagonal}^{\uparrow}$ *carrier $P = (B, W, R, D, G, E, H, C, K, N)$, the local* $\mathsf{NameCert}_{\mathsf{RealPrefixDiagonal}^{\uparrow}}$ *surface consists exactly of prefix-budget admission, finite StreamName window exposure, RegSeqRat readback, DyadicRatCore tolerance exposure, diagonal selector exposure, terminal Real sealing, componentwise transport, displayed replay, package provenance, and local naming.*

The paper-side TasteGate boundary is the same row list: any future gate must preserve visible variation in B, W, R, D, G, E and field-faithful access to H, C, K, N. Until such a gate exists, the chapter claims only the finite NameCert packet and not a positive discovery result.

Proof. Project the carrier of Definition 9042.1. The finite data rows are B, W, R, D, G, E, and the structural rows are H, C, K, N.

Read the diagonal route in order. The prefix budget B admits a bounded observation, the StreamName row W exposes the corresponding window, the RegSeqRat row R supplies regular rational readback, and the DyadicRatCore row D records the tolerance attached to the readback.

The selector row G chooses only among displayed prefix coordinates, and the terminal Real seal E is downstream of that selector. Transport, replay, provenance, and naming preserve this route without adding host-selected subsequences, quotient stream equality, countable choice, ambient Real completeness, or a bridge schema. □

Theorem 9042.3 (Real prefix diagonal limit route)**.** *Every Real-completeness diagonal consumer of an accepted* $\mathsf{RealPrefixDiagonal}^{\uparrow}$ *packet factors through the finite route*

$$B, W, R, D, G, E, H, C, K, N.$$

Equivalently, the consumer must expose a prefix budget, StreamName finite window, RegSeqRat readback, DyadicRatCore tolerance ledger, diagonal selector row, terminal Real seal, componentwise transport, displayed replay, package provenance, and local NameCert row before it can read the diagonal-limit handoff named by chapter 9238.

Proof. Begin with Definition 9042.1. The terminal seal E is not accessible until the budget, window, readback, tolerance, and selector rows are present in the same packet.

Use Definition 9042.2 to exhaust the local ledger. The listed rows account for every data-bearing and structural coordinate of the packet.

The vision route of chapter 9238 can therefore consume this chapter only as a finite prefix-window handoff. Because the carrier has no coordinate for host-selected subsequences, quotient stream equality, countable choice, ambient Real completeness, or a bridge schema, none of those objects can be projected from the packet. □

Closure status for $\mathsf{NameCert}_{\mathsf{RealPrefixDiagonal}^{\uparrow}}$**.**

Constructive story: A $\mathsf{RealPrefixDiagonal}^{\uparrow}$ packet is generated from a finite prefix budget, StreamName window, RegSeqRat readback, DyadicRatCore tolerance ledger, diagonal selector row, Real seal, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\mathsf{RealPrefixDiagonal}\uparrow}$, seed)

Scope closed: Definition 9042.1, Definition 9042.2, Definition 9042.3, the falsifiable prediction, and the independence witness seed the finite prefix-window diagonal route of the Real-completeness vision.

Formal verification: FormalStatus(NameCert$_{\mathsf{RealPrefixDiagonal}\uparrow}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close full Real completeness, quotient stream equality, host-selected subsequences, countable choice, positive discovery status, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, prefix-window exposure, diagonal selector exactness, tolerance-seal handoff, transport, replay, provenance, and local naming for BEDC.Derived.RealPrefixDiagonalUp.

Chapter 9043

A Concrete Naming Certificate for $\mathsf{ZeroFibreNormalSheet}^{\uparrow}$

The $\mathsf{ZeroFibreNormalSheet}^{\uparrow}$ packet realizes the normal zero-sheet geometry of section 9413.30 as finite BEDC NameCert data. It sits after the complex-coordinate carrier of chapter 39, the continuation and zero-consumer ledgers of chapter 580 and chapter 73, the critical-strip window of chapter 8868, the zero-type factorization of chapter 8772, the finite prime-window gluing route of chapter 8765, and the RH boundary separation of chapter 8864. The packet names finite normal-sheet support evidence; it does not assert RH, zero exclusion, analytic continuation completeness, zero simplicity, or an infinite spectral theorem.

Definition 9043.1 (Zero-fibre normal sheet carrier)**.** *A* $\mathsf{ZeroFibreNormalSheet}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Z = (C, V, W, O, M, P, R, H, K, Q, N)$$

with the following displayed rows:

1. *C is the* $\mathsf{Complex}^{\uparrow}$ *mirror-coordinate row, displaying a critical-strip point as* $\frac{1}{2} + \delta + i\tau$*.*
2. *V is the completed-zeta value row read through the existing zeta-continuation and zero-consumer ledgers.*
3. *W is the* $\mathsf{RHCriticalStripWindowCertificate}^{\uparrow}$ *row that keeps the zero read inside a displayed finite critical-strip window.*
4. *O is the* $\mathsf{ZetaZeroTypeFactorization}^{\uparrow}$ *row separating zero-fibre, trivial-zero, generated-zero, and RH-facing support reads.*
5. *M is the* $\mathsf{RHMirrorOrbitTarget}^{\uparrow}$ *row recording the mirror companion of an off-fixed coordinate without identifying it with the fixed line.*
6. *P is the* $\mathsf{FinitePrimeWindowGluing}^{\uparrow}$ *support row used when a normal coordinate is compared with finite prime-window defect evidence.*
7. *R is the support route row from a normal-coordinate read and completed-zero read to the finite no-extra-zero-sheet boundary.*
8. *H records componentwise* hsame *transport for coordinate, completed-zeta, critical-window, zero-factorization, mirror, prime-window, support-route, replay, provenance, and local naming rows.*
9. *K records displayed* Cont *replay from a zero-fibre query through C, V, W, O, M, P, R, H.*

10. *Q is the* Pkg *provenance over* $\mathsf{ZeroFibreNormalSheet}^{\uparrow}$, $\mathsf{Complex}^{\uparrow}$, $\mathsf{ZetaCont}^{\uparrow}$, $\mathsf{ZetaZeros}^{\uparrow}$, RHCriticalStripWindowC ZetaZeroTypeFactorization$^{\uparrow}$, $\mathsf{RHMirrorOrbitTarget}^{\uparrow}$, $\mathsf{FinitePrimeWindowGluing}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{ZeroFibreNormalSheet}^{\uparrow}}$ *row.*

The classifier accepts a normal-sheet support read only through these rows. It has no coordinate for an RH proof, global zero exclusion, analytic continuation completeness, zero simplicity, host complex equality, an infinite prime window, or a spectral trace formula.

Theorem 9043.2 (Zero-fibre normal sheet NameCert obligations)**.** *For every accepted* $\mathsf{ZeroFibreNormalSheet}^{\uparrow}$ *carrier* $Z = (C, V, W, O, M, P, R, H, K, Q, N)$*, the local* $\mathsf{NameCert}_{\mathsf{ZeroFibreNormalSheet}^{\uparrow}}$ *surface consists exactly of carrier admission for the mirror-coordinate row, completed-zeta value row, finite critical-strip window, zero-type factorization, mirror-orbit row, finite prime-window support row, normal-sheet support route, componentwise transport, displayed replay, provenance, and local naming. No accepted consumer may use the packet as an RH proof or zero-exclusion theorem before these finite rows are displayed.*

Proof. Project the carrier of Definition 9043.1. The rows $C, V, W, O, M, P, R, H, K, Q, N$ are the only coordinates available to the local certificate.

The coordinate row C and value row V expose the zero-fibre read, while W keeps the read inside a finite critical-strip window. The factorization row O prevents this zero read from being confused with trivial-zero, generated-zero, or global RH surfaces.

The mirror row M records pairing under the functional-equation symmetry without collapsing the normal coordinate. The finite prime-window row P supplies the support evidence consumed by R when the packet is read as a no-extra-zero-sheet boundary.

Finally H, K, Q, N transport, replay, source, and name the same finite route. Since the carrier contains no RH proof, global zero-exclusion coordinate, analytic-completion coordinate, zero-simplicity coordinate, host equality coordinate, infinite prime window, or spectral trace formula, none of those objects is exported by the local NameCert surface. □

Theorem 9043.3 (Zero-fibre normal sheet RH support route)**.** *Every RH-facing support read from an accepted* $\mathsf{ZeroFibreNormalSheet}^{\uparrow}$ *packet factors through the displayed finite route*

$$\mathsf{Complex}^{\uparrow}, \mathsf{ZetaCont}^{\uparrow}, \mathsf{ZetaZeros}^{\uparrow} \longmapsto \mathsf{RHCriticalStripWindowCertificate}^{\uparrow} \longmapsto \mathsf{ZetaZeroTypeFactorization}^{\uparrow}, \mathsf{RHMirrorO}$$

The route names a finite support certificate for the normal zero-sheet boundary; it does not decide RH, exclude all zeros off the fixed line, prove analytic continuation completeness, or replace finite prime-window evidence by an infinite spectral object.

Proof. Use the obligation surface of Definition 9043.2. It forces every accepted support read to expose the coordinate, completed-zeta, critical-window, zero-factorization, mirror, finite prime-window, and support-route rows before provenance and local naming are consumed.

The support row R is downstream of both the mirror-orbit row and the finite prime-window row. Thus the packet may record normal-sheet support evidence only after the zero-fibre read has been separated from global RH claims and after the finite prime-window comparison has been displayed.

The non-escape statement is carrier inspection. The tuple contains no coordinate for an RH proof, global zero exclusion, analytic continuation completeness, or infinite spectral trace, so the accepted route remains a finite support certificate. □

Falsifiable prediction: A $\mathsf{ZeroFibreNormalSheet}^{\uparrow}$ consumer that claims no-extra-zero-sheet support while omitting the critical-strip window W, zero-factorization row O, mirror-orbit row M, or finite prime-window support row P is not reading an accepted packet of this chapter.

Independence witness: zeta-continuation-witness, zeta-zeros, rh-critical-strip-window, zeta-zero-type-factorization, finite-prime-window-gluing: $\mathsf{ZeroFibreNormalSheet}^{\uparrow}$ is not bijective with any listed sibling because it jointly carries mirror coordinates, completed-zeta zero reads, finite critical-window support, zero-factorization, mirror-orbit, finite prime-window support, transport, replay, provenance, and local naming.

The Lean TasteGate route for this packet must provide explicit $\mathsf{Nontrivial\ ZeroFibreNormalSheet}^{\uparrow}$ and $\mathsf{FieldFaithful\ ZeroFibreNormalSheet}^{\uparrow}$ instances. Those instances must keep $C, V, W, O, M, P, R, H, K, Q, N$ as separate displayed fields before any checked support-route theorem can serve as a public TasteGate realization.

Closure status for $\mathsf{NameCert}_{\mathsf{ZeroFibreNormalSheet}^{\uparrow}}$.

Constructive story: A $\mathsf{ZeroFibreNormalSheet}^{\uparrow}$ packet is generated from ComplexUp mirror coordinates, completed-zeta value rows, a finite critical-strip window, zero-type factorization, mirror-orbit rows, finite prime-window support, a normal-sheet support route, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{ZeroFibreNormalSheet}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 9043.1, Definition 9043.2, and Definition 9043.3 seed the finite normal-sheet support route over zeta, critical-window, mirror, prime-window, transport, replay, provenance, and naming rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{ZeroFibreNormalSheet}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim Lean verification, bridge checking, RH, global zero exclusion, analytic continuation completeness, zero simplicity, host complex equality, infinite prime windows, or a spectral trace formula.

Upgrade path: Obligation closure requires checked carrier admission, completed-zero visibility, critical-window support, zero-factorization separation, mirror-orbit preservation, finite prime-window support, Nontrivial ZeroFibreNormalSheetUp, and FieldFaithful ZeroFibreNormalSheetUp for BEDC.Derived.ZeroFibreNormalSheetUp.

Chapter 9044

A Concrete Naming Certificate for $\mathsf{AbsoluteContinuousCurve}^{\uparrow}$

Following Ambrosio–Gigli–Savare and Burago–Burago–Ivanov metric-curve practice, the $\mathsf{AbsoluteContinuousCurve}^{\uparrow}$ packet records absolute continuity of a displayed metric curve by finite interval windows, Real-valued distance estimates, and a partition-sum modulus. It sits between the L10 metric-completion route of $\mathsf{Met}^{\uparrow}$ in chapter 4230, the path graph surface of $\mathsf{ContinuousMap}^{\uparrow}$ in chapter 130, the Real tolerance ledger of $\mathsf{Real}^{\uparrow}$ in chapter 38, the partition-control discipline of $\mathsf{AbsolutelyContinuousFunction}^{\uparrow}$ in chapter 3361, the finite length handoff of $\mathsf{RectifiableCurve}^{\uparrow}$ in chapter 3443, and the scale row of $\mathsf{ArcLengthParameter}^{\uparrow}$ in chapter 6944. The certificate names the curve-level metric object only through displayed rows; it is not a host path space, a selected representative curve, a measure-completed derivative theorem, or quotient equality of curves.

Definition 9044.1 (Absolute continuous curve carrier)**.** *An* $\mathsf{AbsoluteContinuousCurve}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$A = (M, I, W, G, D, E, U, R, L, S, H, C, P, N)$$

with the following displayed rows:

1. *M is the* $\mathsf{Met}^{\uparrow}$ *source row, containing the accepted metric carrier and the distance read used for curve samples.*
2. *I is the interval row, naming the ordered source interval and its finite endpoint windows.*
3. *W is the* $\mathsf{StreamName}^{\uparrow}$ *parameter-window row recording exactly the sampled subintervals and endpoint requests consumed by the packet.*
4. *G is the* $\mathsf{ContinuousMap}^{\uparrow}$ *curve graph row from the displayed interval windows into the metric carrier.*
5. *D is the* $\mathsf{Real}^{\uparrow}$*-valued distance-estimate row for adjacent sampled curve values, read only through the metric distance in M and the graph row G.*
6. *E is the partition-sum absolute-continuity modulus row: for each displayed Real error budget it records a finite interval-length budget and the corresponding sum of distance estimates over disjoint sampled subintervals.*
7. *U is the* $\mathsf{AbsolutelyContinuousFunction}^{\uparrow}$ *handoff row, exposing the same partition-budget discipline as a function-level finite ledger when a scalar Real-valued consumer asks for it.*
8. *R is the* $\mathsf{RectifiableCurve}^{\uparrow}$ *handoff row, available only after M, I, W, G, D, E have been displayed.*

9. *L is the* $\mathsf{ArcLengthParameter}^{\uparrow}$ *compatibility row, pairing accepted length-parameter requests with the same distance-estimate and partition-sum rows.*
10. *S records componentwise* hsame *transport for metric, interval, window, graph, distance-estimate, modulus, rectifiable, arc-length, replay, provenance, and local naming rows.*
11. *H records displayed* Cont *replay from a curve absolute-continuity request through $M, I, W, G, D, E, U, R, L$.*
12. *C is the* Pkg *provenance row over* $\mathsf{AbsoluteContinuousCurve}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{AbsolutelyContinuousFunction}^{\uparrow}$, $\mathsf{RectifiableCurve}^{\uparrow}$, $\mathsf{ArcLengthParameter}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
13. *P is the downstream handoff ledger, recording which of the function-level, rectifiable-curve, and arc-length consumers has read the displayed rows.*
14. *N is the local* $\mathsf{NameCert}_{\mathsf{AbsoluteContinuousCurve}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $M, I, W, G, D, E, U, R, L, S, H, C, P, N$. It has no coordinate for host function equality, selected curve representatives, quotient paths, measure-completed derivatives, an ambient path-space completion, countable choice, or bridge evidence.

Theorem 9044.2 (Absolute continuous curve NameCert obligations)**.** *For the carrier of Definition 9044.1, the local* $\mathsf{NameCert}_{\mathsf{AbsoluteContinuousCurve}^{\uparrow}}$ *surface consists of exactly five obligation rows:*

1. *carrier admission for the finite packet $A = (M, I, W, G, D, E, U, R, L, S, H, C, P, N)$;*
2. *metric-curve exposure through M, I, W, G, D, so every distance estimate is read from displayed parameter windows and the accepted metric distance;*
3. *partition-sum absolute-continuity control through E and the function-level handoff U;*
4. *rectifiable-curve and arc-length compatibility through R, L, P after the same distance-estimate rows have been displayed;*
5. *componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, local naming, and exclusion of host path spaces, selected representatives, quotient curves, measure-completed derivatives, countable choice, and bridge evidence.*

Proof. Project the carrier in Definition 9044.1. The rows $M, I, W, G, D, E, U, R, L$ are the whole metric and analytic surface before transport, replay, provenance, handoff bookkeeping, and naming are read.

The metric-curve rows are M, I, W, G, D. They expose the accepted metric carrier, the interval and StreamName parameter windows, the continuous curve graph, and the Real-valued distance estimates for adjacent sampled values.

The absolute-continuity row is E, with U giving the function-level handoff. A consumer that asks for partition-sum control must read the same finite interval-length budget and the same finite sum of distance estimates before it can use the scalar ledger.

The curve-length rows are R, L, P. Rectifiable-curve and arc-length consumers receive only the already displayed distance-estimate packet, together with the handoff ledger recording which consumer route is being used.

Finally S, H, C, N transport, replay, source, and name the same finite packet. Since no carrier coordinate stores a host path space, a selected representative curve, quotient equality of curves, a measure-completed derivative, countable choice, or bridge evidence, the five listed obligations exhaust the local NameCert surface. □

Theorem 9044.3 (Absolute continuous curve metric-length handoff)**.** *Every metric-completion, rectifiable-curve, or arc-length consumer of an accepted* $\mathsf{AbsoluteContinuousCurve}^{\uparrow}$ *packet reads the displayed route*

$$\mathsf{Met}^{\uparrow},\ \mathsf{ContinuousMap}^{\uparrow},\ \mathsf{Real}^{\uparrow},\ \mathsf{AbsolutelyContinuousFunction}^{\uparrow},\ \mathsf{RectifiableCurve}^{\uparrow},\ \mathsf{ArcLengthParameter}^{\uparrow}$$

through the finite rows $M, I, W, G, D, E, U, R, L, S, H, C, P, N$*. The handoff exports curve-level absolute continuity as a finite metric partition certificate, not as a host path, quotient curve, selected representative, completed path space, measure derivative, or bridge datum.*

Proof. Start with the metric and graph rows. The accepted metric carrier M and the continuous graph row G can be read only at the displayed interval and StreamName windows I, W.

Next read the numerical control. The row D gives the Real-valued distance estimates for adjacent sampled curve values, while E records the partition-sum modulus that bounds those estimates over finite disjoint subintervals.

Now pass to the sibling consumers. The function-level row U reuses the same partition-control surface, the rectifiable row R reuses the same finite distance-sum ledger, and the arc-length row L reuses the same length-compatible parameter requests.

The structural rows S, H, C, P, N preserve this route by transport, replay, provenance, consumer bookkeeping, and local naming. No step introduces a host path object, quotient equality of curves, selected representative, completed path space, measure-completed derivative, countable-choice schedule, or bridge evidence. □

Closure status for $\mathsf{NameCert}_{\mathsf{AbsoluteContinuousCurve}^{\uparrow}}$**.**

Constructive story: An $\mathsf{AbsoluteContinuousCurve}^{\uparrow}$ packet is generated from a MetricSpace source row, interval and StreamName parameter windows, a ContinuousMap curve graph, Real-valued distance estimates, a partition-sum absolute-continuity modulus, AbsolutelyContinuousFunction handoff, RectifiableCurve handoff, ArcLengthParameter compatibility, componentwise hsame transport, displayed Cont replay, Pkg provenance, downstream handoff bookkeeping, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{AbsoluteContinuousCurve}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 9044.1, Definition 9044.2, and Definition 9044.3 seed the finite metric-curve absolute-continuity route over $\mathsf{Met}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{AbsolutelyContinuousFunction}^{\uparrow}$, $\mathsf{RectifiableCurve}^{\uparrow}$, and $\mathsf{ArcLengthParameter}^{\uparrow}$.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{AbsoluteContinuousCurve}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host path spaces, selected curve representatives, quotient curve equality, measure-completed derivatives, completed path-space structure, countable choice, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, metric-curve exposure, Real-valued distance-estimate exactness, partition-sum absolute-continuity control, rectifiable-curve handoff, arc-length compatibility, transport, replay, provenance, and local naming for BEDC.Derived.AbsoluteContinuousCurveUp.

Chapter 9045

A Concrete Naming Certificate for $\mathsf{DyadicEmbeddingRegularSequence}^{\uparrow}$

Following Bishop and Bridges on regular Cauchy real names, the $\mathsf{DyadicEmbeddingRegularSequence}^{\uparrow}$ packet records the finite L10 route by which one displayed dyadic rational source is embedded as a constant regular rational sequence before a $\mathsf{Real}^{\uparrow}$ consumer may inspect the terminal seal. It sits beside the dyadic carrier of chapter 291, the finite window surface of chapter 126, the regular rational readback of chapter 301, and the terminal real-name seal of chapter 38. The packet names only the finite embedding handoff; it does not assert quotient equality of real names, selected limits, countable choice, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 9045.1 (DyadicEmbeddingRegularSequence carrier)**.** *A* $\mathsf{DyadicEmbeddingRegularSequence}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$E = (D, W, R, L, H, C, P, N)$$

with the following displayed rows:

1. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *source row, naming the dyadic rational being embedded and the dyadic arithmetic cells available to later tolerance reads;*
2. *W is the constant* $\mathsf{StreamName}^{\uparrow}$ *window row, exposing finite observations whose entries all read the same source dyadic row D;*
3. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *regularity row, recording the regular rational Cauchy schedule for the constant stream and its dyadic tolerance comparison;*
4. *L is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row, available only after D, W, R have been displayed;*
5. *H records componentwise* hsame *transport for dyadic source, constant window, regularity, Real seal, replay, provenance, and local naming rows;*
6. *C records displayed* Cont *replay from a Real-facing request through dyadic admission, constant-window inspection, regular rational readback, Real seal consumption, provenance, and local naming;*
7. *P is the* Pkg *provenance over* $\mathsf{DyadicEmbeddingRegularSequence}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* $\mathsf{NameCert}$ *rows;*
8. *N is the local* $\mathsf{NameCert}_{\mathsf{DyadicEmbeddingRegularSequence}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through D, W, R, L, H, C, P, N. No coordinate stores a host real, quotient representative, selected limit, countable-choice schedule, trichotomy branch, or ambient completeness of $\mathsf{Real}^{\uparrow}$.

Theorem 9045.2 (DyadicEmbeddingRegularSequence obligation surface)**.** *For every accepted* $\mathsf{DyadicEmbeddingRegularSequence}^{\uparrow}$ *carrier*

$$E = (D, W, R, L, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{DyadicEmbeddingRegularSequence}^{\uparrow}}$ *surface consists exactly of dyadic source admission, constant* $\mathsf{StreamName}^{\uparrow}$ *window exposure,* $\mathsf{RegSeqRat}^{\uparrow}$ *regularity readback for the constant stream, terminal* $\mathsf{Real}^{\uparrow}$ *seal gating, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. A Real-facing consumer may inspect the embedded dyadic name only through these rows.*

Proof. Project the carrier $E = (D, W, R, L, H, C, P, N)$. The dyadic row D is exposed before any stream or regularity read, so the source rational is a visible BEDC row rather than a hidden scalar.

The window row W repeats the same source dyadic row at every displayed observation. The regularity row R reads that constant window together with the dyadic tolerance budget, so the Cauchy schedule is finite row data.

Only after D, W, R have been displayed can the Real seal L be consumed. The support rows H, C, P, N transport, replay, source, and name the same route. Since the packet has no coordinate for quotient equality, selected limits, countable choice, trichotomy, or ambient Real completeness, those data are not exported by the obligation surface. □

Theorem 9045.3 (DyadicEmbeddingRegularSequence Real seal)**.** *Every* $\mathsf{Real}^{\uparrow}$ *read exported by an accepted* $\mathsf{DyadicEmbeddingRegularSequence}^{\uparrow}$ *carrier first exposes the* $\mathsf{DyadicRatCore}^{\uparrow}$ *source row D, the constant* $\mathsf{StreamName}^{\uparrow}$ *window row W, and the* $\mathsf{RegSeqRat}^{\uparrow}$ *regularity row R. Therefore the Real seal is a finite embedding route from a dyadic rational to a regular sequence name, not a selected host real or an ambient completeness theorem.*

Proof. Read the source row D and the constant window row W. They make the dyadic rational and its repeated finite observations visible before any Real-facing consumer acts.

Use the regularity row R. It supplies the regular rational Cauchy readback and the dyadic tolerance comparison for the constant stream.

The terminal row L is then reached through the displayed embedding route. Componentwise transport, replay, provenance, and local naming preserve that same route and add no host real, quotient representative, selected limit, choice schedule, trichotomy branch, or ambient completeness principle. □

Closure status for $\mathsf{NameCert}_{\mathsf{DyadicEmbeddingRegularSequence}^{\uparrow}}$.

Constructive story: A $\mathsf{DyadicEmbeddingRegularSequence}^{\uparrow}$ packet is generated from a DyadicRatCoreUp source row, a constant StreamNameUp window row, a RegSeqRatUp regularity row, a terminal RealUp seal row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert rows.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{DyadicEmbeddingRegularSequence}^{\uparrow}}$, seed)

Scope closed: Definition 9045.1, Definition 9045.2, and Definition 9045.3 seed the finite dyadic-to-regular-sequence embedding surface.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{DyadicEmbeddingRegularSequence}^{\uparrow}}$, unformalized)

Bridge status: none

Origin: human

Not claimed: This chapter does not close quotient equality of real names, selected limits, countable choice, trichotomy, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, audit cleanliness, or bridge checking.

Upgrade path: Obligation closure requires checked dyadic source admission, constant stream-window exposure, regular rational readback, Real seal gating, transport, replay, provenance, and local naming for BEDC.Derived.DyadicEmbeddingRegularSequenceUp

Chapter 9046

A Concrete Naming Certificate for $\mathsf{FixedHalfZeroWitness}^{\uparrow}$

The $\mathsf{FixedHalfZeroWitness}^{\uparrow}$ packet names only the typed witness-function package of Definition 9333.1. It is not a proof of RH, not a zero-location theorem, and not an analytic exclusion of off-line zeros. The packet sits beside the critical-line witness surface of chapter 548, the basic zeta source of chapter 71, the zeta-zero carrier of chapter 73, and the zero-type factorization packet of chapter 8772.

Definition 9046.1 (FixedHalfZeroWitness carrier)**.** *A* $\mathsf{FixedHalfZeroWitness}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$F = (Z, S, W, T, B, H, C, P, N)$$

with the following displayed rows:

1. *Z is the non-trivial zeta-zero source row, read through the zero and critical-strip typing data of the RH proof-obligation package;*
2. *S is the source-classifier row, recording the projection back to the original zero source before any fixed-half witness is cited;*
3. *W is the fixed-half witness-function row, displaying the typed function from the non-trivial-zero package to the fixed-half-zero package;*
4. *T is the transport row witnessing that the projected source of W is classifier-equal to the source row named by S;*
5. *B is the refusal boundary row, recording that the packet exports no proof of* RH*, no analytic zero exclusion, no global zero classifier, and no host truth value;*
6. *H records componentwise* hsame *transport for source, classifier, witness-function, source-transport, refusal, replay, provenance, and local naming rows;*
7. *C records displayed* Cont *replay from a witness-function request through zero-source admission, classifier projection, fixed-half witness readback, refusal-boundary inspection, provenance, and local naming;*
8. *P is the* Pkg *provenance over* $\mathsf{FixedHalfZeroWitness}^{\uparrow}$*,* $\mathsf{CriticalLineWitness}^{\uparrow}$*,* $\mathsf{ZetaBasic}^{\uparrow}$*,* $\mathsf{ZetaZeros}^{\uparrow}$*,* $\mathsf{ZetaZeroTypeFactorization}^{\uparrow}$*,* BHist*,* hsame*,* Cont*,* Pkg*, and* $\mathsf{NameCert}$ *rows;*
9. *N is the local* $\mathsf{NameCert}_{\mathsf{FixedHalfZeroWitness}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $Z, S, W, T, B, H, C, P, N$. It has no coordinate for an RH proof, a zero-free strip theorem, a completed analytic continuation argument, an ambient truth predicate, Classical choice, quotient equality, or a standard bridge.

Theorem 9046.2 (FixedHalfZeroWitness obligation surface)**.** *For the carrier of Definition 9046.1, the local* $\mathsf{NameCert}_{\mathsf{FixedHalfZeroWitness}^{\uparrow}}$ *surface consists exactly of non-trivial-zero source admission, source-classifier projection, fixed-half witness-function readback, source-transport evidence, refusal-boundary exposure, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming.*

Proof. Project the finite packet $F = (Z, S, W, T, B, H, C, P, N)$. The source row Z and source-classifier row S are visible before the witness-function row is read, so the package starts from typed zero data rather than an untyped analytic assertion.

The witness-function row W supplies only the displayed function package named by Definition 9333.1. The transport row T records the projection back to the same source classifier.

The refusal row B is part of the same carrier. It prevents the read from being cited as an RH proof, an off-line zero exclusion, a global zero classifier, or a host truth value. The support rows H, C, P, N preserve, replay, source, and name that finite package, and no further obligation is stored outside the displayed rows. □

Theorem 9046.3 (FixedHalfZeroWitness RH witness route)**.** *Every accepted* $\mathsf{FixedHalfZeroWitness}^{\uparrow}$ *read routes the typed witness function of Definition 9333.1 through $Z, S, W, T, B, H, C, P, N$. The route may be used as a concrete NameCert landing for the RH witness-function target, but it does not prove* RH*, does not supply analytic zero exclusion, and does not turn fixed-half witness data into a bridge-checked theorem.*

Proof. Read the source row Z and classifier projection row S. They identify the typed non-trivial-zero input and its source before a fixed-half target can be named.

Next read W and T. The witness-function row displays the fixed-half output package, and the transport row records that its projection returns to the source classifier.

Finally inspect B, H, C, P, N. The refusal boundary keeps the route inside the typed package and the structural rows transport, replay, source, and name the same data. Thus the route is a witness-function NameCert surface, not an RH proof or a bridge-checked analytic theorem. □

Falsifiable prediction: If an accepted FixedHalfZeroWitnessUp packet exports a fixed-half witness without displaying the non-trivial-zero source row, source-classifier projection, witness-function row, source-transport row, and refusal boundary, then it is refuted as a NameCert carrier for the RH witness-function package.

Independence witness: criticallinewitness, zeta-basic, zeta-zeros, zeta-zero-type-factorization: none is bijective to $\mathsf{FixedHalfZeroWitness}^{\uparrow}$ because those siblings respectively bind critical-line witness rows, basic zeta source rows, zero carrier rows, or zero-type factorization rows, while this packet binds the typed witness-function route with source projection, refusal boundary, transport, replay, provenance, and local NameCert rows.

The Lean follow-up file `lean4/BEDC/Derived/FixedHalfZeroWitnessUp/TasteGate.lean` must provide explicit $\mathsf{Nontrivial}\ \mathsf{FixedHalfZeroWitness}^{\uparrow}$ and $\mathsf{FieldFaithful}\ \mathsf{FixedHalfZeroWitness}^{\uparrow}$ instances. The nontriviality witness must distinguish an accepted witness-function packet from a packet missing the source-transport or refusal-boundary row, and the field-faithfulness witness must preserve $Z, S, W, T, B, H, C, P, N$ as separate rows.

Closure status for $\mathsf{NameCert}_{\mathsf{FixedHalfZeroWitness}^{\uparrow}}$.

Constructive story: A $\mathsf{FixedHalfZeroWitness}^{\uparrow}$ packet is generated from a non-trivial zero source row, source-classifier row, typed fixed-half witness-function row, source-transport row, refusal-boundary row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert rows.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{FixedHalfZeroWitness}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 9046.1, Definition 9046.2, and Definition 9046.3 seed the typed fixed-half witness-function package without proving RH.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{FixedHalfZeroWitness}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Origin: ai

Not claimed: This chapter does not prove RH, exclude off-line zeros, provide analytic continuation evidence, supply a global zero classifier, close Lean verification, audit cleanliness, or bridge checking.

Upgrade path: Obligation closure requires checked zero-source admission, source projection, witness-function read-back, source transport, refusal-boundary exposure, provenance, local naming, and the required Nontrivial and FieldFaithful instances for BEDC.Derived.FixedHalfZeroWitnessUp.

Chapter 9047

Bishop Separated Cauchy Completion Idempotence NameCert Construction

Following Bishop and Bridges, the $\mathsf{BishopSeparatedCauchyCompletionIdempotence}^{\uparrow}$ packet records the finite certificate by which a separated regular Cauchy completion read remains on the same displayed route when completion is requested again. It sits after the separated completion idempotence row of chapter 6970, the regular Cauchy Hausdorff reflection of chapter 4372, and the Bishop separated real completion packet of chapter 9026. The packet names idempotence of the displayed separated regular Cauchy completion route; it is not quotient equality of completed objects, not a selected completed representative, not countable choice, and not ambient completeness of $\mathsf{Real}^{\uparrow}$.

Definition 9047.1 (Bishop separated Cauchy completion idempotence carrier)**.** *A* BishopSeparatedCauchyCompleti *carrier is a finite* BHist *packet*

$$J = (C, S, R, Q, B, E, H, T, P, N)$$

with the following displayed rows:

1. *C is the* $\mathsf{Completion}^{\uparrow}$ *source row for the repeated completion request.*
2. *S is the* $\mathsf{SeparatedCompletionIdempotence}^{\uparrow}$ *row, exposing the separated classifier before any repeated readback.*
3. *R is the* $\mathsf{RegularCauchyHausdorffReflection}^{\uparrow}$ *row, recording the Hausdorff-separated regular Cauchy comparison surface.*
4. *Q is the* $\mathsf{BishopSeparatedRealCompletion}^{\uparrow}$ *row, giving the Bishop separated real completion route consumed by Real-facing readers.*
5. *B is the regular Cauchy readback row, carrying the displayed finite windows and regular rational data for the completion request.*
6. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row, available only after C, S, R, Q, B have been displayed.*
7. *H records componentwise* hsame *transport for the completion, separated-idempotence, Hausdorff-reflection, Bishop separated completion, readback, seal, replay, provenance, and local naming rows.*
8. *T records displayed* Cont *replay from a second separated regular Cauchy completion request through the same rows.*

9. *P is the* Pkg *provenance over* $\mathsf{BishopSeparatedCauchyCompletionIdempotence}^{\uparrow}$, $\mathsf{Completion}^{\uparrow}$, SeparatedCompletion RegularCauchyHausdorffReflection$^{\uparrow}$, $\mathsf{BishopSeparatedRealCompletion}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

10. *N is the local* $\mathsf{NameCert}_{\mathsf{BishopSeparatedCauchyCompletionIdempotence}^{\uparrow}}$ *row.*

The classifier for accepted packets compares only $C, S, R, Q, B, E, H, T, P, N$. It has no coordinate for quotient equality of completions, selected representatives, countable choice, host equality of completed points, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 9047.2 (Bishop separated Cauchy completion idempotence NameCert obligations)**.** *For every accepted* $\mathsf{BishopSeparatedCauchyCompletionIdempotence}^{\uparrow}$ *carrier $J = (C, S, R, Q, B, E, H, T, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{BishopSeparatedCauchyCompletionIdempotence}^{\uparrow}}$ *surface consists exactly of carrier admission for the repeated completion source, separated completion idempotence row, regular Cauchy Hausdorff reflection row, Bishop separated real completion row, regular Cauchy readback, terminal Real seal, componentwise transport, displayed replay, package provenance, and local naming. A repeated separated regular Cauchy completion read must expose C, S, R, Q, B before any* $\mathsf{Real}^{\uparrow}$*-facing consumer may inspect E.*

Proof. Project the carrier of Definition 9047.1. The rows $C, S, R, Q, B, E, H, T, P, N$ are the complete accepted inventory.

The separated idempotence row S is read before the Hausdorff-reflection row R and the Bishop separated real completion row Q. Thus the second completion request returns to the displayed separated classifier and regular Cauchy comparison surface before any Real-facing boundary is reached.

The regular Cauchy readback B and terminal seal E are downstream of those rows. Transport, replay, provenance, and local naming preserve the same finite route and add no coordinate for quotient equality, selected representatives, countable choice, host equality, or ambient completeness. □

Theorem 9047.3 (Bishop separated Cauchy completion idempotent seal route)**.** *Every terminal* $\mathsf{Real}^{\uparrow}$ *seal read exported by an accepted* $\mathsf{BishopSeparatedCauchyCompletionIdempotence}^{\uparrow}$ *packet factors through*

$$\mathsf{Completion}^{\uparrow} \longmapsto \mathsf{SeparatedCompletionIdempotence}^{\uparrow} \longmapsto \mathsf{RegularCauchyHausdorffReflection}^{\uparrow} \longmapsto \mathsf{BishopSeparatedRea}$$

Consequently, applying separated regular Cauchy completion again returns to the same finite displayed route before the terminal seal is visible. The route is an idempotence certificate for repeated separated regular Cauchy completion reads, not quotient equality, not a representative selector, not countable choice, and not ambient completeness of $\mathsf{Real}^{\uparrow}$*.*

Proof. Start with the NameCert obligations of Definition 9047.2. They force every seal-facing read through C, S, R, Q, B before E can be consumed.

Use the sibling separated idempotence surface of chapter 6970. It supplies the repeated-completion boundary as finite row data, so the second request is not interpreted as equality of completion objects.

Now read the regular Cauchy Hausdorff reflection and Bishop separated real completion siblings, chapter 4372 and chapter 9026. These keep the Hausdorff-separated comparison and Bishop separated completion route visible before the terminal $\mathsf{Real}^{\uparrow}$ seal.

Finally use H, T, P, N only as transport, replay, provenance, and local naming for the same displayed rows. Since the carrier has no selected representative, quotient equality, countable-choice

schedule, host equality, or ambient completeness coordinate, none of those endpoints is exported by the seal route. □

Falsifiable prediction: An accepted $\mathsf{BishopSeparatedCauchyCompletionIdempotence}^{\uparrow}$ read is refuted if a repeated separated regular Cauchy completion request reaches a terminal $\mathsf{Real}^{\uparrow}$ seal without first exposing the $\mathsf{Completion}^{\uparrow}$ source row, $\mathsf{SeparatedCompletionIdempotence}^{\uparrow}$ row, RegularCauchyHausdorffReflec row, $\mathsf{BishopSeparatedRealCompletion}^{\uparrow}$ row, regular Cauchy readback row, transport, replay, provenance, and local naming rows.

Independence witness: separated-completion-idempotence, regular-cauchy-hausdorff-reflection, bishop-separated-real-completion, regseqrat, real: $\mathsf{BishopSeparatedCauchyCompletionIdempotence}^{\uparrow}$ is not bijective with any listed sibling because it jointly carries the repeated completion source, separated idempotence boundary, regular Cauchy Hausdorff reflection, Bishop separated real completion route, regular readback, terminal seal, transport, replay, provenance, and local naming rows.

Closure status for $\mathsf{NameCert}_{\mathsf{BishopSeparatedCauchyCompletionIdempotence}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BishopSeparatedCauchyCompletionIdempotence}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 9047.1, Definition 9047.2, and Definition 9047.3 seed the repeated separated regular Cauchy completion route through separated idempotence, Hausdorff reflection, Bishop separated completion, regular readback, and terminal Real seal rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BishopSeparatedCauchyCompletionIdempotence}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient equality of completion objects, selected representatives, countable choice, host equality of completed points, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean theorem checking, or bridge checking.

Upgrade path: To reach formal target status, add the Lean declaration for BEDC.Derived.BishopSeparatedCauchyCompletionIdempotence and then prove the carrier, obligation, seal-route, transport, replay, provenance, and local naming clauses.

Constructive story: A $\mathsf{BishopSeparatedCauchyCompletionIdempotence}^{\uparrow}$ packet is generated from a Completion source row, separated completion idempotence row, regular Cauchy Hausdorff reflection row, Bishop separated real completion row, regular Cauchy readback, terminal Real seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 9048

A Concrete Naming Certificate for $\mathsf{BurnsideLemma}^{\uparrow}$

Following Burnside's finite group-action counting theorem, the $\mathsf{BurnsideLemma}^{\uparrow}$ packet records the orbit-count formula as finite BEDC NameCert data. It sits over the finite group source of chapter 41 and consumes the stabilizer and fixed-orbit accounting route of chapter 6559. The certificate names fixed-point tables and orbit counts as displayed finite ledgers, not as quotient orbit sets, selected representatives, or an ambient enumeration theorem.

Definition 9048.1 (Burnside lemma carrier)**.** *A* $\mathsf{BurnsideLemma}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$T = (G, X, A, L, F, O, K, H, C, P, N)$$

with the following displayed rows:

1. *G is the finite* $\mathsf{Group}^{\uparrow}$ *action source row, exposing the group operation, unit, inverse, and finite multiplication table used by the action.*
2. *X is the acted finite set/list carrier row, exposing a duplicate-controlled finite list of acted points together with its local classifier.*
3. *A is the finite action row, displaying the unit-action and multiplication-action replay laws over G and X.*
4. *L is the finite group-list ledger, listing the group elements whose fixed-point rows are inspected.*
5. *F is the fixed-point table, assigning to each displayed element of L the finite sublist of points of X fixed by that element.*
6. *O is the orbit-count row, recording the displayed count of action orbits as the averaged fixed-point ledger named by F and L.*
7. *K is the Nat/List count ledger, exposing finite lengths, duplicate control, summation, divisibility, and the final natural-number orbit count.*
8. *H records componentwise* hsame *transport for the group, acted list, action, group-list ledger, fixed-point table, orbit-count row, Nat/List count ledger, replay, provenance, and local naming rows.*
9. *C records displayed* Cont *replay from* $\mathsf{Group}^{\uparrow}$ *and X through A, L, F, O, K, H, P, N into* $\mathsf{BurnsideLemma}^{\uparrow}$.

10. *P is the* Pkg *provenance over* $\mathsf{Group}^{\uparrow}$, $\mathsf{OrbitStabilizer}^{\uparrow}$, *finite action rows, fixed-point rows, Nat/List ledgers,* BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{BurnsideLemma}^{\uparrow}}$ *row.*

The carrier predicate admits exactly these rows. It has no coordinate for quotient orbit sets, selected orbit representatives, external cardinal arithmetic, an infinite group action, cycle-index polynomials, Polya enumeration, or host equality of quotient types.

Theorem 9048.2 (Burnside lemma NameCert obligations)**.** *For an accepted* $\mathsf{BurnsideLemma}^{\uparrow}$ *carrier*

$$T = (G, X, A, L, F, O, K, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{BurnsideLemma}^{\uparrow}}$ *surface consists exactly of carrier admission for the displayed finite* $\mathsf{Group}^{\uparrow}$ *source, finite set/list carrier, action row, group-list ledger, fixed-point table, orbit-count row, Nat/List count ledger, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming row.*

Proof. Project the accepted packet onto its eleven displayed rows. The group source, acted finite list, action law, group-list ledger, fixed-point table, orbit-count row, and Nat/List count ledger are present before the local name can be read.

The fixed-point table is indexed by the displayed group-list ledger L, so it cannot be replaced by an external class function. The orbit-count row is read only after the fixed-point table and Nat/List ledger have exposed the finite average, so it cannot be replaced by a quotient orbit object or selected representative list.

Finally, H, C, P, N transport, replay, source, and name only the displayed rows. Since the carrier has no coordinate for quotient orbit sets, external cardinal arithmetic, infinite actions, cycle-index polynomials, Polya enumeration, or host equality of quotient types, no local NameCert obligation can depend on those objects. □

Theorem 9048.3 (Burnside lemma orbit-count route)**.** *Let $T = (G, X, A, L, F, O, K, H, C, P, N)$ be an accepted* $\mathsf{BurnsideLemma}^{\uparrow}$ *carrier. Every orbit-count read exported by T factors through the finite route*

$$\mathsf{Group}^{\uparrow} \longmapsto X \longmapsto A \longmapsto L \longmapsto F \longmapsto K \longmapsto O \longmapsto (H, C, P, N).$$

The stabilizer and fixed-orbit accounting consumed from chapter 6559 remains a finite ledger over the same action row from chapter 41; it is not a quotient orbit carrier, selected representative family, cycle-index polynomial, Polya enumeration surface, or ambient finite-action category.

Proof. Read the group and acted-list rows G and X, then read the action row A. The group-list ledger L enumerates only the displayed elements whose fixed points are inspected, and the table F records those fixed points as finite sublists of X.

The Nat/List ledger K is the only row where lengths, summation, divisibility, and the averaged fixed-point count are exported. The orbit-count row O is therefore downstream of the fixed-point table and the finite count ledger.

The dependency on chapter 6559 supplies stabilizer and fixed-orbit accounting for the same action surface. Transport through H and replay through C preserve that row order before P and N package the local certificate. Thus every consumer sees the finite Burnside ledger, while quotient orbit carriers, selected representatives, cycle-index polynomials, Polya enumeration, and ambient action categories remain outside the packet. □

Lean4 (statement) `BEDC.Derived.BurnsideLemmaUp`

Closure status for $\mathsf{NameCert}_{\mathsf{BurnsideLemma}^{\uparrow}}$.

Constructive story: A $\mathsf{BurnsideLemma}^{\uparrow}$ packet is generated from a displayed finite GroupUp action source, a finite acted list, an action row, a group-list ledger, a fixed-point table, an orbit-count row, a Nat/List count ledger, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BurnsideLemma}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 9048.1, Definition 9048.2, and Definition 9048.3 seed a finite group-action counting certificate over fixed-point and orbit-count ledgers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BurnsideLemma}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim quotient orbit sets, selected orbit representatives, external cardinal arithmetic, infinite group actions, cycle-index polynomials, Polya enumeration, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, fixed-point table exactness, Nat/List ledger soundness, hsame transport, Cont replay, provenance, and orbit-count nonescape for BEDC.Derived.BurnsideLemmaUp.

Chapter 9049

A Concrete Naming Certificate for $\mathsf{RegularCauchyRateTransformer}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{RegularCauchyRateTransformer}^{\uparrow}$ packet records a certified change of regular-Cauchy rate between two displayed regular-rational reading disciplines. It sits after the rate-realization route of chapter 1673, the regular rational surface of chapter 301, the finite window discipline of chapter 126, the dyadic tolerance ledger of chapter 291, the terminal real seal of chapter 38, and the source-modulus rate transform of chapter 8294. The carrier changes the displayed rate schedule before downstream $\mathsf{Real}^{\uparrow}$ consumers inspect the seal, without quotienting sequences or choosing a limit.

Definition 9049.1 (Regular Cauchy rate transformer carrier)**.** *A* $\mathsf{RegularCauchyRateTransformer}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$T = (S, D, A, B, R, H, C, P, N)$$

with the following displayed coordinates:

1. *S is the finite* $\mathsf{StreamName}^{\uparrow}$ *window through which both regular-Cauchy rate schedules are inspected.*
2. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger. It records the requested target tolerances and the dyadic comparison budget for translating source-rate requests into target-rate requests.*
3. *A is the source* $\mathsf{RegSeqRat}^{\uparrow}$ *rate row.*
4. *B is the target* $\mathsf{RegSeqRat}^{\uparrow}$ *rate row.*
5. *R is the rate-change replay row. For every displayed target request it names the source request, the finite window read, and the dyadic tolerance comparison used to justify the transformed rate.*
6. *H stores componentwise* hsame *transport for S, D, A, B, R and the structural rows below.*
7. *C stores displayed* Cont *replay from the source rate through the window and dyadic ledger into the transformed target rate.*
8. *P records* Pkg *provenance over* $\mathsf{RegularCauchyRateTransformer}^{\uparrow}$, $\mathsf{CauchyRateRealization}^{\uparrow}$, $\mathsf{RegularCauchyRateTran}$ $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
9. *N is the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyRateTransformer}^{\uparrow}}$ *row.*

The carrier has no coordinate for quotient stream equality, selected limits, countable choice, host real equality, ambient completeness, or a detached $\mathsf{Real}^{\uparrow}$ *seal.*

Theorem 9049.2 (Regular Cauchy rate transformer NameCert obligations)**.** *For every accepted* $\mathsf{RegularCauchyRateTransformer}^{\uparrow}$ *carrier* $T = (S, D, A, B, R, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyRateTransformer}^{\uparrow}}$ *surface consists exactly of the following five finite rows:*

1. *carrier admission for the finite window, dyadic tolerance ledger, source rate row, target rate row, rate-change replay, componentwise transport, continuation replay, provenance, and local naming;*
2. *source-rate exposure, requiring each transformed request to cite a displayed* $\mathsf{RegSeqRat}^{\uparrow}$ *source-rate row* A*;*
3. *target-rate exposure, requiring the transformed request to land in the displayed* $\mathsf{RegSeqRat}^{\uparrow}$ *target-rate row* B *through the same* $\mathsf{StreamName}^{\uparrow}$ *window* S*;*
4. *dyadic comparison and replay, requiring* D *and* R *to record the tolerance budget and the finite route from target request back to source request;*
5. *structural stability and nonescape, requiring* H, C, P, N *to transport, replay, source, and name the same packet without adding quotient streams, selected limits, countable choice, host real equality, ambient completeness, or a detached real seal.*

No NameCert obligation is stored outside these rows.

Proof. Project the accepted carrier of Definition 9049.1. Its analytic rows are the window S, dyadic ledger D, source rate A, target rate B, and replay row R.

The source-rate and target-rate obligations are read from A and B. The finite window S keeps both schedules on the same displayed observation surface, so a transformed request cannot bypass the named StreamName row.

The dyadic comparison is exactly the row D, and the finite transformation route is exactly the row R. Together they record how a target tolerance is justified by a source request and a displayed comparison budget.

Finally H, C, P, N provide componentwise transport, continuation replay, provenance, and local naming for the same rows. Since the carrier omits quotient stream equality, selected limits, countable choice, host real equality, ambient completeness, and detached real seals, the local certificate cannot export any of those principles. □

Falsifiable prediction: An accepted $\mathsf{RegularCauchyRateTransformer}^{\uparrow}$ read is refuted if a target $\mathsf{RegSeqRat}^{\uparrow}$ rate request reaches a $\mathsf{Real}^{\uparrow}$ consumer without displaying the source-rate row A, the target-rate row B, the finite $\mathsf{StreamName}^{\uparrow}$ window S, the $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance ledger D, and the replay row R.

Independence witness: cauchy-rate-realization, regular-cauchy-rate-transform, regseqrat, streamname, dyadicratcore, real: $\mathsf{RegularCauchyRateTransformer}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries two regular-Cauchy rate rows, a shared finite window, a dyadic comparison ledger, a rate-change replay row, transport, continuation replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{RegularCauchyRateTransformer}^{\uparrow}}$**.**

Constructive story: A $\mathsf{RegularCauchyRateTransformer}^{\uparrow}$ packet is generated from a finite StreamName window, a DyadicRatCore tolerance ledger, source and target RegSeqRat rate rows, a rate-change replay row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RegularCauchyRateTransformer}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 9049.1 and Definition 9049.2 seed the finite rate-change certificate consumed by regular-rational and Real-facing readers.

Formal verification: FormalStatus(NameCert$_{\mathsf{RegularCauchyRateTransformer}\uparrow}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim quotient stream equality, selected limits, countable choice, host real equality, ambient completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, source-rate exposure, target-rate exposure, dyadic comparison, replay stability, transport, provenance, and local naming for the same finite packet.

Chapter 9050

A Concrete Naming Certificate for CylindricalAlgebraicDecomposition$^{\uparrow}$

Following Collins and the real-closed-field quantifier-elimination tradition, the CylindricalAlgebraicDecomposition$^{\uparrow}$ packet records a finite projection-and-lifting surface for a displayed polynomial family over a real closed field. It sits after the real-closed-field source of chapter 8977, the polynomial rows of chapter 50, the finite reduction ledgers of chapter 2197, the Sturm-chain route of chapter 2079, and the root-isolation carrier of chapter 2269. The packet names the cells and sign rows inspected by a cylindrical decomposition; it is not a host semialgebraic set, a selected root object, classical trichotomy, quotient equality, or choice.

Definition 9050.1 (Cylindrical algebraic decomposition carrier)**.** *A* CylindricalAlgebraicDecomposition$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$D = (R, P, G, S, I, C, L, H, A, Q, N)$$

with the following displayed rows:

1. *R is the* RealClosedField$^{\uparrow}$ *source row, carrying the displayed ordered-field, polynomial, Sturm, and root-isolation reads available to the packet.*
2. *P is the polynomial-family row, listing the admitted coefficient arrays, variable levels, formal derivatives, and specialization requests.*
3. *G is the Groebner/projection ledger, recording resultants, discriminants, leading-coefficient rows, and the finite reduction data used to move from one cylinder level to the next.*
4. *S is the Sturm/root-count row for each projected one-variable request over an admitted base cell.*
5. *I is the root-isolation row, retaining isolating windows for the roots selected by S without exposing a host root element.*
6. *C is the sign-table row, recording the sign of every admitted polynomial on each retained section or sector.*
7. *L is the cell-stack and lifting row, listing base cells, lifted sections, lifted sectors, sample-window requests, and parent-child cylinder links.*
8. *H records componentwise* hsame *transport for the real-closed-field, polynomial, projection, Sturm, isolation, sign-table, lifting, replay, provenance, and local naming rows.*

9. *A records displayed* Cont *replay from any CAD read through the projection ledger, root-isolation rows, sign table, and cell stack.*
10. *Q is the* Pkg *provenance over* CylindricalAlgebraicDecomposition$^{\uparrow}$, RealClosedField$^{\uparrow}$, Poly$^{\uparrow}$, GroebnerBasis$^{\uparrow}$, SturmSequence$^{\uparrow}$, RealRootIsolation$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*
11. *N is the local* NameCert$_{\text{CylindricalAlgebraicDecomposition}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these rows. It has no coordinate for host semialgebraic sets, selected roots, classical trichotomy, quotient equality, global algebraic closure, or choice.

Theorem 9050.2 (Cylindrical algebraic decomposition NameCert obligations)**.** *For the carrier of Definition 9050.1, the local* NameCert$_{\text{CylindricalAlgebraicDecomposition}^{\uparrow}}$ *surface consists exactly of five obligation rows:*

1. *carrier admission for the finite packet $D = (R, P, G, S, I, C, L, H, A, Q, N)$ over the displayed* RealClosedField$^{\uparrow}$ *and* Poly$^{\uparrow}$ *sources;*
2. *projection coverage through G, requiring every discriminant, resultant, leading-coefficient, derivative, and specialization row used by the decomposition to appear in the finite projection ledger;*
3. *sign-invariance through C, requiring every admitted polynomial row from P to have one displayed sign row on each retained section or sector;*
4. *lifting and sample readback through S, I, L, requiring root counts, isolating windows, cell-stack links, and sample windows to be read before any higher cylinder level is accepted;*
5. *nonescape from host semialgebraic sets, selected roots, classical trichotomy, quotient equality, global algebraic closure, and choice, enforced by the transport, replay, provenance, and local naming rows H, A, Q, N.*

Proof. Project the carrier of Definition 9050.1. The rows R and P give the only ordered-field and polynomial sources, while G, S, I, C, L are the finite algebraic rows that can be inspected before the structural rows are read.

Projection coverage is finite because G lists exactly the resultants, discriminants, leading coefficients, derivatives, specialization rows, and reduction traces used by this packet. A consumer cannot appeal to an unlisted projection polynomial.

Sign-invariance is read from C only after the Sturm and isolation rows have split each base cell into the displayed sections and sectors. Thus the sign row is tied to a retained cell, not to a host semialgebraic object.

The lifting read is the sequence S, I, L: first count roots, then retain isolating windows, then attach the lifted section or sector to its parent cell and sample window. The structural rows H, A, Q, N transport, replay, source, and name that same finite packet. Since no coordinate stores host semialgebraic sets, selected roots, trichotomy, quotient equality, global algebraic closure, or choice, the five rows exhaust the local NameCert obligations. □

Falsifiable prediction: Every accepted CylindricalAlgebraicDecomposition$^{\uparrow}$ consumer that reads sign-invariance without the projection ledger, Sturm/root-isolation rows, and cell-stack lifting row is outside the carrier surface.

Independence witness: real-closed-field, polynomial, Groebner-basis, Sturm-sequence, and real-root-isolation: no listed sibling is bijective with CylindricalAlgebraicDecomposition$^{\uparrow}$ because this

packet binds one polynomial family to projection coverage, root isolation, sign tables, cylindrical lifting, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{CylindricalAlgebraicDecomposition}^{\uparrow}}$.

Constructive story: A $\mathsf{CylindricalAlgebraicDecomposition}^{\uparrow}$ packet is generated from a RealClosedField source row, a polynomial-family row, a Groebner/projection ledger, Sturm/root-count rows, retained isolation windows, a sign table, a cylindrical cell stack, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CylindricalAlgebraicDecomposition}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 9050.1 and Definition 9050.2 seed the finite projection-cell packet over $\mathsf{RealClosedField}^{\uparrow}$, $\mathsf{Poly}^{\uparrow}$, $\mathsf{GroebnerBasis}^{\uparrow}$, $\mathsf{SturmSequence}^{\uparrow}$, and $\mathsf{RealRootIsolation}^{\uparrow}$.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CylindricalAlgebraicDecomposition}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host semialgebraic sets, selected roots, classical trichotomy, quotient equality, global algebraic closure, choice, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, projection coverage, sign-invariance, lifting and sample readback, transport, replay, provenance, and local naming for BEDC.Derived.CylindricalAlgebraicDecompositionUp.

Chapter 9051

A Concrete Naming Certificate for $\mathsf{WindowSixBetaSeed}^{\uparrow}$

The $\mathsf{WindowSixBetaSeed}^{\uparrow}$ packet realizes the internal beta seed of Definition 9346.60 and the infrared-stability row of Definition 9346.61 as finite NameCert data. It sits beside the finite golden-mean window of chapter 8802, the Zeckendorf phase shell of chapter 8811, the prime-edge classifier source of chapter 8890, and the beta-sign selection packet of chapter 8846. The packet names the local inverse-coupling derivative and its no-pole interval certificate; it is not a high-energy running law, a continuum renormalization group, or a physical coupling measurement.

Definition 9051.1 (Window-six beta seed carrier)**.** *A* $\mathsf{WindowSixBetaSeed}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (W, G, I, S, R, H, C, P, N)$$

with the following displayed coordinates:

1. *W is the window-six finite source row read through* $\mathsf{GoldenMeanShiftWindowSix}^{\uparrow}$*.*
2. *G is the Green-excess spectral-response row read through the Zeckendorf phase-shell and prime-edge sibling surfaces.*
3. *I is the inverse-coupling derivative row. It records the local derivative $\frac{d}{dz}\alpha_{Z6}^{-1}(z)$ and its negative sign on the displayed activation interval.*
4. *S is the static beta-seed row, recording the displayed value at $z = 0$ and the finite small-z expansion used by the vision theorem.*
5. *R is the infrared-stability row. It records the denominator-root separation needed to keep the spectral response pole-free on the displayed interval.*
6. *H stores componentwise* hsame *transport for W, G, I, S, R and the structural rows below.*
7. *C stores displayed* Cont *replay from the window source through the derivative row and infrared-stability row.*
8. *P records* Pkg *provenance over* $\mathsf{WindowSixBetaSeed}^{\uparrow}$*,* $\mathsf{GoldenMeanShiftWindowSix}^{\uparrow}$*,* $\mathsf{ZeckendorfPhaseShell}^{\uparrow}$*,* $\mathsf{ZeckendorfPrimeEdge}^{\uparrow}$*,* $\mathsf{BetaSignSelection}^{\uparrow}$*,* BHist*,* hsame*,* Cont*, and* $\mathsf{NameCert}$*.*
9. *N is the local* $\mathsf{NameCert}_{\mathsf{WindowSixBetaSeed}^{\uparrow}}$ *row.*

The carrier has no coordinate for continuum running, a host analytic continuation, an unbounded energy-scale law, empirical coupling data, quotient spectra, or a detached real-completion theorem.

Theorem 9051.2 (Window-six beta seed NameCert obligations)**.** *For every accepted* $\mathsf{WindowSixBetaSeed}^{\uparrow}$ *carrier* $B = (W, G, I, S, R, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{WindowSixBetaSeed}^{\uparrow}}$ *surface consists exactly of the following finite rows:*

1. *carrier admission for the window source, spectral-response row, inverse-coupling derivative, static beta seed, infrared-stability row, transport, replay, provenance, and local naming;*
2. *inverse-coupling derivative exposure, requiring* I *to display the negative derivative row before any beta-seed consumer may read* S*;*
3. *static seed exposure, requiring* S *to store the finite small-*z *expansion and the displayed static value rather than a host analytic function;*
4. *infrared-stability exposure, requiring* R *to display the denominator-root separation that excludes poles on the inspected interval;*
5. *structural nonescape, requiring* H, C, P, N *to transport, replay, source, and name only the displayed packet rows.*

No NameCert obligation is stored outside these rows.

Proof. Project the accepted carrier of Definition 9051.1. The analytic rows visible to a consumer are W, G, I, S, R, and the structural rows are H, C, P, N.

The inverse-coupling derivative is read from I. It supplies the sign and derivative route before the static seed row is consumed, so the beta seed is not a detached number.

The static row S records the finite small-z expansion, while R records the no-pole denominator check on the inspected interval. These two rows realize the derivative and infrared-stability claims as finite packet data.

Finally H, C, P, N transport, replay, source, and name the same rows through the cited window-six and Zeckendorf siblings. Since the carrier omits continuum running, host analytic continuation, empirical coupling data, quotient spectra, and real-completion theorems, none of those readings can be exported by the local certificate. □

Falsifiable prediction: An accepted $\mathsf{WindowSixBetaSeed}^{\uparrow}$ read is refuted if a beta-seed consumer receives the static value without first displaying the window-six source W, the spectral-response row G, the inverse-coupling derivative row I, the infrared-stability row R, and the structural rows H, C, P, N.

Independence witness: golden-mean-shift-window-six, zeckendorf-phase-shell, zeckendorf-prime-edge, beta-sign-selection: $\mathsf{WindowSixBetaSeed}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries the window source, spectral response, inverse-coupling derivative, static seed value, infrared-stability denominator row, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{WindowSixBetaSeed}^{\uparrow}}$**.**

Constructive story: A $\mathsf{WindowSixBetaSeed}^{\uparrow}$ packet is generated from a window-six finite source row, a Green-excess spectral-response row, an inverse-coupling derivative row, a static beta-seed row, an infrared-stability row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{WindowSixBetaSeed}^{\uparrow}}$, seed)

Scope closed: Definition 9051.1 and Definition 9051.2 seed the finite beta-seed packet over inverse-coupling derivative, static value, infrared-stability, transport, replay, provenance, and local naming rows.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{WindowSixBetaSeed}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim a continuum running law, host analytic continuation, empirical coupling data, quotient spectrum, real-completion theorem, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, derivative exposure, static seed exposure, infrared-stability exposure, transport, replay, provenance, and local naming for the same finite packet.

Chapter 9052

A Concrete Naming Certificate for CountableCompletionDiagonalRepresentative$^{\uparrow}$

Following Bishop and Bridges on regular Cauchy completions, the CountableCompletionDiagonalRepresentative$^{\uparrow}$ packet realizes the diagonal representative route of Definition 9357.20 in chapter 9357 as finite NameCert data. It sits over the dyadic tolerance arithmetic of chapter 291, the finite observation windows of chapter 126, the regular rational readback of chapter 301, the terminal real-name seal of chapter 38, and the modulus selector surface of chapter 1576. The packet names one diagonal readback route; it is not quotient stream equality, a selected completed limit, countable choice, host real equality, or ambient completeness.

Definition 9052.1 (Countable completion diagonal representative carrier)**.** *A* CountableCompletionDiagonalRepres*carrier is a finite* BHist *packet*

$$D = (F, M, T, W, R, E, H, C, P, N)$$

with the following displayed rows:

1. *F is the regular-Cauchy family row, naming the displayed sequence of* RegSeqRat$^{\uparrow}$ *representatives inspected by the completion request.*
2. *M is the modulus-selector row, read through* RealCauchyModulusSelector$^{\uparrow}$*, which turns each dyadic tolerance request into a displayed family index.*
3. *T is the dyadic tolerance row over* DyadicRatCore$^{\uparrow}$*, including the requests corresponding to $1/(n+1)$ and the internal observation budget.*
4. *W is the* StreamName$^{\uparrow}$ *window row recording the finite family index, the selected regular name, and the internal observation index for each diagonal read.*
5. *R is the* RegSeqRat$^{\uparrow}$ *readback row returning the dyadic value of the selected regular name at the selected observation index.*
6. *E is the* Real$^{\uparrow}$ *seal row available only after the regularity and diagonal tolerance rows have been displayed.*
7. *H records componentwise* hsame *transport for family, selector, tolerance, window, readback, seal, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from a diagonal-representative request through F, M, T, W, R, E, H.*

9. *P is the* Pkg *provenance over* $\mathsf{CountableCompletionDiagonalRepresentative}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{RealCauchyModulusSelector}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*

10. *N is the local* $\mathsf{NameCert}_{\mathsf{CountableCompletionDiagonalRepresentative}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these rows. It has no coordinate for quotient stream equality, selected completed limits, countable choice, host real equality, ambient completeness, or bridge checking.

Theorem 9052.2 (Countable completion diagonal representative NameCert obligations)**.** *For the carrier of Definition 9052.1, the local* $\mathsf{NameCert}_{\mathsf{CountableCompletionDiagonalRepresentative}^{\uparrow}}$ *surface consists exactly of five obligation rows:*

1. *carrier admission for the finite packet $D = (F, M, T, W, R, E, H, C, P, N)$;*
2. *modulus-index exposure through M and T, requiring every diagonal family index and observation index to be tied to a displayed dyadic tolerance request;*
3. *finite window readback through W and R, requiring the selected regular-Cauchy member and its internal* $\mathsf{RegSeqRat}^{\uparrow}$ *observation to be visible before a diagonal value is read;*
4. *Real-seal handoff through E, requiring regularity and diagonal tolerance rows before the completion-facing* $\mathsf{Real}^{\uparrow}$ *name is accepted;*
5. *transport, replay, provenance, local naming, and nonescape from quotient streams, selected limits, countable choice, host real equality, ambient completeness, and bridge checking through H, C, P, N.*

Proof. Project the carrier of Definition 9052.1. The rows F, M, T, W, R, E are the whole diagonal readback surface before transport, replay, provenance, and local naming are applied.

The selector row M and dyadic row T display the tolerance request used to choose the family index. The window row W then records that chosen family index together with the internal observation index, so no countable-choice schedule is hidden behind the diagonal notation.

The readback row R exposes the selected $\mathsf{RegSeqRat}^{\uparrow}$ value at the displayed observation index. The Real-seal row E is downstream of that readback and of the regularity/tolerance rows, so the packet names only the finite diagonal representative route.

Finally H, C, P, N transport, replay, source, and name the same rows. Since the carrier has no coordinate for quotient stream equality, selected completed limits, countable choice, host real equality, ambient completeness, or bridge checking, the five rows exhaust the local NameCert surface. □

Falsifiable prediction: Every accepted $\mathsf{CountableCompletionDiagonalRepresentative}^{\uparrow}$ consumer that reads a Real seal without the modulus selector, dyadic tolerance request, StreamName window, and RegSeqRat readback rows is outside the carrier surface.

Independence witness: dyadicratcore, streamname, regseqrat, real, and realcauchymodulusselector: no listed sibling is bijective with $\mathsf{CountableCompletionDiagonalRepresentative}^{\uparrow}$ because this packet binds one regular-Cauchy family, one tolerance-index selector, one finite diagonal observation window, one RegSeqRat readback, one Real seal, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{CountableCompletionDiagonalRepresentative}^{\uparrow}}$ **·**

Constructive story: A CountableCompletionDiagonalRepresentative$^{\uparrow}$ packet is generated from a regular-Cauchy family row, a RealCauchyModulusSelector row, dyadic tolerance requests, StreamName window rows, RegSeqRat readback rows, a Real seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\text{CountableCompletionDiagonalRepresentative}^{\uparrow}}$, seed)

Scope closed: Definition 9052.1 and Definition 9052.2 seed the finite diagonal-representative packet over DyadicRatCore$^{\uparrow}$, StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, Real$^{\uparrow}$, and RealCauchyModulusSelector$^{\uparrow}$.

Formal verification: FormalStatus(NameCert$_{\text{CountableCompletionDiagonalRepresentative}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close quotient stream equality, selected completed limits, countable choice, host real equality, ambient completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, modulus-index exposure, finite window readback, Real-seal handoff, transport, replay, provenance, and local naming for BEDC.Derived.CountableCompletionDiagonalRepresentativeUp.

Chapter 9053

A Concrete Naming Certificate for FiniteWindowUniformCompletion$^{\uparrow}$

Following Bishop and Bridges on constructive completion, and Bourbaki and Kelley on uniform completion, the FiniteWindowUniformCompletion$^{\uparrow}$ packet records the finite-window surface by which a uniform Cauchy completion request is inspected through StreamName windows, regular rational readback, and dyadic tolerance ledgers before any Real-facing seal is visible. It sits after the reflector of chapter 6282, the finite stream surface of chapter 126, the regular rational surface of chapter 301, and the dyadic core of chapter 291; it also reads the terminal Real$^{\uparrow}$ seal as a named row rather than as ambient completeness.

Definition 9053.1 (Finite-window uniform completion carrier)**.** *A* FiniteWindowUniformCompletion$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$W = (R, U, S, D, Q, E, H, C, P, N)$$

with the following displayed rows:

1. *R is the* UniformCompletionReflector$^{\uparrow}$ *row, naming the source uniform object, completion target, dense route, and reflector-facing route visible to the packet.*
2. *U is the* UniformCauchyCompletion$^{\uparrow}$ *row, recording the uniform Cauchy family and the completion-facing request inspected by the finite window.*
3. *S is the* StreamName$^{\uparrow}$ *finite-window row; it exposes only the stream windows used by the uniform Cauchy request.*
4. *D is the* DyadicRatCore$^{\uparrow}$ *tolerance row, budgeting every displayed comparison made by the finite windows.*
5. *Q is the* RegSeqRat$^{\uparrow}$ *readback row on those same windows and dyadic tolerances.*
6. *E is the* Real$^{\uparrow}$ *seal row reached only after R, U, S, D, Q have been displayed.*
7. *H records componentwise* hsame *transport for the reflector, uniform Cauchy, stream-window, dyadic-tolerance, regular-readback, seal, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from a uniform completion request through $R, U, S, D, Q, E, H, P, N$.*
9. *P is the* Pkg *provenance over* FiniteWindowUniformCompletion$^{\uparrow}$, UniformCompletionReflector$^{\uparrow}$, UniformCauchyCompletion$^{\uparrow}$, StreamName$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, RegSeqRat$^{\uparrow}$, Real$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

10. *N is the local* $\mathsf{NameCert}_{\mathsf{FiniteWindowUniformCompletion}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $R, U, S, D, Q, E, H, C, P, N$. It has no coordinate for quotient completion objects, selected limit representatives, countable choice, host equality of completed points, detached Real completeness, or an ambient completion theorem.

Theorem 9053.2 (Finite-window uniform completion NameCert obligations)**.** *For every accepted* $\mathsf{FiniteWindowUniformCompletion}^{\uparrow}$ *carrier $W = (R, U, S, D, Q, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{FiniteWindowUniformCom}}$ *surface consists exactly of the following finite obligation rows:*

1. *reflector admission through the* $\mathsf{UniformCompletionReflector}^{\uparrow}$ *row R;*
2. *uniform Cauchy admission through the* $\mathsf{UniformCauchyCompletion}^{\uparrow}$ *row U;*
3. *finite observation through the* $\mathsf{StreamName}^{\uparrow}$ *row S;*
4. *dyadic tolerance exactness through the* $\mathsf{DyadicRatCore}^{\uparrow}$ *row D;*
5. *regular rational readback through the* $\mathsf{RegSeqRat}^{\uparrow}$ *row Q;*
6. *terminal sealing through the* $\mathsf{Real}^{\uparrow}$ *row E;*
7. *componentwise* hsame *transport and displayed* Cont *replay through H and C;*
8. Pkg *provenance and local naming through P and N.*

These rows exhaust the certificate surface and add no quotient completion, selected limit, countable-choice, host-equality, detached-completeness, or ambient-completion coordinate.

Proof. Project the carrier of Definition 9053.1. Its visible coordinates are $R, U, S, D, Q, E, H, C, P, N$, so every local obligation must be read from one of those rows.

The completion request enters through the reflector row R and the uniform Cauchy row U. The only observations available to that request are the StreamName windows S, the dyadic tolerance row D, and the RegSeqRat readback row Q.

The terminal row is E. Since E is downstream of the finite observation stack, a Real-facing consumer cannot read a completed point, selected representative, or ambient completeness theorem before the displayed rows have been exposed.

Finally H, C, P, N transport, replay, source, and name the same finite packet. No refused host-side principle appears as a carrier coordinate, so the listed rows exhaust the local NameCert obligations. □

Theorem 9053.3 (Finite-window uniform completion nonescape)**.** *Every Real-facing or completion-facing consumer of an accepted* $\mathsf{FiniteWindowUniformCompletion}^{\uparrow}$ *packet factors through the finite route*

$$\mathsf{UniformCompletionReflector}^{\uparrow}, \mathsf{UniformCauchyCompletion}^{\uparrow} \longmapsto \mathsf{StreamName}^{\uparrow}, \mathsf{DyadicRatCore}^{\uparrow}, \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}$$

The route is transported by hsame*, replayed by* Cont*, sourced by* Pkg*, and locally named by* $\mathsf{NameCert}$ *through the rows H, C, P, N. It exports no quotient completion object, selected limit representative, countable-choice schedule, host equality of completed points, detached* $\mathsf{Real}^{\uparrow}$ *completeness, or ambient uniform-completion theorem.*

Proof. Start with an accepted packet $W = (R, U, S, D, Q, E, H, C, P, N)$. The reflector and uniform Cauchy rows R, U are the only completion-request coordinates.

The finite observational stack is S, D, Q. These rows expose the stream windows, tolerance ledger, and regular rational readback used by the request, and no consumer can bypass them because no other observation coordinate is present.

The only terminal seal is E. The structural rows H, C, P, N preserve and name the same displayed route, while the carrier has no quotient, selection, choice, host-equality, detached-completeness, or ambient-completion coordinate. □

Falsifiable prediction: Every accepted $\mathsf{FiniteWindowUniformCompletion}^{\uparrow}$ consumer that reaches a $\mathsf{Real}^{\uparrow}$ or completion-facing boundary while omitting the reflector row, uniform Cauchy row, StreamName windows, DyadicRatCore tolerance row, RegSeqRat readback row, Real seal, transport, replay, provenance, or local naming row refutes the packet.

Independence witness: uniform-completion-reflector, uniform-cauchy-completion, streamname, dyadicratcore, regseqrat, real: $\mathsf{FiniteWindowUniformCompletion}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries the reflector route, uniform Cauchy request, finite windows, dyadic tolerances, regular readback, Real seal, transport, replay, provenance, and local NameCert rows in one packet.

Closure status for $\mathsf{NameCert}_{\mathsf{FiniteWindowUniformCompletion}^{\uparrow}}$.

Constructive story: A $\mathsf{FiniteWindowUniformCompletion}^{\uparrow}$ packet is generated from UniformCompletionReflector, UniformCauchyCompletion, StreamName, DyadicRatCore, RegSeqRat, RealUp, hsame, Cont, Pkg, and local NameCert rows.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{FiniteWindowUniformCompletion}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 9053.1, Definition 9053.2, Definition 9053.3, the falsifiable prediction, and the independence witness seed the finite-window uniform completion route from uniform Cauchy data to Real-facing consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{FiniteWindowUniformCompletion}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient completion objects, selected limit representatives, countable choice, host equality of completed points, detached $\mathsf{Real}^{\uparrow}$ completeness, ambient uniform completion, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, reflector admission, uniform Cauchy admission, finite-window readback, dyadic tolerance exactness, RegSeqRat readback, Real seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.FiniteWindowUniformCompletionUp.

Chapter 9054

A Concrete Naming Certificate for $\mathsf{BanachFixedPointContraction}^{\uparrow}$

Following Banach, the $\mathsf{BanachFixedPointContraction}^{\uparrow}$ packet records the contraction-mapping principle as finite BEDC NameCert data over a complete metric source, a displayed Lipschitz self-map, a Picard iterate stream, a regular rational Cauchy handoff, and a Real-facing endpoint boundary. It sits beside the complete metric source of chapter 128, the metric comparison surface of chapter 57, the Lipschitz map packet of chapter 3762, the stream-name windows of chapter 126, the regular rational readback of chapter 301, and the terminal Real seal of chapter 38. The chapter names a standard contraction fixed-point neighbour for completion and continuous-map consumers; it does not assert host fixed-point equality, quotient stream equality, selected limits, or ambient completeness outside the displayed $\mathsf{CompleteMetric}^{\uparrow}$ row.

Definition 9054.1 (Banach fixed-point contraction carrier)**.** *A* $\mathsf{BanachFixedPointContraction}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (M, d, L, S, W, R, E, H, C, P, N)$$

with the following displayed rows:

1. *M is the* $\mathsf{CompleteMetric}^{\uparrow}$ *source row, exposing the admitted carrier, the completion boundary, and the finite metric-comparison service.*
2. *d is the* $\mathsf{Met}^{\uparrow}$ *distance row used to compare adjacent Picard iterates and later endpoint windows.*
3. *L is the* $\mathsf{LipschitzMap}^{\uparrow}$ *self-map row with a displayed rational contraction ledger $0 \leq q < 1$.*
4. *S is the finite Picard schedule row, recording the inspected iterates $x_0, \ldots, x_n$ and the application rows $x_{k+1} = L(x_k)$.*
5. *W is the* $\mathsf{StreamName}^{\uparrow}$ *window row for the scheduled iterates.*
6. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row generated from the contraction ledger and the finite stream windows.*
7. *E is the* $\mathsf{Real}^{\uparrow}$ *endpoint seal boundary reached only after R and the carried complete metric route are displayed.*
8. *H records componentwise* hsame *transport for M, d, L, S, W, R, E and the local certificate rows.*
9. *C records displayed* Cont *replay for metric reads, Lipschitz-map application, Picard-window extension, regular rational readback, and endpoint sealing.*

10. *P is the* Pkg *provenance over* $\mathsf{BanachFixedPointContraction}^{\uparrow}$, $\mathsf{CompleteMetric}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{LipschitzMap}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{BanachFixedPointContraction}^{\uparrow}}$ *row.*

The classifier accepts a contraction fixed-point read only through these rows. It has no coordinate for an externally selected fixed point, host equality of endpoints, a quotient of Cauchy streams, a non-displayed completeness theorem, or countable choice.

Theorem 9054.2 (Banach fixed-point contraction obligation surface)**.** *For every accepted* BanachFixedPointContrac *carrier $K = (M, d, L, S, W, R, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{BanachFixedPointContraction}^{\uparrow}}$ *surface consists exactly of complete metric source visibility, metric comparison visibility, Lipschitz self-map visibility, rational contraction ledger visibility, finite Picard schedule visibility, StreamName window visibility, RegSeqRat readback visibility, Real endpoint seal nonescape, componentwise transport, displayed replay, package provenance, and local naming for the packet of Definition 9054.1.*

Proof. Project the carrier. The analytic source rows are M, d, L, the iteration rows are S, W, the completion-facing rows are R, E, and the structural rows are H, C, P, N.

The contraction ledger belongs to L, so a consumer may spend a shrinkage bound only after the self-map row and metric row are visible. The finite Picard schedule S records each inspected application step, while W repacks those steps as stream windows.

The readback row R and endpoint seal E are downstream of that finite route. Since no excluded object is a coordinate of K, the listed rows exhaust the local naming surface. □

Theorem 9054.3 (Banach fixed-point contraction iterate Cauchy route)**.** *Every Cauchy read of an accepted* $\mathsf{BanachFixedPointContraction}^{\uparrow}$ *packet factors through the displayed route*

$$\mathsf{CompleteMetric}^{\uparrow},\ \mathsf{Met}^{\uparrow},\ \mathsf{LipschitzMap}^{\uparrow},\ \mathsf{StreamName}^{\uparrow},\ \mathsf{RegSeqRat}^{\uparrow},\ \mathsf{Real}^{\uparrow}.$$

The finite Picard schedule first reads adjacent iterate distances through d and the contraction ledger in L, then packages the inspected windows through W, then exposes the regular rational readback R, and only then reaches the endpoint seal E. The route does not export host convergence, a selected limit, quotient stream equality, or ambient Real completeness.

Proof. Start with the finite schedule S. Each adjacent row is an application of the displayed Lipschitz self-map L, and every distance comparison is read through the metric row d over the complete metric source M.

The rational contraction ledger in L supplies the tail estimate for the inspected Picard windows. Those windows are recorded by W as a $\mathsf{StreamName}^{\uparrow}$ row rather than as a completed infinite orbit.

The regular rational readback R is therefore generated from displayed finite data, and the endpoint boundary E is reached only after that readback and the carried complete metric route are visible. The absent host objects cannot be recovered from this route because the carrier has no coordinate for them. □

Theorem 9054.4 (Banach fixed-point contraction unique fixed-point boundary)**.** *If two accepted* $\mathsf{BanachFixedPointContraction}^{\uparrow}$ *carriers have the same displayed complete metric row, metric row, Lipschitz self-map row, rational contraction ledger, Picard-window readback, and structural transports, then their* $\mathsf{Real}^{\uparrow}$ *endpoint seal rows are classifier-determinate. This boundary is the BEDC fixed-point uniqueness surface; it is not a host equality statement about completed real points.*

Proof. Compare the two carriers componentwise through their H and C rows. The shared rows M, d, L, S, W, R force both endpoint routes to spend the same contraction ledger and the same regular rational readback.

The usual contraction estimate is used here only as a finite classifier pattern: a rational bound below one identifies two displayed endpoint routes after both are routed through the same Picard windows and completion handoff.

Thus the endpoint rows agree at the $\mathsf{Real}^{\uparrow}$ seal boundary seen by the BEDC classifier. Because the packet contains no host endpoint object, the conclusion cannot be read as external equality. □

Falsifiable prediction: An accepted $\mathsf{BanachFixedPointContraction}^{\uparrow}$ consumer is refuted if it reads a fixed-point endpoint without displaying the complete metric source, metric comparison row, Lipschitz contraction ledger, Picard schedule, StreamName windows, RegSeqRat readback, transport, replay, provenance, and local NameCert rows.

Independence witness: complete-metric, metric, lipschitz-map, streamname, regseqrat, real: $\mathsf{BanachFixedPointContraction}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries a complete metric source, a contraction self-map, a Picard schedule, finite stream windows, a regular rational readback, a Real endpoint seal, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{BanachFixedPointContraction}^{\uparrow}}$.

Constructive story: A $\mathsf{BanachFixedPointContraction}^{\uparrow}$ packet is generated from a complete metric source row, metric comparison row, Lipschitz self-map row with rational contraction ledger, finite Picard schedule, StreamName windows, RegSeqRat readback, Real endpoint seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BanachFixedPointContraction}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 9054.1, Definition 9054.2, Definition 9054.3, and Definition 9054.4 seed the finite contraction fixed-point carrier and its completion-facing endpoint boundary.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BanachFixedPointContraction}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim Lean verification, bridge checking, host fixed-point equality, selected limits, quotient stream equality, countable choice, or ambient completeness beyond the carried $\mathsf{CompleteMetric}^{\uparrow}$ row.

Upgrade path: Obligation closure requires checked carrier admission, contraction-ledger visibility, Picard-window Cauchy readback, endpoint seal nonescape, uniqueness-boundary determinacy, transport, replay, provenance, local naming, and TasteGate support for BEDC.Derived.BanachFixedPointContractionUp.

Chapter 9055

A Concrete Naming Certificate for $\mathsf{Transportability}^{\uparrow}$

Following Pearl and Bareinboim on causal transportability, the $\mathsf{Transportability}^{\uparrow}$ packet records the finite source-to-target selection surface by which causal effects can be transported across displayed domains. It sits after the intervention calculus of chapter 453, the mediator-facing front-door packet of chapter 7600, and the paired-world outcome surface of chapter 3989. The carrier names the source-domain distribution, target selection row, intervention ledger, adjustment ledger, transported distribution row, justification ledger, transport, replay, provenance, and local naming rows; it does not assert a hidden selection oracle or host-level external validity.

Definition 9055.1 (Transportability carrier)**.** *A* $\mathsf{Transportability}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$T = (S, Tg, I, A, D, J, H, C, P, N)$$

with the following displayed rows:

1. *S is the source-domain distribution row whose observational or interventional source probabilities are exposed before any transport read.*
2. *Tg is the target-domain selection row, recording which structural mechanisms or domain coordinates are allowed to differ.*
3. *I is the intervention ledger shared with the* $\mathsf{DoCalculus}^{\uparrow}$ *surface.*
4. *A is the adjustment ledger, including front-door or other displayed admissible adjustment rows when they are consumed.*
5. *D is the transported distribution row produced only after S, Tg, I, A have been replayed.*
6. *J is the justification ledger naming the do-calculus and causal-identification handoff used by the transport step.*
7. *H records componentwise* hsame *transport for source distribution, target selection, intervention, adjustment, transported distribution, justification, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from the source-domain request through the selection row, intervention ledger, adjustment ledger, transported distribution, and justification rows.*
9. *P is the* Pkg *provenance over* $\mathsf{Transportability}^{\uparrow}$, $\mathsf{DoCalculus}^{\uparrow}$, $\mathsf{FrontdoorCriterion}^{\uparrow}$, $\mathsf{CounterfactualOutcome}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.

10. *N is the local* $\mathsf{NameCert}_{\mathsf{Transportability}^{\uparrow}}$ *row.*

The carrier has no coordinate for a hidden selection oracle, host probability equality, unlicensed counterfactual selector, or ambient causal completeness.

Theorem 9055.2 (Transportability NameCert obligations)**.** *For every accepted* $\mathsf{Transportability}^{\uparrow}$ *carrier* $T = (S, Tg, I, A, D, J, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{Transportability}^{\uparrow}}$ *surface is exhausted by the following obligation rows:*

1. *carrier admission for the source-domain distribution, target-domain selection, intervention, adjustment, transported distribution, justification, transport, replay, provenance, and local naming rows;*
2. *selection-row exposure, requiring the target-domain selection row Tg to be displayed before any source-to-target distribution read is served;*
3. *do-calculus handoff, requiring the intervention ledger I and justification ledger J to cite the displayed do-calculus route before a transported distribution row is accepted;*
4. *source-to-target distribution transport, requiring S, Tg, I, A, J to replay through C before D and the local* $\mathsf{NameCert}_{\mathsf{Transportability}^{\uparrow}}$ *row are exposed;*
5. *refusal of hidden selection oracle, host probability equality, unlicensed counterfactual selector, and ambient causal completeness.*

No transportability obligation is stored outside these rows.

Proof. Project the carrier of Definition 9055.1. The rows $S, Tg, I, A, D, J, H, C, P, N$ are the only rows available to a consumer.

The selection row Tg is read before the transported distribution row D. The intervention ledger I and adjustment ledger A are then justified by J, which points to the do-calculus and front-door handoff surface rather than to an unrecorded host causal model.

Replay through C fixes the consumption order from source distribution and target selection to intervention, adjustment, justification, and transported distribution. Componentwise transport through H and provenance through P, N preserve that same finite packet, so the excluded hidden-oracle and host-completeness data cannot be exported. □

Lean4 ✓ `BEDC.Derived.TransportabilityUp.TransportabilityCarrier namecert obligations`

Theorem 9055.3 (Transportability carrier admission)**.** *For every accepted* $\mathsf{Transportability}^{\uparrow}$ *carrier* $T = (S, Tg, I, A, D, J, H, C, P, N)$*, the admitted carrier rows are exactly the source-domain distribution row S, target-domain selection row Tg, intervention ledger I, adjustment ledger A, transported distribution row D, justification ledger J, componentwise transport row H, displayed replay row C, provenance row P, and local naming row N.*

Proof. Project the carrier of Definition 9055.1. Its displayed tuple has precisely the ten coordinates $S, Tg, I, A, D, J, H, C, P, N$.

The obligation surface of Definition 9055.2 names carrier admission only for those coordinates. Since the carrier has no hidden selection, host probability, unlicensed counterfactual, or ambient completeness row, no additional row can be admitted. □

Theorem 9055.4 (Transportability selection-ledger obligation)**.** *For every accepted* $\mathsf{Transportability}^{\uparrow}$ *carrier* $T = (S, Tg, I, A, D, J, H, C, P, N)$*, every transported-effect consumer must expose the source-domain distribution row S, target selection row Tg, intervention ledger I, adjustment ledger A,*

transported distribution row D, justification ledger J, componentwise transport H, replay C, provenance P, and local naming N before reading the transported result. The same packet therefore blocks hidden selection oracles, host probability equality, and ambient causal completeness from entering the public transportability surface.

Proof. Project the carrier of Definition 9055.1. The only rows available to a transported-effect consumer are $S, Tg, I, A, D, J, H, C, P, N$, and the carrier explicitly has no hidden selection-oracle coordinate.

Apply Definition 9055.2. Its source-to-target transport clause requires S, Tg, I, A, J to replay through C before D and the local naming row are exposed.

The sibling routes through do-calculus, front-door adjustment, and counterfactual-outcome bookkeeping are read only by the displayed ledgers I, A, J. Componentwise transport through H and provenance through P, N preserve the same finite packet, so no host probability equality or ambient causal-completeness assumption can be consumed outside the ledger. □

Theorem 9055.5 (Transportability selection row exposure)**.** *For every accepted* $\mathsf{Transportability}^{\uparrow}$ *carrier $T = (S, Tg, I, A, D, J, H, C, P, N)$, the target-domain selection row Tg is displayed before any transported distribution row D is public. A consumer that reads D without first reading S and Tg has left the finite carrier of Definition 9055.1 and the obligation surface of Definition 9055.2.*

Proof. Project the carrier rows $S, Tg, I, A, D, J, H, C, P, N$ from Definition 9055.1. The target selection row Tg is a named coordinate of the same finite packet as the transported distribution row D.

Apply Definition 9055.2. Its selection-row exposure clause requires Tg to be displayed before any source-to-target distribution read is served, and its transport clause requires S, Tg, I, A, J to replay before D and the local naming row are exposed.

Thus the only public route to D passes through S and Tg. Since the carrier has no hidden selection oracle or host external-validity coordinate, a route that omits Tg is outside the accepted $\mathsf{Transportability}^{\uparrow}$ packet. □

Theorem 9055.6 (Transportability distribution transport)**.** *For every accepted* $\mathsf{Transportability}^{\uparrow}$ *carrier $T = (S, Tg, I, A, D, J, H, C, P, N)$, the rows S, Tg, I, A, J replay through C before the transported distribution row D and the local naming row N are exposed.*

Proof. The carrier of Definition 9055.1 separates the source distribution, selection row, intervention ledger, adjustment ledger, justification ledger, replay row, transported distribution, and local naming rows.

Use the source-to-target distribution transport clause in Definition 9055.2. It places S, Tg, I, A, J upstream of D through the displayed replay C, and it names the local $\mathsf{NameCert}_{\mathsf{Transportability}^{\uparrow}}$ row only after that replay route is available. □

Theorem 9055.7 (Transportability source-target replay)**.** *For every accepted* $\mathsf{Transportability}^{\uparrow}$ *carrier $T = (S, Tg, I, A, D, J, H, C, P, N)$, the only public route to the transported distribution row D is the displayed replay from source distribution S through target selection Tg, intervention ledger I, adjustment ledger A, and justification ledger J, followed by componentwise transport H, replay C, provenance P, and local naming N.*

Proof. Project the rows of Definition 9055.1. The source distribution, target selection, intervention, adjustment, transported distribution, justification, transport, replay, provenance, and local naming rows are exactly $S, Tg, I, A, D, J, H, C, P, N$.

Use Definition 9055.2 to read the source-to-target distribution transport clause. It requires S, Tg, I, A, J to replay through C before D and the local $\mathsf{NameCert}_{\mathsf{Transportability}^{\uparrow}}$ row can be exposed.

The structural rows close the route. Componentwise transport through H preserves the same displayed coordinates, provenance through P records the allowed sibling surfaces, and N names the local packet. No carrier coordinate stores an alternate transported distribution, hidden host probability equality, or unlicensed counterfactual selector, so the stated replay is the unique public route. □

Theorem 9055.8 (Transportability domain-selection coverage)**.** *For every accepted* $\mathsf{Transportability}^{\uparrow}$ *carrier* $T = (S, Tg, I, A, D, J, H, C, P, N)$*, a read of the transported distribution row* D *must expose source distribution* S*, target selection* Tg*, intervention ledger* I*, adjustment ledger* A*, justification ledger* J*, componentwise* hsame *transport* H*, displayed* Cont *replay* C*,* Pkg *provenance* P*, and the local* $\mathsf{NameCert}_{\mathsf{Transportability}^{\uparrow}}$ *row* N*. The selection coverage surface is therefore the finite carrier route from the source-domain distribution through the target-domain selection row before any transported distribution is public.*

Proof. Project the carrier of Definition 9055.1. Its displayed rows are exactly $S, Tg, I, A, D, J, H, C, P, N$.

Apply source-target replay, Definition 9055.7. It identifies the only public route to D as the replay from source distribution through target selection, intervention, adjustment, and justification, followed by transport, replay, provenance, and local naming.

The selection row exposure theorem Definition 9055.5 prevents D from being read before S and Tg are visible. Since no alternate transported distribution or hidden selection row exists in the carrier, domain-selection coverage is exhausted by the stated rows. □

Theorem 9055.9 (Transportability intervention-adjustment ledger)**.** *For every accepted* $\mathsf{Transportability}^{\uparrow}$ *carrier* $T = (S, Tg, I, A, D, J, H, C, P, N)$*, each transported-distribution read through* D *must retain both the intervention ledger* I *and adjustment ledger* A *together with source distribution* S*, target selection* Tg*, justification ledger* J*, componentwise transport* H*, displayed replay* C*, provenance* P*, and local naming* N*. The intervention and adjustment rows are not optional annotations; they are part of the carrier route through which* D *is admitted.*

Proof. Project the carrier rows in Definition 9055.1. The intervention ledger I and adjustment ledger A are coordinates of the same finite packet as source distribution S, target selection Tg, transported distribution D, and justification ledger J.

Use the NameCert obligations of Definition 9055.2. The do-calculus handoff requires I and J to cite the displayed intervention route, while the source-to-target transport clause requires S, Tg, I, A, J to replay through C before D and N are exposed.

Componentwise transport through H and provenance through P preserve that same ledger. Therefore no transported-distribution read can bypass the intervention or adjustment rows without leaving the accepted $\mathsf{Transportability}^{\uparrow}$ carrier. □

Theorem 9055.10 (Transportability target-distribution nonescape)**.** *For every accepted* $\mathsf{Transportability}^{\uparrow}$ *carrier* $T = (S, Tg, I, A, D, J, H, C, P, N)$*, the target-side transported distribution* D *is readable only through source distribution* S*, target selection* Tg*, intervention ledger* I*, adjustment ledger* A*, justification ledger* J*, componentwise* hsame *transport* H*, displayed* Cont *replay* C*,* Pkg *provenance* P*, and local* $\mathsf{NameCert}_{\mathsf{Transportability}^{\uparrow}}$ *row* N*. Thus* D *cannot escape into a hidden selection oracle, host probability equality, unlicensed counterfactual selector, or ambient causal-completeness principle.*

Proof. Start from the carrier admission theorem Definition 9055.3. It lists $S, Tg, I, A, D, J, H, C, P, N$ as the full admitted row surface and records no hidden host-level target distribution coordinate.

Apply domain-selection coverage and the intervention-adjustment ledger, Definition 9055.8 and Definition 9055.9. Together they force every read of D to pass through source distribution, target selection, intervention, adjustment, justification, transport, replay, provenance, and local naming rows.

Finally use the refusal clause in Definition 9055.2. Since hidden selection oracles, host probability equality, unlicensed counterfactual selectors, and ambient causal completeness are absent from the finite carrier, the target distribution has no route outside the stated ledger. □

Theorem 9055.11 (Transportability domain-selection obligation)**.** *For every accepted* $\mathsf{Transportability}^{\uparrow}$ *carrier* $T = (S, Tg, I, A, D, J, H, C, P, N)$*, a transported-effect read is admissible only after the source-domain distribution row* S *and target-domain selection row* Tg *have both been exposed. The selection obligation is componentwise:* S *supplies the source distribution being transported,* Tg *supplies the target-domain mechanism boundary, and the later rows* I, A, D, J, H, C, P, N *may be consumed only downstream of that pair.*

Proof. Project the carrier of Definition 9055.1. The source row S and target row Tg are separate coordinates, so the target side cannot be recovered by reading the source row alone.

Apply Definition 9055.5. It places Tg before the transported distribution row D, and Definition 9055.8 keeps S and Tg together on every route to D.

The structural rows do not change the source-target order. Intervention and adjustment are later ledger rows, while H, C, P, N transport, replay, source, and name the same displayed route. Therefore the domain-selection obligation is exactly the displayed S, Tg boundary followed by the remaining carrier rows. □

Theorem 9055.12 (Transportability adjustment-ledger exactness)**.** *For every accepted* $\mathsf{Transportability}^{\uparrow}$ *carrier* $T = (S, Tg, I, A, D, J, H, C, P, N)$*, the intervention-adjustment portion of a transported read is exactly the pair of ledger rows* I, A *together with the justification ledger* J*. The row* I *records the displayed* $\mathsf{DoCalculus}^{\uparrow}$ *intervention route,* A *records the displayed adjustment route, including any* $\mathsf{FrontdoorCriterion}^{\uparrow}$ *row actually consumed, and* J *records the cited handoff; no hidden adjustment oracle or host probability equality is added.*

Proof. Start from Definition 9055.1. The only intervention and adjustment coordinates are I and A, and the only justification coordinate is J.

Use the do-calculus handoff clause of Definition 9055.2. It requires I and J to cite the displayed do-calculus route before a transported distribution is accepted. Use Definition 9055.9 to keep A in the same route whenever D is read.

The provenance row P records the allowed $\mathsf{DoCalculus}^{\uparrow}$ and $\mathsf{FrontdoorCriterion}^{\uparrow}$ sources, while C replays the displayed source-to-target route. Since hidden adjustment data and host probability equality are absent from the carrier, ledger exactness is precisely the finite I, A, J package. □

Theorem 9055.13 (Transportability target replay coverage)**.** *For every accepted* $\mathsf{Transportability}^{\uparrow}$ *carrier* $T = (S, Tg, I, A, D, J, H, C, P, N)$*, every exported transported-distribution read factors through source distribution* S*, target selection* Tg*, intervention ledger* I*, adjustment ledger* A*, transported row* D*, justification ledger* J*, componentwise* hsame *transport* H*, displayed* Cont *replay* C*,* Pkg *provenance* P*, and local* $\mathsf{NameCert}_{\mathsf{Transportability}^{\uparrow}}$ *row* N*. No exported target read bypasses one of these coordinates.*

Proof. Project the full carrier in Definition 9055.1. Its displayed coordinates are exactly $S, Tg, I, A, D, J, H, C, P, N$.

Apply the source-target replay theorem Definition 9055.7. It identifies the public route to D as source distribution, target selection, intervention, adjustment, and justification followed by structural transport, replay, provenance, and naming.

Now apply Definition 9055.10. Since the transported distribution cannot escape into hidden selection, host probability equality, unlicensed counterfactual selection, or ambient causal completeness, every exported target read is covered by the displayed replay route and no extra coordinate remains. □

Theorem 9055.14 (Transportability scope exhaustion)**.** *Every accepted* $\mathsf{Transportability}^{\uparrow}$ *read factors through the displayed* BHist *rows*

$$S, Tg, I, A, D, J, H, C, P, N,$$

componentwise hsame *transport, displayed* Cont *replay,* Pkg *provenance, local* $\mathsf{NameCert}_{\mathsf{Transportability}^{\uparrow}}$ *naming, and the sibling* $\mathsf{DoCalculus}^{\uparrow}$, $\mathsf{FrontdoorCriterion}^{\uparrow}$, *and* $\mathsf{CounterfactualOutcome}^{\uparrow}$ *routes. The packet exports no hidden selection oracle, host probability equality, unlicensed counterfactual selector, or ambient causal completeness.*

Proof. Project the carrier of Definition 9055.1. The displayed rows $S, Tg, I, A, D, J, H, C, P, N$ are the complete local packet, and Definition 9055.13 requires every exported target read to pass through them.

Read the structural rows next. Componentwise hsame transport is stored in H, displayed Cont replay is stored in C, Pkg provenance is stored in P, and local naming is stored in N.

Finally apply Definition 9055.12, Definition 9055.9, and Definition 9055.10. These keep the do-calculus, front-door adjustment, and counterfactual-outcome routes inside the displayed ledgers while refusing hidden selection, host probability equality, unlicensed counterfactual selection, and ambient causal completeness. □

Closure status for $\mathsf{NameCert}_{\mathsf{Transportability}^{\uparrow}}$.

Constructive story: A $\mathsf{Transportability}^{\uparrow}$ packet is generated from source-domain distribution, target-domain selection, intervention, adjustment, transported distribution, justification, componentwise transport, displayed replay, provenance, and local NameCert rows.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{Transportability}^{\uparrow}}$, scopedClosed)

Scope closed: Definition 9055.1, Definition 9055.2, and Definition 9055.14 bind the finite transportability carrier to its BEDC primitive rows and sibling do-calculus, front-door, and counterfactual routes.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{Transportability}^{\uparrow}}$, theoremChecked)

Lean target: `BEDC.Derived.TransportabilityUp.TransportabilityCarrier\_namecert\_obligations`

Bridge status: none

Not claimed: This chapter does not close hidden selection oracles, host probability equality, unlicensed counterfactual selectors, ambient causal completeness, Lean verification, or bridge checking.

Upgrade path: Public closure requires a public transportability export theorem over the displayed source-target rows and sibling causal routes.

Chapter 9056

A Concrete Naming Certificate for $\mathsf{LocalGlobalZeroExclusionCertificate}^{\uparrow}$

The $\mathsf{LocalGlobalZeroExclusionCertificate}^{\uparrow}$ packet realizes the proof target of chapter 9246 as finite NameCert data. It records a critical-strip row, a fixed-half comparison row, an apartness witness, a zero-ledger request, a zeta-continuation application row, a prime-window recursive tower row, a compatibility ledger, transport, replay, provenance, and local naming before any consumer may exclude a zero away from the fixed surface. The packet is a certificate route for the local-global zero exclusion target; it is not a host proof of the Riemann hypothesis or an ambient completeness assertion for zeta zeros.

The fixed-half comparison row is consumed from chapter 9046, whose fixed-surface witness supplies the displayed comparison boundary before the local-global zero-ledger row may be read.

The zeta-continuation application row K is consumed from chapter 588: the certificate reads the displayed eta, functional-equation, pole-zero ledger, Gamma-horizon, and application-route rows before the local-global compatibility ledger G can be exposed.

Definition 9056.1 (Local-global zero exclusion certificate carrier)**.** *A* $\mathsf{LocalGlobalZeroExclusionCertificate}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$E = (C, F, A, Z, K, T, G, H, R, P, N)$$

with the following displayed rows:

1. *C is the critical-strip carrier row being tested.*
2. *F is the fixed-half comparison row naming the mirror-fixed surface.*
3. *A is the apartness witness row separating C from F by displayed positive rational data.*
4. *Z is the zero-ledger request row whose consumption is blocked until A has been exposed.*
5. *K is the zeta-continuation application row used to read the completed zeta carrier.*
6. *T is the prime-window recursive tower row supplying local source compatibility.*
7. *G is the global compatibility ledger tying the local window rows to the completed carrier.*
8. *H records componentwise* hsame *transport for critical-strip, fixed-half, apartness, zero-ledger, zeta-continuation, tower, compatibility, replay, provenance, and local naming rows.*
9. *R records displayed* Cont *replay from the critical-strip request through the apartness witness, zero-ledger gate, zeta-continuation application, tower row, and compatibility ledger.*

10. *P is the* Pkg *provenance over* LocalGlobalZeroExclusionCertificate$^{\uparrow}$, FixedHalfZeroWitness$^{\uparrow}$, *the zeta-continuation application route, the prime-window recursive tower,* BHist, hsame, Cont, *and* NameCert.

11. *N is the local* NameCert$_{\text{LocalGlobalZeroExclusionCertificate}^{\uparrow}}$ *row.*

The carrier has no coordinate for a zero row consumed before apartness, a selected off-fixed zero, a hidden completed-carrier equality, host analytic continuation, or ambient RH completeness.

Theorem 9056.2 (Local-global zero exclusion carrier certificate)**.** *For every accepted* LocalGlobalZeroExclusionCerti *carrier $E = (C, F, A, Z, K, T, G, H, R, P, N)$, a consumer may consume the zero-ledger request row Z only after the apartness witness row A is displayed against the fixed-half comparison row F. The accepted route then reads the zeta-continuation application row K, prime-window recursive tower row T, compatibility ledger G, componentwise transport H, replay R, provenance P, and local* NameCert$_{\text{LocalGlobalZeroExclusionCertificate}^{\uparrow}}$ *row N before any local-global zero exclusion claim is public. The packet exports no selected off-fixed zero, hidden carrier equality, host analytic continuation theorem, or ambient RH completeness.*

Proof. Project the carrier of Definition 9056.1. The rows $C, F, A, Z, K, T, G, H, R, P, N$ are the entire public surface of the packet.

The apartness row A is the gate for the zero-ledger request Z. Thus a consumer that attempts to read Z without first displaying A and the fixed-half comparison row F has left the accepted carrier.

After that gate, replay through R fixes the remaining order: the zeta-continuation application row K, prime-window recursive tower row T, and compatibility ledger G are read before transport, provenance, and local naming. Since no carrier coordinate stores a selected off-fixed zero, hidden completed-carrier equality, host analytic continuation theorem, or ambient RH completeness, the certificate is exactly the finite non-escape route stated above. □

Falsifiable prediction: Any accepted off-fixed zero row must expose the apartness witness before the zero-ledger row can be consumed.

Independence witness: fixed-half-zero-witness, zeta-continuation-application, prime-window-recursive-tower, real: none is bijective to LocalGlobalZeroExclusionCertificate$^{\uparrow}$ because the packet jointly carries critical-strip input, fixed-half comparison, apartness, zero-ledger gate, zeta-continuation application, prime-window tower, compatibility, transport, replay, provenance, and local naming rows.

Closure status for NameCert$_{\text{LocalGlobalZeroExclusionCertificate}^{\uparrow}}$.

Constructive story: A LocalGlobalZeroExclusionCertificate$^{\uparrow}$ packet is generated from critical-strip input, fixed-half comparison, apartness witness, zero-ledger gate, zeta-continuation application, prime-window tower, compatibility, componentwise transport, replay, provenance, and local NameCert rows.

Theory closure: TheoryGate(NameCert$_{\text{LocalGlobalZeroExclusionCertificate}^{\uparrow}}$, seed)

Scope closed: Definition 9056.1, Definition 9056.2, the falsifiable prediction, and the independence witness seed the finite NameCert carrier for the local-global zero exclusion target over critical-strip, fixed-half, apartness, zero-ledger, zeta-continuation, tower, compatibility, transport, replay, provenance, and local naming rows.

Formal verification: FormalStatus(NameCert$_{\text{LocalGlobalZeroExclusionCertificate}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close a host proof of RH, selected off-fixed zeros, host analytic continuation, hidden completed-carrier equality, ambient completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, apartness-before-zero-ledger gating, zeta-continuation application coverage, prime-window tower compatibility, replay non-escape, and the Nontrivial and Field-Faithful rows for the same packet.

Chapter 9057

A Concrete Naming Certificate for $\mathsf{SequentialApartnessCompletionBoundary}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{SequentialApartnessCompletionBoundary}^{\uparrow}$ packet records the finite boundary where sequential completion reads, apartness evidence, and Real-facing seals meet without being allowed to collapse into quotient completions or host-selected limits. It sits after the apartness source surface of chapter 1514, the generic apartness completion route of chapter 1787, the located apartness completion route of chapter 3565, the finite window schedule of chapter 126, the regular rational readback of chapter 301, the dyadic tolerance ledger of chapter 291, and the Real seal discipline of chapter 38. The packet is a Real and Completion seed boundary; it does not assert quotient equality of completion names, selected limits, trichotomy, countable choice, or ambient completeness.

Definition 9057.1 (Sequential apartness completion boundary carrier)**.** *A* $\mathsf{SequentialApartnessCompletionBoundary}$ *carrier is a finite* BHist *packet*

$$B = (A, Q, L, S, R, D, E, H, C, P, N)$$

with the following displayed rows:

1. *A is the* $\mathsf{ApartnessSpace}^{\uparrow}$ *source row exposing positive separation before any completion-facing read is consumed.*
2. *Q is the* $\mathsf{ApartnessCompletion}^{\uparrow}$ *boundary row recording the separated completion route attached to the same apartness source.*
3. *L is the* $\mathsf{LocatedApartnessCompletion}^{\uparrow}$ *row displaying located completion windows and apartness evidence before Real-facing inspection.*
4. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite window schedule for the sequential observations seen by the completion boundary.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *regular rational readback extracted from those windows.*
6. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger recording positive gaps, dyadic radii, and comparison cells used by the readback.*
7. *E is the optional* $\mathsf{Real}^{\uparrow}$ *seal row, available only downstream of A, Q, L, S, R, D.*
8. *H records componentwise* hsame *transport for the apartness-space row, apartness-completion row, located-apartness-completion row, stream windows, regular readback, dyadic ledger, optional seal, replay row, provenance row, and local NameCert row.*

9. *C records displayed* Cont *replay from apartness inspection through apartness completion, located apartness completion, stream windows, regular readback, dyadic tolerance, and the optional Real seal.*

10. *P is the* Pkg *provenance over* $\mathsf{SequentialApartnessCompletionBoundary}^{\uparrow}$, $\mathsf{ApartnessSpace}^{\uparrow}$, $\mathsf{ApartnessCompletion}^{\uparrow}$, $\mathsf{LocatedApartnessCompletion}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

11. *N is the local* $\mathsf{NameCert}_{\mathsf{SequentialApartnessCompletionBoundary}^{\uparrow}}$ *row.*

The carrier has no coordinate for quotient completion classes, host equality of completed points, selected limits, countable-choice schedules, trichotomy rows, or ambient Real completeness.

Theorem 9057.2 (Sequential apartness completion boundary NameCert obligations)**.** *For every accepted* $\mathsf{SequentialApartnessCompletionBoundary}^{\uparrow}$ *carrier* $B = (A, Q, L, S, R, D, E, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{SequentialApartnessCompletionBoundary}^{\uparrow}}$ *surface consists exactly of the following finite obligations:*

1. *carrier admission for the displayed apartness-space source, apartness-completion boundary, located-apartness-completion route, stream windows, regular readback, dyadic tolerance ledger, optional Real seal, transport, replay, provenance, and local naming rows;*

2. *source-first exactness, requiring A to be displayed before the completion rows Q and L are consumed;*

3. *sequential readback discipline, requiring every completion-facing observation to pass through S, R, and D before the optional seal row E is available;*

4. *componentwise stability, requiring H and C to transport and replay only the displayed rows $A, Q, L, S, R, D, E, P, N$;*

5. *provenance exhaustion, requiring P and N to export no quotient completion class, host equality of completed names, selected limit, countable-choice schedule, trichotomy row, or ambient-completeness principle.*

No local obligation is stored outside these rows.

Proof. Carrier admission is projection from Definition 9057.1. The tuple displays the apartness source, apartness-completion boundary, located-apartness-completion route, finite windows, regular readback, dyadic tolerance ledger, optional Real seal, transport, replay, provenance, and local name.

Source-first exactness follows from the row order. A completion-facing read can inspect Q or L only after the positive separation row A has been named, so the completion boundary cannot hide its apartness source.

The sequential readback discipline is carried by S, R, D, E. Each observation first opens a finite stream window, then reads the regular rational row, then consults the dyadic tolerance ledger; the optional Real seal is downstream of that finite route.

Componentwise stability and provenance exhaustion are the roles of H, C, P, N. These rows transport, replay, package, and name only the displayed packet, and therefore cannot add quotient completion classes, host equality, selected limits, countable choice, trichotomy, or ambient completeness. □

Theorem 9057.3 (Sequential apartness completion boundary Real seal nonescape)**.** *Let* $B = (A, Q, L, S, R, D, E, H, C, P, N)$ *be an accepted* $\mathsf{SequentialApartnessCompletionBoundary}^{\uparrow}$ *packet. Every Real-facing or completion-facing read of B, when the optional seal row E is present, factors*

through the finite route

$$A, Q, L, S, R, D \longmapsto E \longmapsto H, C, P, N.$$

Thus the Real seal receives only the displayed apartness-space source, apartness-completion boundary, located-apartness-completion route, StreamName windows, RegSeqRat readback, DyadicRatCore tolerance ledger, transport rows, continuation replay, provenance, and local NameCert row. It receives no quotient completion, host equality of completed points, selected limit, countable-choice schedule, trichotomy row, or ambient-completeness coordinate.

Proof. Start with a downstream completion or Real-facing read. Projection of the carrier gives a single ordered route from the apartness-space source row A through the apartness-completion row Q and the located-apartness-completion row L.

The finite observation rows then exhaust the readback path. The window schedule S, regular readback R, and dyadic tolerance ledger D must be displayed before the Real seal row E can be inspected.

Finally, the transport, replay, provenance, and local name rows H, C, P, N carry the same route without adding coordinates. Row exhaustion therefore blocks quotient completions, host equality, selected limits, countable choice, trichotomy, and ambient completeness from entering the Real seal boundary. □

Closure status for $\mathsf{NameCert}_{\mathsf{SequentialApartnessCompletionBoundary}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{SequentialApartnessCompletionBoundary}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 9057.1, Definition 9057.2, and Definition 9057.3 seed the sequential apartness completion boundary over ApartnessSpace, ApartnessCompletion, LocatedApartnessCompletion, StreamName, RegSeqRat, DyadicRatCore, optional Real, transport, replay, provenance, and local naming rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{SequentialApartnessCompletionBoundary}^{\uparrow}}, \mathsf{formalTarget})$

Bridge status: none

Not claimed: This chapter does not close quotient completions, host equality of completed points, selected limits, countable choice, trichotomy, ambient completeness, bridge checking, or theorem-level Lean verification.

Upgrade path: Obligation closure requires checked carrier admission, source-first exactness, sequential readback discipline, componentwise stability, provenance exhaustion, and Real seal nonescape proofs for BEDC.Derived.SequentialApartnessCompletionBoun

Constructive story: A $\mathsf{SequentialApartnessCompletionBoundary}^{\uparrow}$ packet is generated from an ApartnessSpace source row, an ApartnessCompletion boundary row, a LocatedApartnessCompletion row, StreamName windows, RegSeqRat readback, DyadicRatCore tolerances, an optional RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Lean4 (statement) `BEDC.Derived.SequentialApartnessCompletionBoundaryUp`

Chapter 9058

A Concrete Naming Certificate for $\mathsf{RiemannSampler}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{RiemannSampler}^{\uparrow}$ packet records the finite tagged sampling data used by constructive Riemann-sum interfaces. It sits beside the dyadic arithmetic core of chapter 291, the terminal real-name seal of chapter 38, the interval-subdivision carrier of chapter 7313, the tagged-subinterval surface of chapter 7449, and the tagged-gauge sum route of chapter 4115. The packet names one finite sample row over a displayed partition; it does not assert integrability, convergence of sums, measure, open-cover compactness, host real functions, or choice.

Definition 9058.1 (Riemann sampler carrier)**.** *A* $\mathsf{RiemannSampler}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (D, R, P, T, F, V, H, C, G, N)$$

with the following displayed rows:

1. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *mesh row, recording the dyadic scale, cell-width budget, and endpoint comparison data used by the sample.*
2. *R is the* $\mathsf{Real}^{\uparrow}$ *interval row, carrying the named left and right endpoint seals for the interval being sampled.*
3. *P is the* $\mathsf{RiemannPartition}^{\uparrow}$ *partition row, exposing the ordered finite subdivision and its mesh-refinement data.*
4. *T is the* $\mathsf{TaggedPartition}^{\uparrow}$ *tag row, assigning one displayed tag to each visible cell of P together with its tag-in-cell witness.*
5. *F is the function-readback row, recording the displayed evaluation interface opened at the tags rather than a host function space.*
6. *V is the value row, listing the finite real-facing sample values read from F at the tags in T.*
7. *H records componentwise* hsame *transport for mesh, interval, partition, tags, function readback, values, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay through*

$$D \longrightarrow R \longrightarrow P \longrightarrow T \longrightarrow F \longrightarrow V.$$

9. *G is the* Pkg *provenance over* $\mathsf{RiemannSampler}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{RiemannPartition}^{\uparrow}$, $\mathsf{TaggedPartition}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.

10. N is the local $\mathsf{NameCert}_{\mathsf{RiemannSampler}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $D, R, P, T, F, V, H, C, G, N$. It has no coordinate for integrability, convergence of Riemann sums, measure, open-cover compactness, host real functions, quotient equality of partitions, selected tags outside the displayed ledger, or choice.

Lean4 ✓ `BEDC.Derived.RiemannSamplerUp.RiemannSamplerTasteGate single carrier alignment`

Theorem 9058.2 (Riemann sampler NameCert obligations)**.** *For every accepted* $\mathsf{RiemannSampler}^{\uparrow}$ *carrier*

$$S = (D, R, P, T, F, V, H, C, G, N),$$

the local $\mathsf{NameCert}_{\mathsf{RiemannSampler}^{\uparrow}}$ *surface consists exactly of carrier admission for the dyadic mesh, Real interval, RiemannPartition row, TaggedPartition row, function-readback row, value row, transport, replay, provenance, and local name; tag-in-mesh exactness requiring every tag in T to be read through the same dyadic mesh row D and partition row P; sample readback stability requiring F and V to move only by the componentwise transport row H; mesh-refinement replay requiring any refinement consumer to reopen D, R, P, T before reading F, V; and provenance exhaustion requiring G, N to name only the displayed finite sampling route.*

Proof. Project the carrier of Definition 9058.1. The accepted packet exposes exactly the rows $D, R, P, T, F, V, H, C, G, N$, so carrier admission is the displayed finite list.

The tag-in-mesh obligation is supplied by D, P, T. The dyadic mesh row records the comparison scale, the partition row exposes the finite cells, and the tagged-partition row attaches each displayed tag to one of those same cells. A tag that is not read through this route has no coordinate in the carrier.

The sample-readback obligation is supplied by F, V, H. The function-readback row is opened only at the displayed tags, the value row lists the resulting finite sample values, and componentwise hsame transport is the only available stability mechanism for moving them.

Mesh-refinement replay is supplied by C. A refinement or Riemann-sum consumer replays the route from D through T before reading F, V, so refinement cannot introduce a detached tag selector or a host mesh limit.

Finally, G and N exhaust provenance and local naming. Since the carrier contains no rows for integrability, convergence of sums, measure, open-cover compactness, host real functions, quotient partition equality, or choice, the listed obligations are exactly the local NameCert surface. □

Closure status for $\mathsf{NameCert}_{\mathsf{RiemannSampler}^{\uparrow}}$**.**

Constructive story: A $\mathsf{RiemannSampler}^{\uparrow}$ packet is generated from a DyadicRatCore mesh row, Real interval row, RiemannPartition row, TaggedPartition tag row, function-readback row, finite value row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{RiemannSampler}^{\uparrow}}$, seed)

Scope closed: Definition 9058.1 and Definition 9058.2 seed the finite tagged-sample route over dyadic partitions for downstream Riemann, Darboux, and Henstock-style sum consumers.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{RiemannSampler}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close integrability, convergence of sums, measure, open-cover compactness, host real functions, quotient equality of partitions, selected tag choice, ambient RealUp completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, tag-in-mesh exactness, sample readback stability, mesh-refinement replay, provenance exhaustion, and local naming for BEDC.Derived.RiemannSamplerUp.

Chapter 9059

A Concrete Naming Certificate for $\mathsf{CantorRealCompletionKernel}^{\uparrow}$

Following Cantor and Bishop–Bridges, the $\mathsf{CantorRealCompletionKernel}^{\uparrow}$ packet records the finite nested-dyadic completion route by which a decreasing interval chain becomes a regular rational name and then reaches the terminal $\mathsf{Real}^{\uparrow}$ seal. It sits after the dyadic endpoint ledger of chapter 291, the finite observation surface of chapter 126, the regular rational readback of chapter 301, the terminal real-name seal of chapter 38, and the nested dyadic interval carrier of chapter 328. The packet names the completion kernel as displayed BEDC rows; it does not quotient streams, select a host limit, invoke countable choice, or assert ambient completeness for $\mathsf{Real}^{\uparrow}$.

Definition 9059.1 (Cantor real completion kernel carrier)**.** *A* $\mathsf{CantorRealCompletionKernel}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (I, D, W, Q, E, H, C, P, N)$$

with the following displayed rows:

1. *I is the* $\mathsf{NestedDyadicInterval}^{\uparrow}$ *chain row, listing the retained dyadic intervals and the successor containment ledger.*
2. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *endpoint and diameter row, recording lower endpoints, upper endpoints, midpoint reads, and dyadic diameter bounds for the retained windows.*
3. *W is the* $\mathsf{StreamName}^{\uparrow}$ *finite observation row through which a consumer requests inspected stages of the chain.*
4. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row extracted from the same windows and diameter bounds.*
5. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row, available only after I, D, W, Q have been displayed.*
6. *H records componentwise* hsame *transport for interval rows, endpoint ledgers, observation windows, regular readbacks, terminal seals, replay, provenance, and local naming.*
7. *C records the displayed* Cont *replay of the finite route from nested intervals to regular rational readback.*
8. *P records*

$$\mathsf{Pkg}(K) = \mathsf{Pkg}(\mathsf{CantorRealCompletionKernel}^{\uparrow}, \mathsf{NestedDyadicInterval}^{\uparrow}, \mathsf{DyadicRatCore}^{\uparrow}, \mathsf{StreamName}^{\uparrow}, \mathsf{RegSeqRat}^{\uparrow},$$

9. *N is the local* $\mathsf{NameCert}_{\mathsf{CantorRealCompletionKernel}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $I, D, W, Q, E, H, C, P, N$. It has no coordinate for quotient real equality, a selected completed point, host interval intersection, countable choice, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 9059.2 (Cantor kernel nested-containment obligations)**.** *For every accepted* $\mathsf{CantorRealCompletionKernel}$ *carrier*

$$K = (I, D, W, Q, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{CantorRealCompletionKernel}^{\uparrow}}$ *surface exposes successor containment only through the* $\mathsf{NestedDyadicInterval}^{\uparrow}$ *row I and the endpoint comparisons recorded in the* $\mathsf{DyadicRatCore}^{\uparrow}$ *row D. Every displayed adjacent pair in the retained chain must be read as a finite containment certificate before the corresponding* $\mathsf{StreamName}^{\uparrow}$ *window,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback, or* $\mathsf{Real}^{\uparrow}$ *seal can be consumed.*

Proof. Project the carrier of Definition 9059.1. The rows available before any regular readback are the nested interval row I, the dyadic endpoint row D, and the structural transport rows.

Read the successor containment ledger in I. Each adjacent retained pair is paired with lower-endpoint and upper-endpoint comparisons in D, so containment is witnessed by finite dyadic data rather than by a completed intersection point.

Only after those rows are displayed may the consumer inspect W, Q, E. Since the carrier has no quotient, selected limit, host intersection, or ambient-completeness coordinate, the containment obligation is exactly the finite route stated above. □

Theorem 9059.3 (Cantor kernel shrinking-diameter obligations)**.** *For every accepted* $\mathsf{CantorRealCompletionKernel}^{\uparrow}$ *carrier*

$$K = (I, D, W, Q, E, H, C, P, N),$$

each precision request read by the $\mathsf{StreamName}^{\uparrow}$ *row W must be matched by a displayed dyadic diameter bound in D for a retained interval of I. The* $\mathsf{RegSeqRat}^{\uparrow}$ *row Q may read a Cauchy modulus only through those bounds, and no consumer can replace the displayed shrinking ledger by an ambient compactness or completeness principle.*

Proof. Begin with the finite observation row W. It names only the inspected stages of the nested dyadic chain, so a precision request must point back to one retained interval row of I.

The dyadic row D supplies the corresponding diameter bound. That bound is a displayed dyadic comparison attached to the same retained interval, not a host statement about all unseen stages.

The readback row Q consumes the pair (W, D) as regular rational completion data. The packet therefore exposes shrinking diameter through finite windows and dyadic bounds, while the excluded coordinates prevent compactness, selected limits, quotient equality, or ambient completeness from entering the route. □

Theorem 9059.4 (Cantor kernel RegSeqRat-to-Real sealing)**.** *Every* $\mathsf{Real}^{\uparrow}$*-facing consumer of an accepted* $\mathsf{CantorRealCompletionKernel}^{\uparrow}$ *carrier must pass through the displayed route*

$$\mathsf{NestedDyadicInterval}^{\uparrow} \longmapsto \mathsf{DyadicRatCore}^{\uparrow} \longmapsto \mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}$$

using the rows $I, D, W, Q, E, H, C, P, N$. The terminal seal E is not readable until the nested-containment and shrinking-diameter obligations have been displayed through I, D, W, Q.

Proof. Apply Definition 9059.2. It forces the consumer to read the nested interval row I and the dyadic endpoint comparisons in D before treating the chain as a valid decreasing dyadic packet.

Apply Definition 9059.3. It forces every precision request in W to be witnessed by a displayed dyadic diameter bound in D, and it routes the resulting Cauchy data through Q.

Finally read the terminal seal row E through H, C, P, N. These structural rows transport, replay, source, and name only the displayed route. Since the packet contains no selected point, quotient real equality, host limit, countable-choice schedule, or ambient completeness coordinate, the $\mathsf{Real}^{\uparrow}$ seal is reached only by the stated $\mathsf{RegSeqRat}^{\uparrow}$ handoff. □

Falsifiable prediction: An accepted $\mathsf{CantorRealCompletionKernel}^{\uparrow}$ consumer is refuted if it reaches a $\mathsf{Real}^{\uparrow}$ seal without displaying the nested dyadic interval row, dyadic endpoint and diameter ledger, finite StreamName windows, RegSeqRat readback, componentwise hsame transport, Cont replay, Pkg provenance, and local NameCert row.

Closure status for $\mathsf{NameCert}_{\mathsf{CantorRealCompletionKernel}^{\uparrow}}$.

Constructive story: A $\mathsf{CantorRealCompletionKernel}^{\uparrow}$ packet is generated from a NestedDyadicInterval chain row, a DyadicRatCore endpoint and diameter ledger, StreamName finite windows, RegSeqRat readback, a RealUp seal, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CantorRealCompletionKernel}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 9059.1, Definition 9059.2, Definition 9059.3, and Definition 9059.4 seed the finite Cantor completion route from nested dyadic intervals through dyadic endpoint and diameter rows, finite windows, regular rational readback, terminal Real sealing, transport, replay, provenance, and local naming.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CantorRealCompletionKernel}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient real equality, selected host limits, countable choice, trichotomy, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, axiom-clean audit, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, nested containment, shrinking diameter, RegSeqRat readback, Real seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.CantorRealCompletionKernelUp.

Chapter 9060

A Concrete Naming Certificate for $\mathsf{PhaseObserverShellRealization}^{\uparrow}$

The $\mathsf{PhaseObserverShellRealization}^{\uparrow}$ packet realizes the shell-like observer-expansion branch of chapter 9463 as finite NameCert data. It sits after the boundary-shadow row of chapter 3813, the visual-boundary row of chapter 4181, the phase-distance observer-expansion route of chapter 6017, the reversible disk-boundary transport of chapter 6267, the reversible phase route of chapter 6920, and the shell packet of chapter 6319. The packet is a concrete realization surface for finite observer-phase shells; it is not a physical observer law, a completed visual boundary, a selected far-end point, or an ambient hyperbolic manifold.

Definition 9060.1 (Phase observer shell realization carrier)**.** *A* $\mathsf{PhaseObserverShellRealization}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (B, V, D, T, R, O, H, C, P, N)$$

with the following displayed rows:

1. B *is the* $\mathsf{HyperbolicBoundaryShadow}^{\uparrow}$ *boundary-shadow row.*
2. V *is the* $\mathsf{HyperbolicVisualBoundary}^{\uparrow}$ *visual-boundary readback row.*
3. D *is the* $\mathsf{PhaseDistanceObserverExpansion}^{\uparrow}$ *phase-distance comparison row.*
4. T *is the reversible transport row, read through* $\mathsf{PoincareDiskBoundaryTransport}^{\uparrow}$ *and* $\mathsf{PoincareDiskPhaseTransport}^{\uparrow}$.
5. R *is the* $\mathsf{HyperbolicObserverPhaseRoute}^{\uparrow}$ *route row binding boundary-shadow, visual-boundary, phase-distance, and reversible-transport data.*
6. O *is the* $\mathsf{HyperbolicObserverPhaseShell}^{\uparrow}$ *shell row that keeps the observer-facing packet boundary-facing.*
7. H *records componentwise* hsame *transport for* $B, V, D, T, R, O, C, P, N$.
8. C *records displayed* Cont *replay through boundary shadow, visual boundary, phase distance, transport, route, shell, provenance, and local naming.*
9. P *records*

   $\mathsf{Pkg}(S) = \mathsf{Pkg}(\mathsf{PhaseObserverShellRealization}^{\uparrow}, \mathsf{HyperbolicBoundaryShadow}^{\uparrow}, \mathsf{HyperbolicVisualBoundary}^{\uparrow}, \mathsf{PhaseDis}$

10. N *is the local* $\mathsf{NameCert}_{\mathsf{PhaseObserverShellRealization}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $B, V, D, T, R, O, H, C, P, N$. It has no coordinate for global hyperbolic space, completed visual boundary, selected observer center, physical observer dynamics, host phase equality, or unlogged transport.

Theorem 9060.2 (Phase observer shell realization NameCert obligations)**.** *For every accepted* $\mathsf{PhaseObserverShellRealization}^{\uparrow}$ *carrier*

$$S = (B, V, D, T, R, O, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{PhaseObserverShellRealization}^{\uparrow}}$ *surface consists exactly of boundary-shadow admission through B, visual-boundary readback through V, phase-distance comparison through D, reversible-transport admission through T, route admission through R, shell admission through O, componentwise transport through H, displayed replay through C, package provenance through P, and local naming through N.*

Proof. Project the carrier of Definition 9060.1. Its observable shell data are precisely the boundary-shadow, visual-boundary, phase-distance, reversible-transport, route, and shell rows.

Read the rows in dependency order. Boundary shadow and visual boundary make the shell boundary-facing, phase distance supplies the comparison row, reversible transport records how the surface moves, and the observer phase route binds those data before the shell row is accepted.

The structural rows H, C, P, N transport, replay, source, and name the same finite packet. Since the carrier has no coordinate for a completed boundary, selected center, physical dynamics, host phase equality, or unlogged transport, the listed rows exhaust the NameCert surface. □

Theorem 9060.3 (Phase observer shell realization nonescape)**.** *Every observer-expansion read from an accepted* $\mathsf{PhaseObserverShellRealization}^{\uparrow}$ *carrier must factor through*

$\mathsf{HyperbolicBoundaryShadow}^{\uparrow}$, $\mathsf{HyperbolicVisualBoundary}^{\uparrow}$, $\mathsf{PhaseDistanceObserverExpansion}^{\uparrow}$, $\mathsf{PoincareDiskBou}$

It cannot replace those rows by a global hyperbolic space, a completed visual boundary, a selected far-end point, a physical observer law, host phase equality, or an unlogged reversible transport.

Proof. Apply the NameCert obligations of Definition 9060.2. Any accepted read must consume B, V, D, T, R, O before the structural rows are available.

The boundary-shadow and visual-boundary rows make the reading boundary-facing. The phase-distance and reversible-transport rows make the reading phase-facing. The route and shell rows bind those data as observer-expansion evidence.

Finally, H, C, P, N preserve only that finite route. Because the excluded objects are not carrier coordinates, no observer-expansion read can escape to them through the realization packet. □

Falsifiable prediction: An accepted $\mathsf{PhaseObserverShellRealization}^{\uparrow}$ read is refuted if it exports an observer-phase shell without displaying boundary-shadow, visual-boundary, phase-distance, reversible-transport, route, shell, hsame, Cont, Pkg, and local NameCert rows.

Independence witness: hyperbolic-boundary-shadow, hyperbolic-visual-boundary, phase-distance-observer-expansion, poincare-disk-boundary-transport, hyperbolic-observer-phase-route: no listed sibling is bijective to $\mathsf{PhaseObserverShellRealization}^{\uparrow}$ because this packet jointly carries boundary-shadow, visual-boundary, phase-distance, reversible-transport, route, shell, replay, provenance, and local naming rows as one realization surface.

Closure status for $\mathsf{NameCert}_{\mathsf{PhaseObserverShellRealization}^{\uparrow}}$ **·**

Constructive story: A PhaseObserverShellRealization$^{\uparrow}$ packet is generated from boundary-shadow, visual-boundary, phase-distance, reversible-transport, observer-phase route, observer-phase shell, componentwise hsame, Cont replay, Pkg provenance, and local NameCert rows.

Theory closure: TheoryGate(NameCert$_{\text{PhaseObserverShellRealization}^{\uparrow}}$, seed)

Scope closed: Definition 9060.1, Definition 9060.2, Definition 9060.3, the falsifiable prediction, and the independence witness seed the finite observer-phase shell realization over boundary-shadow, visual-boundary, phase-distance, reversible-transport, route, shell, transport, replay, provenance, and local naming rows.

Formal verification: FormalStatus(NameCert$_{\text{PhaseObserverShellRealization}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close global hyperbolic spaces, completed visual boundaries, selected far-end points, physical observer laws, host phase equality, Lean verification, axiom-clean audit, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, boundary-shadow admission, visual-boundary readback, phase-distance comparison, reversible-transport admission, route admission, shell admission, transport, replay, provenance, and local naming for BEDC.Derived.PhaseObserverShellRealizationUp.

Chapter 9061

A Concrete Naming Certificate for FiniteHerbrandDisjunction$^{\uparrow}$

Following Herbrand's theorem as a proof-search interface for first-order logic, the FiniteHerbrandDisjunction$^{\uparrow}$ packet records only the finite disjunction certificate surfaced by a displayed syntactic proof-search route. It sits over the first-order syntax rows of chapter 197, the model-theory boundary of chapter 198, the typed MetaCIC example gallery of chapter 775, the GroundCompiler audit packet of chapter 827, and the local NameCert discipline used by the proof-tree siblings chapter 3756 and chapter 5907. The packet names a finite certificate surface; it does not claim host completeness, infinite proof search, semantic truth in all models, choice, or quotient proof equality.

Definition 9061.1 (Finite Herbrand disjunction carrier)**.** *A* FiniteHerbrandDisjunction$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$H = (F, D, W, S, Q, R, T, C, P, N)$$

with the following displayed rows:

1. *F is the* FirstOrder$^{\uparrow}$ *formula row containing the prenex source formula, free-variable ledger, quantifier-prefix ledger, and finite term-source alphabet;*
2. *D is the finite disjunct inventory, listing the ground instances admitted into the Herbrand disjunction;*
3. *W is the witness-term and substitution row, attaching each disjunct in D to a displayed tuple of terms and a substitution readback from F;*
4. *S is the syntactic checker row for the displayed disjunction, read through natural-deduction, sequent-calculus, or MetaCIC-facing proof rows only as finite proof-search data;*
5. *Q is the proof-search route row, recording the finite branch order, branch closures, and checker calls that produced D, W, S;*
6. *R records componentwise* hsame *transport for the source formula, disjunct inventory, witness-term rows, checker route, proof-search route, replay row, provenance row, and local naming row;*
7. *T records displayed* Cont *replay from the source formula through Q and then through D, W, S, R, P, N;*
8. *C is the consumer handoff row exposing the certificate to* MetaCICTypedExamplesGallery$^{\uparrow}$ *and* GroundCompilerAuditPacket$^{\uparrow}$ *only after the finite disjunct inventory and checker route are visible;*

9. *P is the* Pkg *provenance over* FiniteHerbrandDisjunction$^{\uparrow}$, FirstOrder$^{\uparrow}$, ModelTheory$^{\uparrow}$, MetaCICTypedExamplesGal GroundCompilerAuditPacket$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows;*
10. *N is the local* NameCert$_{\text{FiniteHerbrandDisjunction}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $F, D, W, S, Q, R, T, C, P, N$. It has no coordinate for semantic completeness, truth in every structure, infinite proof search, selected model construction, choice, quotient proof equality, or a host proof checker outside the displayed rows.

Theorem 9061.2 (Finite Herbrand disjunction NameCert obligations)**.** *For every accepted* FiniteHerbrandDisjuncti *carrier $H = (F, D, W, S, Q, R, T, C, P, N)$, the local* NameCert$_{\text{FiniteHerbrandDisjunction}^{\uparrow}}$ *surface consists exactly of first-order formula exposure through F, finite disjunct inventory exposure through D, witness-term and substitution exposure through W, checker exposure through S, proof-search route exposure through Q, componentwise transport through R, displayed replay through T, downstream certificate handoff through C, provenance through P, and local naming through N.*

Proof. Project the carrier of Definition 9061.1. The source syntax is F, the finite Herbrand inventory is D, and the witness-term data are exactly the substitution rows in W.

The checker and search data are also displayed. The row S records the finite checker calls, while Q records the branch order and branch closures that led to the disjunction.

Transport, replay, and consumer exposure are then forced through R, T, C. The package row P records the cited FirstOrder, ModelTheory, MetaCIC gallery, GroundCompiler, and NameCert dependencies, and N names only this displayed packet.

Since the carrier has no coordinate for semantic completeness, truth in every structure, infinite proof search, selected model construction, choice, quotient proof equality, or a host proof checker outside the displayed rows, no local NameCert obligation can export those principles. □

Theorem 9061.3 (Finite Herbrand disjunction non-escape)**.** *Every accepted* FiniteHerbrandDisjunction$^{\uparrow}$ *consumer reads the Herbrand certificate only through the finite route*

$$F \longmapsto Q \longmapsto (D, W, S) \longmapsto (R, T, C, P, N).$$

The consumer may cite the route as a displayed finite disjunction certificate for a first-order proof-search branch, but it may not read the packet as host completeness, infinite proof search, model-theoretic truth, choice, quotient proof equality, or an ambient proof checker.

Proof. Start with the NameCert obligations of Definition 9061.2. They force every accepted read to expose the source formula, the finite disjunct inventory, the witness-term substitutions, the checker row, and the proof-search route before any downstream consumer sees the packet.

The consumer handoff row C can then pass the certificate to MetaCIC or GroundCompiler-facing rows only after the finite inventory and checker route have been replayed through T and transported through R.

The non-escape clauses are the non-coordinates of Definition 9061.1. Because none of host completeness, infinite proof search, model-theoretic truth, choice, quotient proof equality, or an ambient proof checker appears in H, no accepted consumer can project such data from the packet. □

Closure status for NameCert$_{\text{FiniteHerbrandDisjunction}^{\uparrow}}$.

Constructive story: A FiniteHerbrandDisjunction$^{\uparrow}$ packet is generated from a first-order formula row, a finite Herbrand disjunct inventory, witness-term and substitution rows, a checker row, a proof-search route, componentwise hsame transport, displayed Cont replay, downstream certificate handoff, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\text{FiniteHerbrandDisjunction}^{\uparrow}}$, seed)

Scope closed: Definition 9061.1, Definition 9061.2, and Definition 9061.3 seed the finite proof-search certificate over $F, D, W, S, Q, R, T, C, P, N$.

Formal verification: FormalStatus(NameCert$_{\mathsf{FiniteHerbrandDisjunction}\uparrow}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close host completeness, infinite proof search, model-theoretic truth, choice, quotient proof equality, Lean verification, or a public standard bridge.

Upgrade path: Obligation closure requires checked first-order formula exposure, finite disjunct inventory exposure, witness-term substitution exposure, checker exposure, proof-search route exposure, transport, replay, downstream handoff, provenance, and local naming for BEDC.Derived.FiniteHerbrandDisjunctionUp.

Chapter 9062

A Concrete Naming Certificate for $\mathsf{BarInductionCauchyModulus}^{\uparrow}$

Following Brouwer's bar induction practice, Troelstra–van Dalen's fan arguments, and the Bishop–Bridges use of explicit Cauchy moduli, the $\mathsf{BarInductionCauchyModulus}^{\uparrow}$ packet records a finite route from bar evidence to a modulus row for regular real names. The route sits beside chapter 126, chapter 301, chapter 291, chapter 38, chapter 292, chapter 334, and chapter 400; it exposes only finite BHist rows, transport, replay, provenance, and a local $\mathsf{NameCert}$ seal.

Definition 9062.1 (Bar induction Cauchy modulus carrier)**.** *A* $\mathsf{BarInductionCauchyModulus}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$(B, F, W, S, R, D, E, H, C, P, N)$$

whose rows have the following roles:

1. *B is a decidable bar row for finite prefixes of the displayed branch space.*
2. *F is the fan or finite-cover row certifying that the bar is read through a bounded prefix cover.*
3. *W is the* $\mathsf{StreamName}^{\uparrow}$ *window row that exposes the finite observations used by the bar test.*
4. *S is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row attached to the same window.*
5. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row whose precision request is discharged by the bar.*
6. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row produced after the bounded readback.*
7. *H, C, P, N are respectively the* hsame *transport,* Cont *replay,* Pkg *provenance, and local* $\mathsf{NameCert}_{\mathsf{BarInductionCauchyM}}$ *naming rows for the same finite packet.*

The accepted carrier may be consumed as a $\mathsf{CauchyModulus}^{\uparrow}$ *source only through the displayed bar and fan rows; it contains no countable-choice selector, host infinite branch, quotient stream representative, or ambient Real-completeness witness.*

Theorem 9062.2 (Bar induction Cauchy modulus NameCert obligations)**.** *An accepted* $\mathsf{BarInductionCauchyModulu}$ *carrier satisfies the following five NameCert obligations:*

1. *carrier habitation by the finite rows $B, F, W, S, D, E, H, C, P, N$ of Definition 9062.1;*
2. *bar admissibility, saying that every tolerance request reaches the decidable bar row through a finite prefix accepted by B;*
3. *fan boundedness, saying that the usable prefix is selected only from the finite cover row F;*

4. *readback exactness, saying that the* $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$ *rows read the same bounded prefix and tolerance request;*
5. *transport, replay, provenance, and local naming stability along* H, C, P, N.

Proof. Project the carrier of Definition 9062.1. Its visible rows already name the decidable bar, finite fan cover, StreamName window, RegSeqRat readback, dyadic tolerance, Real seal, and structural naming data.

The bar and fan obligations are read before the analytic rows. The row B supplies the decidable stopping test for the tolerance request, and F supplies the bounded prefix cover through which the stopping test is admitted.

The readback rows then consume the same prefix. The $\mathsf{StreamName}^{\uparrow}$ row gives the finite observation window, $\mathsf{RegSeqRat}^{\uparrow}$ reads the rational data on that window, $\mathsf{DyadicRatCore}^{\uparrow}$ records the tolerance, and $\mathsf{Real}^{\uparrow}$ seals only the resulting bounded readback.

Finally H, C, P, N carry the same packet through transport, replay, provenance, and local naming. No obligation contains a selected infinite branch, a countable-choice function, quotient stream equality, or ambient completeness. □

Theorem 9062.3 (Bar induction Cauchy modulus fan handoff)**.** *Every* $\mathsf{CauchyModulus}^{\uparrow}$ *or* $\mathsf{Real}^{\uparrow}$ *consumer of an accepted* $\mathsf{BarInductionCauchyModulus}^{\uparrow}$ *packet reads the modulus only through the finite route*

$$\mathsf{FanTheorem}^{\uparrow}, \quad \mathsf{BaireSpace}^{\uparrow}, \quad \mathsf{StreamName}^{\uparrow}, \quad \mathsf{RegSeqRat}^{\uparrow}, \quad \mathsf{DyadicRatCore}^{\uparrow}, \quad \mathsf{Real}^{\uparrow}.$$

The consumer must first inspect the decidable bar row B *and the fan cover row* F*, then the StreamName window* W*, RegSeqRat readback* S*, dyadic tolerance* D*, and terminal Real seal* E*. The route exports no countable choice, host infinite branch selection, quotient streams, or ambient Real completeness.*

Proof. Start with the obligation surface of Definition 9062.2. It places the decidable bar and finite fan cover before the analytic readback rows.

The $\mathsf{CauchyModulus}^{\uparrow}$ read is therefore a bounded-prefix read. A tolerance request reaches D only after B admits a finite prefix and F bounds the usable cover, so the modulus row cannot be read as a host function selected from infinitely many branches.

The $\mathsf{Real}^{\uparrow}$ read is also bounded. The terminal seal E is exposed only after the $\mathsf{StreamName}^{\uparrow}$ window and $\mathsf{RegSeqRat}^{\uparrow}$ readback have been matched to the same dyadic tolerance row, so quotient stream representatives and ambient Real completeness are not available to the consumer. □

Closure status for $\mathsf{NameCert}_{\mathsf{BarInductionCauchyModulus}^{\uparrow}}$.

Constructive story: A $\mathsf{BarInductionCauchyModulus}^{\uparrow}$ packet is generated by reading a decidable bar through a finite fan cover, then routing the bounded StreamName, RegSeqRat, DyadicRatCore, and Real rows into a Cauchy-modulus handoff.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{BarInductionCauchyModulus}^{\uparrow}}$, seed)

Scope closed: The seed surface records the finite bar-to-fan-to-Cauchy-modulus route for regular Real names, with only the carrier, obligation, and handoff rows displayed.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{BarInductionCauchyModulus}^{\uparrow}}$, unformalized)

Lean4 (statement) `BEDC.Derived.BarInductionCauchyModulusUp`

Bridge status: none

Not claimed: This chapter does not claim a checked Lean NameCert, public Real completeness, countable choice, selected infinite branches, quotient-stream equality, or a standard bridge.

Upgrade path: Scoped closure requires checked carrier admission, bar admissibility, fan boundedness, readback exactness, transport, replay, provenance, and local naming for BEDC.Derived.BarInductionCauchyModulusUp.

Chapter 9063

A Concrete Naming Certificate for $\mathsf{CofinalStreamReindexing}^{\uparrow}$

Following Bishop–Bridges constructive analysis, the $\mathsf{CofinalStreamReindexing}^{\uparrow}$ packet records the finite route by which a StreamName schedule may be read through a cofinal reindexing ledger before regular rational readback, dyadic tolerance comparison, or Real-facing sealing occurs. It sits after the $\mathsf{StreamName}^{\uparrow}$ naming surface of chapter 126, the $\mathsf{RegSeqRat}^{\uparrow}$ readback route of chapter 301, the $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance arithmetic of chapter 291, the $\mathsf{Real}^{\uparrow}$ seal discipline of chapter 38, and the cofinal subnet route of chapter 1592. The packet names cofinal reindexing as finite NameCert data, not as quotient stream equality, a host-selected subsequence, countable choice, host real equality, or ambient completeness.

Definition 9063.1 (Cofinal StreamName reindexing carrier)**.** *A* $\mathsf{CofinalStreamReindexing}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Q = (S, J, W, R, D, E, H, C, P, N)$$

with the following displayed rows:

1. *S is the source* $\mathsf{StreamName}^{\uparrow}$ *row whose finite observation windows are to be reindexed.*
2. *J is the cofinal reindex ledger. It records finite dominance checks from each accepted target window back to a displayed source window of S.*
3. *W is the finite-window row obtained after replaying the source row and the cofinal ledger.*
4. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row attached to the displayed target windows.*
5. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger used to compare the source and reindexed readbacks.*
6. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row available only after S, J, W, R, D have been displayed.*
7. *H records componentwise* hsame *transport for the source stream, cofinal ledger, target windows, readback, tolerance ledger, Real seal, replay row, provenance row, and local naming row.*
8. *C records displayed* Cont *replay from a target precision request through S, J, W, R, D, E, H in that order.*
9. *P is the* Pkg *provenance over* $\mathsf{CofinalStreamReindexing}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{CofinalStreamReindexing}^{\uparrow}}$ *row.*

The carrier has no coordinate for quotient streams, host-selected subsequences, countable-choice schedules, host real equality, or ambient completeness.

Theorem 9063.2 (Cofinal StreamName reindexing NameCert obligations)**.** *For every accepted* $\mathsf{CofinalStreamReindexing}^{\uparrow}$ *carrier* $Q = (S, J, W, R, D, E, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{CofinalStreamReindexing}^{\uparrow}}$ *surface consists exactly of the following finite obligations:*

1. *carrier admission for the source StreamName row, cofinal reindex ledger, finite windows, RegSeqRat readback, DyadicRatCore tolerance ledger, Real seal, transport, replay, provenance, and local naming rows;*
2. *cofinal coverage, requiring every accepted target window to pass through* J *and to name a displayed source window in* S*;*
3. *finite-window stability, requiring the row* W *to preserve the window requested after the cofinal ledger has been replayed;*
4. *readback preservation, requiring* R *and* D *to be the only rows through which the reindexed window reaches a regular rational comparison;*
5. *seal nonescape, requiring every Real-facing consumer to inspect* S, J, W, R, D *before the seal row* E *is available.*

No local obligation is stored outside these rows.

Proof. Project the carrier of Definition 9063.1. The projection exposes exactly the source StreamName row, cofinal ledger, finite-window row, regular rational readback, dyadic tolerance ledger, Real seal, and structural rows.

Cofinal coverage is the role of J. Each accepted target window must replay a finite dominance check back to the source row S before the target row W can be consumed.

Finite-window stability and readback preservation are then forced by W, R, D. The target window is displayed first, its regular rational readback is exposed next, and the dyadic tolerance ledger is the only comparison row available before the seal.

Finally, H, C, P, N transport, replay, source, and name the same packet. Since no quotient stream, host-selected subsequence, countable-choice schedule, host real equality, or ambient-completeness coordinate appears in the carrier, the listed obligations exhaust the local NameCert surface. □

Theorem 9063.3 (Cofinal StreamName reindexing Real seal nonescape)**.** *Let* $Q = (S, J, W, R, D, E, H, C, P, N)$ *be an accepted* $\mathsf{CofinalStreamReindexing}^{\uparrow}$ *carrier. Every Real-facing consumer of the reindexed stream factors through the finite route*

$$S, J, W, R, D \longmapsto E \longmapsto H, C, P, N.$$

Thus any Real-facing read first consumes the source $\mathsf{StreamName}^{\uparrow}$ *row, the cofinal reindex ledger, the finite target window, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback, and the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger. The* $\mathsf{Real}^{\uparrow}$ *seal receives no quotient stream, host-selected subsequence, countable-choice schedule, host real equality, or ambient-completeness coordinate.*

Proof. Begin with a Real-facing consumer. Carrier admission gives a seal row E, but it is downstream of the source stream, cofinal ledger, target window, readback, and tolerance rows.

Replay the continuation row C. The request first consumes S and J, then inspects W, reads R, and checks the dyadic tolerance ledger D.

Only after this finite route has been displayed can the packet expose E. Componentwise transport and provenance through H, P, N preserve the same dependency order, so the Real seal cannot be reached by quotient stream equality, host-selected subsequence choice, countable choice, host real equality, or ambient completeness. □

Closure status for $\mathsf{NameCert}_{\mathsf{CofinalStreamReindexing}^{\uparrow}}$ **.**

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{CofinalStreamReindexing}^{\uparrow}}$, seed)

Scope closed: Definition 9063.1, Definition 9063.2, and Definition 9063.3 seed the cofinal StreamName reindexing surface over StreamName, RegSeqRat, DyadicRatCore, Real, hsame, Cont, Pkg, and NameCert rows.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{CofinalStreamReindexing}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close quotient streams, host-selected subsequences, countable choice, host real equality, ambient completeness, bridge checking, or theorem-level Lean verification.

Upgrade path: Obligation closure requires checked carrier admission, cofinal coverage, finite-window stability, readback preservation, seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.CofinalStreamReindexingUp.

Constructive story: A $\mathsf{CofinalStreamReindexing}^{\uparrow}$ packet is generated from a StreamName source row, a cofinal reindex ledger, finite target windows, RegSeqRat readback, DyadicRatCore tolerance rows, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 9064

A Concrete Naming Certificate for $\mathsf{FanCauchyModulus}^{\uparrow}$

Following Brouwer and Bishop–Bridges, the $\mathsf{FanCauchyModulus}^{\uparrow}$ packet records the finite fan-bar extraction route by which a decidable bar on binary choice prefixes yields one displayed Cauchy-modulus request before any regular rational readback or real seal is consumed. It sits after the fan-bar surface of chapter 400, the Cauchy-modulus interface of chapter 292, the finite observation window of chapter 126, the regular rational sequence handoff of chapter 301, and the terminal real-name seal of chapter 38. The certificate is a finite NameCert reconstruction of the fan-to-Cauchy-modulus handoff; it does not claim open-cover compactness, choice, quotient streams, host real equality, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 9064.1 (Fan-Cauchy modulus carrier)**.** *A* $\mathsf{FanCauchyModulus}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$F = (B, K, M, W, R, E, H, C, P, N)$$

with the following displayed rows:

1. *B is the finite decidable* $\mathsf{FanTheorem}^{\uparrow}$ *bar row, listing the inspected binary prefixes and the local decision ledger for bar membership.*
2. *K is the prefix-bound row extracted from B, recording one finite depth that meets every displayed branch through the bar.*
3. *M is the* $\mathsf{CauchyModulus}^{\uparrow}$ *request row, translating the prefix bound into a precision-to-window demand for a Cauchy-facing consumer.*
4. *W is the* $\mathsf{StreamName}^{\uparrow}$ *window row through which the consumer inspects exactly the prefixes and tail windows licensed by K and M.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff row, carrying the regular rational readback obtained after the window and modulus rows have been displayed.*
6. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal route, readable only after B, K, M, W, R have been opened.*
7. *H records componentwise* hsame *transport for bar, bound, modulus, stream window, regular readback, real seal, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay through*

$$\mathsf{FanTheorem}^{\uparrow} \longrightarrow \mathsf{CauchyModulus}^{\uparrow} \longrightarrow \mathsf{StreamName}^{\uparrow} \longrightarrow \mathsf{RegSeqRat}^{\uparrow} \longrightarrow \mathsf{Real}^{\uparrow}.$$

9. *P records provenance over* $\mathsf{FanCauchyModulus}^{\uparrow}$, $\mathsf{FanTheorem}^{\uparrow}$, $\mathsf{CauchyModulus}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{FanCauchyModulus}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $B, K, M, W, R, E, H, C, P, N$. It has no coordinate for open-cover compactness, a choice functional, quotient stream equality, a selected infinite branch, host real equality, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 9064.2 (Fan-Cauchy modulus NameCert obligations)**.** *For every accepted* $\mathsf{FanCauchyModulus}^{\uparrow}$ *carrier*

$$F = (B, K, M, W, R, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{FanCauchyModulus}^{\uparrow}}$ *surface consists exactly of finite bar admission through B, prefix-bound extraction through K, Cauchy-modulus request formation through M, StreamName window exposure through W, RegSeqRat handoff through R, Real seal routing through E, componentwise transport through H, displayed replay through C, provenance exhaustion through P, and local naming through N.*

Proof. Project the carrier of Definition 9064.1. The accepted packet exposes exactly the rows $B, K, M, W, R, E, H, C, P, N$, so carrier admission is the displayed finite list.

The fan-facing obligation is supplied by B and K. The decidable bar row lists the inspected prefixes, and the bound row records the finite depth used by all downstream requests. No separate branch selector is present.

The Cauchy-facing obligation is supplied by M, W, R. The modulus request names the demanded precision window, the StreamName row opens only that finite observation surface, and the RegSeqRat row reads regular rational data from the same window.

Finally, E, H, C, P, N seal, transport, replay, source, and name the displayed route. Since the carrier contains no row for open-cover compactness, choice, quotient streams, host real equality, or ambient completeness, the listed rows exhaust the local NameCert surface. □

Theorem 9064.3 (Fan-Cauchy finite-bar extraction)**.** *Every* $\mathsf{RegSeqRat}^{\uparrow}$ *or* $\mathsf{Real}^{\uparrow}$ *consumer of an accepted* $\mathsf{FanCauchyModulus}^{\uparrow}$ *carrier must pass through the displayed finite route*

$$\mathsf{FanTheorem}^{\uparrow} \longmapsto \mathsf{CauchyModulus}^{\uparrow} \longmapsto \mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}$$

using the rows $B, K, M, W, R, E, H, C, P, N$. The prefix bound K is the only source of the Cauchy-modulus request M, and the Real seal row E is not readable until the bar, bound, modulus, window, and regular-readback rows have all been displayed.

Proof. Begin with the finite bar row B. It supplies the decidable prefix ledger read from the fan-theorem sibling, while K records the finite bound extracted from that same ledger.

Read the Cauchy-modulus request M through K. This forces any precision demand to be a displayed finite-window demand rather than a choice functional or a branchwise host argument.

Now open W and R. The StreamName window exposes the inspected prefixes and tail windows, and the RegSeqRat handoff reads regular rational data only from those windows.

The Real seal E is then available through H, C, P, N. These structural rows move, replay, source, and name the same finite route, so no open-cover compactness, quotient stream, selected branch, or ambient $\mathsf{Real}^{\uparrow}$ completeness claim can enter the extraction. □

Closure status for $\mathsf{NameCert}_{\mathsf{FanCauchyModulus}^{\uparrow}}$.

Constructive story: A $\mathsf{FanCauchyModulus}^{\uparrow}$ packet is generated from a finite decidable FanTheorem bar row, prefix-bound row, CauchyModulus request row, StreamName window row, RegSeqRat handoff, Real seal route, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{FanCauchyModulus}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 9064.1, Definition 9064.2, and Definition 9064.3 seed the finite fan-bar to Cauchy-modulus route consumed by later regular-Cauchy and Real-seal arguments.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{FanCauchyModulus}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close open-cover compactness, choice, quotient streams, selected infinite branches, host real equality, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, axiom-clean audit, or bridge checking.

Upgrade path: Obligation closure requires checked finite-bar admission, prefix-bound extraction, Cauchy-modulus request formation, StreamName window exposure, RegSeqRat handoff, Real seal routing, transport, replay, provenance, and local naming for BEDC.Derived.FanCauchyModulusUp.

Chapter 9065

A Concrete Naming Certificate for $\mathsf{LocatedIntervalSampling}^{\uparrow}$

Following Bishop and Bridges on located intervals and constructive real approximation, the $\mathsf{LocatedIntervalSampling}$ packet records the finite sampling route by which a located closed interval is inspected through density-net cells before any completion-facing Real seal is read. It sits beside the finite Cauchy density-net route of chapter 6003, the dyadic interval-cell route of chapter 5966, the finite StreamName windows of chapter 126, the regular rational readback of chapter 301, and the terminal real-name seal of chapter 38. The packet supplies Real and Completion consumers with displayed finite interval samples; it does not assert classical compactness, selected limits, quotient representatives, trichotomy, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 9065.1 (Located interval sampling carrier)**.** *A* $\mathsf{LocatedIntervalSampling}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (I, N, W, R, E, H, C, P, L)$$

with the following displayed rows:

1. *I is the located closed interval row, exposing named endpoint seals and a located endpoint comparison before any sample is read.*
2. *N is the* $\mathsf{FiniteCauchyDensityNet}^{\uparrow}$ *row naming the finite density-net handoff for the same interval source.*
3. *W is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row listing the observed sample windows.*
4. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row extracted from the windows in W.*
5. *E is the downstream* $\mathsf{Real}^{\uparrow}$ *seal row, available only after I, N, W, R have been displayed.*
6. *H records componentwise* hsame *transport for the interval, density-net, window, readback, seal, replay, provenance, and local naming rows.*
7. *C records displayed* Cont *replay through the route*

$$I \longrightarrow N \longrightarrow W \longrightarrow R \longrightarrow E.$$

8. *P is the* Pkg *provenance over* $\mathsf{LocatedIntervalSampling}^{\uparrow}$, $\mathsf{FiniteCauchyDensityNet}^{\uparrow}$, $\mathsf{DyadicIntervalNet}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$ *rows.*
9. *L is the local* $\mathsf{NameCert}_{\mathsf{LocatedIntervalSampling}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $I, N, W, R, E, H, C, P, L$. It has no coordinate for a quotient representative of the interval, a selected completed sample, trichotomy on endpoints, countable choice over windows, classical compactness, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 9065.2 (Located interval sampling NameCert obligations)**.** *For every accepted* $\mathsf{LocatedIntervalSampling}^{\uparrow}$ *carrier*

$$S = (I, N, W, R, E, H, C, P, L),$$

the local $\mathsf{NameCert}_{\mathsf{LocatedIntervalSampling}^{\uparrow}}$ *surface consists exactly of the following finite obligations:*

1. *carrier admission for the displayed located interval, finite Cauchy density-net, StreamName window, RegSeqRat readback, Real seal, transport, replay, provenance, and local naming rows;*
2. *interval-cell exposure, requiring the sample cells to be read through the* $\mathsf{DyadicIntervalNet}^{\uparrow}$ *surface before a density-net row is consumed;*
3. *density-net handoff, requiring N to expose the finite Cauchy density-net route of chapter 6003 for the same located interval row I;*
4. *readback-before-seal discipline, requiring W and R to be displayed before the* $\mathsf{Real}^{\uparrow}$ *seal row E is available;*
5. *refusal of quotient representatives, selected limits, trichotomy, countable choice, and ambient Real completeness as exportable rows of the packet.*

No local obligation is stored outside $I, N, W, R, E, H, C, P, L$.

Proof. Carrier admission is projection from Definition 9065.1. The accepted packet exposes exactly the located interval, density-net, window, readback, Real seal, transport, replay, provenance, and local naming rows.

The interval-cell obligation is supplied by the dyadic interval-net sibling. A sample cell may be consumed only after the displayed interval source has been matched to a finite $\mathsf{DyadicIntervalNet}^{\uparrow}$ cell route, so the packet never treats an interval as an untracked host subset.

The density-net handoff is supplied by N. It names the finite Cauchy density-net route over the same interval row and does not select a completed sample or assert compactness outside the displayed finite rows.

Finally read W, R, E, H, C, P, L. The StreamName windows and RegSeqRat readback must precede the Real seal, while transport, replay, provenance, and local naming preserve only the displayed route. Hence quotient representatives, selected limits, trichotomy, countable choice, and ambient Real completeness have no carrier coordinate from which to escape. □

Closure status for $\mathsf{NameCert}_{\mathsf{LocatedIntervalSampling}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{LocatedIntervalSampling}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 9065.1 and Definition 9065.2 seed the located interval sampling route over located interval, DyadicIntervalNet, FiniteCauchyDensityNet, StreamName, RegSeqRat, Real seal, transport, replay, provenance, and local naming rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{LocatedIntervalSampling}^{\uparrow}}, \mathsf{encodedDef})$

Bridge status: none

Not claimed: This chapter does not close classical compactness, quotient interval representatives, selected limits, trichotomy, countable choice, ambient RealUp completeness, Lean theorem verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, interval-cell exposure, density-net handoff, StreamName and RegSeqRat readback before Real sealing, provenance exhaustion, and local naming for BEDC.Derived.LocatedIntervalSamplin

Constructive story: A $\mathsf{LocatedIntervalSampling}^{\uparrow}$ packet is generated from a located closed interval row, a finite Cauchy density-net row, StreamName windows, RegSeqRat readback, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Lean4 (definition) `BEDC.Derived.LocatedIntervalSamplingUp`

Chapter 9066

A Concrete Naming Certificate for $\mathsf{InfoGenerationTrace}^{\uparrow}$

The $\mathsf{InfoGenerationTrace}^{\uparrow}$ packet realizes the constructive information generation vision of section 9414.11 as finite NameCert data over visible record rows, residue rows, compatible refinement rows, replay, and provenance. It sits beside the finite tower packet of chapter 1128, the reflection-gap audit route of chapter 7705, and the classifier boundary surface of chapter 595. Those siblings supply tower source rows, audit and gap rows, and visible classifier-boundary discipline; this packet binds them into one generated-information trace before any consumer treats a visible record as the whole source.

Definition 9066.1 (InfoGenerationTrace carrier)**.** *An* $\mathsf{InfoGenerationTrace}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$T = (S, V, L, Q, R, J, H, C, P, N)$$

with the following displayed rows:

1. *S is the source-carrier row, naming the displayed $\mathcal{I}_n$ layer or tower source from which the trace is read.*
2. *V is the visible-record row, recording the generated record exposed to the current consumer.*
3. *L is the ledger row, carrying provenance, gap, audit, and classifier-boundary entries that license V.*
4. *Q is the residue row, recording the remaining source fiber over V rather than collapsing it into the visible record.*
5. *R is the compatible refinement row, naming any readback from a later visible surface to the present one.*
6. *J is the visible-refinement join row, displaying how V, Q, R are consumed together by a downstream generated-information read.*
7. *H records componentwise* hsame *transport for source, visible record, ledger, residue, refinement, join, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay through*

$$S \longrightarrow V \longrightarrow L \longrightarrow Q \longrightarrow R \longrightarrow J.$$

9. *P records provenance over* $\mathsf{InfoGenerationTrace}^{\uparrow}$, $\mathsf{RealityConstrainedTowerPacket}^{\uparrow}$, $\mathsf{ReflectionGapAudit}^{\uparrow}$, $\mathsf{ClassifierBoundary}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* $\mathsf{NameCert}$.

10. *N is the local* $\mathsf{NameCert}_{\mathsf{InfoGenerationTrace}^{\uparrow}}$ *row.*

The classifier compares accepted traces only through $S, V, L, Q, R, J, H, C, P, N$. It has no coordinate for a bare information object, hidden source equality, final physical truth, tower-external information, host semantic completeness, or an unrecorded generation step.

Theorem 9066.2 (InfoGenerationTrace NameCert obligations)**.** *For every accepted* $\mathsf{InfoGenerationTrace}^{\uparrow}$ *carrier*

$$T = (S, V, L, Q, R, J, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{InfoGenerationTrace}^{\uparrow}}$ *surface consists exactly of source admission through S, visible-record exposure through V, audit and gap licensing through L, residue display through Q, compatible refinement through R, visible-refinement joining through J, componentwise transport through H, displayed replay through C, provenance exhaustion through P, and local naming through N.*

Proof. Project the carrier of Definition 9066.1. The accepted packet exposes exactly the rows $S, V, L, Q, R, J, H, C, P, N$, so source admission and visible-record exposure are finite displayed data.

The licensing obligation is supplied by L. It records the provenance, gap, audit, and classifier-boundary entries through which the visible row is admitted, so no bare information object can enter the trace.

The non-exhaustion obligation is supplied by Q and R. The residue row keeps the source fiber visible, while the refinement row records any compatible readback from a later surface to the current visible record.

Finally, J, H, C, P, N join, transport, replay, source, and name the same route. Since the carrier contains no row for hidden source equality, final physical truth, tower-external information, host semantic completeness, or unrecorded generation, the listed obligations exhaust the local NameCert surface. □

Theorem 9066.3 (InfoGenerationTrace visible residue)**.** *Every accepted generated-information read through an* $\mathsf{InfoGenerationTrace}^{\uparrow}$ *carrier must expose the visible row V, residue row Q, refinement row R, replay row C, provenance row P, and local NameCert row N before it exports the generated record. A consumer that reads V while omitting Q or R has read only a visible record, not the full generated-information trace.*

Proof. Start with the source and visible rows S, V. They identify the layer source and the record exposed to the consumer, but they do not contain the residual source family by themselves.

Read the ledger and residue rows L, Q. The ledger licenses the visible row, and the residue row records what remains over that visible record. This is the finite trace counterpart of the residue family in Definition 9414.220.

Read the refinement row R and the join row J. They display how later compatible layers may return to the present visible record without erasing the residue data.

The replay, provenance, and local naming rows C, P, N then export the generated-information trace. Since the carrier has no coordinate for bare objects, hidden source equality, tower-external information, or final truth, omitting Q or R leaves the consumer with an incomplete visible read. □

Falsifiable prediction: Any accepted generated-information read through $\mathsf{InfoGenerationTrace}^{\uparrow}$ must expose visible record, residue, compatible refinement, replay, provenance, and local NameCert rows before exporting the generated record.

Independence witness: constructive-information-generation, belief, generation-trace-adjacent, realityconstrainedtowerpacket, reflection-gap-audit, classifierboundary: $\mathsf{InfoGenerationTrace}^{\uparrow}$ is not bijective to any listed sibling because it binds one visible record to residue and compatible-refinement rows together with audit, replay, provenance, and local NameCert data.

The Lean follow-up file `lean4/BEDC/Derived/InfoGenerationTraceUp/TasteGate.lean` must provide explicit $\mathsf{Nontrivial}\ \mathsf{InfoGenerationTrace}^{\uparrow}$ and $\mathsf{FieldFaithful}\ \mathsf{InfoGenerationTrace}^{\uparrow}$ instances. These instances must preserve the rows $S, V, L, Q, R, J, H, C, P, N$ as distinct fields before a checked carrier-alignment theorem can serve as the TasteGate witness.

Closure status for $\mathsf{NameCert}_{\mathsf{InfoGenerationTrace}^{\uparrow}}$.

Constructive story: An $\mathsf{InfoGenerationTrace}^{\uparrow}$ packet is generated from a source-carrier row, visible-record row, audit and gap ledger row, residue row, compatible-refinement row, visible-refinement join row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{InfoGenerationTrace}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 9066.1, Definition 9066.2, and Definition 9066.3 seed the finite trace packet realizing constructive information generation as visible rows plus residue and refinement data.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{InfoGenerationTrace}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close final physical truth, hidden source equality, tower-external information, host semantic completeness, unrecorded generation steps, Lean verification, axiom-clean audit, or bridge checking.

Upgrade path: Obligation closure requires checked source admission, visible-record exposure, audit and gap licensing, residue display, compatible refinement, visible-refinement joining, transport, replay, provenance, and local naming for BEDC.Derived.InfoGenerationTraceUp.

Chapter 9067

A Concrete Naming Certificate for $\mathsf{CauchyProductCompletionSeal}^{\uparrow}$

Following Bishop and Bridges on constructive analysis, the $\mathsf{CauchyProductCompletionSeal}^{\uparrow}$ packet records the finite product-completion route by which two regular rational Cauchy names expose a product row before any $\mathsf{Real}^{\uparrow}$ multiplication consumer reads a completed seal. It sits after the dyadic arithmetic core of chapter 291, the regular rational readback of chapter 301, the terminal real-name seal of chapter 38, the Cauchy product source of chapter 464, the regular product route of chapter 461, and the product-window route of chapter 2238. The packet names the completion-facing product seal as finite BEDC rows; it does not quotient streams, select product representatives, assert host real equality, use countable choice, or appeal to ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 9067.1 (CauchyProductCompletionSeal carrier)**.** *A* $\mathsf{CauchyProductCompletionSeal}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Z = (L, R, P, B, Q, T, S, H, C, K, N)$$

with the following displayed rows:

1. *L and R are the left and right* $\mathsf{RegSeqRat}^{\uparrow}$ *source rows admitted for product formation.*
2. *P is the* $\mathsf{CauchyProduct}^{\uparrow}$ *product-source row.*
3. *B is the finite product-budget row exposing which tail windows and dyadic tolerances are consumed.*
4. *Q is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *product-tolerance row.*
5. *T is the dyadic tail-stability ledger for the product row.*
6. *S is the* $\mathsf{Real}^{\uparrow}$ *completion-seal handoff row.*
7. *H records componentwise* hsame *transport for the source, product, budget, tolerance, stability, seal, provenance, replay, and naming rows.*
8. *C records displayed* Cont *replay from the source rows through product budget, dyadic tolerance, tail stability, and seal handoff.*
9. *K is the* Pkg *provenance over* $\mathsf{CauchyProductCompletionSeal}^{\uparrow}$, $\mathsf{CauchyProduct}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

10. N is the local $\mathsf{NameCert}_{\mathsf{CauchyProductCompletionSeal}^{\uparrow}}$ *row.*
The carrier has no coordinate for quotient streams, selected representatives, host real equality, countable choice, or ambient completion.

Theorem 9067.2 (CauchyProductCompletionSeal classifier)**.** *Two accepted* $\mathsf{CauchyProductCompletionSeal}^{\uparrow}$ *carriers are classified by the displayed rows $L, R, P, B, Q, T, S, H, C, K, N$. A classifier comparison may identify the product-completion seal only when the source regular names, product-source row, product budget, dyadic tolerance, tail-stability ledger, seal handoff, transport, replay, provenance, and local naming rows are all compared through the same finite packet.*

Proof. Project the carrier of Definition 9067.1. The classifier-visible data are exactly the listed rows.

The structural rows H, C, K, N preserve and name the same source, product, budget, tolerance, stability, and seal coordinates. Since the carrier has no quotient-stream or host-real-equality coordinate, no classifier comparison can use one. □

Theorem 9067.3 (CauchyProductCompletionSeal source admission)**.** *Every accepted* CauchyProductCompletionSe *carrier admits its product source only through the two displayed* $\mathsf{RegSeqRat}^{\uparrow}$ *rows L, R and the* $\mathsf{CauchyProduct}^{\uparrow}$ *row P.*

Proof. Read L, R, P from Definition 9067.1. These are the only rows that can serve as product-source data before the budget row is exposed.

The classifier theorem Definition 9067.2 keeps all source comparisons inside the same finite packet, so no unrecorded product source can enter the seal route. □

Theorem 9067.4 (CauchyProductCompletionSeal product-budget exposure)**.** *Every accepted* CauchyProductComp *carrier exposes the product-budget row B before a completion-facing consumer can read the dyadic tolerance row Q, tail-stability ledger T, or seal handoff S.*

Proof. The carrier definition places B between the product-source row P and the downstream tolerance, stability, and seal rows. The replay row C records that same order as displayed Cont data.

By Definition 9067.2, downstream comparisons preserve B as part of the finite packet. Thus a completion consumer cannot read Q, T, S while bypassing the budget exposure row. □

Theorem 9067.5 (CauchyProductCompletionSeal dyadic tail stability)**.** *Every accepted* CauchyProductCompletion *carrier reads dyadic tail stability through the tolerance row Q and the stability ledger T after the product budget has been exposed.*

Proof. Use Definition 9067.1. The dyadic tolerance is the row Q, and the product-tail stability evidence is the ledger T.

Apply product-budget exposure from Definition 9067.4. It places B before Q and T, so the dyadic tail-stability read is a budgeted finite read rather than a host-level convergence claim. □

Theorem 9067.6 (CauchyProductCompletionSeal completion-seal handoff)**.** *Every* $\mathsf{Real}^{\uparrow}$ *or completion-facing consumer of an accepted* $\mathsf{CauchyProductCompletionSeal}^{\uparrow}$ *carrier reaches the seal row S only after reading $L, R, P, B, Q, T, H, C, K, N$.*

Proof. Start with source admission and product-budget exposure. They place L, R, P before B, and B before the dyadic tolerance and tail-stability rows.

Use dyadic tail stability above. It fixes Q, T as the finite stability route. The structural rows H, C, K, N transport, replay, source, and name that same route before the seal row S is consumed. □

Theorem 9067.7 (CauchyProductCompletionSeal quotient and choice refusal)**.** *No accepted* CauchyProductCompl *carrier exports quotient streams, selected representatives, host real equality, countable choice, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Inspect the carrier of Definition 9067.1. Its rows are exactly source, product, budget, dyadic tolerance, tail stability, seal, transport, replay, provenance, and local naming rows.

The completion-seal handoff of Definition 9067.6 routes every completion-facing read through those rows. The refused objects are not rows of the carrier and are not introduced by H, C, K, N. □

Lean4 (definition) `BEDC.Derived.CauchyProductCompletionSealUp`

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyProductCompletionSeal}^{\uparrow}}$.

Constructive story: A $\mathsf{CauchyProductCompletionSeal}^{\uparrow}$ packet is generated from left and right RegSeqRat source rows, a CauchyProduct source row, product-budget exposure, DyadicRatCore tolerance, tail-stability ledger, Real seal handoff, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert rows.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CauchyProductCompletionSeal}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 9067.1, Definition 9067.2, and the five obligation theorems seed the finite product-completion seal route over regular rational sources, dyadic product budgets, tail stability, and Real-facing handoff rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CauchyProductCompletionSeal}^{\uparrow}}, \mathsf{encodedDef})$

Lean target: `BEDC.Derived.CauchyProductCompletionSealUp`

Bridge status: none

Not claimed: This chapter does not close Real multiplication, quotient stream equality, selected product representatives, countable choice, host real equality, ambient Real completeness, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, classifier preservation, product-budget exposure, dyadic tail stability, completion-seal handoff, refusal, and local naming for BEDC.Derived.CauchyProductCompletionSealUp.

Chapter 9068

A Concrete Naming Certificate for $\mathsf{CarlesonMeasure}^{\uparrow}$

Following Carleson and the Hardy-space boundary embedding tradition, the $\mathsf{CarlesonMeasure}^{\uparrow}$ packet records the finite measure-window surface needed before a Hardy-boundary consumer treats a displayed measure row as Carleson-facing data. It sits after the Hardy-space carrier of chapter 5108, the box geometry of chapter 8988, the event-value substrate of chapter 92, the dyadic tolerance core of chapter 291, and the terminal scalar seal of chapter 38. The packet names only displayed boxes, local measure budgets, Hardy boundary rows, dyadic tolerances, Real scalar seals, transport, replay, provenance, and local naming; it does not assert selected boundary limits, completed measure theory, quotient function equality, global embedding constants, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 9068.1 (Carleson measure carrier)**.** *A* $\mathsf{CarlesonMeasure}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M = (B, H, U, D, E, S, C, P, N)$$

with the following displayed rows:

1. *B is the* $\mathsf{CarlesonBox}^{\uparrow}$ *window row from chapter 8988. It exposes the boundary arc, radial dyadic window, tent footprint, and finite box budget inspected by the measure request.*
2. *H is the* $\mathsf{HardySpace}^{\uparrow}$ *handoff row from chapter 5108. It names the Hardy-boundary source that may consume the same box window.*
3. *U is the* $\mathsf{Measure}^{\uparrow}$ *local mass row from chapter 92. It records only the displayed mass assigned to the box window and the finite event-value route supporting that mass.*
4. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row from chapter 291. It stores the dyadic scale, arc length, radial depth, and comparison tolerance used by the window estimate.*
5. *E is the* $\mathsf{Real}^{\uparrow}$ *scalar seal row from chapter 38. It seals the displayed mass, dyadic window size, and local comparison value after B, H, U, D are visible.*
6. *S records componentwise* hsame *transport for B, H, U, D, E.*
7. *C records displayed* Cont *replay from a boundary embedding request through the box, Hardy handoff, measure mass, dyadic tolerance, and Real seal.*
8. *P is the* Pkg *provenance over* $\mathsf{CarlesonMeasure}^{\uparrow}$, $\mathsf{CarlesonBox}^{\uparrow}$, $\mathsf{HardySpace}^{\uparrow}$, $\mathsf{Measure}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.

9. N is the local $\mathsf{NameCert}_{\mathsf{CarlesonMeasure}^{\uparrow}}$ *row.*
The classifier compares carriers only through $B, H, U, D, E, S, C, P, N$. It has no coordinate for a selected boundary limit, a completed measure algebra, quotient equality of Hardy functions, a global embedding theorem, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 9068.2 (Carleson measure NameCert obligations)**.** *For every accepted* $\mathsf{CarlesonMeasure}^{\uparrow}$ *carrier $M = (B, H, U, D, E, S, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{CarlesonMeasure}^{\uparrow}}$ *surface consists exactly of Carleson-box visibility, Hardy-space handoff visibility, displayed measure-mass visibility, dyadic tolerance visibility, Real scalar sealing, componentwise* hsame *transport, displayed* Cont *replay, package provenance, and local naming. A boundary embedding consumer may read the measure row only after B, H, U, D, E are all public in the same packet.*

Proof. Project the carrier of Definition 9068.1. The displayed tuple exposes exactly the box, Hardy handoff, measure mass, dyadic tolerance, Real seal, transport, replay, provenance, and local naming row.

Read the window rows first. The $\mathsf{CarlesonBox}^{\uparrow}$ row B names the boundary arc and radial window, while the $\mathsf{HardySpace}^{\uparrow}$ row H names the Hardy-boundary source allowed to inspect that same window.

The measure and scalar rows are downstream of the window. The row U supplies only the displayed $\mathsf{Measure}^{\uparrow}$ mass for the box, D supplies the dyadic scale and comparison tolerance, and E seals the resulting scalar reads through $\mathsf{Real}^{\uparrow}$.

Finally the structural rows preserve the displayed route. Since S, C, P, N add only transport, replay, provenance, and naming, the packet has no coordinate for selected boundary limits, completed measure algebras, quotient function equality, global embedding theorems, countable choice, or ambient completeness. □

Theorem 9068.3 (Carleson measure window-embedding handoff)**.** *Every Hardy-boundary embedding request that consumes an accepted* $\mathsf{CarlesonMeasure}^{\uparrow}$ *packet factors through the finite route*

$$\mathsf{CarlesonBox}^{\uparrow} \longmapsto \mathsf{Measure}^{\uparrow} \longmapsto \mathsf{DyadicRatCore}^{\uparrow} \longmapsto \mathsf{HardySpace}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}.$$

In carrier notation, the consumer reads the box window B, local mass row U, dyadic tolerance row D, Hardy handoff H, Real seal E, and the structural rows S, C, P, N. The route is a finite Carleson-window measure handoff, not a proof of the host Carleson embedding theorem, a selected boundary-limit principle, a completed measure construction, a quotient-function equality claim, or an ambient completeness claim.

Proof. Start with the box window. The row B is already a finite $\mathsf{CarlesonBox}^{\uparrow}$ packet, so the measure request begins with displayed boundary geometry rather than an ambient measurable subset.

Next read the local mass and tolerance rows. The $\mathsf{Measure}^{\uparrow}$ row U provides only the mass assigned to that displayed box, and D records the dyadic scale and tolerance used by the comparison.

The Hardy-facing read then passes through H and E. The Hardy handoff is visible only after the box, mass, and tolerance rows have been displayed, and the Real seal records the scalar endpoint of the same route.

Transport, replay, provenance, and local naming preserve the packet. Because no carrier row stores a selected boundary limit, completed measure theory, quotient equality of Hardy functions, global embedding theorem, or ambient completeness principle, no boundary embedding consumer can read those endpoints from the packet. □

Falsifiable prediction: An accepted $\mathsf{CarlesonMeasure}^{\uparrow}$ packet is refuted if a Hardy-boundary embedding consumer reads a measure mass without displaying the Carleson box, Hardy handoff, local MeasureUp mass, dyadic tolerance, Real seal, transport, replay, provenance, and local NameCert rows.

Independence witness: hardy-space, carleson-box, measure, dyadicratcore, real: $\mathsf{CarlesonMeasure}^{\uparrow}$ is not bijective to any listed sibling because it jointly stores box geometry, Hardy handoff, local measure mass, dyadic tolerance, Real scalar sealing, and structural support in one packet.

Closure status for $\mathsf{NameCert}_{\mathsf{CarlesonMeasure}^{\uparrow}}$.

Constructive story: A $\mathsf{CarlesonMeasure}^{\uparrow}$ packet is generated from a CarlesonBox window, HardySpace handoff, MeasureUp local mass row, DyadicRatCore tolerance row, RealUp scalar seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CarlesonMeasure}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 9068.1, Definition 9068.2, and Definition 9068.3 seed the finite Hardy-boundary measure packet over box windows, local masses, dyadic tolerances, Real seals, transport, replay, provenance, and local naming.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CarlesonMeasure}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close selected boundary limits, completed measure theory, quotient function equality, the host Carleson embedding theorem, global embedding constants, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Formal verification requires a Lean carrier and checked NameCert obligations for BEDC.Derived.CarlesonMeasureUp.

Chapter 9069

Cauchy Uniform Continuation NameCert Construction

Bishop-style constructive analysis treats the uniformly continuous extension theorem for completions as a modulus theorem: a map defined on dense rational or dyadic Cauchy data extends only when the same explicit modulus transports regular tails to regular tails. The $\mathsf{CauchyUniformContinuation}^{\uparrow}$ packet records that theorem as finite BEDC NameCert data. It sits after the regular rational names of chapter 301, the terminal real-name seal of chapter 38, and the uniformly continuous completion-extension surface of chapter 3699. The packet names continuation across regular Cauchy completion without quotient completion classes, selected limits, host function extensionality, countable choice, or ambient completeness outside the displayed $\mathsf{Real}^{\uparrow}$ seal.

Definition 9069.1 (Cauchy uniform continuation carrier)**.** *A* $\mathsf{CauchyUniformContinuation}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$U = (D, R, S, E, M, G, T, C, P, N)$$

with the following displayed rows:

1. *D is the dense dyadic or rational source row, recording the finite source observations on which the map is already defined.*
2. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *regular-Cauchy name row produced from the source observations and the requested target precision.*
3. *S is the finite stream-window row that records which source and target Cauchy-name prefixes are inspected.*
4. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *completion-name seal, exposed only after D, R, S have been displayed.*
5. *M is the explicit uniform-continuity modulus row, translating each target precision request into a source-window request.*
6. *G is the graph row for the source map on dense dyadic or regular-Cauchy representatives, scoped by D, R, S, M.*
7. *T records componentwise* hsame *transport for source observations, regular-Cauchy names, stream windows, Real seals, moduli, graph rows, replay, provenance, and local naming.*
8. *C records displayed* Cont *replay from a continuation request through D, R, S, E, M, G, T.*
9. *P is the* Pkg *provenance over* $\mathsf{CauchyUniformContinuation}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$ *rows.*

10. *N is the local* $\mathsf{NameCert}_{\mathsf{CauchyUniformContinuation}^{\uparrow}}$ *row.*

The carrier stores no quotient class of Cauchy names, selected completed value, host function equality, countable-choice selector, trichotomy branch, or ambient completeness principle.

Theorem 9069.2 (Cauchy uniform continuation NameCert obligations)**.** *For an accepted* CauchyUniformContinuati *carrier $U = (D, R, S, E, M, G, T, C, P, N)$, the local NameCert surface consists of exactly the following finite obligations:*

1. *carrier admission, requiring every continuation read to display $D, R, S, E, M, G, T, C, P, N$ before the local name row is public;*
2. *classifier locality, comparing accepted packets only through their displayed dense-source, regular-Cauchy, window, Real-seal, modulus, graph, transport, replay, provenance, and naming rows;*
3. *stability, requiring* hsame *transport to preserve the modulus-controlled tail request and the graph row on the displayed regular-Cauchy windows;*
4. *exactness, requiring the target* $\mathsf{Real}^{\uparrow}$ *seal E to be reached only through the source graph G and the modulus row M applied to D, R, S;*
5. *ledger nonescape, requiring P, N to export no quotient completion class, selected limit, host function equality, countable choice, trichotomy, or ambient completeness principle.*

Proof. Project the carrier of Definition 9069.1. Carrier admission and classifier locality are the visible tuple inventory: a continuation request has no analytic row other than $D, R, S, E, M, G, T, C, P, N$.

For stability, use the displayed hsame row T. It transports dense-source observations, regular-Cauchy names, windows, Real seals, moduli, and graph rows componentwise, so the same target precision request is replayed through the same source-window bound.

For exactness, the modulus row M is the only route from target precision to a source-window request, and the graph row G is scoped by that request. The terminal seal E is therefore downstream of D, R, S, M, G and cannot be read as a detached completed value.

Finally, replay and provenance are exhausted by C, P, N. Since the carrier contains no row for quotient completion classes, selected limits, host function equality, countable choice, trichotomy, or ambient completeness, the local certificate cannot export those objects. □

Theorem 9069.3 (Modulus composition for Cauchy uniform continuations)**.** *Let $U = (D, R, S, E, M, G, T, C, P, N$ and $V = (D', R', S', E', M', G', T', C', P', N')$ be accepted* $\mathsf{CauchyUniformContinuation}^{\uparrow}$ *packets whose target seal of U is the displayed dense-source row consumed by V. Then the composite continuation is controlled by the finite modulus route M followed by M': a target precision request for V first opens the M' source window for V, then opens the M source window for U, and the resulting continuation reaches the final* $\mathsf{Real}^{\uparrow}$ *seal only through the displayed rows of U and V.*

Proof. Start with the target precision request for the second packet V. Its NameCert obligations route that request through the modulus row M' and the displayed source-window, regular-Cauchy, graph, and Real-seal rows of V.

The source row consumed by V is the target seal exported by U. Apply the obligations for U to that intermediate request. The row M opens the required source window for U, and G supplies the dense-source graph only on that window.

Compose the two displayed replay rows C and C'. The combined replay first follows M', then M, and then reads the two graph rows in order before the final seal is public.

The provenance rows P, P' and local names N, N' record only this finite route. Because neither carrier contains quotient completion classes, selected limits, host function equality, countable

choice, trichotomy, or ambient completeness, the composite continuation exports none of those surfaces. □

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyUniformContinuation}\uparrow}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CauchyUniformContinuation}\uparrow}, \mathsf{seed})$

Scope closed: Definition 9069.1, Definition 9069.2, and Definition 9069.3 seed the finite modulus-controlled continuation route across regular Cauchy completion names.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CauchyUniformContinuation}\uparrow}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim quotient completion equality, selected completed values, host function extensionality, countable choice, trichotomy, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, classifier locality, modulus stability, continuation exactness, composition exactness, replay, provenance, and local naming for BEDC.Derived.CauchyUniformContinuationUp.

Constructive story: A $\mathsf{CauchyUniformContinuation}^{\uparrow}$ packet is generated from dense dyadic or rational source rows, RegSeqRat regular-Cauchy names, finite stream windows, a RealUp seal, explicit uniform-continuity moduli, source graph rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 9070

A Concrete Naming Certificate for $\mathsf{KKMLemma}^{\uparrow}$

Following Knaster, Kuratowski, and Mazurkiewicz, the $\mathsf{KKMLemma}^{\uparrow}$ packet records the finite simplex-cover intersection datum behind the KKM lemma as a NameCert carrier. It sits downstream of the finite-cover surface of chapter 6671, the compact metric route of chapter 129, the convex-set carrier of chapter 208, the polytope face ledger of chapter 209, and the finite NameCert cover surfaces used by chapter 8591 and chapter 1472. The packet names only finite face-cover rows, convex-hull membership rows, compact-metric support, intersection-window data, transport, replay, provenance, and local naming; it does not select a host intersection point or import arbitrary open-cover compactness.

Definition 9070.1 (KKM lemma carrier)**.** *A* $\mathsf{KKMLemma}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (S, F, V, C, P_0, M, Q, I, H, R, G, N)$$

with the following displayed rows:

1. *S is the finite simplex inventory row.*
2. *F is the face ledger naming every inspected face and its spanning vertex list.*
3. *V is the vertex-indexed cover row inherited from the* $\mathsf{KKMFiniteCover}^{\uparrow}$ *finite-cover surface.*
4. *C is the* $\mathsf{ConvexSet}^{\uparrow}$ *row certifying convex hull membership for the simplex and each displayed face.*
5. *P_0 is the* $\mathsf{Polytope}^{\uparrow}$ *face-incidence row.*
6. *M is the* $\mathsf{CompactMetric}^{\uparrow}$ *finite compactness support row for the inspected simplex carrier.*
7. *Q is the finite cover-qualification row, asserting that each displayed face is covered by the cells indexed by its own vertices.*
8. *I is the intersection-window row naming the finite subfamily whose common intersection is forced by the face-cover inspection.*
9. *H records componentwise* hsame *transport for the simplex, face, cover, convexity, compactness, qualification, and intersection-window rows.*
10. *R records displayed* Cont *replay through the same finite KKM route.*

11. *G is the* Pkg *provenance over* $\mathsf{KKMLemma}^{\uparrow}$, $\mathsf{KKMFiniteCover}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{ConvexSet}^{\uparrow}$, $\mathsf{Polytope}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
12. *N is the local* $\mathsf{NameCert}_{\mathsf{KKMLemma}^{\uparrow}}$ *row.*

The carrier exports a finite intersection certificate. It contains no coordinate for an externally selected intersection point, quotient equality of closed sets, arbitrary open-cover compactness, countable choice, or ambient completeness.

Theorem 9070.2 (KKM lemma NameCert obligations)**.** *For every accepted* $\mathsf{KKMLemma}^{\uparrow}$ *carrier* $K = (S, F, V, C, P_0, M, Q, I, H, R, G, N)$*, the local* $\mathsf{NameCert}_{\mathsf{KKMLemma}^{\uparrow}}$ *surface consists exactly of the following five finite obligation rows:*

1. *simplex and face admission through S, F, P_0, binding every inspected face to a displayed finite vertex list;*
2. *cover-row admission through V, Q, requiring each face to be covered only by cells indexed by vertices of that face;*
3. *convex and compact support through C, M, exposing convex-hull membership and compact-metric finite support before any intersection-window read;*
4. *intersection-window handoff through I, naming the finite subfamily whose common meet is forced by the face-cover inspection;*
5. *transport, replay, provenance, and local naming through H, R, G, N, with no host point selector, quotient cover equality, arbitrary open-cover compactness, countable choice, or ambient completeness row.*

No local KKM lemma obligation is stored outside these rows.

Proof. Project the carrier row by row. The simplex inventory S, face ledger F, and polytope row P_0 determine the only faces that can be inspected.

Next read the finite-cover route. The cover row V and qualification row Q say that each displayed face is covered by the cells indexed by its own vertices, matching the finite KKM cover surface of chapter 6671.

The convex and compact support rows then bind the geometric read. The $\mathsf{ConvexSet}^{\uparrow}$ row C supplies face-hull membership, and the $\mathsf{CompactMetric}^{\uparrow}$ row M supplies only the displayed finite compactness support.

Finally the intersection-window row I is read after those face-cover checks. Componentwise transport, replay, provenance, and the local NameCert row repack the same finite data, so the obligation surface cannot export a selected host point, quotient cover equality, arbitrary open-cover compactness, countable choice, or ambient completeness. □

Theorem 9070.3 (KKM lemma finite simplex-cover handoff)**.** *Every downstream constructive fixed-point, finite intersection, or compact-convex cover consumer reading an accepted* $\mathsf{KKMLemma}^{\uparrow}$ *carrier factors through the finite route*

$$\mathsf{KKMFiniteCover}^{\uparrow},\quad \mathsf{CompactMetric}^{\uparrow},\quad \mathsf{ConvexSet}^{\uparrow},\quad \mathsf{Polytope}^{\uparrow} \longmapsto S, F, V, C, P_0, M, Q, I, H, R, G, N.$$

The consumer receives a displayed finite simplex-cover intersection window, not a host-selected intersection point, arbitrary compactness theorem, quotient cover equality, countable-choice schedule, or ambient completeness assertion.

Proof. Start from the obligation surface of Definition 9070.2. It orders simplex and face admission before cover qualification, and it keeps the convex and compact support rows visible before I can be inspected.

The finite simplex-face inspection is the only handoff mechanism. For each displayed face, the packet checks the listed vertices, reads the cover cells indexed by those vertices, and records the corresponding intersection-window contribution inside the same BHist packet.

Structural rows preserve that order. The hsame transport row H, Cont replay row R, package row G, and local NameCert row N keep the handoff attached to $\mathsf{KKMFiniteCover}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{ConvexSet}^{\uparrow}$, and $\mathsf{Polytope}^{\uparrow}$ rather than to any external compactness or choice principle. □

Closure status for $\mathsf{NameCert}_{\mathsf{KKMLemma}^{\uparrow}}$.

Constructive story: A $\mathsf{KKMLemma}^{\uparrow}$ packet is generated from a finite simplex inventory, face ledger, vertex-indexed KKM cover row, convex-set support, polytope face incidence, compact-metric support, finite cover qualification, intersection-window data, componentwise transport, displayed replay, package provenance, and local naming.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{KKMLemma}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 9070.1, Definition 9070.2, and Definition 9070.3 seed the finite simplex-cover intersection route over KKMFiniteCoverUp, CompactMetricUp, ConvexSetUp, PolytopeUp, BHist, hsame, Cont, Pkg, and NameCert rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{KKMLemma}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim a host-selected intersection point, arbitrary open-cover compactness, quotient equality of closed sets, countable choice, ambient completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, face-cover exactness, convex and compact support, intersection-window nonescape, structural replay, provenance exhaustion, and local naming for BEDC.Derived.KKMLemmaUp.

Chapter 9071

A Concrete Naming Certificate for $\mathsf{HenkinModel}^{\uparrow}$

Following Henkin and the standard completeness proof tradition, the $\mathsf{HenkinModel}^{\uparrow}$ packet reconstructs the witness construction as finite BEDC NameCert data. It is a local consumer of the first-order syntax surface of chapter 197 and the satisfaction surface of chapter 198; it does not assert a host compactness theorem or a global completeness theorem.

9071.1 Finite Henkin packet

A carried $\mathsf{HenkinModel}^{\uparrow}$ row is a displayed BHist tuple $(S, \Theta, C, W, T, M, \mathsf{Sat}, \rho, \lambda)$. The row S is the $\mathsf{FirstOrder}^{\uparrow}$ signature and formula endpoint source. The row Θ is a finite theory window, consisting only of the named formula endpoints currently admitted by the packet. The row C lists the Henkin constants exposed inside that window, and the row W records the witness obligations tying existential formula endpoints to their displayed witness constants.

The row T is the finite term-model table. Its entries are raw term endpoints read through S, together with the congruence comparisons already visible in the local packet. The row M packages the term-model interpretation rows for relation and function symbols over those endpoints. The row Sat is the satisfaction ledger: each entry names a formula endpoint, an assignment or closed-term environment endpoint, and the truth row read from the finite Henkin window.

Transport is part of the carrier. The comparison ledger λ records the hsame and Cont rows that move the finite theory window, Henkin constants, witness obligations, term-model rows, and satisfaction entries between classifier-related packets. The provenance row ρ records the Pkg source of each displayed row, so a downstream consumer can see whether a formula endpoint came from the first-order syntax certificate, a witness extension row, or a term-model readback.

9071.2 Local certificate surface

The local $\mathsf{NameCert}_{\mathsf{HenkinModel}^{\uparrow}}$ accepts exactly the rows exposed by the finite packet. A witness obligation is accepted when its existential formula endpoint lies in Θ, its witness constant lies in C, and its instantiated formula endpoint is recorded in the same finite window. A term-model row is accepted when every term endpoint and interpretation entry is read through S, T, and M, with provenance still attached to ρ. A satisfaction entry is accepted when it is one of the displayed Sat rows and its formula endpoint is carried by the same $\mathsf{FirstOrder}^{\uparrow}$ source.

Classifier stability is rowwise. If two $\mathsf{HenkinModel}^{\uparrow}$ packets are related by the displayed comparison ledger, then the finite theory windows, constants, witness rows, term-model entries, interpretation rows, satisfaction entries, and provenance rows transport together. No comparison appeals to ambient syntax equality, quotient equality on terms, or a chosen infinite model outside the packet.

The certificate is deliberately local. It records how a finite Henkin window can be named, transported, and consumed as a term-model witness surface. It does not choose a completed infinite theory, take a quotient by a host equivalence relation, invoke countable choice to select witnesses, or derive the global model-existence theorem.

Theorem 9071.1 (Henkin model witness-extension obligations)**.** *Let*

$$H = (S, \Theta, C, W, T, M, \mathsf{Sat}, \rho, \lambda)$$

be an accepted $\mathsf{HenkinModel}^{\uparrow}$ *packet. Every witness-extension row in* W *extends only displayed formula histories already carried by* Θ *through the* $\mathsf{FirstOrder}^{\uparrow}$ *source* S*. If an existential endpoint is not present as a* BHist *formula row in the finite theory window, the local* $\mathsf{NameCert}_{\mathsf{HenkinModel}^{\uparrow}}$ *has no coordinate that can attach a Henkin constant, instantiated formula endpoint, or downstream witness read to it.*

Proof. Project the accepted packet. The finite theory window Θ and the witness ledger W are carried as displayed BHist rows, and both are read through the same first-order syntax source S.

The local certificate admits a witness obligation only when the existential endpoint, its witness constant, and the instantiated formula endpoint are visible in the same finite window. Thus the witness-extension read is a rowwise extension of displayed formula histories.

The structural rows ρ and λ preserve this restriction under provenance and transport. They replay already displayed witness rows, but they do not create constants for formula endpoints absent from Θ. □

Theorem 9071.2 (Henkin model term-model satisfaction scope)**.** *For every accepted* $\mathsf{HenkinModel}^{\uparrow}$ *packet*

$$H = (S, \Theta, C, W, T, M, \mathsf{Sat}, \rho, \lambda),$$

term-model satisfaction is readable only through the displayed $\mathsf{FirstOrder}^{\uparrow}$ *syntax row* S*, the term table* T*, the interpretation table* M*, and the satisfaction ledger* Sat*, with the model-theoretic use scoped by the* $\mathsf{ModelTheory}^{\uparrow}$ *rows named in the packet provenance. The read exports no ambient syntax quotient, no host equality of terms, and no satisfaction relation outside the finite ledger.*

Proof. Begin with the term-model rows. The table T lists only raw term endpoints read through S, and M interprets only the relation and function endpoints visible in the same packet.

Next inspect the satisfaction ledger. Each entry of Sat names a formula endpoint and an environment endpoint, so the model-theoretic read is a finite ledger row rather than a host satisfaction relation.

The provenance row ρ records the $\mathsf{FirstOrder}^{\uparrow}$ and $\mathsf{ModelTheory}^{\uparrow}$ sources, while λ transports the same entries under accepted comparisons. Since no carrier coordinate stores quotient syntax equality or an external model, the satisfaction scope is exactly the displayed packet surface. □

Theorem 9071.3 (Henkin model completeness-facing non-escape)**.** *Every completeness-facing consumer of an accepted* $\mathsf{HenkinModel}^{\uparrow}$ *packet must factor through*

$$S, \Theta, C, W, T, M, \mathsf{Sat}, \rho, \lambda.$$

It may read displayed formula histories, witness constants, term-model rows, satisfaction entries, provenance, and transport. It cannot export a selected infinite model, quotient syntax equality, countable choice, host compactness, or a global completeness theorem from the local packet.

Proof. The consumer first exposes the finite theory window and witness rows. These rows show which formula endpoints are present and which witness constants are attached inside the packet.

It then reads the term-model and satisfaction rows through T, M, Sat. Those rows are finite BHist data, so the consumer receives only the displayed term and formula entries.

Finally ρ and λ supply provenance and transport for the same finite route. Because the carrier contains no coordinate for selected infinite models, quotient syntax equality, countable choice, host compactness, or global completeness, none of those objects can escape from the local certificate. □

Closure status for $\mathsf{NameCert}_{\mathsf{HenkinModel}\uparrow}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{HenkinModel}\uparrow}, \mathsf{seed})$

Scope closed: The chapter seeds the finite Henkin witness packet, its term-model rows, satisfaction ledger, transport rows, provenance rows, and local NameCert surface.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{HenkinModel}\uparrow}, \mathsf{unformalized})$

Bridge status: none

Constructive story: The construction starts from a finite first-order window, adjoins displayed witness constants for accepted existential endpoints, reads closed terms into the term-model table, and records satisfaction only through the resulting finite ledger.

Not claimed: The chapter does not close host compactness, quotient syntax equality, a selected infinite model, countable choice, or global completeness.

Upgrade path: A scoped certificate requires Lean carriers for the finite theory window, Henkin constants, witness obligations, term-model rows, and satisfaction transport.

Chapter 9072

A Concrete Naming Certificate for FiniteIntervalMeshRefinement$^{\uparrow}$

Following Bishop and Bridges, finite interval arguments are read through displayed meshes, endpoint comparisons, and rational tolerances rather than through a completed continuum of hidden subdivision choices. The FiniteIntervalMeshRefinement$^{\uparrow}$ packet sits between the dyadic arithmetic of chapter 291, the compact interval surfaces of chapter 5937, the compact metric finite-net route of chapter 129, the total-boundedness surface of chapter 127, and the terminal real-name seal of chapter 38. It names the finite refinement discipline used by compact interval and dyadic-net consumers without asserting open-cover compactness, selected partitions, or ambient Real$^{\uparrow}$ completeness.

Definition 9072.1 (Finite interval mesh refinement packet)**.** *A* FiniteIntervalMeshRefinement$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M = (I, D, Q, R, U, H, C, P, N)$$

with the following displayed rows:

1. *I is the* CompactInterval$^{\uparrow}$ *endpoint row, displaying the interval source and the endpoint order data used by the mesh read.*
2. *D is the* DyadicRatCore$^{\uparrow}$ *mesh ledger, listing the dyadic breakpoints, dyadic cell radii, endpoint incidence, and finite containment comparisons.*
3. *Q is the refinement map from a coarse finite mesh to the displayed finer mesh, including the finite parent-cell table.*
4. *R is the stability row saying that each refined dyadic cell inherits its endpoint, radius, and incidence rows from the parent cell through the same dyadic comparisons.*
5. *U is the coverage row, recording that the refined mesh covers the same compact interval source and that a downstream* TotallyBounded$^{\uparrow}$ *or* CompactMetric$^{\uparrow}$ *consumer reads only the displayed finite cells.*
6. *H records componentwise* hsame *transport for interval endpoints, dyadic mesh rows, refinement maps, stability rows, coverage rows, replay, provenance, and local naming.*
7. *C records displayed* Cont *replay from an interval-mesh request through I, D, Q, R, U, H.*
8. *P is the* Pkg *provenance over* FiniteIntervalMeshRefinement$^{\uparrow}$, CompactInterval$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, CompactMetric$^{\uparrow}$, TotallyBounded$^{\uparrow}$, Real$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*

9. N is the local $\mathsf{NameCert}_{\mathsf{FiniteIntervalMeshRefinement}^{\uparrow}}$ *row.*

The carrier has no coordinate for an infinite subdivision, a selected limiting mesh, an open-cover choice principle, quotient equality of intervals, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 9072.2 (Finite interval mesh refinement NameCert obligations)**.** *For every accepted* $\mathsf{FiniteIntervalMeshRefinement}^{\uparrow}$ *carrier*

$$M = (I, D, Q, R, U, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{FiniteIntervalMeshRefinement}^{\uparrow}}$ *surface consists exactly of five finite obligation rows:*

1. *carrier admission for the compact interval source I, dyadic mesh ledger D, refinement table Q, stability row R, coverage row U, transport row H, replay row C, provenance row P, and local name N;*
2. *mesh refinement stability, requiring every refined cell in Q to inherit its dyadic endpoint, radius, and incidence rows from a displayed parent cell through R;*
3. *coverage monotonicity, requiring the refined mesh to cover the same interval source as the coarse mesh and to expose no smaller domain when read by a* $\mathsf{CompactMetric}^{\uparrow}$ *or* $\mathsf{TotallyBounded}^{\uparrow}$ *consumer;*
4. hsame *and* Cont *transport, requiring H and C to preserve the same interval source, dyadic rows, refinement table, stability row, coverage row, provenance row, and local name under accepted renamings and replay;*
5. *ledger refusal, requiring the packet to export no infinite subdivision, selected limiting mesh, open-cover choice principle, quotient interval equality, hidden Real selector, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

No finite interval mesh-refinement obligation is stored outside these rows.

Proof. Project the carrier of Definition 9072.1. The interval row I, dyadic ledger D, refinement table Q, stability row R, coverage row U, and structural rows H, C, P, N are the entire displayed packet.

Carrier admission is therefore admission of those rows. Mesh refinement stability is read from Q together with R: each refined cell points to a displayed parent cell, and the endpoint, radius, and incidence data are transported through dyadic comparisons already present in D.

Coverage monotonicity is read from U. The refined mesh may subdivide cells, but it keeps the same compact interval source and the same finite coverage target before any compact metric or totally bounded consumer reads it.

Finally H, C, P, N transport, replay, source, and locally name the same finite route. Since the carrier contains no coordinate for infinite subdivision, selected limiting meshes, open-cover choice, quotient interval equality, hidden Real selectors, or ambient Real completeness, the five listed rows exhaust the local NameCert surface. □

Theorem 9072.3 (Finite interval mesh refinement compact handoff)**.** *Every compact interval, compact metric, totally bounded, dyadic-net, or* $\mathsf{Real}^{\uparrow}$*-facing consumer of an accepted* $\mathsf{FiniteIntervalMeshRefinement}^{\uparrow}$ *packet must read the displayed route*

$$I, D, Q, R, U, H, C, P, N$$

before treating a refined mesh as usable finite data. The handoff is a finite BEDC mesh route, not a selected subdivision limit, not an open-cover compactness theorem, and not an appeal to ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start with the NameCert obligations of Definition 9072.2. They force the refined mesh to expose carrier admission, refinement stability, coverage monotonicity, transport, replay, provenance, local naming, and ledger refusal.

A compact interval or dyadic-net consumer reads I, D, Q, R, U first. These rows display the source interval, dyadic cells, parent-cell table, inherited endpoint data, and coverage ledger.

A compact metric, totally bounded, or Real-facing consumer is downstream of the same displayed route. The rows H, C, P, N preserve and name it without creating a selected limiting partition or a hidden completeness principle. Thus every accepted handoff remains finite and local to the packet. □

Falsifiable prediction: Every accepted $\mathsf{FiniteIntervalMeshRefinement}^{\uparrow}$ read exposes a compact interval source row, dyadic mesh ledger, finite refinement table, stability row, coverage row, hsame transport, Cont replay, provenance, and local NameCert before a compact interval or Real-facing consumer reads the refined mesh.

Independence witness: dyadicratcore, compact-interval, compactmetric, totallybounded, real: no listed sibling simultaneously carries a finite parent-cell refinement table, inherited dyadic endpoint rows, coverage monotonicity, transport, replay, provenance, and local NameCert rows for compact interval mesh refinement.

Closure status for $\mathsf{NameCert}_{\mathsf{FiniteIntervalMeshRefinement}^{\uparrow}}$.

Constructive story: A $\mathsf{FiniteIntervalMeshRefinement}^{\uparrow}$ packet is generated from a compact interval source, a DyadicRatCore mesh ledger, a finite parent-cell refinement table, stability and coverage rows, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{FiniteIntervalMeshRefinement}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 9072.1, Definition 9072.2, and Definition 9072.3 seed the finite compact-interval mesh refinement route from dyadic cell rows to compact and Real-facing consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{FiniteIntervalMeshRefinement}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim open-cover compactness, infinite subdivisions, selected limiting meshes, quotient interval equality, ambient RealUp completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, mesh refinement stability, coverage monotonicity, transport, replay, provenance, and ledger refusal for BEDC.Derived.FiniteIntervalMeshRefinementUp.

Chapter 9073

A Concrete Naming Certificate for $\mathsf{CompactIntervalLipschitzEnvelope}^{\uparrow}$

Following Bishop and Bridges, Lipschitz control on a compact interval is read through finite interval meshes, displayed bounds, and regular rational readback rather than through an ambient supremum over an uninspected continuum. The $\mathsf{CompactIntervalLipschitzEnvelope}^{\uparrow}$ packet sits after the compact metric surface of chapter 129, the continuous-map route of chapter 130, the Lipschitz-map carrier of chapter 410, the regular rational readback surface of chapter 301, and the terminal real-name seal of chapter 38. It realizes the compact interval finite-envelope route without claiming open-cover compactness, ambient $\mathsf{Real}^{\uparrow}$ completeness, or a selected global extremum.

Definition 9073.1 (Compact interval Lipschitz-envelope packet)**.** *A* $\mathsf{CompactIntervalLipschitzEnvelope}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$E = (K, F, L, M, B, R, S, H, C, P, N)$$

with the following displayed rows:

1. *K is the* $\mathsf{CompactMetric}^{\uparrow}$ *compact interval source, including the finite mesh rows accepted by the interval carrier.*
2. *F is the* $\mathsf{ContinuousMap}^{\uparrow}$ *or* $\mathsf{LipschitzMap}^{\uparrow}$ *function row whose values are being bounded.*
3. *L is the finite Lipschitz-bound row, displaying the rational or dyadic bound used to compare values across mesh cells.*
4. *M is the finite mesh row, read through* $\mathsf{FiniteIntervalMeshRefinement}^{\uparrow}$ *or an existing compact interval finite-net sibling when the consumer supplies one.*
5. *B is the envelope row assigning displayed lower and upper rational bounds to each mesh cell.*
6. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the displayed envelope bounds.*
7. *S is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row for envelope values exposed after K, F, L, M, B, R have all been displayed.*
8. *H records componentwise* hsame *transport for compact source rows, map rows, Lipschitz bounds, mesh rows, envelope rows, readback rows, Real seals, replay, provenance, and local naming.*
9. *C records displayed* Cont *replay from an envelope request through K, F, L, M, B, R, S, H.*

10. *P is the* Pkg *provenance over* $\mathsf{CompactIntervalLipschitzEnvelope}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{LipschitzMap}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*
11. *N is the local* $\mathsf{NameCert}_{\mathsf{CompactIntervalLipschitzEnvelope}^{\uparrow}}$ *row.*

The carrier has no coordinate for an uninspected supremum, a selected maximizing point, an open-cover choice principle, quotient function equality, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 9073.2 (Compact interval Lipschitz-envelope NameCert obligations)**.** *For every accepted* $\mathsf{CompactIntervalLipschitzEnvelope}^{\uparrow}$ *carrier*

$$E = (K, F, L, M, B, R, S, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{CompactIntervalLipschitzEnvelope}^{\uparrow}}$ *surface requires exactly the displayed compact interval source K, function row F, finite Lipschitz-bound row L, finite mesh row M, envelope bound row B, regular readback row R, Real seal S, transport H, replay C, provenance P, and local name N. A consumer may read a compact interval envelope only after these rows expose the finite mesh, Lipschitz bound, uniform-modulus handoff,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback, and* $\mathsf{Real}^{\uparrow}$ *seal route.*

Proof. Project the carrier of Definition 9073.1. The source, map, Lipschitz bound, mesh, envelope, readback, seal, and structural rows are the whole packet.

The finite mesh row M is the only place where the interval is inspected. The Lipschitz row L then transports pointwise control across cells, and B records the resulting lower and upper rational envelope bounds.

The readback and seal rows R, S make the envelope usable by regular rational and Real-facing consumers only after the finite rows have been displayed. Rows H, C, P, N preserve, replay, source, and name the same route. Since no additional coordinate is present, the certificate exports no uninspected supremum, selected maximizer, open-cover choice, quotient function equality, or ambient Real completeness. □

Theorem 9073.3 (Compact interval Lipschitz-envelope uniform route)**.** *Every compact-uniform-continuity consumer of an accepted* $\mathsf{CompactIntervalLipschitzEnvelope}^{\uparrow}$ *packet factors through*

$$K, F, L, M, B, R, S, H, C, P, N.$$

The packet supplies finite mesh rows, a Lipschitz bound, envelope bounds, uniform-modulus handoff data, $\mathsf{RegSeqRat}^{\uparrow}$ *readback, and a terminal* $\mathsf{Real}^{\uparrow}$ *seal. It does not supply open-cover compactness, selected extrema, quotient function representatives, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Apply Definition 9073.2. It identifies the carrier rows that must be exposed before an envelope is public.

The compact-uniform-continuity consumer reads K, M as the finite compact interval mesh route and reads F, L as the map and Lipschitz-control route. It then reads B as the finite envelope ledger.

The rows R, S turn that ledger into regular rational readback and a Real-facing seal. The structural rows H, C, P, N keep the route stable under transport and replay. Thus the consumer receives exactly the displayed finite envelope and none of the refused ambient principles. □

Falsifiable prediction: Every accepted $\mathsf{CompactIntervalLipschitzEnvelope}^{\uparrow}$ read exposes compact interval finite mesh rows, a ContinuousMap or LipschitzMap row, a finite Lipschitz bound, envelope bounds, RegSeqRat readback, a RealUp seal, transport, replay, provenance, and local NameCert before a compact-uniform-continuity consumer reads the envelope.

Independence witness: compactmetric, continuousmap, lipschitzmap, regseqrat, real: no listed sibling simultaneously carries compact interval mesh rows, Lipschitz envelope bounds, regular rational readback, Real sealing, transport, replay, provenance, and local NameCert rows for a compact interval envelope.

Closure status for $\mathsf{NameCert}_{\mathsf{CompactIntervalLipschitzEnvelope}^{\uparrow}}$.

Constructive story: A $\mathsf{CompactIntervalLipschitzEnvelope}^{\uparrow}$ packet is generated from a compact interval finite-mesh source, a ContinuousMap or LipschitzMap row, a finite Lipschitz-bound row, envelope bound rows, RegSeqRat readback, a RealUp seal, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CompactIntervalLipschitzEnvelope}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 9073.1, Definition 9073.2, and Definition 9073.3 seed the compact interval Lipschitz-envelope route from finite mesh and Lipschitz rows to RegSeqRat and Real-facing consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CompactIntervalLipschitzEnvelope}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim open-cover compactness, selected extrema, quotient function representatives, ambient RealUp completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked compact-source admission, map admission, Lipschitz-bound stability, finite mesh envelope bounds, RegSeqRat readback, Real sealing, transport, replay, provenance, and ledger refusal for BEDC.Derived.CompactIntervalLipschitzEnvelopeUp.

Chapter 9074

A Concrete Naming Certificate for $\mathsf{BorelMeasure}^{\uparrow}$

Following Halmos and Bourbaki on Borel measures, the $\mathsf{BorelMeasure}^{\uparrow}$ packet records the finite route from a displayed measurable space and its generated Borel event row to a measure value surface. It sits after the measurable-space carrier of chapter 3537, the cover-valued outer-measure boundary of chapter 3385, and the regular-measure consumer surface of chapter 2263. The packet names a Borel-event measure route for downstream Radon and probability consumers; it is not a completed measure algebra, a host sigma-finiteness theorem, a quotient equality of measures, or an ambient standard Borel oracle.

Definition 9074.1 (BorelMeasure carrier)**.** *A* $\mathsf{BorelMeasure}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (X, A, E, O, M, R, H, C, P, N)$$

with the following displayed rows:

1. *X is the underlying measurable-space carrier row read through* $\mathsf{MeasurableSpace}^{\uparrow}$*.*
2. *A is the displayed Borel event-family row over X, read through the generated-event surface already exposed by the measurable-space packet.*
3. *E is the event-admission classifier, recording that every measured event is read through A before any value row is exposed.*
4. *O is the outer-measure boundary row, carrying empty-set, monotonicity, finite-cover, and Caratheodory test data from* $\mathsf{OuterMeasure}^{\uparrow}$*.*
5. *M is the Borel measure value row, assigning displayed real values only to admitted Borel events.*
6. *R is the regular-measure handoff row for consumers that later read the same values through* $\mathsf{RadonMeasure}^{\uparrow}$*.*
7. *H records componentwise* hsame *transport for measurable-space, Borel-event, outer-measure, value, Radon-handoff, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from the Borel event request through event admission, outer-measure boundary, measure value, Radon handoff, provenance, and local naming.*
9. *P is the* Pkg *provenance over* $\mathsf{BorelMeasure}^{\uparrow}$*,* $\mathsf{MeasurableSpace}^{\uparrow}$*,* $\mathsf{OuterMeasure}^{\uparrow}$*,* $\mathsf{RadonMeasure}^{\uparrow}$*,* $\mathsf{Measure}^{\uparrow}$*,* $\mathsf{ProbSpace}^{\uparrow}$*,* BHist*,* hsame*,* Cont*, and* NameCert*.*

10. N is the local $\mathsf{NameCert}_{\mathsf{BorelMeasure}^{\uparrow}}$ *row.*
The carrier has no coordinate for a completed measure algebra, host sigma-finiteness, quotient equality of measures, choice-selected Borel codes, or an ambient standard-model probability space.

Theorem 9074.2 (BorelMeasure NameCert obligations)**.** *For every accepted* $\mathsf{BorelMeasure}^{\uparrow}$ *carrier $B = (X, A, E, O, M, R, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{BorelMeasure}^{\uparrow}}$ *surface consists exactly of carrier admission through the measurable-space row X, Borel-event admission through A and E, outer-measure boundary exposure through O, Borel measure valuation through M, Radon-facing regularity handoff through R, componentwise transport through H, displayed replay through C, provenance through P, and local naming through N.*

Every downstream measure, probability, or Radon consumer must read the Borel event row before the value row. The packet exports no completed measure algebra, host sigma-finiteness theorem, quotient measure equality, choice-selected code enumeration, or ambient standard Borel oracle.

Proof. Project the carrier of Definition 9074.1. The rows $X, A, E, O, M, R, H, C, P, N$ are the entire public surface of the packet.

The measurable-space row X and Borel event rows A, E supply the domain on which value reads are legal. The outer-measure boundary row O is the only route by which finite cover and Caratheodory test data enter the carrier.

The measure value row M is therefore exposed only after Borel event admission and outer-measure boundary data. The Radon handoff row R records a downstream regularity request, but it does not add a host regularity theorem or a completed measure object.

Finally H, C, P, N preserve, replay, source, and name the same finite packet. Since no further coordinate is present, the listed rows exhaust the local NameCert obligation surface. □

Theorem 9074.3 (BorelMeasure measurable-space handoff)**.** *Every accepted* $\mathsf{BorelMeasure}^{\uparrow}$ *packet hands a measure-facing consumer the route*

$$X, A, E, O \longmapsto M \longmapsto R, H, C, P, N$$

where X, A, E are read through chapter 3537, O is read through chapter 3385, and R is the regularity-facing row consumed by chapter 2263. Thus Borel measure values are public only after the measurable-event and outer-measure boundary rows have been displayed.

Proof. Start with the measurable-space carrier. It supplies the underlying point row and generated Borel event family, so the Borel measure packet cannot expose M before X, A, E have been read.

Next use the outer-measure boundary. The row O supplies the finite cover and Caratheodory test data that make the Borel valuation a displayed measure route rather than a host assignment of values to arbitrary subsets.

The Radon handoff row R is downstream from M. Transport, replay, provenance, and local naming through H, C, P, N keep the same order, so a Radon or probability consumer receives only the displayed Borel measure route and no hidden completed measure algebra. □

Falsifiable prediction: A $\mathsf{BorelMeasure}^{\uparrow}$ consumer that reads a measure value M without first exposing the Borel event rows A, E and the outer-measure boundary row O refutes the carrier surface.

Independence witness: measurable-space, outer-measure, radon-measure, measure, probspace: no listed sibling supplies the full ten-row packet $B = (X, A, E, O, M, R, H, C, P, N)$, because each

sibling contributes only event admission, cover boundary, regularity, value, or normalization data while this chapter binds the Borel measure route with transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{BorelMeasure}^{\uparrow}}$.

Constructive story: A $\mathsf{BorelMeasure}^{\uparrow}$ packet is generated from measurable-space carrier rows, Borel event rows, event admission, outer-measure boundary data, Borel measure values, Radon handoff rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert rows.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BorelMeasure}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 9074.1, Definition 9074.2, and Definition 9074.3 seed the finite Borel measure route over measurable-space, Borel-event, outer-measure, value, Radon-handoff, transport, replay, provenance, and local naming rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BorelMeasure}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close measure completion, sigma-finiteness, quotient measure equality, selected Borel code enumeration, probability normalization, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, Borel-event exposure, outer-measure boundary coverage, Borel value exactness, Radon handoff, transport, replay, provenance, and local naming for BEDC.Derived.BorelMeasureUp.

Chapter 9075

A Concrete Naming Certificate for $\mathsf{SolenoidPhase}^{\uparrow}$

Following Pontryagin duality and the classical theory of solenoids, the $\mathsf{SolenoidPhase}^{\uparrow}$ packet records the finite phase carrier associated to an S-localized integer row and its compact inverse-limit circle presentation. It realizes the solenoid carrier described in section 9413.63 as concrete NameCert data, reading prime rows from chapter 64, visible circle phase rows from chapter 4010 and chapter 58, and compact group operation rows from chapter 204. The packet names only displayed localization, circle projection, compact fibre, resonance phase, transport, replay, provenance, and local naming rows; it does not assert a zeta zero theorem, a hidden Pontryagin-dual object, quotient equality of characters, or an ambient compactness principle.

Definition 9075.1 (SolenoidPhase carrier)**.** *A* $\mathsf{SolenoidPhase}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (P, L, Q, V, F, R, H, C, G, N)$$

with the following displayed rows:

1. *P is the displayed prime-family row, read through* $\mathsf{Prime}^{\uparrow}$*, naming the finite prime set or prime-window source whose elements are made invertible.*
2. *L is the S-localization row for the integer carrier, recording the denominators whose prime divisors are constrained by P.*
3. *Q is the compact solenoid phase row, read as the dual or inverse-limit phase carrier generated by L.*
4. *V is the visible circle projection row, routed through the* $\mathsf{Circle}^{\uparrow}$ *and* $\mathsf{S}^{1\uparrow}$ *phase surfaces.*
5. *F is the compact fibre row, recording the kernel of the visible projection without naming a hidden quotient space.*
6. *R is the resonance phase row, carrying the displayed prime-local phase coordinates consumed by the solenoid Lee–Yang route.*
7. *H records componentwise* hsame *transport for prime-family, localization, compact phase, circle projection, fibre, resonance, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from prime-family selection through localization, compact solenoid phase, visible circle projection, fibre, resonance row, provenance, and local naming.*

9. *G is the* Pkg *provenance over* $\mathsf{SolenoidPhase}^{\uparrow}$, $\mathsf{Prime}^{\uparrow}$, $\mathsf{Circle}^{\uparrow}$, $\mathsf{S}^{1\uparrow}$, $\mathsf{TopGroup}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

10. *N is the local* $\mathsf{NameCert}_{\mathsf{SolenoidPhase}^{\uparrow}}$ *row.*

The carrier has no coordinate for a host Pontryagin-dual construction, an undisplayed character group, quotient equality of phase points, a zeta-zero locator, or a noncompact positive scale.

Theorem 9075.2 (SolenoidPhase NameCert obligations)**.** *For every accepted* $\mathsf{SolenoidPhase}^{\uparrow}$ *carrier* $S = (P, L, Q, V, F, R, H, C, G, N)$*, the local* $\mathsf{NameCert}_{\mathsf{SolenoidPhase}^{\uparrow}}$ *surface consists exactly of prime-family admission through P, S-localization exposure through L, compact solenoid phase admission through Q, visible circle projection through V, compact fibre exposure through F, resonance phase exposure through R, componentwise transport through H, displayed replay through C, provenance through G, and local naming through N.*

Every solenoid-facing resonance consumer must read the localization and visible circle projection before the resonance phase row is public. The packet exports no hidden Pontryagin-dual carrier, quotient character equality, zeta-zero theorem, ambient compactness principle, or noncompact scale coordinate.

Proof. Project the carrier of Definition 9075.1. The rows $P, L, Q, V, F, R, H, C, G, N$ are the only rows available to a consumer.

The prime-family row P and localization row L supply the arithmetic source. The compact solenoid phase row Q, visible projection row V, and compact fibre row F are then displayed before the resonance row R can be consumed.

The structural rows H, C, G, N transport, replay, source, and name the same finite packet. Since no coordinate stores a hidden character group, quotient phase equality, zeta-zero locator, or noncompact scale, the listed rows exhaust the local NameCert obligation surface. □

Theorem 9075.3 (SolenoidPhase resonance handoff)**.** *Every accepted* $\mathsf{SolenoidPhase}^{\uparrow}$ *packet hands a resonance consumer the route*

$$P, L \longmapsto Q, V, F \longmapsto R, H, C, G, N$$

where P is read through chapter 64, V is read through the circle phase rows of chapter 4010 and chapter 58, and Q, V, F are compatible with the topological-group operation surface of chapter 204. Thus the resonance phase row is public only after the displayed localization, compact phase, visible circle, and compact fibre rows have been exposed.

Proof. Start with the arithmetic source. The prime-family row P fixes the admitted prime directions, and the localization row L records exactly which denominator primes can appear.

Next expose the compact phase carrier. The solenoid row Q is read together with its visible circle projection V and compact fibre F, so a resonance consumer cannot treat the phase as a noncompact positive scale or as an undisplayed character group.

Finally read R, H, C, G, N. The resonance row R is downstream from the localization and compact phase rows, while transport, replay, provenance, and local naming preserve that order. Hence the handoff is a finite phase certificate, not a proof of the zeta-specific dominance theorem. □

Falsifiable prediction: A $\mathsf{SolenoidPhase}^{\uparrow}$ consumer that reads a resonance phase row R without first exposing the prime-family row P, localization row L, visible circle projection V, and compact fibre row F refutes the carrier surface.

Independence witness: prime, circle, s1, topgroup: no listed sibling supplies the full ten-row packet $S = (P, L, Q, V, F, R, H, C, G, N)$, because each sibling contributes only prime admission, visible phase, group operation, or compactness-facing data while this chapter binds the solenoid phase route with transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{SolenoidPhase}\uparrow}$.

Constructive story: A $\mathsf{SolenoidPhase}^{\uparrow}$ packet is generated from prime-family rows, localization rows, compact solenoid phase rows, visible circle projection rows, compact fibre rows, resonance phase rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert rows.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{SolenoidPhase}\uparrow}, \mathsf{seed})$

Scope closed: Definition 9075.1, Definition 9075.2, and Definition 9075.3 seed the finite solenoid phase route over prime-family, localization, compact phase, visible circle, fibre, resonance, transport, replay, provenance, and local naming rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{SolenoidPhase}\uparrow}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close the zeta solenoid Lee–Yang row, zeta-zero classification, host Pontryagin duality, quotient character equality, noncompact positive scale exclusion, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, localization exposure, compact phase admission, visible circle projection, compact fibre exposure, resonance handoff, transport, replay, provenance, and local naming for BEDC.Derived.SolenoidPhaseUp.

Chapter 9076

A Concrete Naming Certificate for $\mathsf{FrobeniusCharacterFormula}^{\uparrow}$

Following Serre and Fulton–Harris on finite-group characters, the $\mathsf{FrobeniusCharacterFormula}^{\uparrow}$ packet records the finite value formula for an induced character as NameCert data. It consumes the finite group and subgroup sources of chapter 41 and chapter 80, the finite representation row of chapter 3662, the induced-character packet of chapter 7757, the character-table consumer of chapter 3574, and the reciprocity comparison surface of chapter 5806. The packet names only the displayed coset-filtered summation rule, its conjugacy stability, its finite table handoff, and its reciprocity-facing provenance.

Definition 9076.1 (FrobeniusCharacterFormula carrier)**.** *A* $\mathsf{FrobeniusCharacterFormula}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$\mathcal{F} = (G, H, Q, V, \theta, \chi, \sigma, \eta, \tau, \rho, \lambda, P, N)$$

with the following displayed rows:

1. *G is the consumed* $\mathsf{NameCert}_{\mathsf{Group}^{\uparrow}}$ *row naming the finite group source.*
2. *H is the consumed* $\mathsf{NameCert}_{\mathsf{Subgroup}^{\uparrow}}$ *row naming the subgroup inclusion inside G.*
3. *Q is the finite coset ledger whose accepted rows are used as the only summation indices.*
4. *V is the consumed* $\mathsf{NameCert}_{\mathsf{FiniteGroupRepresentation}^{\uparrow}}$ *row whose restricted trace supplies the source character on H.*
5. *θ is the source character value row on H.*
6. *χ is the consumed* $\mathsf{NameCert}_{\mathsf{InducedCharacter}^{\uparrow}}$ *row naming the induced character to be evaluated.*
7. *σ is the displayed finite formula ledger: for each accepted group element row g, it lists exactly those accepted coset rows q whose transported element row lies in H, and it assigns the finite sum of the corresponding θ values to $\chi(g)$.*
8. *η is the representative-independence row, recording that* hsame *replacement of accepted coset rows in Q preserves the displayed summand ledger.*
9. *τ is the conjugacy-stability row, recording that the value row is transported through conjugation in G as a class-function value.*
10. *ρ is the* $\mathsf{NameCert}_{\mathsf{FrobeniusReciprocity}^{\uparrow}}$ *provenance row that lets reciprocity consumers read the same induction–restriction boundary.*

11. *λ is the downstream consumer ledger for* $\mathsf{CharacterTable}^{\uparrow}$, $\mathsf{InducedCharacter}^{\uparrow}$, *and* $\mathsf{FrobeniusReciprocity}^{\uparrow}$ *reads.*
12. *P is the* Pkg *provenance over the consumed rows,* BHist, hsame, Cont, *and* NameCert.
13. *N is the local* $\mathsf{NameCert}_{\mathsf{FrobeniusCharacterFormula}^{\uparrow}}$ *row.*

The carrier contains no irreducible decomposition, no quotient-character row, no host representation category, and no selected coset representatives outside the displayed ledger Q.

Theorem 9076.2 (FrobeniusCharacterFormula NameCert obligations)**.** *For every accepted* FrobeniusCharacterForm *packet*

$$\mathcal{F} = (G, H, Q, V, \theta, \chi, \sigma, \eta, \tau, \rho, \lambda, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{FrobeniusCharacterFormula}^{\uparrow}}$ *surface consists exactly of the following six finite obligations:*

1. *carrier admission exposes precisely the rows listed in Definition 9076.1;*
2. *subgroup admissibility checks every summand of σ against the consumed* $\mathsf{NameCert}_{\mathsf{Subgroup}^{\uparrow}}$ *row H inside the same* $\mathsf{NameCert}_{\mathsf{Group}^{\uparrow}}$ *source G;*
3. *source-character routing requires every summand value to be read through θ and the finite representation row V;*
4. *representative independence is the row η, so changing an accepted coset representative by* hsame *changes only the displayed index, not the named value row;*
5. *conjugacy stability is the row τ, so the formula exports a class-function value row to character-table consumers;*
6. *reciprocity provenance requires every comparison read to pass through ρ and the Frobenius reciprocity boundary named by chapter 5806.*

Proof. Project the carrier of Definition 9076.1. The tuple $\mathcal{F}$ already displays the group, subgroup, coset, representation, source-character, induced-character, formula, stability, reciprocity, consumer, provenance, and local naming rows, giving carrier admission.

Subgroup admissibility and source-character routing are checked on each listed summand of σ. The admissibility test reads only the row H inside G, and the summand value reads only θ through the finite representation row V.

Representative independence is exactly the row η. It compares two accepted rows of the same finite coset ledger Q by hsame transport and leaves the subgroup test and source-character value row unchanged.

Conjugacy stability is the row τ. It transports the displayed group element row through conjugation in G and repacks the same formula value as the class-function row consumed by $\mathsf{CharacterTable}^{\uparrow}$.

Finally, ρ supplies the reciprocity-facing provenance. Repacking these projected rows with λ, P, and N gives exactly the six listed NameCert obligations and no additional host character theory. □

Theorem 9076.3 (FrobeniusCharacterFormula induced value route)**.** *Any* $\mathsf{InducedCharacter}^{\uparrow}$ *or* $\mathsf{CharacterTable}^{\uparrow}$ *consumer of an accepted* $\mathsf{FrobeniusCharacterFormula}^{\uparrow}$ *packet may read the induced value at a displayed group row only through*

$$G,\ H,\ Q,\ V,\ \theta,\ \chi,\ \sigma,\ \eta,\ \tau,\ \lambda.$$

It may not import an irreducible decomposition, a host representation category, a quotient-character row, or a coset representative outside Q.

Proof. Route the consumer request through the local packet. The group and subgroup boundary is supplied by G and H, and the only indexing surface is the finite coset ledger Q.

The source values are read through V and θ. The induced-character name is χ, and the value itself is the finite formula row σ.

The independence and table-facing stability checks are η and τ. The downstream read is recorded by λ, so no other row of $\mathcal{F}$ can supply an irreducible decomposition, host representation category, quotient character, or external representative selector. □

Closure status for $\mathsf{NameCert}_{\mathsf{FrobeniusCharacterFormula}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{FrobeniusCharacterFormula}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 9076.1, Definition 9076.2, and Definition 9076.3 seed the finite induced-character value formula over displayed $\mathsf{Group}^{\uparrow}$, $\mathsf{Subgroup}^{\uparrow}$, $\mathsf{FiniteGroupRepresentation}^{\uparrow}$, $\mathsf{InducedCharacter}^{\uparrow}$, $\mathsf{CharacterTable}^{\uparrow}$, and $\mathsf{FrobeniusReciprocity}^{\uparrow}$ rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{FrobeniusCharacterFormula}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close irreducible decomposition, host representation categories, quotient characters, selected coset representatives outside the displayed ledger, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, subgroup admissibility, source-character routing, representative independence, conjugacy stability, and reciprocity provenance for the same finite packet.

Constructive story: A $\mathsf{FrobeniusCharacterFormula}^{\uparrow}$ packet is generated from finite group and subgroup sources, a finite coset ledger, a represented source character, an induced-character row, a displayed finite formula ledger, representative-independence and conjugacy-stability rows, reciprocity provenance, downstream consumer rows, package provenance, and a local NameCert row.

Chapter 9077

A Concrete Naming Certificate for $\mathsf{FloydWarshallClosure}^{\uparrow}$

Following Floyd and Warshall, finite all-pairs shortest-path closure is read here as a stage-indexed matrix certificate rather than as an ambient graph-theoretic oracle. The $\mathsf{FloydWarshallClosure}^{\uparrow}$ packet sits after the finite graph rows of chapter 118, the single-path ledger of chapter 236, the matrix surface of chapter 49, the finite order and natural-stage rows of $\mathsf{Order}^{\uparrow}$ and $\mathsf{Nat}^{\uparrow}$, and the nonnegative weight seal of $\mathsf{Real}^{\uparrow}$. It records the all-pairs closure route consumed by finite algorithm certificates, not negative-cycle detection, choice of a canonical path representative, quotient equality of paths, or ambient completeness of weights.

Definition 9077.1 (FloydWarshallClosure certificate)**.** *A* $\mathsf{FloydWarshallClosure}^{\uparrow}$ *certificate is a finite* BHist *packet*

$$F = (G, W, D, K, R, H, C, P, N)$$

with the following displayed rows:

1. *G is the finite* $\mathsf{Graph}^{\uparrow}$ *row listing vertices and directed edge incidence.*
2. *W is the nonnegative weight row, read through* $\mathsf{Real}^{\uparrow}$ *and the finite order surface of* $\mathsf{Order}^{\uparrow}$*.*
3. *D is the distance-matrix row, read as a finite* $\mathsf{Mat}^{\uparrow}$ *table indexed by ordered vertex pairs.*
4. *K is the* $\mathsf{Nat}^{\uparrow}$ *intermediate-vertex stage index, displaying the finite order in which vertices are admitted as possible internal nodes.*
5. *R is the relaxation table; its k, i, j entry records the displayed comparison between the old distance D_{ij} and the routed candidate $D_{ik} + D_{kj}$.*
6. *H records componentwise* hsame *transports for the graph, weight, matrix, stage, and relaxation rows.*
7. *C records displayed* Cont *replays of the finite relaxation passes.*
8. *P is the* Pkg *provenance over* $\mathsf{FloydWarshallClosure}^{\uparrow}$*,* $\mathsf{Graph}^{\uparrow}$*,* $\mathsf{ShortestPath}^{\uparrow}$*,* $\mathsf{Mat}^{\uparrow}$*,* $\mathsf{Order}^{\uparrow}$*,* $\mathsf{Nat}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*,* BHist*,* hsame*,* Cont*, and* NameCert*.*
9. *N is the local* $\mathsf{NameCert}_{\mathsf{FloydWarshallClosure}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $G, W, D, K, R, H, C, P, N$. It has no coordinate for an infinite graph, a selected global path representative, a negative-cycle oracle, quotient path equality, or an ambient real-completeness principle.

Theorem 9077.2 (FloydWarshallClosure NameCert obligations)**.** *For every accepted* $\mathsf{FloydWarshallClosure}^{\uparrow}$ *certificate* $F = (G, W, D, K, R, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{FloydWarshallClosure}^{\uparrow}}$ *surface consists exactly of finite graph admission, nonnegative weight exposure, matrix-entry exposure, intermediate-stage admission, relaxation-table exactness, componentwise transport, continuation replay, package provenance, and local naming. Every all-pairs shortest-path consumer must read those rows before interpreting the matrix* D *as a closed distance table.*

Proof. Project the certificate of Definition 9077.1. The rows G, W, D, K, R are the only graph, weight, distance-matrix, stage, and relaxation data available to a consumer.

The relaxation obligation is finite because K lists the displayed intermediate vertices and D is a finite $\mathsf{Mat}^{\uparrow}$ table over ordered vertex pairs. For each k, i, j, the row R stores the comparison between the previous entry and the route through k, so no hidden shortest-path oracle is needed.

Transport and replay preserve the same displayed rows. Componentwise hsame through H cannot add a new graph, weight, or path representative, and the Cont replay through C only replays the listed relaxation passes.

Finally P and N source and name the same finite packet. Since the carrier contains no infinite graph, negative-cycle oracle, quotient path equality, selected representative, or ambient completeness row, the local NameCert surface is exactly the displayed all-pairs closure certificate. □

Theorem 9077.3 (FloydWarshallClosure induction invariant)**.** *Let* $F = (G, W, D, K, R, H, C, P, N)$ *be an accepted* $\mathsf{FloydWarshallClosure}^{\uparrow}$ *certificate. Inducting over the displayed intermediate-vertex row* K*, after the stage prefix* k *every matrix entry in* D *records the least displayed route whose internal vertices are drawn from that prefix, as witnessed by the relaxation entries of* R *and the nonnegative weight comparisons in* W*. The invariant is transported only through* H *and replayed only through* C*.*

Proof. At the empty stage prefix, the matrix row D reads only the direct graph edges and diagonal entries exposed by G and W. The order and nonnegativity rows make each base comparison visible without selecting an external path representative.

For the successor stage, expose the next intermediate vertex from K. For each ordered pair i, j, the relaxation row R compares the previous entry with the displayed routed candidate through that vertex. The finite order row decides which displayed entry is retained in the certificate table.

The induction step is componentwise over the matrix indices. Because the matrix is finite, the proof rebuilds the invariant entry-by-entry, using only rows already present in G, W, D, K, R.

Transport through H and replay through C preserve that finite inventory. They cannot introduce a hidden path oracle, quotient path equality, or ambient real-completeness principle, so the induction invariant remains the displayed Floyd-Warshall stage invariant. □

Theorem 9077.4 (FloydWarshallClosure shortest-path handoff)**.** *Every* $\mathsf{ShortestPath}^{\uparrow}$ *or finite algorithm consumer of an accepted* $\mathsf{FloydWarshallClosure}^{\uparrow}$ *certificate must read the route*

$$G, W, D, K, R, H, C, P, N$$

before using any all-pairs distance entry. The handoff interprets each selected source-target entry of D *through the finite graph row, nonnegative weight row, stage induction row, and relaxation table, not through a detached Dijkstra ledger, Bellman–Ford ledger, quotient path equality, or selected global path representative.*

Proof. Begin with the NameCert obligations of Definition 9077.2. They require every consumer to expose the graph, weight, matrix, stage, relaxation, transport, replay, provenance, and naming rows before the matrix can be read as closed.

Apply the induction invariant of Definition 9077.3. It identifies each matrix entry after the final stage as the result of the finite relaxation pass over the displayed intermediate-vertex row K.

A $\mathsf{ShortestPath}^{\uparrow}$ consumer can therefore project a single source-target entry only after the all-pairs closure route has been read. The projected entry remains tied to $G, W, D, K, R, H, C, P, N$.

The packet has no coordinate for a detached single-source ledger, a selected global path representative, quotient path equality, negative-cycle detection, or ambient completeness of weights. Thus the shortest-path handoff is the displayed finite closure certificate itself. □

Falsifiable prediction: Every accepted $\mathsf{FloydWarshallClosure}^{\uparrow}$ all-pairs read exposes one finite Graph row, one nonnegative weight row, one Matrix distance table, one Nat stage row, one relaxation table, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming before a shortest-path consumer reads a distance entry.

Independence witness: graph, shortestpath, matrix, order, nat, real: $\mathsf{FloydWarshallClosure}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries the finite all-pairs distance matrix, the displayed intermediate-stage row, and the relaxation table in one NameCert packet.

Closure status for $\mathsf{NameCert}_{\mathsf{FloydWarshallClosure}^{\uparrow}}$.

Constructive story: A $\mathsf{FloydWarshallClosure}^{\uparrow}$ packet is generated from a finite graph row, nonnegative weight row, finite distance matrix, intermediate-vertex stage index, relaxation table, componentwise transport, continuation replay, provenance, and local naming.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{FloydWarshallClosure}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 9077.1, Definition 9077.2, Definition 9077.3, and Definition 9077.4 seed the finite all-pairs shortest-path closure certificate and its handoff to shortest-path consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{FloydWarshallClosure}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close negative-cycle detection, selected global path representatives, quotient path equality, ambient real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, relaxation-table exactness, stage induction, transport stability, replay stability, provenance, and local naming for BEDC.Derived.FloydWarshallClosureUp.

Chapter 9078

A Concrete Naming Certificate for FiniteNetSelectionPrinciple$^{\uparrow}$

Following Bishop and Bridges on constructive compactness and total boundedness, the FiniteNetSelectionPrinciple$^{\uparrow}$ packet records finite net selection as displayed interval or metric data rather than as an open-cover compactness principle. It sits after the finite interval mesh discipline of chapter 9072, the modulus-controlled completion route of chapter 9069, and the density window surface of chapter 1809. The packet supplies the Real and Completion corridor with an L10 selector object for finite dyadic nets, without claiming a host choice function, selected Cauchy limits, Heine–Borel compactness, or ambient Real$^{\uparrow}$ completeness.

Definition 9078.1 (Finite net selection principle carrier)**.** *A* FiniteNetSelectionPrinciple$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (X, L, M, Q, W, R, T, H, C, P, N)$$

with the following displayed rows:

1. *X is the certified located interval or located metric source row whose points may be inspected only through displayed finite probes.*
2. *L is the locatedness row, giving the interval endpoint or metric-ball witness used to decide finite covering incidence.*
3. *M is the finite dyadic mesh or finite metric-net row, read through* FiniteIntervalMeshRefinement$^{\uparrow}$ *when the source is an interval and through the accepted total-bounded or compact-metric net row when the source is metric.*
4. *Q is the finite selector table assigning each requested dyadic or metric tolerance to a displayed finite list of net centers.*
5. *W is the mesh monotonicity row, saying that a sharper requested tolerance refines the previous finite selector table through displayed parent-cell or parent-ball incidence.*
6. *R is the cover soundness row, recording that every admitted source probe is covered by one displayed net center at the requested tolerance.*
7. *T is the selector stability row, requiring* hsame *transport to preserve source rows, located witnesses, mesh rows, selector tables, monotonicity rows, cover rows, replay, provenance, and local naming.*
8. *H records componentwise* hsame *transport for the displayed selector route.*

9. *C records displayed* Cont *replay from a finite-net request through X, L, M, Q, W, R, T, H.*
10. *P is the* Pkg *provenance over* FiniteNetSelectionPrinciple$^{\uparrow}$, FiniteIntervalMeshRefinement$^{\uparrow}$, CauchyUniformContinu RealSeparability$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*
11. *N is the local* $\mathsf{NameCert}_{\mathsf{FiniteNetSelectionPrinciple}^{\uparrow}}$ *row.*

The carrier has no coordinate for an infinite open cover, a global choice function, a selected limit point, quotient completion equality, countable choice, or ambient Real$^{\uparrow}$ *completeness.*

Lean4 (statement) `BEDC.Derived.FiniteNetSelectionPrincipleUp`

Theorem 9078.2 (Finite net selection principle obligations)**.** *For every accepted* FiniteNetSelectionPrinciple$^{\uparrow}$ *carrier*

$$S = (X, L, M, Q, W, R, T, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{FiniteNetSelectionPrinciple}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the source X, locatedness witness L, mesh or net row M, selector table Q, monotonicity row W, cover row R, selector stability row T, transport row H, replay row C, provenance row P, and local name N;*
2. *classifier locality, comparing accepted selectors only through the displayed located source, finite mesh or net, selector table, monotonicity, cover, stability, transport, replay, provenance, and naming rows;*
3. *mesh monotonicity, requiring sharper tolerances to refine the selected finite net through the parent-cell or parent-ball incidence recorded in W;*
4. *cover soundness, requiring every admitted located source probe to be covered by a displayed net center before a Real or Completion consumer reads the selector;*
5. *selector stability, requiring T, H, C, P, N to preserve, replay, source, and locally name the same finite selector route under accepted renamings.*

No finite net selector obligation is stored outside these rows.

Proof. Project the carrier of Definition 9078.1. The source row, locatedness row, mesh or net row, selector table, monotonicity row, cover row, and structural rows are the whole displayed packet.

Carrier admission and classifier locality are therefore row inventory facts. A consumer can compare two accepted selectors only by reading $X, L, M, Q, W, R, T, H, C, P, N$, so no hidden open-cover or choice coordinate can enter the classifier.

Mesh monotonicity is read from W. A sharper tolerance may subdivide interval cells or metric balls, but the refinement must point back to displayed parent incidence in the same finite route.

Cover soundness is read from R. The selected net is usable only after every admitted located probe has a displayed center at the requested tolerance.

Finally T, H, C, P, N transport, replay, source, and locally name the same finite route. Since the carrier contains no row for infinite covers, global choice functions, selected limits, quotient completion equality, countable choice, or ambient Real completeness, the listed rows exhaust the local NameCert surface. □

Theorem 9078.3 (Finite net selection principle ledger)**.** *Every Real or Completion consumer of an accepted* FiniteNetSelectionPrinciple$^{\uparrow}$ *packet must read the finite route*

FiniteIntervalMeshRefinement$^{\uparrow}$ $\longmapsto$ FiniteNetSelectionPrinciple$^{\uparrow}$ $\longmapsto$ CauchyUniformContinuation$^{\uparrow}$ $\longmapsto$ RealSeparabilit

through the displayed rows $X, L, M, Q, W, R, T, H, C, P, N$ before it treats a finite net as available selector data. The ledger exports a finite dyadic or metric net handoff; it exports no classical open-cover compactness theorem, no choice-based Heine–Borel principle, no selected Cauchy limit, and no ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start with the NameCert obligations of Definition 9078.2. They force every selector read to expose the located source, finite mesh or net, selector table, monotonicity, cover, stability, transport, replay, provenance, and local naming rows.

The interval-facing branch reads M through chapter 9072. Thus dyadic refinement data remain finite parent-cell data before any selector table is public.

The completion-facing branch then reads continuation requests through chapter 9069. The selector table can be used only as a finite window for a modulus-controlled Cauchy route, not as a detached completed value.

The Real-facing density branch reads chapter 1809 only after the selector has displayed its net centers and cover row. Hence the consumer receives finite density windows and not a host dense subset, a countable-choice enumeration, or an ambient compactness theorem. □

Falsifiable prediction: Every accepted $\mathsf{FiniteNetSelectionPrinciple}^{\uparrow}$ read exposes a located interval or metric source row, locatedness witness, finite dyadic mesh or metric-net row, selector table, mesh monotonicity row, cover soundness row, selector stability row, hsame transport, Cont replay, provenance, and local NameCert before a Real or Completion consumer reads finite-net selector data.

Independence witness: finite-interval-mesh-refinement, cauchy-uniform-continuation, real-separability: no listed sibling simultaneously carries located source witnesses, finite selector tables, mesh monotonicity, cover soundness, selector stability, completion continuation handoff, density-window handoff, transport, replay, provenance, and local NameCert rows for constructive finite-net selection.

Closure status for $\mathsf{NameCert}_{\mathsf{FiniteNetSelectionPrinciple}^{\uparrow}}$.

Constructive story: A $\mathsf{FiniteNetSelectionPrinciple}^{\uparrow}$ packet is generated from a certified located interval or metric source, a locatedness witness, a finite dyadic mesh or metric-net row, a finite selector table, mesh monotonicity, cover soundness, selector stability, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{FiniteNetSelectionPrinciple}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 9078.1, Definition 9078.2, and Definition 9078.3 seed the finite selector route for located interval and metric finite-net reads in the Real and Completion corridor.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{FiniteNetSelectionPrinciple}^{\uparrow}}, \mathsf{formalTarget})$

Lean target: `BEDC.Derived.FiniteNetSelectionPrincipleUp`

Bridge status: none

Not claimed: This chapter does not claim classical open-cover compactness, choice-based Heine–Borel selection, global choice functions, selected Cauchy limits, quotient completion equality, ambient RealUp completeness, theorem checking, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, classifier locality, mesh monotonicity, cover soundness, selector stability, transport, replay, provenance, and ledger refusal for BEDC.Derived.FiniteNetSelectionPrincipleUp.

Chapter 9079

A Concrete Naming Certificate for $\mathsf{DyadicReciprocalNewton}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{DyadicReciprocalNewton}^{\uparrow}$ packet records the finite Newton reciprocal route used when a positive dyadic source supplies an approximate inverse to Real and Completion consumers. It sits over the dyadic arithmetic rows of chapter 291, the nonnegative tolerance route of chapter 293, and the interval-enclosure surface of chapter 306. The packet exposes a positive source, a displayed reciprocal iterate, an interval enclosure, and an exact error budget before any real-facing inverse language is consumed; it does not assert host division, quotient equality, selected inverse, trichotomy, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 9079.1 (Dyadic reciprocal Newton carrier)**.** *A* $\mathsf{DyadicReciprocalNewton}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$R = (D, P, I, E, H, C, Q, N)$$

with the following displayed rows:

1. *D is the positive* $\mathsf{DyadicRatCore}^{\uparrow}$ *source row, carrying the dyadic input, its displayed positivity witness, and the arithmetic rows used by the Newton step.*
2. *P is the reciprocal-iterate row, recording the current dyadic approximation and the displayed update*
$$p \longmapsto p(2 - dp)$$
inside the dyadic arithmetic ledger.
3. *I is the* $\mathsf{DyadicInterval}^{\uparrow}$ *enclosure row, recording the interval in which the accepted reciprocal iterate remains confined.*
4. *E is the* $\mathsf{DyadicAbsoluteValue}^{\uparrow}$ *error-budget row, recording the displayed residual endpoint and tolerance ledger for the expression $1 - dp$.*
5. *H records componentwise* hsame *transport for the source, iterate, interval, error budget, replay, provenance, and local naming rows.*
6. *C records displayed* Cont *replay for the finite route from the source row through the reciprocal step, interval enclosure, and error-budget readback.*
7. *Q records* Pkg *provenance over* $\mathsf{DyadicReciprocalNewton}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{DyadicAbsoluteValue}^{\uparrow}$, $\mathsf{DyadicInterval}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

8. *N is the local* $\mathsf{NameCert}_{\mathsf{DyadicReciprocalNewton}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through D, P, I, E, H, C, Q, N. It has no coordinate for host division, quotient rational equality, a selected inverse, trichotomy, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 9079.2 (Dyadic reciprocal Newton NameCert obligations)**.** *For every accepted* $\mathsf{DyadicReciprocalNewton}^{\uparrow}$ *carrier*

$$R = (D, P, I, E, H, C, Q, N),$$

the local $\mathsf{NameCert}_{\mathsf{DyadicReciprocalNewton}^{\uparrow}}$ *surface consists exactly of the following finite obligations:*

1. *carrier admission for the positive* $\mathsf{DyadicRatCore}^{\uparrow}$ *source row D;*
2. *positive-source visibility before the reciprocal iterate row P is read;*
3. *reciprocal-step exposure for the displayed update $p \mapsto p(2 - dp)$ inside the dyadic arithmetic ledger;*
4. *enclosure preservation through the* $\mathsf{DyadicInterval}^{\uparrow}$ *row I;*
5. *error-budget exactness through the* $\mathsf{DyadicAbsoluteValue}^{\uparrow}$ *row E for the displayed residual;*
6. *componentwise* hsame *transport through H;*
7. *displayed* Cont *replay through C;*
8. Pkg *provenance through Q;*
9. *local naming through N.*

Thus the packet supplies a finite dyadic reciprocal-iteration certificate, not a host inverse operation, quotient rational equality, selected inverse, trichotomy, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the carrier of Definition 9079.1. Its rows display the positive source, reciprocal iterate, interval enclosure, error budget, transport, replay, provenance, and local naming data.

Read the rows in dependency order. The source row D exposes positivity and dyadic arithmetic before the reciprocal iterate row P is consumed. The interval row I then records enclosure preservation, and the error row E records the residual budget through the existing absolute-value route.

Finally apply H, C, Q, N. These rows transport, replay, source, and name the same finite packet. Since the carrier contains no coordinate for host division, quotient equality, selected inverse, trichotomy, countable choice, or ambient completeness, none can be exported by the local certificate. □

Theorem 9079.3 (Dyadic reciprocal Newton quadratic-error route)**.** *Every Real-facing inverse consumer reading an accepted* $\mathsf{DyadicReciprocalNewton}^{\uparrow}$ *packet must first pass through the displayed route*

$$\mathsf{DyadicRatCore}^{\uparrow},\ \mathsf{DyadicAbsoluteValue}^{\uparrow},\ \mathsf{DyadicInterval}^{\uparrow},\ D,\ P,\ I,\ E,\ H,\ C,\ Q,\ N.$$

In particular, each accepted Newton reciprocal read factors through the dyadic source arithmetic, residual absolute-value budget, and interval enclosure rows before any $\mathsf{RegSeqRat}^{\uparrow}$ *or* $\mathsf{Real}^{\uparrow}$ *inverse consumer can use the resulting approximation.*

Proof. Begin with the source row D. It is the only positive dyadic input row in the carrier, so the reciprocal step cannot be read before the displayed $\mathsf{DyadicRatCore}^{\uparrow}$ arithmetic and positivity witness are visible.

Next read the error and enclosure rows. The residual budget is exposed through E, the $\mathsf{DyadicAbsoluteValue}^{\uparrow}$ row attached to the displayed residual, and the accepted iterate remains bounded by the $\mathsf{DyadicInterval}^{\uparrow}$ enclosure row I.

Only after those rows are displayed may a $\mathsf{RegSeqRat}^{\uparrow}$ or $\mathsf{Real}^{\uparrow}$ consumer attach inverse terminology to the approximation. The transport, replay, provenance, and local naming rows H, C, Q, N preserve the same route and add no hidden host division, quotient equality, selected inverse, trichotomy, countable choice, or ambient completeness data. □

Falsifiable prediction: An accepted $\mathsf{DyadicReciprocalNewton}^{\uparrow}$ read is refuted by any Real-facing inverse consumer that consumes the reciprocal iterate before displaying the positive $\mathsf{DyadicRatCore}^{\uparrow}$ source row, the $\mathsf{DyadicAbsoluteValue}^{\uparrow}$ residual budget, the $\mathsf{DyadicInterval}^{\uparrow}$ enclosure row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming.

Independence witness: dyadicratcore, dyadicabsolutevalue, dyadicinterval, regseqrat, real: none is bijective to $\mathsf{DyadicReciprocalNewton}^{\uparrow}$ because this packet jointly carries a positive dyadic source, a reciprocal iterate, an interval enclosure, a residual error budget, transport, replay, provenance, and a local NameCert row.

Closure status for $\mathsf{NameCert}_{\mathsf{DyadicReciprocalNewton}^{\uparrow}}$.

Constructive story: A $\mathsf{DyadicReciprocalNewton}^{\uparrow}$ packet is generated from a positive DyadicRatCore source row, a reciprocal-iterate row, a DyadicInterval enclosure row, a DyadicAbsoluteValue residual-budget row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{DyadicReciprocalNewton}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 9079.1, Definition 9079.2, and Definition 9079.3 seed the finite constructive reciprocal-iteration route over source, iterate, enclosure, error budget, transport, replay, provenance, and local naming rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{DyadicReciprocalNewton}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim Lean verification, host division, quotient equality, selected inverse, trichotomy, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, positive-source visibility, reciprocal-step exposure, enclosure preservation, error-budget exactness, transport, replay, provenance, and local naming for BEDC.Derived.DyadicReciprocalNewto

Chapter 9080

A Concrete Naming Certificate for $\mathsf{SerreSwanFiniteProjective}^{\uparrow}$

Following Serre and Swan, the $\mathsf{SerreSwanFiniteProjective}^{\uparrow}$ packet records the finite bridge by which a vector-bundle row over a compact base is read as a finite-projective module row, and conversely by which displayed finite-projective module data supplies the local vector-bundle surface consumed by BEDC readers. It sits between the vector-bundle certificate of chapter 210, the module carrier of chapter 46, and the scalar ring source of chapter 43. The packet names only displayed section rows, idempotent matrix rows, local trivialization rows, transport, replay, provenance, and local naming; it does not import a host equivalence of categories, selected global bases, quotient module equality, or ambient compactness outside the carried rows.

Definition 9080.1 (Serre–Swan finite-projective carrier)**.** *A* $\mathsf{SerreSwanFiniteProjective}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (X, R, M, E, V, L, Q, H, C, P, N)$$

with the following displayed rows:

1. *X is the compact-base naming row over which the section and vector-bundle reads are scoped.*
2. *R is the scalar* $\mathsf{Ring}^{\uparrow}$ *row for continuous scalar functions on the displayed base.*
3. *M is the* $\mathsf{Module}^{\uparrow}$ *row carrying the finite-projective section module with its displayed scalar action.*
4. *E is the idempotent or finite-summand ledger witnessing finite projectivity through matrix rows over R.*
5. *V is the* $\mathsf{VectorBundle}^{\uparrow}$ *row carrying fibres, local trivializations, transition maps, and overlap checks.*
6. *L is the local section ledger, displaying the finite windows in which module generators read as bundle sections and bundle sections read back as module elements.*
7. *Q is the comparison row tying the projective-module idempotent surface to the vector-bundle transition surface.*
8. *H records componentwise* hsame *transport for the base, scalar ring, module, idempotent, vector-bundle, section, comparison, replay, provenance, and local naming rows.*
9. *C records displayed* Cont *replay from a Serre–Swan request through $X, R, M, E, V, L, Q, H, P, N$.*

10. *P is the* Pkg *provenance over* SerreSwanFiniteProjective$^{\uparrow}$, VectorBundle$^{\uparrow}$, Module$^{\uparrow}$, Ring$^{\uparrow}$, Mat$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

11. *N is the local* NameCert$_{\text{SerreSwanFiniteProjective}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through $X, R, M, E, V, L, Q, H, C, P, N$. It has no coordinate for a host category equivalence, a selected basis, quotient equality of modules, an ambient sheaf of sections, or external compactness data.

Theorem 9080.2 (Serre–Swan finite-projective NameCert obligations)**.** *For every accepted* SerreSwanFiniteProjecti *carrier*

$$S = (X, R, M, E, V, L, Q, H, C, P, N),$$

the local NameCert$_{\text{SerreSwanFiniteProjective}^{\uparrow}}$ *surface consists exactly of carrier admission for the displayed base row, scalar ring row, finite-projective module row, idempotent ledger, vector-bundle row, local section ledger, comparison row, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. Every consumer of the Serre–Swan handoff must expose $X, R, M, E, V, L, Q, H, C, P, N$ before reading either the finite-projective module side or the vector-bundle side as public.*

Proof. Project the carrier of Definition 9080.1. The finite packet contains only the base, ring, module, idempotent, vector-bundle, section, comparison, transport, replay, provenance, and local naming rows.

The module-facing read is routed through R, M, E. The scalar ring row supplies the displayed coefficients, the module row supplies the carrier and scalar action, and the idempotent ledger supplies the finite-projective witness rather than a selected basis or quotient-module equality.

The bundle-facing read is routed through V, L, Q. The vector-bundle row exposes fibres and transition data, the local section ledger records the finite section windows, and the comparison row is the only bridge between those windows and the finite-projective module surface.

Finally H, C, P, N transport, replay, source, and name the same finite rows. Since no host category equivalence, ambient section sheaf, external compactness assertion, or selected global basis is present in the carrier, the listed rows exhaust the public NameCert obligations. □

Closure status for NameCert$_{\text{SerreSwanFiniteProjective}^{\uparrow}}$.

Constructive story: A SerreSwanFiniteProjective$^{\uparrow}$ packet is generated from a displayed base row, scalar Ring row, finite-projective Module row, idempotent ledger, VectorBundle row, local section ledger, comparison row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert row.

Theory closure: TheoryGate(NameCert$_{\text{SerreSwanFiniteProjective}^{\uparrow}}$, seed)

Scope closed: Definition 9080.1 and Definition 9080.2 seed the finite Serre–Swan handoff between finite-projective module rows and vector-bundle rows.

Formal verification: FormalStatus(NameCert$_{\text{SerreSwanFiniteProjective}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close a host equivalence of categories, selected global bases, quotient module equality, ambient sheaf semantics, external compactness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, idempotent-ledger exposure, vector-bundle section handoff, comparison-row exactness, transport, replay, provenance, and local naming for BEDC.Derived.SerreSwanFiniteProjectiveUp.

Chapter 9081

A Concrete Naming Certificate for $\mathsf{LocatedApartnessSplit}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{LocatedApartnessSplit}^{\uparrow}$ packet records the finite branch evidence by which a located real and a displayed apartness witness are routed to Real and Completion consumers without importing constructive trichotomy. It sits over the located-real carrier of **??**, the positive-separation surface of chapter 304, the dyadic tolerance ledger of chapter 291, the finite window interface of chapter 126, the regular rational readback route of chapter 301, and the terminal real-name seal of chapter 38. The packet names a guarded positive or negative branch split for already displayed apartness data; it is not a selected sign decision, not a quotient equality of real names, not countable choice, not ambient $\mathsf{Real}^{\uparrow}$ completeness, and not Lean verification.

Definition 9081.1 (Located apartness split carrier)**.** *A* $\mathsf{LocatedApartnessSplit}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (L, A, D, W, Q, E, H, C, P, N)$$

with the following displayed rows:

1. *L is the* $\mathsf{LocatedReal}^{\uparrow}$ *source row whose located interval data fixes the endpoint presentation under inspection.*
2. *A is the* $\mathsf{ApartnessReal}^{\uparrow}$ *branch-evidence row, displaying either the positive-side or negative-side separation witness from the named comparison boundary.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger carrying the branch radius, endpoint comparison arithmetic, and displayed tolerance budget.*
4. *W is the* $\mathsf{StreamName}^{\uparrow}$ *finite observation window on which the branch evidence is inspected.*
5. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the same finite window and dyadic ledger.*
6. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached only after L, A, D, W, Q have been displayed.*
7. *H records componentwise* hsame *transport for the located-real source, apartness branch evidence, dyadic ledger, window, readback, Real seal, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from the split request through the located source, branch evidence, dyadic tolerance ledger, finite window, regular rational readback, Real seal, transport, provenance, and local naming rows.*

9. *P is the* Pkg *provenance over* $\mathsf{LocatedApartnessSplit}^{\uparrow}$, $\mathsf{LocatedReal}^{\uparrow}$, $\mathsf{ApartnessReal}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{LocatedApartnessSplit}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through the displayed rows $L, A, D, W, Q, E, H, C, P, N$. It has no coordinate for trichotomy, total sign on $\mathsf{Real}^{\uparrow}$*, quotient equality, countable choice, a selected branch independent of the apartness row, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 9081.2 (Located apartness split NameCert obligations)**.** *For every accepted* $\mathsf{LocatedApartnessSplit}^{\uparrow}$ *carrier*

$$S = (L, A, D, W, Q, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{LocatedApartnessSplit}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the located-real source, apartness branch evidence, dyadic tolerance ledger, finite window, regular rational readback, terminal Real seal, transport, replay, provenance, and local naming rows;*
2. *located source exposure through L, requiring the branch request to begin from the displayed* $\mathsf{LocatedReal}^{\uparrow}$ *interval data rather than from a host real value;*
3. *branch evidence exposure through A, requiring the positive or negative side to be read as already displayed* $\mathsf{ApartnessReal}^{\uparrow}$ *evidence;*
4. *dyadic tolerance exactness through D, requiring the branch radius and comparison arithmetic to be the rows used by the split;*
5. *window and readback routing through W, Q, E, requiring the Real-facing seal to be downstream of the finite stream window and regular rational readback;*
6. *componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local* NameCert *naming through H, C, P, N for the same rows;*
7. *refusal of trichotomy, selected sign decisions, quotient real equality, countable choice, ambient* $\mathsf{Real}^{\uparrow}$ *completeness, Lean verification, and bridge checking as certificate data.*

No located apartness split obligation is stored outside $L, A, D, W, Q, E, H, C, P, N$.

Proof. Project the carrier of Definition 9081.1. The accepted packet exposes exactly the located source row L, the apartness evidence row A, the dyadic tolerance ledger D, the finite observation window W, the readback row Q, the Real seal E, and the structural rows H, C, P, N.

Read the mathematical rows in dependency order. The located source L fixes the displayed endpoint presentation, and the apartness row A supplies one already evidenced positive or negative branch. The dyadic ledger D then fixes the radius and comparison arithmetic attached to that evidence.

The completion-facing route is finite. The stream window W and regular rational readback Q are the only observation rows available before the Real seal E is reached.

Finally use H, C, P, N to transport, replay, source, and name the same packet. Since no row contains trichotomy, a selected sign decision, quotient equality, countable choice, or completeness, those principles cannot become local NameCert obligations. □

Theorem 9081.3 (Located apartness split branch extraction)**.** *Every branch extracted from an accepted* $\mathsf{LocatedApartnessSplit}^{\uparrow}$ *packet factors through the displayed route*

$$\mathsf{LocatedReal}^{\uparrow}, \quad \mathsf{ApartnessReal}^{\uparrow}, \quad \mathsf{DyadicRatCore}^{\uparrow}, \quad \mathsf{StreamName}^{\uparrow}, \quad \mathsf{RegSeqRat}^{\uparrow}.$$

The extracted branch is positive or negative only relative to the apartness row A and the tolerance ledger D. It does not decide a sign for arbitrary $\mathsf{Real}^{\uparrow}$ *names and does not choose between equality and apartness.*

Proof. Start with the located source row L. It supplies the named endpoint presentation and interval data, so any branch read is tied to the displayed located-real packet.

Next read the apartness row A. The branch side is already present as positive or negative separation evidence; the split packet does not compute a side by trichotomy.

The dyadic and finite-window rows then determine the scope of the branch. The ledger D supplies the tolerance radius and comparison arithmetic, while W and Q supply the finite observation and regular rational readback used by the same evidence.

Thus branch extraction is row projection from L, A, D, W, Q followed by the structural nonescape rows. Without those rows, the packet has no branch to export; with them, it exports only the guarded branch stated above. □

Theorem 9081.4 (Located apartness split Real handoff)**.** *Every* $\mathsf{Real}^{\uparrow}$*-facing consumer of an accepted* $\mathsf{LocatedApartnessSplit}^{\uparrow}$ *packet must read the terminal seal E only after the located-real source L, apartness branch evidence A, dyadic tolerance ledger D, finite stream window W, regular rational readback Q, componentwise transport H, displayed replay C, provenance P, and local naming row N have been displayed. The handoff supplies a guarded branch certificate over finite located-apartness data, not trichotomy, a selected sign decision, quotient real equality, countable choice, ambient* $\mathsf{Real}^{\uparrow}$ *completeness, Lean verification, or bridge checking.*

Proof. Apply Definition 9081.2. The Real-facing seal is one row of the same finite packet, and the certificate obligations require the located source, apartness evidence, dyadic ledger, window, readback, transport, replay, provenance, and local naming rows to be visible.

Apply Definition 9081.3. The only branch available to the consumer is the one that has already passed through L, A, D, W, Q.

The structural rows enforce nonescape. Componentwise transport H, displayed replay C, package provenance P, and local naming N preserve the same finite route at the Real seal boundary. Since the carrier has no coordinate for trichotomy, selected sign decisions, quotient equality, countable choice, or completeness, none of those objects can be exported by the handoff. □

Falsifiable prediction: A consumer refutes a $\mathsf{LocatedApartnessSplit}^{\uparrow}$ packet if it exports a positive or negative branch without displaying the located-real source, apartness branch evidence, dyadic tolerance ledger, finite stream window, regular rational readback, Real seal, componentwise transport, replay, provenance, and local NameCert rows.

Independence witness: locatedreal, apartnessreal, dyadicratcore, streamname, regseqrat, real: none is bijective to $\mathsf{LocatedApartnessSplit}^{\uparrow}$ because only this packet binds the located source, apartness branch evidence, dyadic tolerance ledger, finite observation window, regular rational readback, Real seal, transport, replay, provenance, and local naming into one guarded branch carrier.

Closure status for $\mathsf{NameCert}_{\mathsf{LocatedApartnessSplit}^{\uparrow}}$**.**

Constructive story: A $\mathsf{LocatedApartnessSplit}^{\uparrow}$ packet is generated from a LocatedReal source row, an ApartnessReal positive or negative branch-evidence row, a DyadicRatCore tolerance ledger, a finite StreamName window, a RegSeqRat readback row, a Real seal boundary, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{LocatedApartnessSplit}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 9081.1, Definition 9081.2, Definition 9081.3, and Definition 9081.4 seed the finite located-apartness branch route from displayed source and apartness evidence to Real and Completion consumers.

Formal verification: FormalStatus(NameCert$_{\mathsf{LocatedApartnessSplit}\uparrow}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim trichotomy, selected sign decisions, quotient real equality, countable choice, ambient Real$^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, located source exposure, apartness branch exposure, dyadic tolerance exactness, finite-window readback routing, Real seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.LocatedApartnessSplitUp.

Chapter 9082

A Concrete Naming Certificate for $\mathsf{SequentialCompactInterval}^{\uparrow}$

Following Bishop and Bridges' constructive treatment of compact intervals by finite approximation and subsequence extraction, the $\mathsf{SequentialCompactInterval}^{\uparrow}$ packet records the sequential compactness surface for a displayed closed real interval. It consumes the finite-net route of chapter 1808, the terminal real-name surface of chapter 38, the regular rational readback of chapter 301, and the finite observation windows of chapter 126. The packet supplies explicit finite-net and subsequence data for interval sequences; it does not export open-cover compactness, selected subcovers, countable choice, quotient real equality, host subsequence selectors, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 9082.1 (Sequential compact interval carrier)**.** *A* $\mathsf{SequentialCompactInterval}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (I, F, Q, W, R, A, D, E, H, C, P, N)$$

with the following displayed rows:

1. *I is the located closed interval source row, displaying the endpoint names and interval membership boundary consumed by sequence readers.*
2. *F is the* $\mathsf{LocatedClosedIntervalFiniteNet}^{\uparrow}$ *finite-net row, listing the mesh scale, finite interval net, and coverage checks used to classify sequence tails.*
3. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the sequence observations and endpoint comparisons attached to the same interval boundary.*
4. *W is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row opened for the sequence prefixes, endpoint names, and finite-net membership tests already displayed by I, F, Q.*
5. *R is the* $\mathsf{Real}^{\uparrow}$ *seal row for the interval endpoints and the retained subsequence candidate, available only after the finite windows and regular rational readbacks have been displayed.*
6. *A is the accumulation-cell row, naming a descending finite-net cell chain and a retained infinite-tail witness as finite BEDC data.*
7. *D is the subsequence-decision ledger, recording the finite choices of cells, tail indices, and comparison checks used to produce the displayed subsequence route.*
8. *E is the extraction row, exposing the selected finite prefixes and regular rational convergence budgets for the retained subsequence.*

9. *H records componentwise* hsame *transport for the interval source, finite net, sequence readback, stream windows, real seal, accumulation-cell row, subsequence ledger, extraction row, replay row, provenance row, and local naming row.*
10. *C records displayed* Cont *replay from a sequence request through the interval source, finite-net row, finite observation windows, regular rational readback, real seal, accumulation-cell ledger, and extraction row.*
11. *P is the* Pkg *provenance over* $\mathsf{SequentialCompactInterval}^{\uparrow}$, $\mathsf{LocatedClosedIntervalFiniteNet}^{\uparrow}$, $\mathsf{Compact}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
12. *N is the local* $\mathsf{NameCert}_{\mathsf{SequentialCompactInterval}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $I, F, Q, W, R, A, D, E, H, C, P, N$. It has no coordinate for open-cover compactness, unrestricted Heine–Borel compactness, countable choice, host real equality, quotient interval representatives, an external subsequence selector, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 9082.2 (Sequential compact interval NameCert obligations)**.** *For every accepted* SequentialCompactInter *carrier*

$$S = (I, F, Q, W, R, A, D, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{SequentialCompactInterval}^{\uparrow}}$ *surface consists exactly of located interval admission, finite-net exposure through* $\mathsf{LocatedClosedIntervalFiniteNet}^{\uparrow}$, *sequence readback through* $\mathsf{RegSeqRat}^{\uparrow}$ *and* $\mathsf{StreamName}^{\uparrow}$, *terminal* $\mathsf{Real}^{\uparrow}$ *seal admission, accumulation-cell formation, subsequence-decision recording, extraction-row exposure, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. The* $\mathsf{Compact}^{\uparrow}$ *dependency in P is readable only as a finite-net compatibility row and not as open-cover compactness.*

Proof. Project the accepted carrier. The interval source is I, and the only compactness-facing row is the displayed finite-net row F; therefore every compactness read starts with finite interval coverage rather than with an open cover.

The sequence data are finite at each stage. The rows W and Q expose only the inspected stream windows and regular rational readbacks, while R seals those observations as $\mathsf{Real}^{\uparrow}$ data after the finite windows have been displayed.

The extraction rows are also internal to the packet. The accumulation row A records a finite chain of net cells with retained tail witnesses, D records the finite subsequence-decision ledger, and E exposes the resulting subsequence prefixes and convergence budgets.

Finally H, C, P, N transport, replay, source, and name the same packet. Since no carrier coordinate stores an arbitrary open cover, selected subcover, countable-choice functional, quotient representative, host subsequence selector, or ambient completeness principle, the listed rows exhaust the local NameCert obligations. □

Theorem 9082.3 (Sequential compact interval finite-net subsequence extraction)**.** *Every accepted* $\mathsf{SequentialCompactInterval}^{\uparrow}$ *packet supplies subsequence data only through the finite route*

$$\mathsf{LocatedClosedIntervalFiniteNet}^{\uparrow} \longrightarrow \mathsf{StreamName}^{\uparrow} \longrightarrow \mathsf{RegSeqRat}^{\uparrow} \longrightarrow \mathsf{Real}^{\uparrow}.$$

Concretely, the packet first reads the finite interval net F, then opens the finite sequence windows W, then checks the regular rational readback Q, then reaches the terminal $\mathsf{Real}^{\uparrow}$ *seal R, and only then exposes the accumulation-cell row A, subsequence ledger D, and extraction row E. Thus the route supplies explicit finite-net and subsequence data rather than open-cover compactness, a selected subcover principle, countable choice, or an external subsequence selector.*

Proof. Start with the finite-net row F. Its coverage data come from chapter 1808, so the sequence is inspected against displayed interval cells and mesh ledgers before any extraction row is available.

Next read W and Q. These rows expose finite $\mathsf{StreamName}^{\uparrow}$ windows and $\mathsf{RegSeqRat}^{\uparrow}$ readbacks for the sequence values and endpoint comparisons attached to the same interval source.

The terminal seal R is downstream of those finite observations. It provides the $\mathsf{Real}^{\uparrow}$ boundary for the retained subsequence candidate but does not create a host real representative or an ambient completeness argument.

Finally inspect A, D, E. The accumulation-cell chain and subsequence ledger are finite BEDC rows, and the extraction row reports the retained prefixes and convergence budgets produced by those rows. No row in the carrier exports open-cover compactness, selected subcovers, countable choice, or an external selector, so the finite-net subsequence route is the only available extraction surface. □

Closure status for $\mathsf{NameCert}_{\mathsf{SequentialCompactInterval}^{\uparrow}}$.

Constructive story: A $\mathsf{SequentialCompactInterval}^{\uparrow}$ packet is generated from a located closed interval source, a LocatedClosedIntervalFiniteNet row, finite StreamName windows, RegSeqRat readback, RealUp seals, accumulation-cell data, subsequence-decision rows, extraction rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{SequentialCompactInterval}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 9082.1, Definition 9082.2, and Definition 9082.3 seed the explicit finite-net subsequence route for closed real intervals.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{SequentialCompactInterval}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close open-cover compactness, unrestricted Heine–Borel compactness, selected subcovers, countable choice, quotient real equality, host subsequence selectors, ambient RealUp completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked interval admission, finite-net exposure, sequence readback, RealUp seal admission, accumulation-cell formation, subsequence-decision recording, extraction-row exposure, transport, replay, provenance, and local naming for BEDC.Derived.SequentialCompactIntervalUp.

Chapter 9083

A Concrete Naming Certificate for $\mathsf{RegularCauchySumCriterion}^{\uparrow}$

Following Bishop and Bridges on regular Cauchy real names, the $\mathsf{RegularCauchySumCriterion}^{\uparrow}$ packet records the finite addition criterion that lets two displayed regular rational Cauchy sources produce a summed readback before any $\mathsf{Real}^{\uparrow}$ consumer receives the seal. It sits beside the addition route of chapter 1695, the finite product sufficiency of chapter 3672, and the difference criterion of chapter 1874. The packet names only synchronized windows, dyadic endpoint-sum budgets, regular readback, and seal routing; it does not import host real addition, quotient equality, trichotomy, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 9083.1 (Regular Cauchy sum criterion carrier)**.** *A* $\mathsf{RegularCauchySumCriterion}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (A, B, W_A, W_B, D, L, R, E, H, C, P, N)$$

with the following displayed rows:

1. *A and B are the two* $\mathsf{RegSeqRat}^{\uparrow}$ *source rows whose rational observations are being added.*
2. *W_A and W_B are synchronized* $\mathsf{StreamName}^{\uparrow}$ *window rows for the same precision request.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *endpoint-sum and tolerance-budget row.*
4. *L is the* $\mathsf{RegularCauchyAddition}^{\uparrow}$ *route row, read only after A, B, W_A, W_B, D have been displayed.*
5. *R is the summed* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row produced by the finite addition route.*
6. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row, available only after R has been displayed.*
7. *H records componentwise* hsame *transport for the source, window, dyadic, route, readback, seal, replay, provenance, and naming rows.*
8. *C records displayed* Cont *replay from the two source rows through windows, dyadic sum budget, regular addition route, readback, and seal.*
9. *P is the* Pkg *provenance over* $\mathsf{RegularCauchySumCriterion}^{\uparrow}$, $\mathsf{RegularCauchyAddition}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{RegularCauchyProductCriterion}^{\uparrow}$, $\mathsf{CauchyProductCriterion}^{\uparrow}$, $\mathsf{CauchyDifferenceCriterion}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{RegularCauchySumCriterion}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $A, B, W_A, W_B, D, L, R, E, H, C, P, N$. It has no coordinate for completed-real addition, quotient stream equality, trichotomy, selected representatives, countable choice, or ambient completeness.

Lean4 ✓ `BEDC.Derived.RegularCauchySumCriterionUp.RegularCauchySumCriterionTasteGate single carrier alignment`

Theorem 9083.2 (Regular Cauchy sum criterion NameCert obligations)**.** *For every accepted* $\mathsf{RegularCauchySumCriterion}^{\uparrow}$ *carrier* $S = (A, B, W_A, W_B, D, L, R, E, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{RegularCauchySumC}}$ *surface consists exactly of source admission for* A, B*, synchronized finite-window exposure through* W_A, W_B*, dyadic endpoint-sum budgeting through* D*, the* $\mathsf{RegularCauchyAddition}^{\uparrow}$ *route* L*, summed regular readback through* R*, terminal* $\mathsf{Real}^{\uparrow}$ *sealing through* E*, componentwise transport through* H*, displayed replay through* C*, provenance through* P*, and local naming through* N*.*

Proof. Project the carrier of Definition 9083.1. The only analytic rows are the two source rows, the paired finite windows, the dyadic sum budget, the addition route, the regular readback, and the terminal Real seal.

Read the source and window rows first. The rows A, B, W_A, W_B display exactly the finite regular-Cauchy observations available to the sum request.

Next read the dyadic and addition rows. The row D records the endpoint-sum tolerance budget, and the route row L consumes that budget before the summed regular readback R is exposed.

Finally read E, H, C, P, N. These rows seal, transport, replay, source, and name the same finite route. Since no carrier coordinate names host addition, quotient stream equality, trichotomy, choice, or ambient completeness, the listed rows exhaust the local NameCert surface. □

Theorem 9083.3 (Regular Cauchy sum criterion window-budget exactness)**.** *For every accepted* $\mathsf{RegularCauchySumCriterion}^{\uparrow}$ *carrier, the synchronized windows* W_A, W_B *and dyadic row* D *determine the finite sum budget consumed by the* $\mathsf{RegularCauchyAddition}^{\uparrow}$ *route* L*. Every summed* $\mathsf{RegSeqRat}^{\uparrow}$ *readback factors through*

$$A, B \longmapsto W_A, W_B \longmapsto D \longmapsto L \longmapsto R.$$

No budget rule is read from host real addition, quotient stream equality, trichotomy, selected representatives, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. The windows W_A, W_B are the only displayed observation windows for the two sources. They synchronize the source rows before any dyadic endpoint-sum row is available.

The dyadic row D is the only tolerance and endpoint-sum ledger in the carrier. The addition route L is downstream of D, and the readback row R is downstream of L.

Transport, replay, provenance, and local naming preserve that same row order. Therefore every summed regular readback follows the displayed finite chain, and no excluded external budget can be consumed. □

Falsifiable prediction: An accepted $\mathsf{RegularCauchySumCriterion}^{\uparrow}$ read is refuted if a summed RegSeqRatUp or RealUp output is exposed without first displaying two RegSeqRatUp sources, paired StreamNameUp windows, a DyadicRatCoreUp endpoint-sum budget, the RegularCauchyAdditionUp route, transport, replay, provenance, and local naming rows.

Independence witness: streamname, regseqrat, dyadicratcore, real, regular-cauchy-addition, regular-cauchy-product-criterion, cauchy-product-criterion, cauchy-difference-criterion: $\mathsf{RegularCauchySumCriterion}$

is not bijective to any listed sibling because it carries the two-source addition criterion, synchronized finite windows, dyadic endpoint-sum budget, summed regular readback, Real seal, transport, replay, provenance, and local NameCert in one packet.

Closure status for $\mathsf{NameCert}_{\mathsf{RegularCauchySumCriterion}\uparrow}$.

Constructive story: A $\mathsf{RegularCauchySumCriterion}^{\uparrow}$ packet is generated from two RegSeqRat source rows, paired StreamName windows, a DyadicRatCore endpoint-sum budget, a RegularCauchyAddition route, a summed RegSeqRat readback, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RegularCauchySumCriterion}\uparrow}, \mathsf{seed})$

Scope closed: Definition 9083.1, Definition 9083.2, and Definition 9083.3 seed the finite addition criterion for regular Cauchy real names through StreamName, RegSeqRat, DyadicRatCore, RegularCauchyAddition, and Real rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RegularCauchySumCriterion}\uparrow}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host real addition, quotient stream equality, trichotomy, selected representatives, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, synchronized-window admission, dyadic endpoint-sum budgeting, RegularCauchyAddition routing, RegSeqRat readback, Real seal handoff, transport stability, replay stability, provenance nonescape, and local naming for BEDC.Derived.RegularCauchySumCriterionUp.

Chapter 9084

A Concrete Naming Certificate for $\mathsf{DyadicCauchySandwich}^{\uparrow}$

Bishop and Bridges constructive analysis treats a real presentation as inspectable Cauchy data with explicit finite tolerances rather than as a completed quotient object. The $\mathsf{DyadicCauchySandwich}^{\uparrow}$ packet records the L10 finite-means sandwich in which lower, middle, and upper regular rational rows share one dyadic tolerance ledger before a $\mathsf{Real}^{\uparrow}$ seal is read. It sits beside the squeeze route of chapter 1772, the dyadic enclosure packet of chapter 3627, the tolerance source of chapter 291, the finite window discipline of chapter 126, the regular rational readback of chapter 301, and the terminal real-name boundary of chapter 38. The packet names only displayed finite rows; it does not assert quotient real equality, selected limits, trichotomy, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 9084.1 (Dyadic Cauchy sandwich carrier)**.** *A* $\mathsf{DyadicCauchySandwich}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$T = (L, M, U, D, W, R, E, H, C, P, N)$$

with the following displayed rows:

1. *L is the lower regular Cauchy row, exposed only through finite* $\mathsf{StreamName}^{\uparrow}$ *windows and* $\mathsf{RegSeqRat}^{\uparrow}$ *readback.*
2. *M is the middle regular Cauchy row whose observations are squeezed between the lower and upper rows at the displayed dyadic precisions.*
3. *U is the upper regular Cauchy row, exposed through the same finite-window and regular-readback discipline.*
4. *D is the shared* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, recording the requested radii, refinements, and lower-middle-upper containment inequalities.*
5. *W is the finite* $\mathsf{StreamName}^{\uparrow}$ *window family inspected by every tolerance request for L, M, U.*
6. *R records the three* $\mathsf{RegSeqRat}^{\uparrow}$ *readbacks reached from those windows.*
7. *E is the* $\mathsf{Real}^{\uparrow}$ *seal, readable only after the rows L, M, U, D, W, R have been displayed.*
8. *H records componentwise* hsame *transport for the three Cauchy rows, shared tolerance ledger, windows, readbacks, seal, replay, provenance, and local name.*
9. *C records displayed* Cont *replay for tolerance admission, window inspection, regular readback, squeeze handoff, real sealing, and local naming.*

10. *P is the* Pkg *provenance over* $\mathsf{DyadicCauchySandwich}^{\uparrow}$, $\mathsf{RegularCauchySqueeze}^{\uparrow}$, $\mathsf{DyadicSandwich}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{DyadicCauchySandwich}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $L, M, U, D, W, R, E, H, C, P, N$. It has no coordinate for quotient real equality, a selected limit, detached trichotomy, countable choice, or ambient real completeness.

Theorem 9084.2 (Dyadic Cauchy sandwich NameCert obligations)**.** *For every accepted* $\mathsf{DyadicCauchySandwich}^{\uparrow}$ *carrier*

$$T = (L, M, U, D, W, R, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{DyadicCauchySandwich}^{\uparrow}}$ *surface consists exactly of six finite obligation rows: carrier admission for the displayed triple of regular Cauchy rows; shared dyadic tolerance admission through D; finite window inspection through W; threefold* $\mathsf{RegSeqRat}^{\uparrow}$ *readback through R; squeeze-compatible* $\mathsf{Real}^{\uparrow}$ *sealing through E; and transport, replay, provenance, and local ledgering through H, C, P, N. No obligation row exports quotient real equality, selected limits, trichotomy, countable choice, hidden tail selection, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the accepted carrier. The object-facing data are the three regular Cauchy rows L, M, U, the shared tolerance ledger D, the finite windows W, and the regular readback row R.

The squeeze boundary is finite because the middle row M is checked only against the lower and upper rows through the dyadic ledger D and the displayed windows W. This is the shared row consumed by the $\mathsf{RegularCauchySqueeze}^{\uparrow}$ and $\mathsf{DyadicSandwich}^{\uparrow}$ sibling routes.

The terminal row E seals the same displayed packet for $\mathsf{Real}^{\uparrow}$ consumers after the regular readbacks have been exposed. It is not a quotient, a chosen representative, or an ambient completion principle.

Finally H, C, P, N transport, replay, source, and name the packet. Since the carrier lists no coordinate for quotient equality, selected limits, trichotomy, choice, hidden tails, or ambient completeness, the six obligation rows exhaust the local NameCert surface. □

Theorem 9084.3 (Dyadic Cauchy sandwich squeeze route)**.** *Every* $\mathsf{Real}^{\uparrow}$*-facing read from an accepted* $\mathsf{DyadicCauchySandwich}^{\uparrow}$ *carrier factors through the displayed route*

$$\mathsf{RegularCauchySqueeze}^{\uparrow},\ \mathsf{DyadicSandwich}^{\uparrow},\ \mathsf{DyadicRatCore}^{\uparrow},\ \mathsf{StreamName}^{\uparrow},\ \mathsf{RegSeqRat}^{\uparrow},\ \mathsf{Real}^{\uparrow}.$$

In particular, a consumer may use the middle row as trapped between lower and upper regular Cauchy rows only after the shared dyadic tolerance ledger, finite windows, regular rational readbacks, and terminal real seal have all been projected.

Proof. Start with the carrier $T = (L, M, U, D, W, R, E, H, C, P, N)$. The rows L, M, U provide the lower, middle, and upper regular Cauchy observations, but the consumer cannot inspect them outside the finite windows W.

Use D to read the shared dyadic tolerance ledger. This is the row that makes the lower-middle and middle-upper containment checks visible to the dyadic sandwich route.

Use R to pass the three windowed observations through $\mathsf{RegSeqRat}^{\uparrow}$. The squeeze route is then the regular Cauchy route named by $\mathsf{RegularCauchySqueeze}^{\uparrow}$, with the dyadic enclosure discipline named by $\mathsf{DyadicSandwich}^{\uparrow}$.

The real-facing read reaches E only after those rows have been projected, and H, C, P, N preserve the same route under transport, replay, provenance, and local naming. Hence the consumer receives a finite sandwich certificate, not quotient real equality, a selected limit, trichotomy, countable choice, hidden tail selection, or ambient $\mathsf{Real}^{\uparrow}$ completeness. □

Falsifiable prediction: Every accepted $\mathsf{DyadicCauchySandwich}^{\uparrow}$ read exposes lower, middle, upper Cauchy rows, a shared DyadicRatCore tolerance ledger, finite StreamName windows, RegSeqRat readbacks, a RealUp seal, hsame transport, Cont replay, Pkg provenance, and local NameCert data before a Real or Completion consumer receives the packet.

Independence witness: regularcauchysqueeze, dyadicsandwich, dyadicratcore, streamname, regseqrat, real: $\mathsf{DyadicCauchySandwich}^{\uparrow}$ is not bijective to any listed sibling because it binds a three-row regular Cauchy sandwich to one shared dyadic ledger, finite windows, readbacks, seal, transport, replay, provenance, and local NameCert row.

Closure status for $\mathsf{NameCert}_{\mathsf{DyadicCauchySandwich}^{\uparrow}}$.

Constructive story: A $\mathsf{DyadicCauchySandwich}^{\uparrow}$ packet is generated from lower, middle, and upper regular Cauchy rows, a shared DyadicRatCore tolerance ledger, finite StreamName windows, RegSeqRat readbacks, a RealUp seal, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{DyadicCauchySandwich}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 9084.1, Definition 9084.2, Definition 9084.3, the falsifiable prediction, and the independence witness seed the finite lower-middle-upper Cauchy sandwich route.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{DyadicCauchySandwich}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient real equality, selected limits, trichotomy, countable choice, hidden tail selection, ambient $\mathsf{Real}^{\uparrow}$ completeness, theorem verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, shared dyadic tolerance exactness, finite-window readback, squeeze-route stability, real-seal nonescape, transport, replay, provenance, and local ledgering for BEDC.Derived.DyadicCauchySandwichUp.

Chapter 9085

A Concrete Naming Certificate for $\mathsf{DyadicModulusComparisonBoundary}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{DyadicModulusComparisonBoundary}^{\uparrow}$ packet realizes the finite comparison-modulus boundary of section 9238.4. It records two located-real endpoint presentations, one displayed dyadic comparison modulus, finite inspection windows, rational readbacks, and real seals before any comparison-facing consumer reads the packet. The chapter sits beside the located-real comparison packet of chapter 1730, the comparison-modulus sibling of chapter 5813, the tolerance ledger of chapter 291, the finite-window source of chapter 126, the regular rational readback of chapter 301, and the terminal seal of chapter 38. The packet is constructive: it does not export exact trichotomy, LPO, quotient real equality, or selected representative limits.

Definition 9085.1 (Dyadic modulus comparison boundary carrier)**.** *A* $\mathsf{DyadicModulusComparisonBoundary}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$C = (A, B, D, M, W, R, E, H, K, P, N)$$

with the following displayed rows:

1. *A is the left* $\mathsf{LocatedReal}^{\uparrow}$ *endpoint row, exposed through finite stream windows and regular rational readback.*
2. *B is the right* $\mathsf{LocatedReal}^{\uparrow}$ *endpoint row, exposed through the same finite-window discipline.*
3. *D is the shared* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger for the comparison request.*
4. *M is the displayed dyadic comparison modulus assigning each requested tolerance to a finite common observation boundary.*
5. *W is the paired* $\mathsf{StreamName}^{\uparrow}$ *window family selected by M for the two endpoint rows.*
6. *R records the paired* $\mathsf{RegSeqRat}^{\uparrow}$ *readbacks reached from those windows.*
7. *E records the two* $\mathsf{Real}^{\uparrow}$ *seals, readable only after A, B, D, M, W, R have been projected.*
8. *H records componentwise* hsame *transport for endpoint rows, tolerance ledger, modulus, windows, readbacks, real seals, replay, comparison boundary, provenance, and local name.*
9. *K records the displayed comparison-boundary row: finite tolerance closeness, finite apartness window, or common-refinement handoff, but not exact trichotomy.*

10. *P is the* Pkg *provenance over* $\mathsf{DyadicModulusComparisonBoundary}^{\uparrow}$, $\mathsf{LocatedReal}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{DyadicModulusComparisonBoundary}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $A, B, D, M, W, R, E, H, K, P, N$. It has no coordinate for arbitrary exact order trichotomy, LPO*, quotient real equality, countable choice, or selected completion limits.*

Theorem 9085.2 (Dyadic modulus comparison boundary NameCert obligations)**.** *For every accepted* $\mathsf{DyadicModulusComparisonBoundary}^{\uparrow}$ *carrier*

$$C = (A, B, D, M, W, R, E, H, K, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{DyadicModulusComparisonBoundary}^{\uparrow}}$ *surface consists exactly of six finite obligation rows: endpoint admission for A and B; dyadic tolerance admission through D; comparison-modulus determinacy through M; paired finite-window and* $\mathsf{RegSeqRat}^{\uparrow}$ *readback through W and R; Real-seal nonescape through E; and transport, comparison-boundary replay, provenance, and local ledgering through H, K, P, N. No obligation row exports exact trichotomy,* LPO*, quotient real equality, countable choice, or a selected real representative.*

Proof. Project the accepted carrier. The endpoint data are A and B, while D supplies the shared dyadic request against which comparison is read.

The modulus row M turns a requested tolerance into a finite common observation boundary. The paired windows W and readbacks R then expose only the rational observations selected by that displayed modulus.

The comparison row K records the constructive boundary: finite tolerance closeness, finite apartness, or a common-refinement handoff. It does not return a total exact order branch for arbitrary located-real presentations.

The real-seal row E and structural rows H, P, N preserve the same finite packet under sealing, transport, provenance, and local naming. Since no carrier coordinate names exact trichotomy, LPO, quotient equality, choice, or selected representatives, the six obligation rows exhaust the local NameCert surface. □

Theorem 9085.3 (Dyadic modulus comparison common refinement)**.** *Let $C = (A, B, D, M, W, R, E, H, K, P, N)$ be an accepted* $\mathsf{DyadicModulusComparisonBoundary}^{\uparrow}$ *carrier. Every comparison read for the two endpoint rows factors through the common refinement selected by the dyadic modulus row M and the tolerance ledger D. Thus the comparison route may compose finite moduli and read two* $\mathsf{Real}^{\uparrow}$ *seals, but it cannot produce exact trichotomy,* LPO*, quotient real equality, or a selected limit.*

Proof. Read the requested tolerance through D. The dyadic ledger fixes the scale at which the two endpoints may be compared.

Apply the modulus row M. It selects a common finite observation boundary for both endpoints, and the paired StreamName row W exposes exactly those windows.

Use R to read the rational observations and K to record the comparison boundary. When two comparison steps are composed, the common refinement is obtained by taking the displayed finite boundary that serves both modulus rows, as in the finite comparison composition of section 9238.4.

The real seals E are read only after the finite comparison rows have been projected, and H, P, N preserve the same packet under transport, provenance, and local naming. Therefore the route supplies a constructive common refinement, not exact trichotomy, omniscience, quotient equality, choice, or selected limits. □

Falsifiable prediction: Every accepted $\mathsf{DyadicModulusComparisonBoundary}^{\uparrow}$ read exposes two located-real endpoint rows, a dyadic tolerance ledger, displayed comparison modulus, paired StreamName windows, paired RegSeqRat readbacks, two RealUp seals, comparison-boundary row, hsame transport, Pkg provenance, and local NameCert data before a comparison consumer receives the packet.

Independence witness: locatedreal, located-real-comparison, located-real-comparison-modulus, dyadicratcore, streamname, regseqrat, real: $\mathsf{DyadicModulusComparisonBoundary}^{\uparrow}$ is not bijective to any listed sibling because it binds two endpoint rows to one displayed dyadic comparison modulus, paired finite windows, paired readbacks, Real seals, comparison-boundary replay, transport, provenance, and local NameCert row.

Closure status for $\mathsf{NameCert}_{\mathsf{DyadicModulusComparisonBoundary}^{\uparrow}}$.

Constructive story: A $\mathsf{DyadicModulusComparisonBoundary}^{\uparrow}$ packet is generated from two located-real endpoint rows, a DyadicRatCore tolerance ledger, a displayed comparison modulus, paired StreamName windows, paired RegSeqRat readbacks, two RealUp seals, hsame transport, a comparison-boundary row, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{DyadicModulusComparisonBoundary}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 9085.1, Definition 9085.2, Definition 9085.3, the falsifiable prediction, and the independence witness seed the finite dyadic comparison-modulus boundary for located-real reads.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{DyadicModulusComparisonBoundary}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close exact trichotomy, LPO, quotient real equality, countable choice, selected real representatives, ambient $\mathsf{Real}^{\uparrow}$ completeness, theorem verification, or bridge checking.

Upgrade path: Obligation closure requires checked endpoint admission, dyadic tolerance admission, comparison-modulus determinacy, finite-window readback, common-refinement stability, real-seal nonescape, transport, provenance, and local ledgering for BEDC.Derived.DyadicModulusComparisonBoundaryUp.

Chapter 9086

A Concrete Naming Certificate for $\mathsf{GaussianElimination}^{\uparrow}$

Following Gaussian and standard finite-dimensional linear algebra, the $\mathsf{GaussianElimination}^{\uparrow}$ packet records field-based row reduction as a finite pivot, normalization, and elimination ledger over displayed $\mathsf{Mat}^{\uparrow}$ and $\mathsf{Field}^{\uparrow}$ rows. It sits beside the fraction-free determinant route of chapter 7715: Bareiss elimination records determinant-preserving updates over ring and polynomial rows, while this packet names the finite field-division surface used by row-reduction consumers. The packet exports no ambient quotient matrix equality, no selected solution set, no rank-nullity theorem, no Smith normal form, and no host proof that every matrix reaches a canonical echelon form.

Definition 9086.1 (GaussianElimination carrier)**.** *A* $\mathsf{GaussianElimination}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$G = (F, M, I, P, N, L, Z, R, H, C, K, Q)$$

with the following displayed rows:

1. *F is the consumed* $\mathsf{Field}^{\uparrow}$ *scalar row, including the displayed zero, one, addition, multiplication, negation, and inverse reads used by the ledger.*
2. *M is the consumed* $\mathsf{Mat}^{\uparrow}$ *row, including the finite row and column index sets and the initial entry readbacks.*
3. *I lists the pivot-search windows inspected by the packet and the finite row-swap rows used before each pivot is normalized.*
4. *P records the chosen pivot entries and their nonzero-field witnesses.*
5. *N records the pivot-normalization rows, including the displayed inverse read through F and the row-scaling operation on M.*
6. *L records the elimination rows that cancel each displayed nonpivot entry using finite field operations.*
7. *Z records the zero-row and terminal echelon-window checks obtained from the finite ledger.*
8. *R is the row-reduction readback row exported to downstream finite linear-algebra consumers.*
9. *H records componentwise* hsame *transport for F, M, I, P, N, L, Z, R and the local naming rows.*
10. *C records displayed* Cont *replay from a row-reduction request through the scalar, matrix, pivot, normalization, elimination, terminal-window, and readback rows.*

11. *K is the* Pkg *provenance over* $\mathsf{GaussianElimination}^{\uparrow}$, $\mathsf{Field}^{\uparrow}$, $\mathsf{Mat}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

12. *Q is the local* $\mathsf{NameCert}_{\mathsf{GaussianElimination}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through these rows. It has no coordinate for an unlogged pivot inverse, quotient equality of matrices, arbitrary solution-space selection, rank theory, or a host canonical-form theorem.

Theorem 9086.2 (GaussianElimination NameCert obligations)**.** *For every accepted* $\mathsf{GaussianElimination}^{\uparrow}$ *carrier* $G = (F, M, I, P, N, L, Z, R, H, C, K, Q)$*, the local* $\mathsf{NameCert}_{\mathsf{GaussianElimination}^{\uparrow}}$ *surface consists exactly of carrier admission, field-source exposure, matrix-source exposure, finite pivot-window exposure, pivot nonzero evidence, pivot normalization, elimination-row exposure, terminal echelon-window readback, componentwise transport, replay, provenance, local naming, and refusal of unlogged inverses, quotient matrix equality, selected solution sets, rank theory, Smith normal form, and host canonical-form theorems.*

Proof. Project the carrier of Definition 9086.1. The source rows F and M must be read before any pivot operation is available.

Inspect the finite ledger rows I, P, N, L, Z, R. Pivot windows and swaps are displayed in I, nonzero pivot evidence is stored in P, normalization reads field inverses through N, elimination rows are listed in L, and terminal echelon-window checks are recorded in Z before the row-reduction readback R is exported.

The rows H, C, K, Q transport, replay, source, and name the same finite route. Since no additional coordinate is present, the packet cannot export an unlogged inverse, quotient matrix equality, selected solution set, rank theorem, Smith normal form, or host canonical-form theorem. □

Theorem 9086.3 (GaussianElimination Bareiss row-reduction handoff)**.** *The* $\mathsf{GaussianElimination}^{\uparrow}$ *packet and the* $\mathsf{BareissFractionFreeElimination}^{\uparrow}$ *packet share the displayed matrix-ledger boundary at* $\mathsf{Mat}^{\uparrow}$*, but they expose different finite routes. A Gaussian row-reduction consumer must read*

$$\mathsf{Field}^{\uparrow},\ \mathsf{Mat}^{\uparrow} \longmapsto I, P, N, L, Z, R \longmapsto H, C, K, Q,$$

whereas the Bareiss determinant route of chapter 7715 reads the fraction-free pivot, divisibility, branch, and determinant handoff rows. Thus the Gaussian packet may hand a finite row-reduction read to matrix consumers without claiming the fraction-free determinant exactness of Bareiss, and the Bareiss packet may hand determinant data to $\mathsf{Determinant}^{\uparrow}$ *without claiming arbitrary field-based Gaussian elimination.*

Proof. Start with the shared matrix boundary. Both packets consume a displayed $\mathsf{Mat}^{\uparrow}$ row, so downstream consumers can compare that source row through ordinary hsame transport and Pkg provenance.

Separate the scalar routes. The Gaussian packet reads field inverses through F and pivot normalization through N, while the Bareiss packet reads ring rows, previous-pivot denominators, exact-divisibility witnesses, and determinant exactness rows. These rows are not interchangeable.

The handoff is therefore a dependency comparison, not an identification. The Gaussian route exports finite row-reduction readback through R, and the Bareiss route exports determinant-facing fraction-free data through its determinant handoff. Neither packet imports the other's refused claims. □

Closure status for $\mathsf{NameCert}_{\mathsf{GaussianElimination}^{\uparrow}}$.

Constructive story: A $\mathsf{GaussianElimination}^{\uparrow}$ packet is generated from FieldUp scalar rows, MatrixUp entry rows, finite pivot-window rows, pivot nonzero witnesses, pivot-normalization rows, elimination rows, terminal echelon-window rows, row-reduction readback, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{GaussianElimination}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 9086.1, Definition 9086.2, and Definition 9086.3 seed the finite field-based row-reduction route over displayed matrix, field, pivot, normalization, elimination, readback, transport, replay, provenance, and naming rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{GaussianElimination}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim Lean verification, quotient matrix equality, selected solution sets, rank-nullity, Smith normal form, Bareiss determinant exactness, host canonical echelon form, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, pivot-window exposure, pivot nonzero evidence, normalization exactness, elimination replay, terminal-window readback, structural transport, provenance, and consumer nonescape for BEDC.Derived.GaussianEliminationUp.

Chapter 9087

A Concrete Naming Certificate for $\mathsf{SternBrocotRealCompletion}^{\uparrow}$

Following Stern and Brocot's mediant enumeration and the Hardy–Wright continued-fraction treatment of rational bracketing, the $\mathsf{SternBrocotRealCompletion}^{\uparrow}$ packet reconstructs a real-completion route from finite rational intervals. It sits beside the tree carrier of chapter 1704 and the expansion carrier of chapter 6738, then hands its regular refinement stream to chapter 291, chapter 301, and chapter 38. The packet records only finite bracketing, mediant refinement, dyadic tolerance, stream handoff, transport, replay, provenance, and local naming rows; it does not import Dedekind cuts, quotient real equality, selected limits, completeness, or choice.

Definition 9087.1 (Stern-Brocot real-completion carrier)**.** *A* $\mathsf{SternBrocotRealCompletion}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (B, M, T, D, R, E, H, C, P, N)$$

with the following displayed rows:

1. *B is a finite* $\mathsf{SternBrocot}^{\uparrow}$ *bracket row, naming adjacent rational endpoints and the finite path that generated them.*
2. *M is the mediant-refinement row, recording the next finite bracket rows obtained by the Stern–Brocot mediant rule.*
3. *T is the dyadic tolerance row, bounding each active bracket width by a displayed* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance.*
4. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *rational-core readback used to compare bracket widths and tolerances.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *stream row obtained by reading the bracket representatives through the dyadic tolerance schedule.*
6. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row receiving the regular rational stream as a completion candidate.*
7. *H records componentwise* hsame *transport for brackets, mediant refinements, tolerances, dyadic rational rows, regular rational streams, Real seals, provenance, and local names.*
8. *C records displayed* Cont *replay from finite bracket data through mediant refinement, dyadic tolerance,* $\mathsf{RegSeqRat}^{\uparrow}$ *stream handoff, and the* $\mathsf{Real}^{\uparrow}$ *seal.*
9. *P is the* Pkg *provenance over* $\mathsf{SternBrocotRealCompletion}^{\uparrow}$, $\mathsf{SternBrocot}^{\uparrow}$, $\mathsf{ContinuedFractionReal}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.

10. N is the local $\mathsf{NameCert}_{\mathsf{SternBrocotRealCompletion}^{\uparrow}}$ *row.*
The classifier compares accepted carriers only through $B, M, T, D, R, E, H, C, P, N$. It contains no coordinate for Dedekind cuts, quotient real equality, selected limiting points, completeness of $\mathsf{Real}^{\uparrow}$*, host real arithmetic, or choice.*

Theorem 9087.2 (Stern-Brocot real-completion NameCert obligations)**.** *For every accepted* SternBrocotRealComp *carrier*

$$S = (B, M, T, D, R, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{SternBrocotRealCompletion}^{\uparrow}}$ *surface consists exactly of Stern–Brocot bracket exposure through B, mediant refinement exposure through M, dyadic tolerance exposure through T,* $\mathsf{DyadicRatCore}^{\uparrow}$ *readback through D,* $\mathsf{RegSeqRat}^{\uparrow}$ *stream handoff through R,* $\mathsf{Real}^{\uparrow}$ *seal exposure through E, componentwise* hsame *transport through H, displayed* Cont *replay through C,* Pkg *provenance through P, and local naming through N.*

Proof. Project the carrier of Definition 9087.1. Rows B, M, T, D, R, E are the completion-facing data, while H, C, P, N are the structural certificate rows.

The rational bracketing route begins with B and M. The Stern–Brocot row supplies adjacent rational endpoints, and the mediant row records the finite refinement step without reading an infinite path as a completed object.

The tolerance route then runs through T and D. The dyadic row bounds bracket widths by finite rational data, so the regular stream handoff has a displayed tolerance source rather than an ambient real limit.

Finally the handoff through R and E presents the regular rational stream to the $\mathsf{Real}^{\uparrow}$ seal. The transport, replay, provenance, and local naming rows preserve this finite route, so no Dedekind cut, quotient equality, selected limit, completeness principle, or choice coordinate is available. □

Theorem 9087.3 (Stern-Brocot real-completion sibling route)**.** *Every public read of an accepted* $\mathsf{SternBrocotRealCompletion}^{\uparrow}$ *packet factors through the sibling rows named by the carrier: the* $\mathsf{SternBrocot}^{\uparrow}$ *bracket row, the continued-fraction bracketing discipline of* $\mathsf{ContinuedFractionReal}^{\uparrow}$*, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row, the* $\mathsf{RegSeqRat}^{\uparrow}$ *regular stream row, and the terminal* $\mathsf{Real}^{\uparrow}$ *seal. A consumer cannot read the packet as an isolated completeness theorem or as quotient real equality.*

Proof. Begin with the carrier. Its first two rows, B and M, are finite Stern–Brocot bracket data; they match the rational bracketing route also exposed by the continued-fraction real packet.

Next read the dyadic tolerance and rational-core rows T, D. These rows keep the finite bracket widths explicit before any regular stream can be named.

The $\mathsf{RegSeqRat}^{\uparrow}$ row R and $\mathsf{Real}^{\uparrow}$ seal E then provide the completion-facing handoff. Since the structural rows H, C, P, N replay and source only this route, the consumer receives a rational-refinement certificate rather than a Dedekind cut, quotient equality class, selected limit, or completeness theorem. □

Closure status for $\mathsf{NameCert}_{\mathsf{SternBrocotRealCompletion}^{\uparrow}}$.

Constructive story: A $\mathsf{SternBrocotRealCompletion}^{\uparrow}$ packet is generated from finite Stern–Brocot bracket rows, mediant refinement rows, dyadic tolerance rows, $\mathsf{DyadicRatCore}^{\uparrow}$ rational-core readback, a $\mathsf{RegSeqRat}^{\uparrow}$ stream handoff, a $\mathsf{Real}^{\uparrow}$ seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{SternBrocotRealCompletion}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 9087.1, Definition 9087.2, and Definition 9087.3 seed the finite rational-bracketing route from Stern–Brocot refinement to a regular rational stream and a Real seal.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{SternBrocotRealCompletion}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close Dedekind cuts, quotient real equality, selected limits, completeness, host real arithmetic, choice, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, mediant refinement, dyadic tolerance exactness, RegSeqRat stream handoff, Real seal exposure, hsame transport, Cont replay, Pkg provenance, and local NameCert coverage for BEDC.Derived.SternBrocotRealCompletionUp.

Chapter 9088

A Concrete Naming Certificate for $\mathsf{GelfandNaimark}^{\uparrow}$

Following Gelfand and Naimark's representation theorem for C^*-algebras, the $\mathsf{GelfandNaimark}^{\uparrow}$ packet records the finite NameCert surface by which a displayed C^*-algebra source is handed to a Hilbert-space operator-action reader. It sits after the C^*-algebra carrier of chapter 211, the Hilbert carrier of chapter 91, the bounded-linear-operator interface of chapter 1644, the real seal of chapter 38, and the complex scalar carrier of chapter 39. The chapter names only the finite representation packet; it does not import the full standard representation theorem, a selected faithful representation, quotient host equality, spectral completeness, or ambient choice.

Definition 9088.1 (Gelfand–Naimark representation carrier)**.** *A* $\mathsf{GelfandNaimark}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$G = (A, H, O, R, C, M, T, K, P, N)$$

with the following displayed rows:

1. *A is the* $\mathsf{CStarAlg}^{\uparrow}$ *source row, exposing the algebra, involution, norm, and C^*-identity surface that the representation reader may inspect.*
2. *H is the* $\mathsf{Hilbert}^{\uparrow}$ *representation-space row, naming the target Hilbert carrier without selecting a host completion.*
3. *O is the* $\mathsf{BoundedLinearOperator}^{\uparrow}$ *operator-action row, recording the displayed action of source elements on the Hilbert row.*
4. *R is the* $\mathsf{Real}^{\uparrow}$ *scalar seal row for norm comparisons, positivity readbacks, and displayed operator bounds.*
5. *C is the* $\mathsf{Complex}^{\uparrow}$ *scalar seal row for complex scalar multiplication, involution compatibility, and inner-product scalar reads.*
6. *M stores the multiplicative and involutive compatibility ledger tying A to the operator-action row O.*
7. *T records componentwise* hsame *transport for $A, H, O, R, C, M, K, P, N$.*
8. *K records displayed* Cont *replay from source-algebra reads through Hilbert-space action, scalar seals, and local naming.*
9. *P is the* Pkg *provenance over* $\mathsf{GelfandNaimark}^{\uparrow}$, $\mathsf{CStarAlg}^{\uparrow}$, $\mathsf{Hilbert}^{\uparrow}$, $\mathsf{BoundedLinearOperator}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{Complex}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.

10. N is the local $\mathsf{NameCert}_{\mathsf{GelfandNaimark}^{\uparrow}}$ *row.*

The carrier compares accepted packets only through these rows. It has no coordinate for a host faithful representation, universal representation, quotient operator algebra, selected state space, unrestricted spectrum, ambient Hilbert completion, or choice principle.

Theorem 9088.2 (Gelfand–Naimark NameCert obligations)**.** *For every accepted* $\mathsf{GelfandNaimark}^{\uparrow}$ *carrier* $G = (A, H, O, R, C, M, T, K, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{GelfandNaimark}^{\uparrow}}$ *surface consists exactly of* C^**-algebra source admission, Hilbert representation-space admission, bounded-operator action exposure, real and complex scalar seal rows, multiplicative and involutive compatibility, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming.*

Any representation-facing consumer must first display the sibling routes through chapter 211, chapter 91, chapter 1644, chapter 38, and chapter 39. Replacing one of those rows by a host representation theorem, selected state space, quotient operator algebra, unrestricted spectrum, or ambient choice leaves the accepted carrier.

Proof. Project the accepted carrier $G = (A, H, O, R, C, M, T, K, P, N)$. The source row A is the only C^*-algebra input, while H and O display the Hilbert carrier and bounded-operator action consumed by the representation reader.

The scalar rows R and C keep norm, positivity, complex scalar, and inner-product reads on displayed Real and Complex seals. The compatibility row M attaches multiplicative and involutive checks to the same operator-action route.

The structural rows T, K, P, N transport, replay, source, and name this finite inventory. Since no row stores a host faithful representation, universal representation, quotient operator algebra, selected state space, unrestricted spectrum, ambient Hilbert completion, or choice principle, the listed rows exhaust the NameCert obligations. □

Theorem 9088.3 (Gelfand–Naimark representation handoff)**.** *Every representation-facing read from an accepted* $\mathsf{GelfandNaimark}^{\uparrow}$ *packet factors through the finite route*

$$\mathsf{CStarAlg}^{\uparrow} \longmapsto \mathsf{Hilbert}^{\uparrow} \longmapsto \mathsf{BoundedLinearOperator}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow},\ \mathsf{Complex}^{\uparrow} \longmapsto \mathsf{NameCert}_{\mathsf{GelfandNaimark}^{\uparrow}}.$$

For $G = (A, H, O, R, C, M, T, K, P, N)$*, the consumer must expose the* C^**-algebra source row, Hilbert representation-space row, bounded-operator action row, real and complex scalar seal rows, compatibility ledger, transport, replay, provenance, and local naming before any standard-facing representation domain can be compared. The handoff exports no full standard representation theorem, selected faithful representation, quotient host equality, unrestricted spectrum, ambient Hilbert completion, or choice schedule.*

Proof. Begin with a representation-facing request. The carrier gives access to the source only through A, so the consumer first reads the displayed C^*-algebra surface.

Next expose the representation target. The Hilbert row H and bounded-operator row O provide the finite action surface, while M records the multiplicative and involutive compatibility that the action may claim.

The scalar checks then pass through R and C. These rows keep norm, positivity, complex scalar, and inner-product reads on the displayed scalar seals before any standard-facing comparison is attempted.

Finally T, K, P, N preserve the same route under transport, continuation replay, provenance, and local naming. The absent host representation theorem, selected faithful representation, quotient equality, unrestricted spectrum, ambient completion, and choice data cannot be recovered from the packet. □

Falsifiable prediction: An accepted $\mathsf{GelfandNaimark}^{\uparrow}$ read is refuted if a representation-facing consumer obtains a standard-facing representation comparison without displaying the CStarAlg source row, Hilbert representation row, BoundedLinearOperator action row, Real and Complex scalar seals, compatibility ledger, hsame transport, Cont replay, Pkg provenance, and local NameCert row.

Independence witness: cstaralgebra, hilbert, boundedlinearoperator, real, and complex: none is bijective to $\mathsf{GelfandNaimark}^{\uparrow}$ because only this packet jointly records a C^*-algebra source, Hilbert representation carrier, bounded-operator action, scalar seal rows, compatibility ledger, transport, replay, provenance, and local NameCert naming as one representation surface.

Closure status for $\mathsf{NameCert}_{\mathsf{GelfandNaimark}^{\uparrow}}$.

Constructive story: A $\mathsf{GelfandNaimark}^{\uparrow}$ packet is generated from a CStarAlg source row, Hilbert representation-space row, BoundedLinearOperator action row, Real and Complex scalar seals, multiplicative and involutive compatibility ledger, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{GelfandNaimark}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 9088.1, Definition 9088.2, and Definition 9088.3 seed the finite representation handoff from CStarAlg rows through Hilbert and BoundedLinearOperator rows to Real and Complex scalar seals.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{GelfandNaimark}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim the full standard representation theorem, selected faithful representation, quotient host equality, unrestricted spectrum, ambient Hilbert completion, choice, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, Hilbert and bounded-operator action exposure, scalar seal compatibility, multiplicative and involutive exactness, transport, replay, provenance, and local naming for BEDC.Derived.GelfandNaimarkUp.

Chapter 9089

A Concrete Naming Certificate for $\mathsf{UnscentedKalmanFilter}^{\uparrow}$

Following Julier and Uhlmann on the unscented transform, the $\mathsf{UnscentedKalmanFilter}^{\uparrow}$ packet records a nonlinear filtering certificate whose sigma-point generation, propagation, covariance ledger, and update row are all displayed as finite BEDC data before a downstream estimator reads the filter. It sits beside the continuous-time $\mathsf{KalmanBucyFilter}^{\uparrow}$ packet of chapter 6360 and the finite Gramian ledger of $\mathsf{ObservabilityGramian}^{\uparrow}$ in chapter 5787. Its carrier is read through the $\mathsf{Mat}^{\uparrow}$ rows of chapter 49, the $\mathsf{VecSpace}^{\uparrow}$ rows of chapter 47, the $\mathsf{ProbSpace}^{\uparrow}$ rows of chapter 184, and the $\mathsf{RandomVar}^{\uparrow}$ rows of chapter 185. The packet names only the finite unscented-filter ledger; it does not claim an ambient stochastic process, analytic convergence theorem, selected nonlinear model class, or optimality theorem.

Definition 9089.1 (UnscentedKalmanFilter carrier)**.** *An* $\mathsf{UnscentedKalmanFilter}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$U = (X, Y, \mu, \Sigma, S, W, F, G, \widehat{\mu}, \widehat{\Sigma}, Z, K, R, E, H, C, P, N)$$

with the following visible rows:

1. *X and Y are the state and observation rows, each displayed through* $\mathsf{VecSpace}^{\uparrow}$ *and* $\mathsf{Mat}^{\uparrow}$ *coordinates;*
2. *μ and Σ are the prior mean and covariance rows read through* $\mathsf{ProbSpace}^{\uparrow}$ *and* $\mathsf{RandomVar}^{\uparrow}$ *provenance;*
3. *S is the finite sigma-point row and W is the corresponding weight row;*
4. *F is the propagated state-sigma row and G is the propagated observation-sigma row;*
5. *$\widehat{\mu}$ and $\widehat{\Sigma}$ are the predicted mean and covariance rows, and Z, K, R are the innovation, gain, and residual-ledger rows;*
6. *E records sibling readback through the* $\mathsf{KalmanBucyFilter}^{\uparrow}$ *and* $\mathsf{ObservabilityGramian}^{\uparrow}$ *surfaces without identifying the nonlinear sigma-point packet with either sibling;*
7. *H records componentwise* hsame *transport of state, observation, covariance, sigma-point, weight, propagation, innovation, gain, and residual rows;*
8. *C records displayed* Cont *replay for accepted prediction and update routes;*

9. *P is the* Pkg *provenance naming* $\mathsf{UnscentedKalmanFilter}^{\uparrow}$, $\mathsf{KalmanBucyFilter}^{\uparrow}$, $\mathsf{ObservabilityGramian}^{\uparrow}$, $\mathsf{Mat}^{\uparrow}$, $\mathsf{VecSpace}^{\uparrow}$, $\mathsf{ProbSpace}^{\uparrow}$, $\mathsf{RandomVar}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert*;*
10. *N is the local* $\mathsf{NameCert}_{\mathsf{UnscentedKalmanFilter}^{\uparrow}}$ *row.*

No external nonlinear dynamics oracle, host probability space, selected noise process, analytic approximation bound, or optimality certificate is part of the carrier.

Theorem 9089.2 (UnscentedKalmanFilter NameCert obligations)**.** *For the carrier of Definition 9089.1, the local* $\mathsf{NameCert}_{\mathsf{UnscentedKalmanFilter}^{\uparrow}}$ *surface consists exactly of the following five obligation rows:*

1. *carrier admission for the displayed packet* $U = (X, Y, \mu, \Sigma, S, W, F, G, \widehat{\mu}, \widehat{\Sigma}, Z, K, R, E, H, C, P, N)$*;*
2. *sigma-point classifier stability, saying that the accepted classifier depends only on the displayed* S, W, F, G *rows and their stated state, observation, mean, and covariance sources;*
3. *covariance and update ledger exactness, saying that* $\widehat{\mu}$*,* $\widehat{\Sigma}$*,* Z*,* K*, and* R *are read only through the displayed sigma-point, weight, propagated-observation, innovation, and residual rows;*
4. *componentwise* hsame *transport through* H *for state, observation, covariance, sigma-point, weight, propagation, innovation, gain, residual, provenance, and local naming rows;*
5. *displayed* Cont *replay through* C *for every prediction, update, and sibling-consumer route exported by the packet.*

Proof. Project the accepted carrier of Definition 9089.1. Carrier admission is coordinate inspection: every row used by the certificate is a displayed BHist coordinate of U.

The sigma-point classifier is stable because it reads the finite sigma-point row S, weight row W, and propagated rows F, G together with their displayed state, observation, mean, and covariance sources. Componentwise replacement by hsame-matched rows preserves that finite shape.

The covariance and update ledger is exact by the same projection. The predicted mean, predicted covariance, innovation, gain, and residual rows have no route except through $S, W, F, G, \widehat{\mu}, \widehat{\Sigma}, Z, K, R$.

Finally, H and C are the only transport and replay rows. A downstream Kalman, Gramian, matrix, vector-space, probability, or random-variable consumer must therefore read the same finite packet through the package provenance P and the local name row N, not through an undisplayed stochastic or analytic object. □

Falsifiable prediction: An accepted $\mathsf{UnscentedKalmanFilter}^{\uparrow}$ packet is refuted by any estimator consumer that reads a covariance, gain, innovation, residual, or propagated sigma-point row while bypassing the displayed sigma-point row S, weight row W, covariance ledger $\widehat{\Sigma}$, update rows Z, K, R, transport row H, replay row C, or package provenance P.

Independence witness: kalman-bucy-filter, observability-gramian, matrix, vecspace, probspace: none is bijective to $\mathsf{UnscentedKalmanFilter}^{\uparrow}$ because the packet jointly carries sigma-point generation, weights, nonlinear propagation, covariance prediction, innovation update, sibling readback, transport, replay, provenance, and local NameCert rows.

Closure status for $\mathsf{NameCert}_{\mathsf{UnscentedKalmanFilter}^{\uparrow}}$**.**

Constructive story: An $\mathsf{UnscentedKalmanFilter}^{\uparrow}$ packet is generated from finite state, observation, mean, covariance, sigma-point, weight, propagation, innovation, gain, residual, sibling readback, transport, replay, provenance, and local naming rows.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{UnscentedKalmanFilter}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 9089.1, Definition 9089.2, the displayed falsifiable prediction, and the displayed independence witness seed the finite nonlinear filtering NameCert surface over KalmanBucy, Gramian, matrix, vector-space, probability-space, and random-variable rows.

Formal verification: FormalStatus(NameCert$_{\text{UnscentedKalmanFilter}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim Lean verification, bridge checking, host stochastic-process semantics, analytic convergence, nonlinear filtering optimality, or a selected external probability model.

Upgrade path: Obligation closure requires checked carrier admission, sigma-point classifier stability, covariance and update ledger exactness, componentwise transport, replay, package provenance, and local NameCert exhaustion for BEDC.Derived.UnscentedKalmanFilterUp.

Chapter 9090

A Concrete Naming Certificate for $\mathsf{FiniteHellySelection}^{\uparrow}$

Following Helly and Bishop–Bridges, the $\mathsf{FiniteHellySelection}^{\uparrow}$ packet records the finite interval-selection surface needed in the L10 real-completion route. It sits between the dyadic cell machinery of chapter 291, the finite window naming discipline of chapter 126, the regular rational readback of chapter 301, the terminal real seal of chapter 38, and the subsequence-facing compactness packet of chapter 1254. The chapter names only finite closed-interval rows and located handoff data; it does not invoke open-cover compactness, arbitrary choice, selected infinite subsequences, quotient real equality, or ambient real completeness.

Definition 9090.1 (FiniteHellySelection carrier)**.** *A* $\mathsf{FiniteHellySelection}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (I, D, W, Q, R, S, H, C, P, N)$$

with the following displayed rows:

1. *I is the finite closed-interval family row. It lists the inspected interval names and their rational endpoint witnesses.*
2. *D is the dyadic cell row. It records the finite tolerance grid read through* $\mathsf{DyadicRatCore}^{\uparrow}$ *and keeps each cell boundary as rational data.*
3. *W is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row naming the bounded observation windows used by the selection request.*
4. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row. It translates the finite window and dyadic cell data into regular rational approximants.*
5. *R is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row for the selected closed-interval witness, read only after I, D, W, Q have been exposed.*
6. *S is the finite selection ledger. It records which inspected interval row supplies the local witness and which finite compatibility checks were used.*
7. *H records componentwise* hsame *transport for interval, dyadic, window, readback, real-seal, selection-ledger, replay, provenance, and naming rows.*
8. *C records displayed* Cont *replay from a consumer request through the interval family, dyadic cell, finite window, regular readback, real seal, selection ledger, provenance, and local naming rows.*

9. *P is the* Pkg *provenance over* $\mathsf{FiniteHellySelection}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{BolzanoWeierstrass}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*

10. *N is the local* $\mathsf{NameCert}_{\mathsf{FiniteHellySelection}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $I, D, W, Q, R, S, H, C, P, N$. It has no coordinate for open-cover compactness, arbitrary choice, selected infinite subsequences, quotient real equality, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 9090.2 (FiniteHellySelection NameCert obligations)**.** *For every accepted* $\mathsf{FiniteHellySelection}^{\uparrow}$ *carrier*

$$K = (I, D, W, Q, R, S, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{FiniteHellySelection}^{\uparrow}}$ *surface consists exactly of carrier admission for the finite closed-interval family, dyadic cell grid,* $\mathsf{StreamName}^{\uparrow}$ *finite windows,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback, terminal* $\mathsf{Real}^{\uparrow}$ *seal, finite selection ledger, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming rows. Every compatibility read must expose the finite interval rows I, dyadic tolerance row D, window row W, and regular readback row Q before the selected real seal R is handed to an L10 consumer.*

Proof. Project the carrier of Definition 9090.1. The tuple lists exactly the interval, dyadic, window, readback, real-seal, selection-ledger, transport, replay, provenance, and naming rows.

The selection ledger S records only finite compatibility checks among the displayed interval rows. Thus a consumer cannot replace the ledger by an open-cover compactness argument, a choice function over all intervals, or a selected infinite subsequence.

The structural rows H, C, P, N preserve the same finite route under transport, replay, provenance, and naming. Since quotient real equality and ambient completeness are not coordinates of the carrier, the NameCert surface exports only the displayed L10 interval-selection packet. □

Theorem 9090.3 (FiniteHellySelection interval handoff)**.** *Every* $\mathsf{Real}^{\uparrow}$ *or* $\mathsf{BolzanoWeierstrass}^{\uparrow}$ *consumer reading a selected interval witness from an accepted* $\mathsf{FiniteHellySelection}^{\uparrow}$ *packet must pass through*

$$I, D, W, Q \longmapsto R, S \longmapsto H, C, P, N.$$

The handoff uses the dyadic tolerance source of chapter 291, the finite-window route of chapter 126, the regular rational readback of chapter 301, and the terminal seal of chapter 38 before it can feed the compactness-facing consumer of chapter 1254. It supplies a finite closed-interval selection row, not open-cover compactness, arbitrary choice, selected infinite subsequences, quotient real equality, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start with the NameCert obligations of Definition 9090.2. They force every selection read through $I, D, W, Q, R, S, H, C, P, N$.

The dyadic and finite-window rows are read before the regular rational row. This keeps the L10 route finite: the consumer sees only inspected cells and windows, then the regular readback that feeds the terminal real seal.

Finally the handoff to $\mathsf{Real}^{\uparrow}$ or $\mathsf{BolzanoWeierstrass}^{\uparrow}$ consumes R and S through the same transport, replay, provenance, and naming rows. No coordinate in the carrier names open-cover compactness, choice over arbitrary families, an infinite subsequence selector, quotient real equality, or ambient completeness, so none can be exported by the handoff. □

Closure status for $\mathsf{NameCert}_{\mathsf{FiniteHellySelection}^{\uparrow}}$.

Constructive story: A $\mathsf{FiniteHellySelection}^{\uparrow}$ packet is generated from finite closed-interval rows, dyadic cell rows, StreamName finite windows, RegSeqRat readback rows, terminal RealUp seals, a finite selection ledger, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{FiniteHellySelection}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 9090.1, Definition 9090.2, and Definition 9090.3 define the finite interval-selection packet and its L10 real-completion handoff surface.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{FiniteHellySelection}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close open-cover compactness, arbitrary choice, selected infinite subsequences, quotient real equality, ambient RealUp completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, dyadic-cell compatibility, finite-window readback, selection-ledger stability, RealUp seal handoff, provenance, and local naming for BEDC.Derived.FiniteHellySelectionUp.

Chapter 9091

Buckingham Pi NameCert Construction

Following Buckingham's dimensional-analysis theorem, the $\mathsf{BuckinghamPi}^{\uparrow}$ packet records the finite unit-exponent route by which a displayed physical law is read through dimensionless monomial coordinates. It sits beside the finite vector-space carrier of chapter 47, the linear-map row of chapter 48, the matrix ledger of chapter 49, and the terminal scalar seal of chapter 38. The packet names the traditional Pi-theorem surface as BEDC data; it does not import host units, choose a basis outside the displayed exponent matrix, quotient physical quantities, or assert analytic smoothness of the modeled law.

Definition 9091.1 (Buckingham Pi carrier)**.** *A* $\mathsf{BuckinghamPi}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (U, M, K, T, E, H, C, P, N)$$

with the following displayed rows:

1. *U is the finite unit-exponent carrier, listing the base-unit coordinates of every inspected quantity.*
2. *M is the* $\mathsf{Mat}^{\uparrow}$ *row for the displayed dimension matrix over the same finite coordinate window.*
3. *K is the dimensionless monomial classifier, exposing exactly the nullspace rows whose exponent vectors cancel all base-unit coordinates.*
4. *T is the exponent-transport stability row, recording componentwise* hsame *transport for unit rows, exponent vectors, matrix reads, and monomial classifiers.*
5. *E is the nullspace and exactness ledger, showing that each exported Pi row is read through M and K before any scalar readback is consumed.*
6. *H records the no-host-units non-escape boundary: every accepted read remains inside the displayed unit-exponent packet.*
7. *C is the displayed* Cont *replay row for finite unit windows, matrix rows, nullspace rows, and dimensionless monomial reads.*
8. *P is the* Pkg *provenance over* $\mathsf{BuckinghamPi}^{\uparrow}$, $\mathsf{VecSpace}^{\uparrow}$, $\mathsf{LinMap}^{\uparrow}$, $\mathsf{Mat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$ *rows.*
9. *N is the local* $\mathsf{NameCert}_{\mathsf{BuckinghamPi}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these nine rows. It has no coordinate for host units, quotient dimensions, selected physical constants, analytic regularity, or an ambient real-valued law outside the displayed finite packet.

Theorem 9091.2 (Buckingham Pi NameCert surface)**.** *For every accepted* $\mathsf{BuckinghamPi}^{\uparrow}$ *carrier* $B = (U, M, K, T, E, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{BuckinghamPi}^{\uparrow}}$ *surface consists exactly of carrier admission for the finite unit-exponent row, matrix readback for the dimension map, dimensionless monomial classification, exponent-transport stability, nullspace and exactness accounting, no-host-units non-escape, displayed replay, provenance, and local naming.*

Proof. Project the carrier of Definition 9091.1. The rows U and M display the finite unit coordinates and the dimension matrix before any monomial read is available.

Read the classifier row K through the nullspace ledger E. A dimensionless monomial is therefore a finite exponent vector whose matrix read is zero in the displayed unit window, not an equality of host physical quantities.

Transport and replay through T and C. These rows preserve the same unit-exponent coordinates and the same classifier row, while H prevents escape to unlisted host units.

Finally package the route through P and N. Since the carrier has no coordinate for host units, quotient dimensions, selected physical constants, or analytic regularity, the listed rows exhaust the NameCert surface. □

Theorem 9091.3 (Buckingham Pi non-escape)**.** *Every consumer of an accepted* $\mathsf{BuckinghamPi}^{\uparrow}$ *packet that reads a dimensionless Pi coordinate must first expose the route*

$$\mathsf{VecSpace}^{\uparrow},\ \mathsf{LinMap}^{\uparrow},\ \mathsf{Mat}^{\uparrow},\ \mathsf{Real}^{\uparrow}$$

through the carrier rows $U, M, K, T, E, H, C, P, N$*. The exported read is a finite nullspace and monomial-classifier packet; it is not a host-unit equation, a quotient-dimension object, a selected physical constant, or an analytic theorem about the modeled system.*

Proof. Begin with the requested Pi coordinate. The finite unit-exponent row U fixes the displayed basis of dimensions, and the matrix row M records the corresponding dimension map.

Use the classifier K and exactness ledger E to read only exponent vectors annihilated by that displayed map. The read is stable under T because transport acts componentwise on the same exponent and unit rows.

The no-host-units row H then blocks any appeal to unlisted dimensions or ambient physical quantities. Replay, provenance, and naming through C, P, N preserve the finite route, so no excluded host object is exported. □

Falsifiable prediction: Any accepted $\mathsf{BuckinghamPi}^{\uparrow}$ read must display the unit-exponent carrier, dimension matrix, dimensionless monomial classifier, exponent-transport row, nullspace exactness ledger, no-host-units boundary, replay, provenance, and local NameCert row before a Pi coordinate is public.

Independence witness: vecspace, linearmap, matrix, real: $\mathsf{BuckinghamPi}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries finite unit-exponent data, a dimension matrix, nullspace classification, exponent transport, exactness, no-host-units non-escape, replay, provenance, and local naming in one physical-law-facing packet.

Closure status for $\mathsf{NameCert}_{\mathsf{BuckinghamPi}^{\uparrow}}$**.**

Constructive story: A BuckinghamPi$^{\uparrow}$ packet is generated from finite unit-exponent rows, a displayed dimension matrix, dimensionless monomial classifier rows, exponent-transport stability, nullspace exactness, no-host-units non-escape, displayed replay, package provenance, and local NameCert data.

Theory closure: TheoryGate(NameCert$_{\text{BuckinghamPi}\uparrow}$, seed)

Scope closed: Definition 9091.1, Definition 9091.2, and Definition 9091.3 seed the finite Buckingham Pi NameCert surface.

Formal verification: FormalStatus(NameCert$_{\text{BuckinghamPi}\uparrow}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close host physical-unit equality, quotient dimensions, selected physical constants, analytic regularity of a modeled law, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, dimension-matrix readback, monomial classification, exponent transport, nullspace exactness, no-host-units non-escape, replay, provenance, and local naming for BEDC.Derived.BuckinghamPiUp.

Chapter 9092

Axis-Zeckendorf Running Coordinate NameCert Construction

The $\mathsf{AxisZeckendorfRunningCoordinate}^{\uparrow}$ packet realizes the phase-shell running-coordinate branch of Definition 9346.62 as finite BEDC data. It sits beside the Zeckendorf phase-shell surface of chapter 8811, the carry-classifier boundary of chapter 567, the hyperbolic observer phase-shell packet of chapter 6319, and the golden projection surface used by phase readouts. The packet separates shell-exponent motion from denominator response: a consumer may read a running coordinate only after the shell exponent, denominator response, readout route, transport, provenance, and local NameCert rows remain visible.

Definition 9092.1 (Axis-Zeckendorf running-coordinate carrier)**.** *An* $\mathsf{AxisZeckendorfRunningCoordinate}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Z = (S, D, R, T, V, P, N)$$

with the following displayed rows:

1. *S is the shell-exponent row, naming the Zeckendorf phase shell and the finite golden-radius exponent being inspected.*
2. *D is the denominator-response row, recording the fixed-window denominator coordinate without changing the shell exponent.*
3. *R is the readout route row, displaying how the shell exponent and denominator response are consumed by the running-coordinate read.*
4. *T is the transport row, recording componentwise* hsame *stability for shell exponents, denominator responses, readout rows, replay, provenance, and local naming.*
5. *V is the displayed* Cont *replay row for fixed-denominator transport and shell-exponent readback.*
6. *P is the* Pkg *provenance over* $\mathsf{AxisZeckendorfRunningCoordinate}^{\uparrow}$, $\mathsf{ZeckendorfPhaseShell}^{\uparrow}$, $\mathsf{ZeckendorfCarryClassifie}$ $\mathsf{HyperbolicObserverPhaseShell}^{\uparrow}$, $\mathsf{GoldenPhaseProjection}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$ *rows.*
7. *N is the local* $\mathsf{NameCert}_{\mathsf{AxisZeckendorfRunningCoordinate}^{\uparrow}}$ *row.*

The classifier reads only these seven rows. It has no coordinate for a hidden electroweak running law, an untracked denominator drift, a host real equality of readouts, or a shell change not exposed by S.

Theorem 9092.2 (Axis-Zeckendorf running-coordinate surface)**.** *For every accepted* AxisZeckendorfRunningCoordin *carrier* $Z = (S, D, R, T, V, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{AxisZeckendorfRunningCoordinate}^{\uparrow}}$ *surface consists exactly of shell-exponent exposure, denominator-response exposure, readout-route exposure, componentwise transport, displayed replay, provenance, and local naming. Fixed denominator transport preserves the shell-exponent row: any read that changes* D *without exposing a new* S *remains in the same shell.*

Proof. Project the carrier of Definition 9092.1. The shell exponent S and denominator response D are separate rows, so a read cannot identify denominator motion with shell motion.

Read the route row R. It consumes S and D in the displayed order and exposes the running coordinate as finite readout data rather than as a host real law.

Transport through T and replay through V. Because transport is componentwise, fixed denominator transport acts on D and the readout route while preserving the shell-exponent row S unless a new shell row is explicitly supplied.

Finally package the route through P and N. The packet therefore exports only the displayed shell-exponent, denominator-response, readout, transport, provenance, and naming surface. □

Theorem 9092.3 (Axis-Zeckendorf fixed-denominator non-escape)**.** *Every fixed-denominator read of an accepted* $\mathsf{AxisZeckendorfRunningCoordinate}^{\uparrow}$ *packet factors through the same shell-exponent row* S *before it reaches the readout route* R*. The read may alter denominator response data inside* D*, but it cannot change shell exponent, phase-shell provenance, or local NameCert identity without exposing a new accepted carrier row.*

Proof. Start with a fixed-denominator read. The row S names the shell exponent, while D names the denominator response inspected inside that shell.

Use the readout route R and transport row T. Fixed-denominator transport has no coordinate that rewrites S, so the transported read remains attached to the same shell-exponent row.

Replay and source the read through V and P, then name it through N. Since no hidden shell-change coordinate exists in the carrier, every fixed-denominator read remains in the original shell until a new accepted shell-exponent row is displayed. □

Falsifiable prediction: For an accepted $\mathsf{AxisZeckendorfRunningCoordinate}^{\uparrow}$ packet, fixed denominator transport cannot change the shell-exponent row; any observed shell change must expose a new S row and a new local NameCert read.

Independence witness: zeckendorf-phase-shell, zeckendorf-carry-classifier, hyperbolic-observer-phase-shell, golden-phase-projection: $\mathsf{AxisZeckendorfRunningCoordinate}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries shell exponent, denominator response, readout route, transport, provenance, replay, and local naming as one running-coordinate packet.

Lean's TasteGate surface for $\mathsf{AxisZeckendorfRunningCoordinate}^{\uparrow}$ must provide Nontrivial and FieldFaithful instances for the seven-row carrier, so downstream consumers can distinguish shell-exponent rows from denominator-response rows.

Closure status for $\mathsf{NameCert}_{\mathsf{AxisZeckendorfRunningCoordinate}^{\uparrow}}$**.**

Constructive story: An $\mathsf{AxisZeckendorfRunningCoordinate}^{\uparrow}$ packet is generated from shell-exponent rows, denominator-response rows, readout-route rows, componentwise transport, displayed replay, package provenance, and local NameCert rows.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{AxisZeckendorfRunningCoordinate}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 9092.1, Definition 9092.2, and Definition 9092.3 seed the finite Axis-Zeckendorf running-coordinate packet.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{AxisZeckendorfRunningCoordinate}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close a hidden electroweak running law, host real equality of readouts, shell changes without displayed shell-exponent rows, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, shell-exponent exposure, denominator-response exposure, readout routing, fixed-denominator non-escape, transport, replay, provenance, local naming, Nontrivial evidence, and FieldFaithful evidence for BEDC.Derived.AxisZeckendorfRunningCoordinateUp.

Chapter 9093

A Concrete Naming Certificate for $\mathsf{SingletonMetric}^{\uparrow}$

Following Bourbaki and Kelley, the $\mathsf{SingletonMetric}^{\uparrow}$ packet records the terminal one-point metric space as finite BEDC NameCert data. It sits at the boundary shared by chapter 4230, chapter 128, chapter 129, and chapter 38: every displayed distance is the zero $\mathsf{Real}^{\uparrow}$ distance, every point-read is the unique point-read, and every classifier comparison is total because there is no second point from which a distance, cover, or Cauchy tail could diverge.

Definition 9093.1 (Singleton metric carrier)**.** *A* $\mathsf{SingletonMetric}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (P, D, T, H, C, G, N)$$

with the following displayed rows:

1. *P is the unique point row.*
2. *D is the zero-distance row, recording that every displayed distance read has value $0_{\mathsf{Real}^{\uparrow}}$.*
3. *T is the total classifier row: any two accepted point reads are classified as the same singleton point.*
4. *H records componentwise* hsame *transport for the point row, zero-distance row, total classifier, replay, provenance, and local naming rows.*
5. *C records displayed* Cont *replay for the unique-point metric query.*
6. *G records*

$$\mathsf{Pkg}(S) = \mathsf{Pkg}(\mathsf{SingletonMetric}^{\uparrow}, \mathsf{Met}^{\uparrow}, \mathsf{CompleteMetric}^{\uparrow}, \mathsf{CompactMetric}^{\uparrow}, \mathsf{Real}^{\uparrow}, \mathsf{BHist}, \mathsf{hsame}, \mathsf{Cont}, \mathsf{NameCert}).$$

7. *N is the local* $\mathsf{NameCert}_{\mathsf{SingletonMetric}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through P, D, T, H, C, G, N. It has no coordinate for a nonzero distance, a second point, a selected Cauchy limit, an open-cover choice, quotient equality, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 9093.2 (Singleton metric NameCert obligations)**.** *For every accepted* $\mathsf{SingletonMetric}^{\uparrow}$ *carrier*

$$S = (P, D, T, H, C, G, N),$$

the local $\mathsf{NameCert}_{\mathsf{SingletonMetric}^{\uparrow}}$ *surface consists exactly of carrier admission for the unique point row, zero* $\mathsf{Real}^{\uparrow}$ *distance row, total classifier row, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. The packet therefore presents the terminal one-point* $\mathsf{Met}^{\uparrow}$ *boundary case, with immediate* $\mathsf{CompleteMetric}^{\uparrow}$ *and* $\mathsf{CompactMetric}^{\uparrow}$ *readings only through the same displayed zero-distance and total-classifier rows.*

Proof. Project the carrier of Definition 9093.1. The only point data are the row P, the zero-distance row D, and the total classifier row T.

The metric, completeness, and compactness readings are terminal readings of the same finite surface. Since every point read is P and every distance read is the zero $\mathsf{Real}^{\uparrow}$ row D, a Cauchy request has no independent limit choice and a finite-cover request has no independent cover-selection coordinate.

The structural rows H, C, G, N transport, replay, source, and name exactly this terminal surface. Because the carrier contains no nonzero distance, second point, selected limit, open-cover choice, quotient equality, or ambient-completeness coordinate, none can be exported by the local certificate. □

Closure status for $\mathsf{NameCert}_{\mathsf{SingletonMetric}^{\uparrow}}$.

Constructive story: A $\mathsf{SingletonMetric}^{\uparrow}$ packet is generated from one point row, zero RealUp distance row, total classifier row, componentwise hsame transport, Cont replay, Pkg provenance, and local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{SingletonMetric}^{\uparrow}}$, seed)

Scope closed: Definition 9093.1 and Definition 9093.2 seed the terminal one-point metric packet over the displayed rows P, D, T, H, C, G, N.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{SingletonMetric}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close nontrivial metric spaces, nonzero distances, selected Cauchy limits, open-cover choice, quotient equality, ambient RealUp completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, zero-distance exactness, total-classifier stability, hsame transport, Cont replay, Pkg provenance, and local naming for BEDC.Derived.SingletonMetricUp.

Chapter 9094

A Concrete Naming Certificate for $\mathsf{UniformOscillationModulus}^{\uparrow}$

Bishop–Bridges constructive analysis treats uniform control as finite tolerance data rather than as an ambient compactness theorem. The $\mathsf{UniformOscillationModulus}^{\uparrow}$ packet records the finite route by which displayed oscillation windows become a uniform oscillation-control row before any compact-uniform, regular-real, or continuity-modulus consumer reads a seal. It sits beside the oscillation-modulus carrier of chapter 2224, the finite partition surface of chapter 3800, the finite stream names of chapter 126, the regular rational readback of chapter 301, the dyadic tolerance core of chapter 291, and the terminal real-name seal of chapter 38. The packet names only finite oscillation rows, partition cells, stream windows, dyadic budgets, regular readback, transport, replay, provenance, and local naming data.

Definition 9094.1 (Uniform oscillation modulus carrier)**.** *A* $\mathsf{UniformOscillationModulus}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$U = (O, F, S, R, D, E, H, C, P, N)$$

with the following displayed rows:

1. *O is the* $\mathsf{OscillationModulus}^{\uparrow}$ *source row, recording tolerance requests and displayed oscillation bounds.*
2. *F is the* $\mathsf{FiniteOscillationPartition}^{\uparrow}$ *row, recording the finite cells on which the oscillation request is checked.*
3. *S is the* $\mathsf{StreamName}^{\uparrow}$ *observation-window row for the cell endpoints and sample names.*
4. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the regular rational bounds produced by the displayed windows.*
5. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance-budget row, recording dyadic precision requests, local comparison margins, and finite budget transfers.*
6. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row, available only after the displayed oscillation, partition, stream, regular-rational, and dyadic rows have been read.*
7. *H records componentwise* hsame *transport for the oscillation, partition, stream, readback, dyadic, seal, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from each uniform oscillation request through*

$$O, F, S, R, D, E \longmapsto H, P, N.$$

9. *P is the* Pkg *provenance over* $\mathsf{UniformOscillationModulus}^{\uparrow}$, $\mathsf{OscillationModulus}^{\uparrow}$, $\mathsf{FiniteOscillationPartition}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{UniformOscillationModulus}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $O, F, S, R, D, E, H, C, P, N$. It has no coordinate for open-cover compactness, selected limits, quotient streams, host real equality, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 9094.2 (Uniform oscillation modulus NameCert obligations)**.** *For every accepted* UniformOscillationModu *carrier*

$$U = (O, F, S, R, D, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{UniformOscillationModulus}^{\uparrow}}$ *surface consists exactly of oscillation-modulus admission through O, finite partition exposure through F, stream-window observation through S, regular rational readback through R, dyadic tolerance budgeting through D, terminal real-name sealing through E, componentwise transport through H, displayed replay through C, provenance through P, and local naming through N.*

Proof. Project the carrier of Definition 9094.1. The analytic rows are exactly the oscillation source, finite partition, stream observations, regular rational readback, dyadic budget, and terminal Real seal.

Read O and F first. The source oscillation row supplies the tolerance request, while the finite partition row supplies the cells on which the request is witnessed.

Next read S, R, D, E. Stream windows expose the finite observations, regular rational readback records the numeric bound, the dyadic row stores the budget used by the comparison, and the terminal Real seal is available only after those displayed rows.

Finally read H, C, P, N. These rows transport, replay, source, and name the same finite route. Since the carrier has no coordinate for open-cover compactness, selected limits, quotient streams, host real equality, countable choice, or ambient Real completeness, the listed rows exhaust the local NameCert surface. □

Theorem 9094.3 (Uniform oscillation modulus finite-partition readback)**.** *Every compact-uniform, regular-real, or continuity-modulus consumer read accepted by a* $\mathsf{UniformOscillationModulus}^{\uparrow}$ *packet must factor through*

$\mathsf{OscillationModulus}^{\uparrow}$, $\mathsf{FiniteOscillationPartition}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame,

Equivalently, the consumer may inspect $O, F, S, R, D, E, H, C, P, N$, but it cannot bypass the finite partition and dyadic readback by invoking open-cover compactness, selected limits, quotient streams, host real equality, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Apply Definition 9094.2. It forces every accepted consumer read to open the oscillation source O, finite partition F, stream observations S, regular rational readback R, dyadic budget D, and terminal seal E before the structural rows are available.

The finite-partition step is carried by F and S. These rows display the cells and observations used by the uniform request, so no consumer can replace them by an open-cover compactness argument or a selected external limit.

The numeric readback is carried by R, D, E. Regular rational bounds, dyadic budgets, and the terminal Real seal provide the only exported route to downstream real-facing packets.

Transport, replay, provenance, and naming through H, C, P, N preserve exactly that displayed route. Therefore compact-uniform, regular-real, and continuity-modulus consumers receive a finite partition readback and no quotient-stream, choice, host-equality, or ambient-completeness principle. □

Falsifiable prediction: An accepted $\mathsf{UniformOscillationModulus}^{\uparrow}$ read is refuted if a compact-uniform, regular-real, or continuity-modulus consumer receives an oscillation-control output without first displaying an OscillationModulus row, a FiniteOscillationPartition row, StreamName observations, RegSeqRat readback, a DyadicRatCore budget, a Real seal, transport, replay, provenance, and local naming rows.

Independence witness: oscillation-modulus, finite-oscillation-partition, streamname, regseqrat, dyadicratcore, real: $\mathsf{UniformOscillationModulus}^{\uparrow}$ is not bijective to any listed sibling because it carries the finite partition readback, dyadic tolerance budget, terminal seal, and uniform consumer handoff in one packet.

Closure status for $\mathsf{NameCert}_{\mathsf{UniformOscillationModulus}^{\uparrow}}$.

Constructive story: A $\mathsf{UniformOscillationModulus}^{\uparrow}$ packet is generated from an OscillationModulus source row, a FiniteOscillationPartition row, StreamName finite observations, RegSeqRat readback, a DyadicRatCore tolerance budget, a Real seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{UniformOscillationModulus}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 9094.1, Definition 9094.2, and Definition 9094.3 seed the finite uniform oscillation-control packet for compact-uniform, regular-real, and continuity-modulus consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{UniformOscillationModulus}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim open-cover compactness, selected limits, quotient streams, host real equality, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, oscillation-modulus admission, finite partition exposure, stream-window observation, regular rational readback, dyadic budgeting, Real seal handoff, transport stability, replay stability, provenance nonescape, and local naming for BEDC.Derived.UniformOscillationModulusUp.

Chapter 9095

A Concrete Naming Certificate for $\mathsf{RegularCauchyContinuityModulus}^{\uparrow}$

Following Bishop and Bridges, continuity on regular Cauchy names is witnessed by an explicit finite modulus that turns a target tolerance into a source-window and dyadic-tolerance budget. The $\mathsf{RegularCauchyContinuityModulus}^{\uparrow}$ packet sits between the dyadic arithmetic core of chapter 291, the finite window surface of chapter 126, the regular rational readback of chapter 301, the terminal real-name seal of chapter 38, and the finite transformer surface of chapter 1401. It names the regular-Cauchy continuity budget consumed by later completion arguments without asserting ambient completeness of $\mathsf{Real}^{\uparrow}$.

Definition 9095.1 (Regular Cauchy continuity-modulus carrier)**.** *A* $\mathsf{RegularCauchyContinuityModulus}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M = (F, E, D, W, R, S, H, C, P, N)$$

with the following displayed rows:

1. *F is the* $\mathsf{CauchyContinuousMap}^{\uparrow}$ *transformer row whose source and target regular-name reads are being controlled.*
2. *E is the target-error row, a finite* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance request presented before any source-window read is served.*
3. *D is the dyadic control ledger, recording the source tolerance, target tolerance, and finite comparison rows used by the modulus.*
4. *W is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row opened on the source and target Cauchy names.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row obtained from the displayed stream windows and dyadic ledger.*
6. *S is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row, exposed only after F, E, D, W, R have all been replayed.*
7. *H records componentwise* hsame *transport for transformer, tolerance, dyadic-control, stream-window, regular-readback, seal, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from a target tolerance request through the transformer, dyadic control, finite windows, regular readback, and terminal seal.*
9. *P is the* Pkg *provenance over* $\mathsf{RegularCauchyContinuityModulus}^{\uparrow}$, $\mathsf{CauchyContinuousMap}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$ *rows.*

10. N is the local $\mathsf{NameCert}_{\mathsf{RegularCauchyContinuityModulus}^{\uparrow}}$ *row.*
The carrier has no coordinate for a host function on reals, quotient stream equality, countable choice over source windows, selected representatives, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 9095.2 (Regular Cauchy continuity-modulus NameCert obligations)**.** *For every accepted* $\mathsf{RegularCauchyContinuityModulus}^{\uparrow}$ *carrier* $M = (F, E, D, W, R, S, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyC}}$ *surface is exhausted by carrier admission for the displayed transformer, target-error, dyadic-control, stream-window, regular-readback, real-seal, transport, replay, provenance, and local naming rows; target tolerance exposure through E; dyadic control through D; finite-window accountability through W; regular readback through R; and refusal of host real functions, quotient stream equality, selected representatives, countable choice, trichotomy, and ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the carrier rows of Definition 9095.1. The tuple $F, E, D, W, R, S, H, C, P, N$ is the only packet available to the local naming row.

The target tolerance first appears as the row E. The dyadic control row D then records the source-side tolerance and comparison data, and the finite stream window row W records exactly which Cauchy-name prefixes are opened before the transformer row F is read.

Regular readback through R and terminal sealing through S are downstream of the same finite route. Componentwise transport through H, replay through C, provenance through P, and local naming through N preserve that packet without adding a host function, quotient equality, representative selector, choice schedule, trichotomy, or Real-completeness coordinate. □

Theorem 9095.3 (Regular Cauchy continuity dyadic control)**.** *Every accepted* $\mathsf{RegularCauchyContinuityModulus}^{\uparrow}$ *read that is consumed by a* $\mathsf{CauchyContinuousMap}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*, or* $\mathsf{Real}^{\uparrow}$ *route must expose the finite* $\mathsf{DyadicRatCore}^{\uparrow}$ *target tolerance E, the dyadic control ledger D, the* $\mathsf{StreamName}^{\uparrow}$ *window row W, and the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row R before the terminal* $\mathsf{Real}^{\uparrow}$ *seal S is available. The packet therefore supplies finite regular-Cauchy continuity control, not an ambient continuity theorem for completed reals.*

Proof. Start with Definition 9095.2. It places target tolerance exposure, dyadic control, finite-window accountability, and regular readback inside the same local NameCert surface.

The consumer route through $\mathsf{CauchyContinuousMap}^{\uparrow}$ reads the transformer row F only together with the tolerance rows E, D and the finite stream windows W. The $\mathsf{RegSeqRat}^{\uparrow}$ row R is then the visible regular-name readback produced from those displayed rows.

Only after that readback may the terminal seal S be consumed by a $\mathsf{Real}^{\uparrow}$-facing route. Since the carrier of Definition 9095.1 has no row for completed-real continuity, quotient streams, selected representatives, countable choice, trichotomy, or host real equality, the dyadic control route is exactly the finite packet described above. □

Closure status for $\mathsf{NameCert}_{\mathsf{RegularCauchyContinuityModulus}^{\uparrow}}$**.**

Constructive story: A $\mathsf{RegularCauchyContinuityModulus}^{\uparrow}$ packet is generated from a CauchyContinuousMap transformer row, target dyadic tolerance, dyadic control ledger, finite StreamName windows, RegSeqRat readback, Real seal, componentwise hsame transport, Cont replay, provenance, and local NameCert rows.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RegularCauchyContinuityModulus}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 9095.1, Definition 9095.2, and Definition 9095.3 seed the finite regular-Cauchy continuity-modulus carrier and its dyadic control route.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RegularCauchyContinuityModulus}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close completed-real continuity, quotient stream equality, selected representatives, countable choice over windows, trichotomy, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires binding the transformer, target-error, dyadic-control, finite-window, regular-readback, seal, transport, replay, provenance, and local naming rows to BEDC primitives.

Chapter 9096

A Concrete Naming Certificate for $\mathsf{BirkhoffPolytope}^{\uparrow}$

Following Birkhoff and von Neumann, the $\mathsf{BirkhoffPolytope}^{\uparrow}$ packet records the finite convex-combinatorial object whose points are doubly stochastic matrices and whose displayed vertices are permutation matrices. It sits after the matrix carrier of chapter 49, the polytope carrier of chapter 209, the convex-set surface of chapter 208, the rational and real scalar readbacks of chapter 37 and chapter 38, the finite permutation rows of chapter 116, the finite list carrier of chapter 36, and the permutation-flow decomposition route of chapter 8080. The packet names the finite convex hull and stochastic-row boundary; it is not a host theorem about arbitrary matrix spaces, quotient matrix equality, selected decompositions, linear-programming duality, or compactness by choice.

Definition 9096.1 (Birkhoff polytope carrier)**.** *A* $\mathsf{BirkhoffPolytope}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (M, R, C, V, L, A, D, H, K, P, N)$$

with the following displayed rows:

1. *M is the* $\mathsf{Mat}^{\uparrow}$ *square-matrix row, including the finite row and column index lists on which every entry is read.*
2. *R is the row-stochastic ledger, displaying nonnegative entries and unit row sums through* $\mathsf{Rat}^{\uparrow}$ *or* $\mathsf{Real}^{\uparrow}$ *scalar rows.*
3. *C is the column-stochastic ledger, displaying the matching unit column sums over the same finite index spine.*
4. *V is the finite permutation-vertex row, listing the* $\mathsf{Permutation}^{\uparrow}$ *matrix rows admitted as vertices of the polytope.*
5. *L is the finite* $\mathsf{List}^{\uparrow}$ *convex-combination ledger, carrying displayed scalar weights, total-one readback, and support membership for the listed vertices.*
6. *A is the* $\mathsf{ConvexSet}^{\uparrow}$ *affine-membership row for the convex hull generated by V and L.*
7. *D is the decomposition handoff row, available only after the stochastic ledgers and the finite vertex list have been displayed; it may cite the route of chapter 8080.*
8. *H records componentwise* hsame *transport for matrix, stochastic, vertex-list, convex-combination, affine-membership, decomposition, provenance, and local naming rows.*

9. *K records displayed* Cont *replay through the same finite convex-combinatorial rows.*
10. *P is the* Pkg *provenance over* $\mathsf{BirkhoffPolytope}^{\uparrow}$, $\mathsf{Mat}^{\uparrow}$, $\mathsf{Polytope}^{\uparrow}$, $\mathsf{ConvexSet}^{\uparrow}$, $\mathsf{Rat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{Permutation}^{\uparrow}$, $\mathsf{List}^{\uparrow}$, $\mathsf{BirkhoffVonNeumannFinite}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*
11. *N is the local* $\mathsf{NameCert}_{\mathsf{BirkhoffPolytope}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $M, R, C, V, L, A, D, H, K, P, N$. It has no coordinate for host matrix equality, arbitrary ambient matrix spaces, selected convex decompositions, linear-programming duality, open-cover compactness, Lean verification, or bridge checking.

Theorem 9096.2 (Birkhoff polytope NameCert obligations)**.** *For every accepted* $\mathsf{BirkhoffPolytope}^{\uparrow}$ *carrier*

$$B = (M, R, C, V, L, A, D, H, K, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{BirkhoffPolytope}^{\uparrow}}$ *surface consists exactly of finite matrix admission, row-stochastic exposure, column-stochastic exposure, permutation-vertex exposure, finite-list convex-combination exposure, convex-set affine membership, decomposition handoff, componentwise transport, displayed replay, package provenance, and local naming. Every consumer that treats a doubly stochastic matrix as a point of the Birkhoff polytope must read M, R, C before V, L, A, D; every consumer that treats the point as a convex combination of permutation matrices must read the finite list and decomposition rows before transport or local naming is public.*

Proof. Project the carrier of Definition 9096.1. The stochastic matrix surface is exactly M, R, C: the finite square matrix row, nonnegative entry reads, and unit row and column sum ledgers.

The vertex and convex-combination surface is V, L, A. The permutation vertices are displayed as finite $\mathsf{Permutation}^{\uparrow}$ matrix rows, the convex weights are displayed as a $\mathsf{List}^{\uparrow}$ ledger with scalar readbacks through $\mathsf{Rat}^{\uparrow}$ or $\mathsf{Real}^{\uparrow}$, and the affine-membership row reads those two surfaces through $\mathsf{ConvexSet}^{\uparrow}$ and $\mathsf{Polytope}^{\uparrow}$.

The decomposition handoff D is downstream from both surfaces. When a decomposition-facing consumer needs the Birkhoff–von Neumann finite route, it cites chapter 8080 only after the stochastic rows and vertex-list rows are already visible.

Finally H, K, P, N transport, replay, source, and name the same finite packet. Since the carrier has no row for host matrix equality, arbitrary ambient matrix spaces, selected decompositions, linear-programming duality, compactness by choice, Lean verification, or bridge checking, the listed obligations exhaust the local NameCert surface. □

Theorem 9096.3 (Birkhoff polytope finite vertex route)**.** *Every accepted* $\mathsf{BirkhoffPolytope}^{\uparrow}$ *read that exports a convex-combinatorial conclusion factors through the finite route*

$$\mathsf{Mat}^{\uparrow} \longmapsto \mathsf{Permutation}^{\uparrow} \longmapsto \mathsf{List}^{\uparrow} \longmapsto \mathsf{ConvexSet}^{\uparrow} \longmapsto \mathsf{Polytope}^{\uparrow}.$$

The route exposes the doubly stochastic matrix rows, the finite permutation-matrix vertex list, the convex weight ledger, affine membership, and the polytope naming row before any downstream matrix, optimization, or decomposition consumer may inspect the result.

Proof. Start with Definition 9096.2. A convex-combinatorial read cannot bypass the matrix row M, the stochastic ledgers R, C, or the permutation-vertex row V.

Next read the finite list row L. It supplies the displayed weights and vertex support, so the affine row A receives an actual finite convex-combination ledger rather than an external selector.

The $\mathsf{Polytope}^{\uparrow}$ source is present through provenance and the affine-membership row: it names the convex hull surface generated by those vertices, while chapter 8080 may supply the finite decomposition route when a stochastic matrix is consumed as such a convex combination.

The structural rows then preserve exactly that route. No host equality, selected decomposition oracle, linear-programming theorem, or compactness principle is available inside the packet. □

Closure status for $\mathsf{NameCert}_{\mathsf{BirkhoffPolytope}^{\uparrow}}$**.**

Constructive story: A $\mathsf{BirkhoffPolytope}^{\uparrow}$ packet is generated from finite MatrixUp rows, row-stochastic and column-stochastic ledgers, finite PermutationUp vertex rows, ListUp convex-combination weights, ConvexSetUp affine membership, PolytopeUp provenance, BirkhoffVonNeumannFiniteUp decomposition handoff, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BirkhoffPolytope}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 9096.1, Definition 9096.2, and Definition 9096.3 seed the finite convex-combinatorial carrier over matrix, stochastic, permutation-vertex, finite-list, convex-set, polytope, rational, and real scalar rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BirkhoffPolytope}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host matrix equality, arbitrary ambient matrix spaces, selected decompositions, linear-programming duality, compactness by choice, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, stochastic-row exposure, permutation-vertex exposure, finite-list convex-combination exactness, affine-membership routing, decomposition handoff, transport, replay, provenance, and local naming for BEDC.Derived.BirkhoffPolytopeUp.

Chapter 9097

A Concrete Naming Certificate for $\mathsf{SchauderProjection}^{\uparrow}$

Following Schauder's projection-theorem tradition in constructive functional analysis, the $\mathsf{SchauderProjection}^{\uparrow}$ packet records a displayed finite-rank approximation route for projection-facing consumers without asserting a global nearest-point selector. It sits after the Hilbert projection boundary of chapter 2356, the Hilbert carrier of chapter 91, the convex subset surface of chapter 208, the complete-metric limit service of chapter 128, and the terminal real-name seal of chapter 38. The packet names a finite Schauder approximation certificate, not a choice-heavy nearest-point map, quotient equality of points, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 9097.1 (Schauder projection carrier)**.** *A* $\mathsf{SchauderProjection}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (M, H, V, K, F, E, R, T, C, P, N)$$

with the following displayed rows:

1. *M is the parent* $\mathsf{MetricProjection}^{\uparrow}$ *boundary row, read only as the existing projection-facing endpoint discipline.*
2. *H is the* $\mathsf{Hilbert}^{\uparrow}$ *source row containing the inner-product, norm, and induced metric surfaces.*
3. *V is the* $\mathsf{ConvexSet}^{\uparrow}$ *source row naming the closed convex or affine target surface to which the projection request is confined.*
4. *K is the* $\mathsf{CompleteMetric}^{\uparrow}$ *convergence-service row used by the approximation window.*
5. *F is the finite-rank approximation ledger: displayed finite subspaces, endpoint witnesses, and approximation tolerances.*
6. *E is the endpoint-candidate row produced by the displayed approximation ledger.*
7. *R is the terminal* $\mathsf{Real}^{\uparrow}$ *seal for the distance or norm bound read after M, H, V, K, F, E have been displayed.*
8. *T records componentwise* hsame *transport for the projection, Hilbert, convex, complete-metric, finite-rank, endpoint, real-seal, replay, provenance, and local naming rows.*
9. *C records displayed* Cont *replay from a projection request through finite-rank approximation, endpoint admission, and real-seal readback.*

10. *P is the* Pkg *provenance over* $\mathsf{SchauderProjection}^{\uparrow}$, $\mathsf{MetricProjection}^{\uparrow}$, $\mathsf{Hilbert}^{\uparrow}$, $\mathsf{ConvexSet}^{\uparrow}$, $\mathsf{CompleteMetric}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{SchauderProjection}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through $M, H, V, K, F, E, R, T, C, P, N$. It has no coordinate for a host projection operator, quotient point equality, selected representatives, countable choice, or ambient real completeness.

Theorem 9097.2 (Schauder projection NameCert obligations)**.** *For every accepted* $\mathsf{SchauderProjection}^{\uparrow}$ *carrier*

$$S = (M, H, V, K, F, E, R, T, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{SchauderProjection}^{\uparrow}}$ *surface consists exactly of carrier admission for the parent metric-projection boundary, Hilbert source, convex target row, complete-metric convergence service, finite-rank approximation ledger, endpoint candidate, terminal real seal, componentwise transport, displayed replay, package provenance, and local naming. Every projection-facing consumer must expose those rows before reading E or R.*

Proof. Project the carrier of Definition 9097.1. The displayed tuple lists every row available to the local certificate, so carrier admission can only expose $M, H, V, K, F, E, R, T, C, P, N$.

Read the analytic rows in order. The parent $\mathsf{MetricProjection}^{\uparrow}$ boundary supplies the nonescape discipline for projection endpoints, while H and V supply the Hilbert and convex source data. The complete-metric row K is then consumed only by the finite-rank approximation ledger F.

The endpoint candidate E and real seal R are downstream of that finite ledger. The structural rows T, C, P, N transport, replay, source, and name the same route, and they add no hidden projection operator or selected representative. □

Theorem 9097.3 (Schauder projection endpoint nonescape)**.** *Every endpoint read exported by an accepted* $\mathsf{SchauderProjection}^{\uparrow}$ *packet factors through*

$$\mathsf{MetricProjection}^{\uparrow},\ \mathsf{Hilbert}^{\uparrow},\ \mathsf{ConvexSet}^{\uparrow},\ \mathsf{CompleteMetric}^{\uparrow},\ \mathsf{Real}^{\uparrow}$$

by way of the displayed rows $M, H, V, K, F, E, R, T, C, P, N$. The exported endpoint is a finite Schauder-approximation candidate only; it cannot be read as a host nearest-point selector, quotient representative, countable-choice selection, or ambient $\mathsf{Real}^{\uparrow}$ *completeness principle.*

Proof. Start with the NameCert obligations of Definition 9097.2. They force every endpoint consumer to expose the parent projection boundary, Hilbert source, convex target, complete-metric service, finite-rank ledger, endpoint row, and real seal before the local name can be used.

Use the parent nonescape boundary from Definition 2356.3. It permits a projection endpoint only as a displayed BEDC projection-facing row, not as a host projection map or selected representative.

Finally inspect the Schauder carrier. The only approximation data are the finite rows in F, and the only numerical boundary is the real seal R. Since no coordinate stores quotient point equality, countable choice, or ambient completeness, none of those objects can escape through E. □

Theorem 9097.4 (Schauder projection finite approximation route)**.** *Any consumer that uses a* $\mathsf{SchauderProjection}^{\uparrow}$ *packet for a projection-facing approximation must first display the finite-rank ledger F over the Hilbert row H, convex row V, complete-metric service K, and parent metric-projection boundary M. Only after that route is replayed may the consumer inspect the endpoint candidate E and the terminal* $\mathsf{Real}^{\uparrow}$ *seal R.*

Proof. Apply Definition 9097.2. The finite-rank ledger is one of the mandatory certificate rows, and the endpoint and real seal occur only after the source and convergence-service rows have been exposed.

Next apply Definition 9097.3. It keeps the endpoint as a finite approximation candidate, so the consumer cannot replace F by a hidden nearest-point operator or a selected sequence of representatives.

The structural rows T, C, P, N then preserve the same displayed route. Thus the only accepted projection-facing use is the finite approximation route through M, H, V, K, F, E, R. □

Falsifiable prediction: An accepted $\mathsf{SchauderProjection}^{\uparrow}$ consumer that reads an endpoint without displaying the finite-rank ledger F and the parent $\mathsf{MetricProjection}^{\uparrow}$ boundary refutes the carrier surface.

Independence witness: metricprojection, hilbert, convexset, completemetric, real: $\mathsf{SchauderProjection}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries a finite-rank approximation ledger, a parent projection boundary, Hilbert and convex source rows, a complete-metric convergence service, and a terminal real seal while refusing host projection operators and choice-heavy nearest-point selection.

Closure status for $\mathsf{NameCert}_{\mathsf{SchauderProjection}^{\uparrow}}$.

Constructive story: A $\mathsf{SchauderProjection}^{\uparrow}$ packet is generated from a MetricProjection boundary row, Hilbert source row, ConvexSet target row, CompleteMetric convergence-service row, finite-rank approximation ledger, endpoint candidate, Real seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{SchauderProjection}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 9097.1, Definition 9097.2, and Definition 9097.3 seed the finite Schauder projection route through displayed approximation data.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{SchauderProjection}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close a host projection operator, nearest-point selection, quotient point equality, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, finite-rank ledger exactness, endpoint nonescape, real-seal ordering, transport, replay, provenance, and local naming for BEDC.Derived.SchauderProjectionUp.

Chapter 9098

A Concrete Naming Certificate for $\mathsf{RegularCauchyInterleavingMerge}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{RegularCauchyInterleavingMerge}^{\uparrow}$ packet records the finite merge route by which two displayed regular Cauchy real names are read through one interleaved window and one regular-real tail-equivalence boundary before a $\mathsf{Real}^{\uparrow}$ consumer receives the seal. It sits after the finite stream schedules of chapter 126, the regular rational readback route of chapter 301, the dyadic tolerance ledger of chapter 291, the terminal real-name surface of chapter 38, the even/odd interlacing packet of chapter 5870, and the same-real tail route of chapter 5940. The packet specializes interlacing to the regular-Cauchy merge boundary: it names the finite source rows, shared window, tolerance ledger, tail-equivalence route, and Real seal together, without turning them into quotient streams, selected representatives, countable choice, host equality, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 9098.1 (Regular Cauchy interleaving merge carrier)**.** *A* $\mathsf{RegularCauchyInterleavingMerge}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M = (A, B, W, D, I, T, R, H, C, P, N)$$

with the following displayed rows:

1. *A and B are the two* $\mathsf{RegSeqRat}^{\uparrow}$ *source rows whose regular Cauchy tails are merged.*
2. *W is the shared* $\mathsf{StreamName}^{\uparrow}$ *finite-window row. It records the requests at which both sources are inspected before a merge read is served.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger for the two source tails, the interleaved tail, and the terminal seal request.*
4. *I is the* $\mathsf{CauchyInterlacing}^{\uparrow}$ *schedule row, read only after A, B, W, D have been displayed.*
5. *T is the* $\mathsf{RegularRealTailEquivalence}^{\uparrow}$ *handoff row witnessing that the interleaved regular read and the displayed source route reach the same regular-real tail boundary.*
6. *R is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row, available only after A, B, W, D, I, T have been displayed.*
7. *H records componentwise* hsame *transport for the source, window, dyadic, interlacing, tail-equivalence, seal, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay of the finite route*

$$A, B, W, D \longmapsto I \longmapsto T \longmapsto R.$$

9. *P is the* Pkg *provenance over* $\mathsf{RegularCauchyInterleavingMerge}^{\uparrow}$, $\mathsf{CauchyInterlacing}^{\uparrow}$, $\mathsf{RegularRealTailEquivalence}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyInterleavingMerge}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $A, B, W, D, I, T, R, H, C, P, N$. It has no coordinate for quotient streams, selected representatives, countable choice, host equality, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 9098.2 (Regular Cauchy interleaving merge NameCert obligations)**.** *For every accepted* $\mathsf{RegularCauchyInterleavingMerge}^{\uparrow}$ *carrier*

$$M = (A, B, W, D, I, T, R, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{RegularCauchyInterleavingMerge}^{\uparrow}}$ *surface consists exactly of source admission for A, B, shared finite-window exposure through W, dyadic tolerance exposure through D, interlacing-schedule exposure through I, regular-real tail-equivalence exposure through T, terminal* $\mathsf{Real}^{\uparrow}$ *seal exposure through R, componentwise transport through H, displayed continuation replay through C, package provenance through P, and local naming through N.*

Proof. Project the carrier of Definition 9098.1. The first two rows expose the regular rational source names, while the shared window row W records the finite requests through which both tails are inspected.

Next read the merge rows. The dyadic ledger D supplies the tolerance accounting, the interlacing row I supplies the finite even/odd schedule already certified by chapter 5870, and the tail-equivalence row T places the merged read inside the regular-real same-tail route of chapter 5940.

Finally read R, H, C, P, N. The seal row is downstream of the source, window, tolerance, interlacing, and tail-equivalence rows, and the structural rows only transport, replay, source, and name that same displayed packet. Since no excluded host object has a carrier coordinate, replay edge, provenance entry, or local naming row, the displayed rows exhaust the local NameCert surface. □

Theorem 9098.3 (Regular Cauchy interleaving merge Real seal nonescape)**.** *Every* $\mathsf{Real}^{\uparrow}$*-facing read of an accepted* $\mathsf{RegularCauchyInterleavingMerge}^{\uparrow}$ *carrier reaches the seal row R only through the finite route*

$$A, B, W, D, I, T, H, C, P, N.$$

Thus the merge read is a carrier-local certificate over two displayed $\mathsf{RegSeqRat}^{\uparrow}$ *sources, one* $\mathsf{StreamName}^{\uparrow}$ *window, one* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, one* $\mathsf{CauchyInterlacing}^{\uparrow}$ *schedule row, and one* $\mathsf{RegularRealTailEquivalence}^{\uparrow}$ *handoff row. It is not a quotient stream, selected representative, countable-choice schedule, host equality, trichotomy, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness theorem.*

Proof. Project the accepted carrier. The seal row R is listed after the two source rows, shared window, dyadic ledger, interlacing schedule, and regular-real tail-equivalence handoff, so it is not available as an independent endpoint.

Apply the NameCert obligations of Definition 9098.2. They identify the complete route that must be displayed before the local certificate can expose the Real-facing seal.

Use the sibling routes only at their displayed boundaries. The interlacing row I supplies the finite merge schedule from chapter 5870, and the handoff row T supplies the same-real tail boundary from chapter 5940. The remaining rows H, C, P, N transport, replay, source, and name that route, so the seal cannot leak quotient streams, selected representatives, countable choice, host equality, trichotomy, or ambient completeness. □

Falsifiable prediction: Every accepted $\mathsf{RegularCauchyInterleavingMerge}^{\uparrow}$ Real-facing read displays two RegSeqRatUp source rows, one shared StreamNameUp window, one DyadicRatCoreUp tolerance ledger, one CauchyInterlacingUp schedule row, one RegularRealTailEquivalenceUp handoff row, componentwise hsame transport, displayed Cont replay, Pkg provenance, local naming, and one terminal RealUp seal.

Independence witness: streamname, regseqrat, dyadicratcore, real, cauchy-interlacing, regular-real-tail-equivalence: $\mathsf{RegularCauchyInterleavingMerge}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries two regular rational source rows, a shared finite window, a dyadic tolerance ledger, an interlacing schedule, a regular-real tail-equivalence handoff, a terminal Real seal, transport, replay, provenance, and local NameCert in one packet.

Closure status for $\mathsf{NameCert}_{\mathsf{RegularCauchyInterleavingMerge}^{\uparrow}}$ **.**

Constructive story: A $\mathsf{RegularCauchyInterleavingMerge}^{\uparrow}$ packet is generated from two RegSeqRat source rows, one shared StreamName window, one DyadicRatCore tolerance ledger, one CauchyInterlacing schedule row, one RegularRealTailEquivalence handoff row, one RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RegularCauchyInterleavingMerge}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 9098.1, Definition 9098.2, and Definition 9098.3 seed the finite regular-Cauchy merge packet over StreamName, RegSeqRat, DyadicRatCore, CauchyInterlacing, RegularRealTailEquivalence, and Real rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RegularCauchyInterleavingMerge}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient streams, selected representatives, countable choice, host equality, trichotomy, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires binding the source, shared-window, dyadic-tolerance, interlacing, regular-real tail-equivalence, seal, transport, replay, provenance, and local naming rows to BEDC.Derived.RegularCauchyInterleavingMergeUp.

Chapter 9099

A Concrete Naming Certificate for $\mathsf{StreamShuffle}^{\uparrow}$

Following Bishop and Bridges on sequences in constructive analysis, the $\mathsf{StreamShuffle}^{\uparrow}$ packet records the finite recombination route by which two displayed stream-name windows are read through parity-indexed windows before a regular rational readback and Real-seal handoff are available. It sits beside the stream carrier of chapter 126, the regular rational route of chapter 301, the even/odd Cauchy shuffle of chapter 1721, and the finite merge boundary of chapter 1944. The packet is a finite NameCert object; it is not a host stream, quotient stream equality, selected representative, countable-choice schedule, or ambient completeness principle.

Definition 9099.1 (Stream shuffle carrier)**.** *A* $\mathsf{StreamShuffle}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (A, B, E, O, W, Q, R, H, C, P, N)$$

with the following displayed rows:

1. *A and B are the two source* $\mathsf{StreamName}^{\uparrow}$ *rows.*
2. *E is the even-index window row reading source A.*
3. *O is the odd-index window row reading source B.*
4. *W is the combined finite window exposed to downstream stream consumers.*
5. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row assembled from the parity-indexed windows when the shuffled stream is read as a regular rational sequence.*
6. *R is the Real-seal handoff row available only after A, B, E, O, W, Q have been displayed.*
7. *H records componentwise* hsame *transport for the source, parity, window, readback, seal, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay of the finite route*

$$A, B, E, O \longmapsto W \longmapsto Q \longmapsto R.$$

9. *P is the* Pkg *provenance over* $\mathsf{StreamShuffle}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{StreamMerge}^{\uparrow}$, $\mathsf{RegularCauchyShuffle}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{StreamShuffle}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $A, B, E, O, W, Q, R, H, C, P, N$.

Theorem 9099.2 (Stream shuffle NameCert obligations)**.** *For every accepted* $\mathsf{StreamShuffle}^{\uparrow}$ *carrier*

$$S = (A, B, E, O, W, Q, R, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{StreamShuffle}^{\uparrow}}$ *surface consists exactly of the following five obligation rows:*

1. *source admission for the two* $\mathsf{StreamName}^{\uparrow}$ *rows A, B;*
2. *parity-window exposure through E, O, W;*
3. $\mathsf{RegSeqRat}^{\uparrow}$ *readback through Q;*
4. *Real-seal handoff through R;*
5. *componentwise transport, replay, provenance, and local naming through H, C, P, N.*

Proof. Project the carrier of Definition 9099.1. The source rows A, B are displayed before either parity window is read, so the shuffled stream cannot be introduced as an external host stream.

Next read the parity-indexed windows. The even row E and odd row O expose finite windows of the two source streams, and the combined row W is the only window made public to a downstream $\mathsf{StreamName}^{\uparrow}$ or $\mathsf{StreamMerge}^{\uparrow}$ consumer.

Now attach the readback and seal rows. The $\mathsf{RegSeqRat}^{\uparrow}$ row Q reads the same parity-indexed window, and the Real-seal handoff R is downstream of Q. This is the point at which the packet can meet the $\mathsf{RegularCauchyShuffle}^{\uparrow}$ route, but it still exposes only the displayed finite rows.

Finally use H, C, P, N. Componentwise hsame transport, displayed Cont replay, package provenance, and local naming preserve the same carrier surface. Since no coordinate names quotient stream equality, a selected representative, countable choice, host stream equality, or ambient completeness, the five listed obligation rows exhaust the local certificate. □

Theorem 9099.3 (Stream shuffle parity-window nonescape)**.** *Every accepted* $\mathsf{StreamShuffle}^{\uparrow}$ *consumer reads the shuffled window only through*

$$A, B, E, O, W, H, C, P, N.$$

If the consumer asks for regular rational or Real data, the same route continues through Q and R; no consumer receives a separate host stream, quotient stream equality, selected representative, or countable-choice schedule.

Proof. Start with the source admission and parity rows of Definition 9099.2. They force each finite window read to enter through A, B, E, O before W is public.

For regular rational and Real-facing reads, use the readback and seal rows Q, R. These rows are downstream of the same parity window and cannot select a second source schedule.

The structural rows H, C, P, N only transport, replay, source, and name the displayed packet. Therefore the consumer remains inside the finite shuffle surface and cannot escape to the excluded host or quotient objects. □

Falsifiable prediction: Every accepted $\mathsf{StreamShuffle}^{\uparrow}$ read displays two StreamNameUp source rows, even and odd parity windows, one combined window, one RegSeqRatUp readback row when rational data is requested, one RealUp seal row when Real data is requested, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming.

Independence witness: streamname, streammerge, regular-cauchy-shuffle, regseqrat: $\mathsf{StreamShuffle}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries two source StreamName rows, parity-indexed windows, a combined downstream window, optional regular rational readback, a Real-seal handoff, transport, replay, provenance, and local NameCert in one packet.

Closure status for $\mathsf{NameCert}_{\mathsf{StreamShuffle}^{\uparrow}}$.

Constructive story: A $\mathsf{StreamShuffle}^{\uparrow}$ packet is generated from two StreamName source rows, even and odd parity windows, one combined window, a RegSeqRat readback row, a Real-seal handoff row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{StreamShuffle}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 9099.1, Definition 9099.2, and Definition 9099.3 seed the finite stream recombination packet over StreamName, StreamMerge, RegularCauchyShuffle, RegSeqRat, and Real rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{StreamShuffle}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient stream equality, selected representatives, countable-choice schedules, host stream equality, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires binding the source, parity-window, combined-window, readback, Real-seal, transport, replay, provenance, and local naming rows to BEDC.Derived.StreamShuffleUp.

Chapter 9100

A Concrete Naming Certificate for $\mathsf{CommonCarrierCompletionBoundary}^{\uparrow}$

Following the common-carrier programme of chapter 9413 and the completion-boundary analysis of section 9413.33, the $\mathsf{CommonCarrierCompletionBoundary}^{\uparrow}$ packet records the finite route by which shared carrier rows are allowed to reach completion-facing readback. It reads the dyadic scale surface of chapter 291, the finite stream windows of chapter 126, the regular rational handoff of chapter 301, and the terminal real-name boundary of chapter 38. The packet names a completion boundary for a common carrier; it does not assert a universal object, quotient completion, selected representative, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 9100.1 (Common-carrier completion-boundary carrier)**.** *A* $\mathsf{CommonCarrierCompletionBoundary}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Q = (G, O, D, S, R, E, H, C, P, N)$$

with the following displayed rows:

1. *G is the common-carrier source row, exposing only the shared generated carrier and its public classifier boundary.*
2. *O is the object-specific observable ledger, recording which public rows of the carrier are being tested for completion-facing faithfulness.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row used to measure finite completion windows.*
4. *S is the* $\mathsf{StreamName}^{\uparrow}$ *window row generated from G, O, D.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row attached to the same stream windows.*
6. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *or completion-seal row reached only after D, S, R have been displayed.*
7. *H records componentwise* hsame *transport for the source, observable ledger, dyadic tolerance, stream window, regular readback, real seal, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from common-carrier observation through completion-facing readback and back to the same carrier rows.*
9. *P is the* Pkg *provenance over* $\mathsf{CommonCarrierCompletionBoundary}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{CommonCarrierCompletionBoundary}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through $G, O, D, S, R, E, H, C, P, N$. It has no coordinate for an unlicensed fourth observable, a universal completed carrier, quotient representatives, countable choice, or ambient real completeness.

Theorem 9100.2 (Common-carrier boundary NameCert obligations)**.** *For every accepted* $\mathsf{CommonCarrierCompletio}$ *carrier*

$$Q = (G, O, D, S, R, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{CommonCarrierCompletionBoundary}^{\uparrow}}$ *surface consists exactly of carrier admission for the common source G, observable-ledger admission for O, dyadic tolerance admission for D, stream-window generation through S, regular rational readback through R, terminal sealing through E, componentwise transport through H, displayed replay through C, provenance through P, and local naming through N.*

Proof. Project the carrier of Definition 9100.1. The displayed tuple gives the only rows available to the local certificate, so the NameCert surface can expose only $G, O, D, S, R, E, H, C, P, N$.

Read the completion-facing rows in order. The observable ledger O chooses which public rows of the common source are under test, the dyadic row D fixes the finite tolerance scale, the stream row S supplies the windows, and the regular readback R is attached to those windows before the terminal seal E can be inspected.

The structural rows H, C, P, N transport, replay, source, and name the same route. Since none of the excluded objects appears in the carrier, the obligations cannot export a universal completed carrier, a quotient representative, countable choice, or ambient real completeness. □

Theorem 9100.3 (Common-carrier completion nonescape)**.** *Every completion-facing consumer of an accepted* $\mathsf{CommonCarrierCompletionBoundary}^{\uparrow}$ *packet must read the finite route*

$$G, O, D, S, R, E, H, C, P, N.$$

In particular, a consumer moving from a shared carrier row toward $\mathsf{RegSeqRat}^{\uparrow}$ *or* $\mathsf{Real}^{\uparrow}$ *readback cannot bypass the observable ledger O, the dyadic tolerance row D, or the stream window S, and cannot replace them by an unledgered fourth observable, quotient completion, selected representative, or ambient completeness theorem.*

Proof. Start with the NameCert obligations of Definition 9100.2. They force every completion-facing read to expose the common source, observable ledger, dyadic tolerance, stream windows, regular readback, terminal seal, transport, replay, provenance, and local name.

Use the core-completeness boundary of Definition 9413.451. Any row that is not a core readout must be carried as a displayed extension, bridge, boundary, or refusal. Here the boundary row is exactly O, D, S, R, E over the common source G.

Finally inspect the carrier. Since no coordinate stores quotient completion, selected representatives, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness, none of those objects can be read from the accepted packet. □

Theorem 9100.4 (Common-carrier regular readback handoff)**.** *Let $Q = (G, O, D, S, R, E, H, C, P, N)$ be an accepted* $\mathsf{CommonCarrierCompletionBoundary}^{\uparrow}$ *carrier. Any* $\mathsf{RegSeqRat}^{\uparrow}$ *or* $\mathsf{Real}^{\uparrow}$ *read from Q is tied to the same common source row G and observable ledger O through the dyadic tolerance row D and stream window S. The handoff is therefore a displayed completion boundary, not a claim that the common carrier itself is a completed universal object.*

Proof. Read D as the finite dyadic tolerance row admitted over the common source and observable ledger. It supplies the scale for the stream windows, but it does not choose a completed object.

The stream windows S are displayed before the regular readback R and terminal seal E can be consumed. Thus every completion-facing read remains attached to the same G, O, D, S route.

Transport, replay, provenance, and local naming preserve those rows. A readback that omits O, D, or S would use a coordinate absent from Definition 9100.1, so it is not a read of the accepted packet. □

Falsifiable prediction: An accepted $\mathsf{CommonCarrierCompletionBoundary}^{\uparrow}$ consumer that reaches $\mathsf{RegSeqRat}^{\uparrow}$ or $\mathsf{Real}^{\uparrow}$ completion-facing data without displaying the observable ledger O, dyadic tolerance row D, and $\mathsf{StreamName}^{\uparrow}$ window row S refutes the carrier surface.

Independence witness: dyadicratcore, streamname, regseqrat, real: no listed sibling supplies the whole ten-row packet $Q = (G, O, D, S, R, E, H, C, P, N)$, because each sibling contributes only tolerance, window, regular readback, or terminal seal data while this chapter binds those rows to a common-carrier source and an observable completion-boundary ledger.

Closure status for $\mathsf{NameCert}_{\mathsf{CommonCarrierCompletionBoundary}^{\uparrow}}$.

Constructive story: A $\mathsf{CommonCarrierCompletionBoundary}^{\uparrow}$ packet is generated from a common-carrier source row, an observable ledger, a DyadicRatCore tolerance row, a StreamName window row, a RegSeqRat readback row, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert evidence.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CommonCarrierCompletionBoundary}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 9100.1, Definition 9100.2, Definition 9100.3, and Definition 9100.4 seed the common-carrier completion-boundary route over source, observable, dyadic, stream, regular-readback, seal, transport, replay, provenance, and local naming rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CommonCarrierCompletionBoundary}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close a universal completed carrier, quotient completion, selected representative, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking for $\mathsf{CommonCarrierCompletionBoundary}^{\uparrow}$.

Upgrade path: Obligation closure requires checked carrier admission, observable-ledger exactness, dyadic-window admission, stream generation, regular readback, real-seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.CommonCarrierCompletionBoundaryUp.

Chapter 9101

A Concrete Naming Certificate for FiniteFourierTailProjector$^{\uparrow}$

Following Fourier and Fejer, the FiniteFourierTailProjector$^{\uparrow}$ packet records the finite tail-projection surface used when a displayed Fourier series is inspected only beyond a named cutoff. It sits after the coefficient-window packet of chapter 6529, the symmetric partial-sum kernel of chapter 2311, the positive averaging sibling of chapter 1939, the real-series corridor of chapter 1581, the regular rational readback of chapter 301, the dyadic tolerance ledger of chapter 291, and the terminal real seal of chapter 38. The packet names a constructive finite projector: it does not assert Fourier convergence, host function equality, quotient coefficient streams, countable choice, or a selected infinite tail limit.

Definition 9101.1 (Finite Fourier tail projector carrier)**.** *A* FiniteFourierTailProjector$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$T = (K, A, W, D, S, R, E, H, C, P, N)$$

with the following displayed rows:

1. *K is the cutoff row, naming the first frequency excluded from the head window and the finite right endpoint of the inspected tail window.*
2. *A is the coefficient-prefix row inherited from the* FourierSeries$^{\uparrow}$ *packet, including the finite coefficient names that determine the inspected partial sums.*
3. *W is the finite tail-window row, listing exactly the frequencies whose coefficients are projected into the tail read.*
4. *D is the* DyadicRatCore$^{\uparrow}$ *frequency ledger, storing the dyadic tolerance, frequency bounds, and finite comparison scale used by the projector.*
5. *S is the* RealSeries$^{\uparrow}$ *partial-sum row for the displayed tail block.*
6. *R is the* RegSeqRat$^{\uparrow}$ *readback row reached from S and D.*
7. *E is the terminal* Real$^{\uparrow}$ *seal for the projected tail block, readable only after K, A, W, D, S, R have been exposed.*
8. *H records componentwise* hsame *transport for cutoff, coefficient prefix, tail window, dyadic ledger, series row, readback, real seal, replay, provenance, and local naming.*
9. *C records displayed* Cont *replay from a Fourier-series request through the tail projector and into the same finite tail-window read.*

10. *P is the* Pkg *provenance over* $\mathsf{FiniteFourierTailProjector}^{\uparrow}$, $\mathsf{FourierSeries}^{\uparrow}$, $\mathsf{DirichletKernel}^{\uparrow}$, $\mathsf{FejerKernel}^{\uparrow}$, $\mathsf{RealSeries}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

11. *N is the local* $\mathsf{NameCert}_{\mathsf{FiniteFourierTailProjector}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through $K, A, W, D, S, R, E, H, C, P, N$. It has no coordinate for host function equality, a quotient coefficient stream, an unbounded tail predicate, countable choice, Fourier convergence, or a selected infinite sum.

Lean4 (definition) `BEDC.Derived.FiniteFourierTailProjectorUp.FiniteFourierTailProjectorUp`

Theorem 9101.2 (Finite Fourier tail projector NameCert obligations)**.** *For every accepted* FiniteFourierTailProjecto *carrier*

$$T = (K, A, W, D, S, R, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{FiniteFourierTailProjector}^{\uparrow}}$ *surface consists exactly of cutoff admission through K, coefficient-prefix exposure through A, finite tail-window admission through W, dyadic frequency-ledger exactness through D,* $\mathsf{RealSeries}^{\uparrow}$ *tail-block readback through S,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback through R,* $\mathsf{Real}^{\uparrow}$ *seal nonescape through E, componentwise* hsame *transport through H, displayed* Cont *replay through C,* Pkg *provenance through P, and local naming through N.*

Proof. Project the accepted carrier. The cutoff row K fixes the boundary between the head coefficients and the tail block, while A supplies only the finite coefficient prefix already visible to the $\mathsf{FourierSeries}^{\uparrow}$ packet.

Read the projector window next. The row W lists the displayed frequencies, and D records the dyadic scale at which those frequencies and their coefficient reads are inspected. Thus the projector is a finite window operation before any real-facing seal is available.

The tail read then passes through S, R, E. The $\mathsf{RealSeries}^{\uparrow}$ row S records the displayed tail-block partial sum, R gives the regular rational readback, and E seals that endpoint as a $\mathsf{Real}^{\uparrow}$ row only after the preceding data have been projected.

Finally H, C, P, N preserve the same route under transport, replay, provenance, and local naming. Since no row stores host function equality, a quotient coefficient stream, Fourier convergence, countable choice, or a selected infinite tail limit, the listed rows exhaust the NameCert obligation surface. □

Theorem 9101.3 (Finite Fourier tail projector Fourier-series handoff)**.** *Every* $\mathsf{FourierSeries}^{\uparrow}$, $\mathsf{DirichletKernel}^{\uparrow}$, *or* $\mathsf{FejerKernel}^{\uparrow}$ *consumer of an accepted* $\mathsf{FiniteFourierTailProjector}^{\uparrow}$ *packet reaches the projected tail only through the finite route*

$$\mathsf{FourierSeries}^{\uparrow} \longmapsto \mathsf{FiniteFourierTailProjector}^{\uparrow} \longmapsto \mathsf{RealSeries}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{DyadicRatCore}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}.$$

The handoff may compare the projected block with Dirichlet or Fejer kernel windows, but it cannot replace the carrier rows by host function equality, quotient coefficient streams, pointwise convergence, countable choice, or a selected infinite tail.

Proof. Begin with the Fourier-series source. The coefficient-prefix row A is read as finite $\mathsf{FourierSeries}^{\uparrow}$ data, not as a completed coefficient stream.

Apply the tail projector. The cutoff K and tail window W identify the finite block that may be passed to a kernel-facing or series-facing consumer, and the dyadic ledger D fixes the comparison scale for that block.

Read the real-facing rows. The tail block enters $\mathsf{RealSeries}^{\uparrow}$ through S, then $\mathsf{RegSeqRat}^{\uparrow}$ through R, and finally the terminal $\mathsf{Real}^{\uparrow}$ seal through E. Dirichlet and Fejer consumers may inspect the same displayed window only through their named kernel rows.

The structural rows H, C, P, N keep the handoff inside the local certificate. Therefore the route exports a finite Fourier tail projection certificate rather than convergence, quotient equality, choice, or a selected limit. □

Falsifiable prediction: Every accepted $\mathsf{FiniteFourierTailProjector}^{\uparrow}$ read exposes a cutoff row, coefficient-prefix row, finite tail window, dyadic frequency ledger, RealSeriesUp tail-block row, RegSeqRatUp readback, RealUp seal, hsame transport, Cont replay, Pkg provenance, and local NameCert data before a Fourier-series or kernel consumer receives the projected tail.

Independence witness: fourier-series, dirichlet-kernel, fejer-kernel, realseries, regseqrat, dyadicratcore, real: $\mathsf{FiniteFourierTailProjector}^{\uparrow}$ is not bijective to any listed sibling because it jointly binds a cutoff, coefficient prefix, finite tail window, dyadic frequency ledger, tail-block series row, regular rational readback, real seal, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{FiniteFourierTailProjector}^{\uparrow}}$ **.**

Constructive story: A $\mathsf{FiniteFourierTailProjector}^{\uparrow}$ packet is generated from a cutoff row, coefficient-prefix row, finite tail window, DyadicRatCore frequency ledger, RealSeries tail-block row, RegSeqRat readback, Real seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{FiniteFourierTailProjector}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 9101.1, Definition 9101.2, Definition 9101.3, the falsifiable prediction, and the independence witness seed the finite Fourier tail-projection packet over displayed coefficient windows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{FiniteFourierTailProjector}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close Fourier convergence, pointwise convergence, host function equality, quotient coefficient streams, countable choice, selected infinite tails, theorem verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, cutoff exactness, coefficient-prefix exposure, finite tail-window admission, dyadic frequency-ledger stability, RealSeries readback, RegSeqRat readback, Real seal nonescape, transport, replay, provenance, and local ledgering for BEDC.Derived.FiniteFourierTailProjectorUp.

Chapter 9102

A Concrete Naming Certificate for $\mathsf{FiniteObservationBoundary}^{\uparrow}$

Following Bishop-style located-real comparison, the $\mathsf{FiniteObservationBoundary}^{\uparrow}$ packet realizes the exact-comparison boundary of section 9238.4 as finite BEDC data. It records two located-real endpoint moduli, the requested exact comparison surface, a finite apartness or equality window, and a refusal ledger for total trichotomy before any comparison-facing consumer reads the packet. It sits beside the located-real comparison packet of chapter 1730, the comparison-modulus packet of chapter 5813, the dyadic comparison boundary of chapter 9085, the finite separation packet of chapter 1202, and the located-order packet of chapter 3640. The packet names a finite observation boundary, not arbitrary exact trichotomy, quotient real equality, LPO, countable choice, or ambient real completeness.

Definition 9102.1 (Finite observation boundary carrier)**.** *A* $\mathsf{FiniteObservationBoundary}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (L, R, Q, W, A, E, F, H, C, P, N)$$

with the following displayed rows:

1. *L is the left* $\mathsf{LocatedReal}^{\uparrow}$ *endpoint modulus row, exposing only the finite observations selected by its displayed modulus.*
2. *R is the right* $\mathsf{LocatedReal}^{\uparrow}$ *endpoint modulus row, exposed by the same finite-window discipline.*
3. *Q is the requested exact comparison surface, recording that a consumer asked for total left/equal/right classification.*
4. *W is the finite observation window selected from the two endpoint moduli for the request.*
5. *A is the finite apartness or equality row visible at W, using* $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$ *readback data.*
6. *E is the refusal ledger for total trichotomy: it records that Q may be answered only by finite apartness or finite equality evidence, not by arbitrary exact comparison.*
7. *F records the sibling comparison handoff through located comparison, comparison-modulus, dyadic comparison boundary, finite separation, or located order rows when one of those rows is displayed.*

8. *H records componentwise* hsame *transport for endpoint moduli, request surface, finite window, apartness or equality evidence, refusal ledger, sibling handoff, replay, provenance, and local naming.*
9. *C records displayed* Cont *replay from the exact-comparison request back through the finite observation window.*
10. *P is the* Pkg *provenance over* $\mathsf{FiniteObservationBoundary}^{\uparrow}$, $\mathsf{LocatedReal}^{\uparrow}$, $\mathsf{DyadicModulusComparisonBoundary}^{\uparrow}$, $\mathsf{LocatedRealComparison}^{\uparrow}$, $\mathsf{LocatedRealComparisonModulus}^{\uparrow}$, $\mathsf{FiniteWindowRealSeparation}^{\uparrow}$, $\mathsf{RealLocatedOrder}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{FiniteObservationBoundary}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through $L, R, Q, W, A, E, F, H, C, P, N$. It has no coordinate for total trichotomy of arbitrary located reals, quotient-real equality, LPO*, countable choice, a selected representative, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 9102.2 (Finite observation boundary NameCert obligations)**.** *For every accepted* FiniteObservationBound *carrier*

$$B = (L, R, Q, W, A, E, F, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{FiniteObservationBoundary}^{\uparrow}}$ *surface consists exactly of left and right endpoint-modulus admission through L, R, exact-comparison request exposure through Q, finite observation-window admission through W, apartness or equality evidence through A, trichotomy refusal through E, sibling comparison handoff through F, componentwise* hsame *transport through H, displayed* Cont *replay through C,* Pkg *provenance through P, and local naming through N.*

Proof. Project the accepted carrier. The endpoint rows L and R expose only the observations selected by the two located-real moduli.

Read the request row Q. It records the exact-comparison demand as a surface to be refused or finitely witnessed, not as an available trichotomy operator.

Use the finite window W and the evidence row A. These rows can display a positive apartness witness or a finite equality approximation through dyadic, regular-rational, and Real readbacks, but they do not classify every arbitrary pair of located reals.

The refusal ledger E and sibling handoff F preserve the boundary: downstream comparison consumers must pass through located comparison, comparison-modulus, dyadic boundary, finite separation, or located-order rows when those rows are present. The structural rows H, C, P, N add only transport, replay, provenance, and local naming, so no row can export total trichotomy, quotient equality, omniscience, choice, or ambient completeness. □

Falsifiable prediction: An accepted $\mathsf{FiniteObservationBoundary}^{\uparrow}$ read is refuted if a located-real comparison consumer returns total left/equal/right trichotomy without first exposing two endpoint modulus rows, the requested exact-comparison surface, a finite observation window, finite apartness or equality evidence, the trichotomy refusal ledger, sibling comparison handoff, transport, replay, provenance, and local NameCert data.

Independence witness: located-real-comparison, located-real-comparison-modulus, dyadic-modulus-comparison-boundary, finite-window-real-separation, real-located-order: $\mathsf{FiniteObservationBoundary}^{\uparrow}$ is not bijective to any listed sibling because it stores the exact-comparison request surface and refusal ledger together with two endpoint moduli, one finite observation window, finite apartness or equality evidence, sibling handoff, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{FiniteObservationBoundary}^{\uparrow}}$**.**

Constructive story: A FiniteObservationBoundary$^{\uparrow}$ packet is generated from two LocatedReal endpoint modulus rows, a requested exact-comparison surface, a finite observation window, finite apartness or equality evidence, a total-trichotomy refusal ledger, sibling comparison handoff, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\text{FiniteObservationBoundary}^{\uparrow}}$, seed)

Scope closed: Definition 9102.1, Definition 9102.2, the falsifiable prediction, and the independence witness seed the finite observation boundary for exact located-real comparison requests.

Formal verification: FormalStatus(NameCert$_{\text{FiniteObservationBoundary}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close arbitrary exact trichotomy, quotient-real equality, LPO, countable choice, selected representatives, ambient real completeness, theorem verification, or bridge checking.

Upgrade path: Obligation closure requires checked endpoint-modulus admission, exact-request exposure, finite-window admission, apartness-or-equality evidence, trichotomy refusal, sibling handoff, transport, replay, provenance, and local ledgering for BEDC.Derived.FiniteObservationBoundaryUp.

Chapter 9103

A Concrete Naming Certificate for $\mathsf{MorseHomology}^{\uparrow}$

Following Morse and Milnor, the $\mathsf{MorseHomology}^{\uparrow}$ packet records the finite BEDC surface on which a Morse function, its critical-point rows, oriented unstable-cell data, boundary-count ledgers, and homology readback are consumed as one NameCert. It sits beside the manifold carrier of chapter 96, the homology carrier of chapter 98, the differential-form surface of chapter 136, and the Morse-theory packet of chapter 3533. The certificate names a finite Morse chain and boundary route; it does not import a host transversality theorem, selected gradient-flow compactification, quotient chain equality, or ambient smooth-function space.

Definition 9103.1 ($\mathsf{MorseHomology}^{\uparrow}$ finite carrier)**.** *A* $\mathsf{MorseHomology}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M = (X, F, C, G, B, D, H, T, R, P, N)$$

with the following displayed rows:

1. *X is the* $\mathsf{Manifold}^{\uparrow}$ *source row, exposing the charted space on which the Morse data are read.*
2. *F is the finite Morse-function row, read through* $\mathsf{MorseTheory}^{\uparrow}$ *and carrying the displayed critical values and index windows.*
3. *C is the critical-point row family, with each point tied to a chart row of X and an index row of F.*
4. *G is the gradient-incidence row, recording only finite oriented flow-line counts between adjacent index rows.*
5. *B is the boundary ledger for the Morse chain rows; it stores the signed incidence data used to form the differential.*
6. *D is the differential-squared boundary row, recording the finite cancellation surface that later homology consumers may inspect.*
7. *H is the* $\mathsf{Homology}^{\uparrow}$ *readback row, exposing cycles, boundaries, and degree windows through the displayed Morse chain ledger.*
8. *T records componentwise* hsame *transport for the manifold, Morse-function, critical-point, incidence, boundary, cancellation, homology, replay, provenance, and local naming rows.*
9. *R records displayed* Cont *replay from a Morse-homology request through X, F, C, G, B, D, H, T.*

10. *P is the* Pkg *provenance over* $\mathsf{MorseHomology}^{\uparrow}$, $\mathsf{Manifold}^{\uparrow}$, $\mathsf{Homology}^{\uparrow}$, $\mathsf{DiffForm}^{\uparrow}$, $\mathsf{MorseTheory}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

11. *N is the local* $\mathsf{NameCert}_{\mathsf{MorseHomology}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these rows. It has no coordinate for an ambient moduli space, a host flow-category quotient, chosen perturbations, selected triangulations, or a completed smooth-function universe.

Theorem 9103.2 ($\mathsf{MorseHomology}^{\uparrow}$ NameCert obligations)**.** *For every accepted* $\mathsf{MorseHomology}^{\uparrow}$ *carrier*

$$M = (X, F, C, G, B, D, H, T, R, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{MorseHomology}^{\uparrow}}$ *surface consists exactly of carrier admission for the manifold row, Morse-function row, critical-point rows, gradient-incidence row, boundary ledger, differential-squared boundary row, homology readback, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. Every* $\mathsf{Homology}^{\uparrow}$ *consumer reads the cycle and boundary data through H only after X, F, C, G, B, D are displayed, and every differential-form-facing consumer reads orientation or index bookkeeping through the* $\mathsf{DiffForm}^{\uparrow}$ *and* $\mathsf{MorseTheory}^{\uparrow}$ *provenance rows rather than through a separate host complex.*

Proof. Project the carrier of Definition 9103.1. The rows $X, F, C, G, B, D, H, T, R, P, N$ are the only coordinates available to a consumer of the packet.

The Morse chain stage is X, F, C, G, B. The manifold row supplies the charted source, the Morse-function row supplies critical values and index windows, and the critical-point and gradient-incidence rows supply the finite signed boundary counts.

The homology stage is D, H. The cancellation row D records the finite boundary-of-boundary surface, and H exposes only the resulting cycle, boundary, and degree-window readbacks to $\mathsf{Homology}^{\uparrow}$.

Finally T, R, P, N transport, replay, source, and name the same packet. Since the carrier contains no ambient moduli coordinate, quotient chain equality, selected perturbation, or host flow-category object, the displayed rows exhaust the local NameCert obligations. □

Theorem 9103.3 ($\mathsf{MorseHomology}^{\uparrow}$ sibling handoff)**.** *Every* $\mathsf{Manifold}^{\uparrow}$*-,* $\mathsf{Homology}^{\uparrow}$*-, or* $\mathsf{DiffForm}^{\uparrow}$*-facing read of an accepted* $\mathsf{MorseHomology}^{\uparrow}$ *packet factors through the finite route*

$$\mathsf{Manifold}^{\uparrow},\ \mathsf{MorseTheory}^{\uparrow},\ \mathsf{DiffForm}^{\uparrow},\ \mathsf{Homology}^{\uparrow},\ \mathsf{BHist},\ \mathsf{hsame},\ \mathsf{Cont},\ \mathsf{Pkg},\ \mathsf{NameCert}_{\mathsf{MorseHomology}^{\uparrow}}.$$

The handoff supplies displayed chart, critical-point, incidence, boundary, cancellation, and homology rows; it does not supply a host transversality theorem, completed moduli space, smooth-function quotient, or selected chain representative outside the packet.

Proof. Start with the obligation surface of Definition 9103.2. A consumer must first read the manifold source X, Morse-function row F, critical-point rows C, and gradient-incidence row G before it can inspect the boundary ledger B.

The differential-form and homology sides are then separated. Orientation and index bookkeeping are carried only through the displayed $\mathsf{DiffForm}^{\uparrow}$ and $\mathsf{MorseTheory}^{\uparrow}$ provenance rows, while homology readback is carried only through D and H.

Transport, replay, provenance, and local naming preserve the same rows. Thus the sibling handoff reaches manifold, homology, and differential-form consumers without adding any of the excluded host-side structures. □

Closure status for $\mathsf{NameCert}_{\mathsf{MorseHomology}^{\uparrow}}$.

Constructive story: A $\mathsf{MorseHomology}^{\uparrow}$ packet is generated from a manifold source row, Morse-function row, critical-point rows, gradient-incidence row, boundary ledger, differential-squared boundary row, homology readback, component-wise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{MorseHomology}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 9103.1, Definition 9103.2, and Definition 9103.3 seed the finite Morse chain, boundary, cancellation, and homology readback route over manifold, homology, and differential-form siblings.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{MorseHomology}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close transversality, compactified moduli spaces, continuation invariance, selected perturbations, quotient chain equality, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, critical-point exposure, incidence boundary exactness, cancellation rows, homology readback, transport, replay, provenance, and local naming for BEDC.Derived.MorseHomologyUp.

Chapter 9104

A Concrete Naming Certificate for $\mathsf{NuclearSpace}^{\uparrow}$

Following Grothendieck and Treves on nuclear locally convex spaces, the $\mathsf{NuclearSpace}^{\uparrow}$ packet records the finite BEDC surface by which a locally convex source is inspected through seminorm windows, bounded-set ledgers, nuclear factorization data, and tensor-test rows before a functional-analysis consumer may cite nuclearity. It sits after the locally convex surface of chapter 3386, the topological-vector source of chapter 205, the tensor-product carrier of chapter 87, the functional-analysis consumer frontier of chapter 94, and the scalar readback of chapter 38. The packet names a displayed nuclearity test route, not a completed locally convex space, a strong duality theorem, Grothendieck's theorem, choice-selected bases, or an ambient function-space quotient.

Definition 9104.1 (Nuclear space carrier)**.** *A* $\mathsf{NuclearSpace}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$U = (L, S, B, F, T, R, Q, H, C, P, N)$$

with the following displayed rows:

1. *L is the* $\mathsf{LocallyConvexSpace}^{\uparrow}$ *source row, read through its topological-vector, finite-seminorm, and convex-neighbourhood data.*
2. *S is the finite seminorm-family row selected for the nuclearity test window.*
3. *B is the bounded-set ledger, recording the displayed bounded probes against which the seminorm window is read.*
4. *F is the nuclear-map factorization row: it records the finite source seminorm, target seminorm, scalar coefficient readback, and intermediate finite-rank witness used by the local test.*
5. *T is the* $\mathsf{TensorProduct}^{\uparrow}$ *tensor-test row, available only after L, S, B, F have been displayed.*
6. *R is the* $\mathsf{Real}^{\uparrow}$ *scalar-readback row for coefficient bounds, summability budgets, and seminorm estimates.*
7. *Q is the* $\mathsf{FunctionalAnalysis}^{\uparrow}$ *consumer row that may replay nuclearity only through L, S, B, F, T, R.*
8. *H records componentwise* hsame *transport for locally convex source, seminorm, bounded-set, factorization, tensor-test, scalar-readback, consumer, replay, provenance, and local naming rows.*
9. *C records displayed* Cont *replay from a seminorm or bounded-set query through the factorization and tensor-test rows.*

10. *P is the* Pkg *provenance over* $\mathsf{NuclearSpace}^{\uparrow}$, $\mathsf{LocallyConvexSpace}^{\uparrow}$, $\mathsf{FunctionalAnalysis}^{\uparrow}$, $\mathsf{TopVecSpace}^{\uparrow}$, $\mathsf{TensorProduct}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

11. *N is the local* $\mathsf{NameCert}_{\mathsf{NuclearSpace}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through $L, S, B, F, T, R, Q, H, C, P, N$. It has no coordinate for topological-vector-space completion, strong duality, Grothendieck theorem, choice-selected bases, ambient function-space quotients, Lean verification, or bridge checking.

Theorem 9104.2 (Nuclear space NameCert obligations)**.** *For every accepted* $\mathsf{NuclearSpace}^{\uparrow}$ *carrier*

$$U = (L, S, B, F, T, R, Q, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{NuclearSpace}^{\uparrow}}$ *surface consists exactly of carrier admission for the locally convex source, finite seminorm-family window, bounded-set ledger, nuclear-map factorization row, tensor-test row, real scalar readback, functional-analysis consumer row, componentwise transport, displayed replay, package provenance, and local naming. Every consumer that treats U as a nuclear-space certificate must expose L, S, B, F, T, R before Q, H, C, P, N are public.*

Proof. Project the carrier of Definition 9104.1. The locally convex source is the row L, and the only local probes available to it are the finite seminorm-family row S and bounded-set ledger B.

Read the factorization surface next. The row F stores the finite nuclear-map factorization witness for the displayed test window, while the scalar budgets used by that witness are read through the $\mathsf{Real}^{\uparrow}$ row R.

The tensor-test row T is downstream of the same data. It receives the locally convex source, the seminorm and bounded-set windows, the factorization row, and the scalar readback before a functional-analysis consumer may inspect Q.

Finally H, C, P, N transport, replay, source, and name exactly those rows. Since the carrier contains no completion object, strong-duality row, Grothendieck theorem, choice-selected basis, or quotient function-space carrier, the listed rows exhaust the local NameCert surface. □

Theorem 9104.3 (Nuclear space finite tensor-test handoff)**.** *Every accepted* $\mathsf{NuclearSpace}^{\uparrow}$ *read that is consumed by* $\mathsf{FunctionalAnalysis}^{\uparrow}$ *must factor through*

$$\mathsf{LocallyConvexSpace}^{\uparrow},\ \mathsf{TopVecSpace}^{\uparrow},\ \mathsf{TensorProduct}^{\uparrow},\ \mathsf{Real}^{\uparrow}$$

by way of the displayed rows $L, S, B, F, T, R, Q, H, C, P, N$. The handoff exposes finite seminorm probes, bounded-set tests, nuclear factorization data, tensor-test evidence, and scalar readback; it does not export completed locally convex spaces, strong duals, Grothendieck theorem, selected bases, or quotient function spaces.

Proof. Start from the NameCert obligations of Definition 9104.2. They force a nuclearity consumer to read the locally convex source row, finite seminorm window, bounded-set ledger, factorization row, tensor-test row, and real scalar readback before the local certificate can be used.

The $\mathsf{TopVecSpace}^{\uparrow}$ dependency is already inside the $\mathsf{LocallyConvexSpace}^{\uparrow}$ source route, so a consumer cannot detach the seminorm window from the underlying topological-vector operations and continuity data.

The $\mathsf{TensorProduct}^{\uparrow}$ row then receives only the displayed factorization data. Its tensor test is a finite BEDC handoff from F and R, not a completed projective tensor product or a host theorem about all continuous linear maps.

The structural rows H, C, P, N preserve that finite route into $\mathsf{FunctionalAnalysis}^{\uparrow}$. Because no coordinate stores strong duality, a Grothendieck theorem, a selected basis, or an ambient quotient function space, none of those endpoints can be exported by the packet. □

Falsifiable prediction: An accepted $\mathsf{NuclearSpace}^{\uparrow}$ consumer that reads nuclearity without first displaying a $\mathsf{LocallyConvexSpace}^{\uparrow}$ source, finite seminorm-family window, bounded-set ledger, nuclear-map factorization row, $\mathsf{TensorProduct}^{\uparrow}$ tensor test, $\mathsf{Real}^{\uparrow}$ scalar readback, componentwise hsame transport, Cont replay, Pkg provenance, and local NameCert row refutes the carrier surface.

Independence witness: locally-convex-space, functional-analysis, topvecspace, tensor-product, real: $\mathsf{NuclearSpace}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries a locally convex source, finite seminorm windows, bounded-set ledgers, nuclear factorization rows, tensor-test rows, scalar readback, transport, replay, provenance, and local NameCert data while refusing completion, strong duality, selected bases, and quotient function-space endpoints.

Closure status for $\mathsf{NameCert}_{\mathsf{NuclearSpace}^{\uparrow}}$.

Constructive story: A $\mathsf{NuclearSpace}^{\uparrow}$ packet is generated from a LocallyConvexSpace source row, finite seminorm-family window, bounded-set ledger, nuclear-map factorization row, TensorProduct test row, Real scalar readback, FunctionalAnalysis consumer row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{NuclearSpace}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 9104.1, Definition 9104.2, and Definition 9104.3 seed the finite nuclear-space route through locally convex, topological-vector, tensor-test, scalar-readback, transport, replay, provenance, and local naming rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{NuclearSpace}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close full topological-vector-space completion, strong duality, Grothendieck theorem, choice-selected bases, ambient function-space quotients, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, finite seminorm-window exactness, bounded-set ledger routing, nuclear factorization routing, tensor-test handoff, scalar readback, transport, replay, provenance, and local naming for BEDC.Derived.NuclearSpaceUp.

Chapter 9105

A Concrete Naming Certificate for $\mathsf{CauchySequenceMorphism}^{\uparrow}$

Following Bishop and Bridges, *Constructive Analysis*, a $\mathsf{CauchySequenceMorphism}^{\uparrow}$ packet names a finite modulus-preserving route between accepted $\mathsf{CauchySequenceSpace}^{\uparrow}$ packets. It is not a host function between streams and not a quotient map between completion classes. The route consumes the source and target spaces of chapter 406, the scheduled windows of chapter 126, the regular rational rows of chapter 301, the dyadic tolerance ledger of chapter 291, the modulus rows of chapter 292, and the completion boundary of chapter 360. Its Real-facing read remains compatible with the seal discipline of chapter 38.

Definition 9105.1 (Cauchy sequence morphism carrier)**.** *A* $\mathsf{CauchySequenceMorphism}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$F = (S, T, M, D, E, H, C, P, N)$$

with the following displayed rows:

1. *S is the accepted source* $\mathsf{CauchySequenceSpace}^{\uparrow}$ *packet.*
2. *T is the accepted target* $\mathsf{CauchySequenceSpace}^{\uparrow}$ *packet.*
3. *M is the modulus-preserving row, carrying each source finite-window request to a target window request with the displayed* $\mathsf{CauchyModulus}^{\uparrow}$ *bound.*
4. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger that records how the source tolerance is carried to the target tolerance.*
5. *E is the* $\mathsf{RealCauchyCompletion}^{\uparrow}$ *and* $\mathsf{Real}^{\uparrow}$ *handoff row reached only after S, T, M, D have been displayed.*
6. *H records componentwise* hsame *transport for the source, target, modulus-preserving row, tolerance ledger, Real-seal handoff, replay, provenance, and local naming.*
7. *C records displayed* Cont *replay of the same finite route.*
8. *P is the* Pkg *provenance over* $\mathsf{CauchySequenceMorphism}^{\uparrow}$, $\mathsf{CauchySequenceSpace}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{CauchyModulus}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RealCauchyCompletion}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
9. *N is the local* $\mathsf{NameCert}_{\mathsf{CauchySequenceMorphism}^{\uparrow}}$ *row.*

The classifier compares accepted morphism packets only through $S, T, M, D, E, H, C, P, N$. It has no coordinate for a host function, quotient stream map, selected limit, countable choice schedule, ambient completeness principle, or full category of completions.

Theorem 9105.2 (Cauchy sequence morphism NameCert obligations)**.** *For every accepted* CauchySequenceMorphis *carrier*

$$F = (S, T, M, D, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{CauchySequenceMorphism}^{\uparrow}}$ *surface consists exactly of five finite rows:*

1. *source and target admission for the accepted* $\mathsf{CauchySequenceSpace}^{\uparrow}$ *packets S and T;*
2. *modulus preservation, saying that every source window request consumed by the morphism is routed through M to a target window request with the displayed* $\mathsf{CauchyModulus}^{\uparrow}$ *bound;*
3. *dyadic tolerance exactness for D, tying the transported source tolerance to the target tolerance ledger;*
4. *Real-seal handoff nonescape for E, forcing every completion-facing read through S, T, M, D before any* $\mathsf{RealCauchyCompletion}^{\uparrow}$ *or* $\mathsf{Real}^{\uparrow}$ *seal is consumed;*
5. *structural stability for H, C, P, N, transporting, replaying, sourcing, and locally naming only the same displayed route.*

No morphism obligation is stored outside these rows.

Proof. Project the carrier of Definition 9105.1. The source and target sequence-space packets are the only endpoints available, and M is the only row that transports window requests between them.

Read the dyadic ledger D. It is stored beside the same source, target, and modulus rows, so tolerance transfer cannot be supplied by an external real equality or by a quotient stream map.

Finally read the handoff row E and the structural rows H, C, P, N. They preserve the displayed route through transport, replay, provenance, and local naming, and they add no coordinate for host functions, selected limits, countable choice, ambient completeness, or a category-of-completions theorem. □

Theorem 9105.3 (Cauchy sequence morphism Real-seal nonescape)**.** *Let*

$$F = (S, T, M, D, E, H, C, P, N)$$

be an accepted $\mathsf{CauchySequenceMorphism}^{\uparrow}$ *carrier. Every* $\mathsf{RealCauchyCompletion}^{\uparrow}$*- or* $\mathsf{Real}^{\uparrow}$*-facing read exported by F factors first through the source packet S, the target packet T, the modulus-preserving row M, the dyadic tolerance ledger D, the transport row H, the replay row C, the provenance row P, and the local naming row N before the seal row E is consumed.*

Consequently the morphism exports no host function, quotient stream map, selected limit, countable-choice schedule, ambient completeness principle, or full category-of-completions structure.

Proof. Start with the accepted carrier. The only Real-facing coordinate is E, and it is stored in the same packet as S, T, M, D, H, C, P, N.

Apply the NameCert obligation surface of Definition 9105.2. The source-target admission row and modulus-preservation row place S, T, M before any completion-facing read, while dyadic exactness places D on the same route.

The structural stability row then routes the read through H, C, P, N. Since these rows only transport, replay, source, and locally name the displayed packet, the seal row cannot be consumed through a host function, quotient stream map, selected limit, choice schedule, ambient completeness principle, or category-of-completions structure. □

Closure status for $\mathsf{NameCert}_{\mathsf{CauchySequenceMorphism}^{\uparrow}}$.

Constructive story: A $\mathsf{CauchySequenceMorphism}^{\uparrow}$ packet is generated from source and target $\mathsf{CauchySequenceSpace}^{\uparrow}$ rows, a modulus-preserving row, a $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance ledger, a $\mathsf{RealCauchyCompletion}^{\uparrow}$ and $\mathsf{Real}^{\uparrow}$ handoff row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CauchySequenceMorphism}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 9105.1, Definition 9105.2, and Definition 9105.3 seed the finite modulus-preserving morphism route between accepted Cauchy-sequence-space packets.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CauchySequenceMorphism}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim host functions, quotient stream maps, selected limits, countable choice, ambient completeness, a full category of completions, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked source-target admission, modulus preservation, dyadic tolerance exactness, Real-seal nonescape, transport stability, replay stability, provenance, and local naming for BEDC.Derived.CauchySequenceMorphism

Chapter 9106

A Concrete Naming Certificate for $\mathsf{BishopRealNameRealizer}^{\uparrow}$

Following Bishop and Bridges, *Constructive Analysis*, the $\mathsf{BishopRealNameRealizer}^{\uparrow}$ packet records the finite route by which a rational source window is realized as a constructive real name before any host real equality, quotient class, countable-choice selector, or ambient completeness theorem is available. It sits beside the finite observation discipline of chapter 126, the dyadic tolerance core of chapter 291, the regular rational readback of chapter 301, the located-real witness surface of chapter 6180, and the terminal real-name seal of chapter 38. The packet names a finite real-name realization layer for later Real and RegSeqRat consumers, not a completed host real.

Definition 9106.1 (Bishop real-name realizer carrier)**.** *A* $\mathsf{BishopRealNameRealizer}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$R = (Q, W, D, G, L, E, H, C, P, N)$$

with the following displayed rows:

1. *Q is the rational source-window row, listing the finite rational observations and requested precision bounds before any real-facing read is allowed.*
2. *W is the* $\mathsf{StreamName}^{\uparrow}$ *finite observation window opened for exactly the positions named by Q.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, recording the dyadic radii, slack bounds, and comparison budgets used by the window.*
4. *G is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row, exposing the same window as regular rational data.*
5. *L is the* $\mathsf{BishopLocatedReal}^{\uparrow}$ *witness row, recording located lower and upper tests only through the displayed rational and dyadic rows.*
6. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal, exposed only after Q, W, D, G, L have been replayed.*
7. *H records componentwise* hsame *transport for the source window, stream window, dyadic ledger, regular readback, located witness, real seal, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from a real-name request through $Q, W, D, G, L, E, H, P, N$.*
9. *P is the* Pkg *provenance over* $\mathsf{BishopRealNameRealizer}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{BishopLocatedReal}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{BishopRealNameRealizer}^{\uparrow}}$ *row.*

The classifier compares accepted packets only by $Q, W, D, G, L, E, H, C, P, N$. It has no coordinate for host real equality, quotient classes of names, countable choice, trichotomy, selected limits, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 (statement) `BEDC.Derived.BishopRealNameRealizerUp`

Theorem 9106.2 (Bishop real-name realizer NameCert obligations)**.** *For every accepted* $\mathsf{BishopRealNameRealizer}^{\uparrow}$ *carrier $R = (Q, W, D, G, L, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{BishopRealNameRealizer}^{\uparrow}}$ *surface consists exactly of rational source-window exposure through Q, finite* $\mathsf{StreamName}^{\uparrow}$ *observation through W,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance accounting through D,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback through G,* $\mathsf{BishopLocatedReal}^{\uparrow}$ *witness exposure through L, terminal* $\mathsf{Real}^{\uparrow}$ *sealing through E, componentwise transport through H, displayed replay through C, provenance through P, and local naming through N.*

Proof. Project the carrier of Definition 9106.1. The finite analytic rows are exactly Q, W, D, G, L, E, and the structural rows are exactly H, C, P, N.

The source window Q fixes the rational data being realized. The finite observation row W supplies only the named stream positions, while the dyadic ledger D supplies the comparison budget for those observations.

The real-facing rows remain downstream. The regular rational row G reads the displayed observations, the located witness L records only the located tests supported by the same rational and dyadic budget, and the terminal seal E is reached only after those rows have been replayed.

Finally H, C, P, N preserve, replay, source, and name the same packet. Since no excluded host equality, quotient, choice, trichotomy, selected-limit, or ambient-completeness object is a carrier coordinate, the listed rows exhaust the NameCert obligations. □

Theorem 9106.3 (Bishop real-name realizer finite-window readback)**.** *Every* $\mathsf{RegSeqRat}^{\uparrow}$ *or* $\mathsf{Real}^{\uparrow}$ *consumer of an accepted* $\mathsf{BishopRealNameRealizer}^{\uparrow}$ *carrier reads the real name through the finite route*

$$Q \longmapsto W \longmapsto D \longmapsto G \longmapsto L \longmapsto E \longmapsto H, C, P, N.$$

The exported read is a finite real-name realization from displayed rational windows; it is not an equality class of streams, a choice-selected Cauchy limit, host real equality, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Begin with Definition 9106.2. It requires every real-name read to expose the rational source window, StreamName observation window, dyadic tolerance ledger, regular rational readback, located witness, Real seal, transport, replay, provenance, and local naming rows.

The readback route is finite because Q and W name only displayed windows. The dyadic row D fixes the tolerance ledger for the window, and G is the only regular-rational readback row available to the consumer.

The located witness L and real seal E are downstream of that finite route. Componentwise transport, replay, provenance, and naming through H, C, P, N preserve the same order and do not add a detached tail or completed host object. □

Theorem 9106.4 (Bishop real-name realizer Real-seal nonescape)**.** *For every accepted* $\mathsf{BishopRealNameRealizer}^{\uparrow}$ *carrier $R = (Q, W, D, G, L, E, H, C, P, N)$, the terminal* $\mathsf{Real}^{\uparrow}$ *seal E is readable only after the rational source window Q, finite observation window W, dyadic tolerance ledger D, regular rational readback G, located-real witness L, componentwise transport H, displayed replay C, provenance P, and local naming N have been exposed. Thus E cannot be consumed as host real equality, quotient-name identity, countable choice, a selected limit, trichotomy, or ambient completeness.*

Proof. Project the carrier of Definition 9106.1. The only Real-facing coordinate is E, and it appears in the same finite packet as $Q, W, D, G, L, H, C, P, N$.

Apply finite-window readback, Definition 9106.3. It places E after the rational source, StreamName window, dyadic tolerance ledger, RegSeqRat readback, and Bishop located witness.

The refusal follows from the absence of the excluded objects in the carrier. Since no row stores host real equality, quotient-name identity, countable choice, selected limits, trichotomy, or ambient completeness, the Real seal has no escape route outside the displayed NameCert surface. □

Falsifiable prediction: Every accepted $\mathsf{BishopRealNameRealizer}^{\uparrow}$ read that reaches a Real seal factors through one rational source window, one StreamName finite observation window, one DyadicRatCore tolerance ledger, one RegSeqRat readback, one BishopLocatedReal witness, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert row.

Independence witness: streamname, dyadicratcore, regseqrat, bishoplocatedreal, real: $\mathsf{BishopRealNameRealizer}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries a rational source window, finite observation window, dyadic tolerance ledger, regular readback, located witness, Real seal, componentwise transport, replay, provenance, and local naming as one realization packet.

Closure status for $\mathsf{NameCert}_{\mathsf{BishopRealNameRealizer}^{\uparrow}}$.

Constructive story: A $\mathsf{BishopRealNameRealizer}^{\uparrow}$ packet is generated from a rational source window, StreamName finite observation window, DyadicRatCore tolerance ledger, RegSeqRat readback, BishopLocatedReal witness, RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BishopRealNameRealizer}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 9106.1, Definition 9106.2, Definition 9106.3, and Definition 9106.4 seed the finite constructive real-name realization route from rational windows to a downstream RealUp seal.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BishopRealNameRealizer}^{\uparrow}}, \mathsf{formalTarget})$

Lean target: `BEDC.Derived.BishopRealNameRealizerUp`

Bridge status: none

Not claimed: This chapter does not close host real equality, quotient-name identity, countable choice, selected limits, trichotomy, ambient $\mathsf{Real}^{\uparrow}$ completeness, theorem checking, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, finite-window readback, located-witness exposure, Real-seal nonescape, componentwise transport, replay, provenance, and local naming for BEDC.Derived.BishopRealNameRealizerUp.

Chapter 9107

A Concrete Naming Certificate for $\mathsf{ParacompactSpace}^{\uparrow}$

Following Bourbaki and Engelking on paracompact Hausdorff spaces, the $\mathsf{ParacompactSpace}^{\uparrow}$ packet records the space-level certificate that binds a topology source, Hausdorff separation, normal-space separation, locally finite refinement, and partition-refinement ledgers into one finite BEDC NameCert surface. It sits over the open-cover refinement route of chapter 1963, the point-separation rows of chapter 1925, and the closed-pair separation route of chapter 1866. The packet names only displayed topological, refinement, and partition-refinement rows; it does not assert arbitrary subcover selection, host powersets of open sets, unrestricted partitions of unity, or ambient choice principles.

Definition 9107.1 (Paracompact space carrier)**.** *A* $\mathsf{ParacompactSpace}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (T, H, N, A, R, L, P, W, E, K, C, G, Z)$$

with the following displayed rows:

1. *T is the* $\mathsf{Topology}^{\uparrow}$ *source row, exposing the ambient open-row operations on the displayed space surface.*
2. *H is the* $\mathsf{HausdorffSpace}^{\uparrow}$ *point-separation row, read only as the sibling neighbourhood-separation certificate.*
3. *N is the* $\mathsf{NormalSpace}^{\uparrow}$ *closed-pair separation row over the same topology source.*
4. *A is the displayed open-cover request row.*
5. *R is the locally finite open-refinement ledger inherited from the* $\mathsf{Paracompact}^{\uparrow}$ *refinement surface.*
6. *L is the coverage and containment ledger, recording that refinement cells cover the displayed region and sit inside their assigned cover cells.*
7. *P is the partition-refinement ledger, recording displayed support rows, local finiteness of the support family, and assignment of each support row to the refinement cell that licenses it.*
8. *W is the exactness row tying the partition-refinement support ledger to the same cover and refinement windows A, R, L.*
9. *E records componentwise* hsame *transport for the topology, separation, refinement, partition-refinement, exactness, replay, provenance, and local naming rows.*

10. *K records displayed* Cont *replay from a paracompact-space request through* $T, H, N, A, R, L, P, W, E, G, Z$.
11. *C is the classifier row comparing accepted packets only through the displayed coordinates* $T, H, N, A, R, L, P, W, E$
12. *G is the* Pkg *provenance over* $\mathsf{ParacompactSpace}^{\uparrow}$, $\mathsf{Topology}^{\uparrow}$, $\mathsf{HausdorffSpace}^{\uparrow}$, $\mathsf{NormalSpace}^{\uparrow}$, $\mathsf{Paracompact}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
13. *Z is the local* $\mathsf{NameCert}_{\mathsf{ParacompactSpace}^{\uparrow}}$ *row.*

The classifier has no coordinate for a selected subcover, an arbitrary host-indexed open family, unrestricted partition-of-unity weights, host complement selection, Lean verification, or bridge checking.

Theorem 9107.2 (Paracompact space NameCert obligations)**.** *For every accepted* $\mathsf{ParacompactSpace}^{\uparrow}$ *carrier*

$$S = (T, H, N, A, R, L, P, W, E, K, C, G, Z),$$

the local $\mathsf{NameCert}_{\mathsf{ParacompactSpace}^{\uparrow}}$ *surface consists exactly of carrier admission, topology-source exposure, Hausdorff and normal-space separation exposure, open-cover exposure, locally finite refinement exactness, partition-refinement ledger exposure, support-to-refinement exactness, componentwise transport, displayed replay, classifier comparison, provenance, and local naming.*

Proof. Carrier admission is projection from Definition 9107.1. The accepted tuple displays exactly the topology source, the Hausdorff and normal separation rows, the cover request, the locally finite refinement ledger, the coverage and containment ledger, the partition-refinement ledger, exactness, transport, replay, classifier, provenance, and local naming.

The topological and separation obligations are read from T, H, N. Point-separation information must pass through the $\mathsf{HausdorffSpace}^{\uparrow}$ row, while closed-pair separation information must pass through the $\mathsf{NormalSpace}^{\uparrow}$ row over the same topology source.

The refinement obligations are read from A, R, L. The cover request is displayed before the refinement is consumed, and the ledger records both local finiteness and containment in the assigned cover rows.

The partition-refinement obligations are read from P, W. These rows expose only support rows tied to the displayed locally finite refinement; they do not create a host partition-of-unity object or a selected subcover.

Finally, E, K, C, G, Z exhaust transport, replay, classifier comparison, provenance, and local naming. Since the packet has no further coordinate, no NameCert obligation can export arbitrary cover choice, host powersets, unrestricted weights, ambient normality, Lean verification, or bridge checking. □

Theorem 9107.3 (Paracompact space locally finite refinement route)**.** *Every accepted* $\mathsf{ParacompactSpace}^{\uparrow}$ *refinement read factors through the displayed route*

$$\mathsf{Topology}^{\uparrow} \longrightarrow \mathsf{HausdorffSpace}^{\uparrow} \longrightarrow \mathsf{NormalSpace}^{\uparrow} \longrightarrow \mathsf{Paracompact}^{\uparrow} \longrightarrow \mathsf{ParacompactSpace}^{\uparrow}.$$

The exported refinement data are exactly the cover request, locally finite refinement ledger, coverage and containment ledger, separation rows, transport, replay, provenance, and local naming rows of the carrier.

Proof. Start with an accepted carrier $S = (T, H, N, A, R, L, P, W, E, K, C, G, Z)$. The topology source T is displayed before any separation or refinement row is read.

The separation segment is H, N. The Hausdorff row supplies point-neighbourhood separation as a sibling certificate, and the normal-space row supplies closed-pair separation over the same displayed topology.

The refinement segment is A, R, L. It is the only route from the open-cover request to a locally finite refinement read and to the corresponding coverage and containment exactness rows.

The structural rows E, K, C, G, Z preserve this order under transport, replay, classifier comparison, provenance, and naming. Hence a refinement consumer reaches $\mathsf{ParacompactSpace}^{\uparrow}$ only through the displayed topology, separation, and locally finite refinement rows. □

Theorem 9107.4 (Paracompact space partition-refinement ledger)**.** *Every partition-refinement read exported by an accepted* $\mathsf{ParacompactSpace}^{\uparrow}$ *packet factors through the locally finite refinement ledger before any support row can be consumed. The partition-refinement ledger is the finite pair* (P, W)*:* P *displays support rows and their assignment to refinement cells, while* W *records exactness against the same cover and refinement windows* A, R, L*.*

Proof. Project the carrier of Definition 9107.1. The rows P and W are the only partition-refinement coordinates in the packet.

Before P can be read, the cover and refinement rows A, R, L have already displayed the local finiteness, coverage, and containment data. Thus every support row named by P is tied to a displayed refinement cell rather than to an arbitrary host open family.

The exactness row W then checks the support assignment against the same cover and refinement windows. This prevents the partition-refinement read from escaping to unrestricted partition-of-unity weights, host complement selection, or a separate ambient normality theorem.

Transport, replay, classifier comparison, provenance, and local naming are exhausted by E, K, C, G, Z, so the partition-refinement ledger remains a finite NameCert row over the displayed paracompact-space carrier. □

Closure status for $\mathsf{NameCert}_{\mathsf{ParacompactSpace}^{\uparrow}}$**.**

Constructive story: A $\mathsf{ParacompactSpace}^{\uparrow}$ packet is generated from a $\mathsf{Topology}^{\uparrow}$ source row, $\mathsf{HausdorffSpace}^{\uparrow}$ point-separation row, $\mathsf{NormalSpace}^{\uparrow}$ closed-pair separation row, displayed open-cover request, locally finite refinement ledger, coverage and containment ledger, partition-refinement support ledger, exactness row, componentwise hsame transport, displayed Cont replay, classifier row, Pkg provenance, and local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{ParacompactSpace}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 9107.1, Definition 9107.2, Definition 9107.3, and Definition 9107.4 seed the finite space-level route from topology and separation rows through locally finite refinement into partition-refinement support ledgers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{ParacompactSpace}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close selected subcovers, unrestricted partitions of unity, host powersets of opens, ambient choice principles, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, Hausdorff and normal separation exposure, locally finite refinement exactness, partition-refinement ledger exactness, transport, replay, provenance, and local naming for BEDC.Derived.ParacompactSpaceUp.

Chapter 9108

A Concrete Naming Certificate for $\mathsf{RegulatedCauchyStepEnvelope}^{\uparrow}$

Following Bishop and Bridges on regulated functions and regular Cauchy real names, the RegulatedCauchyStepEnvel packet records the finite route by which a regulated step approximant supplies regular rational readback before a $\mathsf{Real}^{\uparrow}$ completion-facing seal is consumed. It sits after the dyadic tolerance core of chapter 291, the finite stream windows of chapter 126, the regular rational name surface of chapter 301, the regulated-function packet of chapter 1906, and the terminal real-name seal of chapter 38. The packet names the finite step-envelope handoff without importing quotient functions, selected limits, measure completion, host step functions, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 9108.1 (Regulated Cauchy step-envelope carrier)**.** *A* $\mathsf{RegulatedCauchyStepEnvelope}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$E = (F, S, W, D, Q, R, H, C, P, N)$$

with the following displayed rows:

1. *F is the accepted* $\mathsf{RegulatedFunction}^{\uparrow}$ *source row whose finite step approximants are being read.*
2. *S is the step-envelope row, listing the inspected partition cells, rational step values, and the finite oscillation budget attached to the request.*
3. *W is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row opened on the approximant schedule before any regular readback is served.*
4. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger for the partition mesh, the step-value comparisons, and the terminal seal request.*
5. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row obtained from F, S, W, D.*
6. *R is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row, available only after the regulated source, step envelope, finite windows, dyadic ledger, and regular readback have been displayed.*
7. *H records componentwise* hsame *transport for the source, envelope, window, dyadic, regular-readback, seal, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay of the finite route*

$$F, S, W, D \longmapsto Q \longmapsto R.$$

9. *P is the* Pkg *provenance over* $\mathsf{RegulatedCauchyStepEnvelope}^{\uparrow}$, $\mathsf{RegulatedFunction}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{RegulatedCauchyStepEnvelope}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $F, S, W, D, Q, R, H, C, P, N$. It has no coordinate for a quotient function, selected limit, measure completion, host step function, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ *completeness theorem.*

Theorem 9108.2 (Regulated Cauchy step-envelope NameCert obligations)**.** *For every accepted* $\mathsf{RegulatedCauchyStepEnvelope}^{\uparrow}$ *carrier*

$$E = (F, S, W, D, Q, R, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{RegulatedCauchyStepEnvelope}^{\uparrow}}$ *surface consists exactly of carrier admission for the displayed regulated-function source, step-envelope schedule, finite-window row, dyadic-tolerance ledger, regular rational readback, terminal real seal, componentwise transport, displayed replay, provenance, and local naming rows. A consumer may read the* $\mathsf{RegSeqRat}^{\uparrow}$ *row Q only through F, S, W, D, and may read the* $\mathsf{Real}^{\uparrow}$ *seal R only through $F, S, W, D, Q, H, C, P, N$.*

Proof. Project the carrier of Definition 9108.1. The regulated source row F and step-envelope row S are the only rows that expose approximant data, while the window row W records the finite stream requests through which the approximant schedule is inspected.

Read the dyadic ledger D. It stores the mesh and step-value tolerance comparisons attached to the same finite request, so no external real comparison or hidden selected representative can supply the error budget.

Finally read Q, R, H, C, P, N. The regular readback Q is downstream of F, S, W, D, and the Real seal R is downstream of that readback. The structural rows transport, replay, source, and locally name only the displayed packet, so the local certificate surface has no further coordinate from which a quotient function, selected limit, measure completion, host step function, trichotomy, or ambient completeness principle could be read. □

Theorem 9108.3 (Regulated Cauchy step-envelope Real-completion handoff)**.** *Every* $\mathsf{Real}^{\uparrow}$*-facing or completion-facing read of an accepted* $\mathsf{RegulatedCauchyStepEnvelope}^{\uparrow}$ *carrier factors first through the finite route*

$$F, S, W, D, Q, H, C, P, N.$$

Thus the handoff from regulated step approximants to a real-name seal is a carrier-local certificate over $\mathsf{RegulatedFunction}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, *and* $\mathsf{RegSeqRat}^{\uparrow}$ *rows. It exports no quotient function space, selected limiting function, measure completion, hidden step-function representative, trichotomy, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness row.*

Proof. Start with the accepted carrier. The only terminal real-name coordinate is R, and it is stored in the same finite packet as the regulated source row, step envelope, stream window, dyadic ledger, regular readback, transport, replay, provenance, and local naming rows.

Apply the obligation surface of Definition 9108.2. It places F, S, W, D before the regular rational readback Q, and places Q before any $\mathsf{Real}^{\uparrow}$-facing seal can be consumed.

The remaining rows H, C, P, N preserve the displayed route by componentwise transport, replay, provenance, and local naming. Since the carrier of Definition 9108.1 contains no row for quotient function equality, selected limits, measure completion, host step functions, trichotomy, or ambient Real completeness, every completion-facing read is forced through the finite envelope route above. □

Falsifiable prediction: Every accepted $\mathsf{RegulatedCauchyStepEnvelope}^{\uparrow}$ completion-facing read displays one RegulatedFunction source row, one finite step-envelope row, one StreamName window row, one DyadicRatCore tolerance ledger, one RegSeqRat readback row, componentwise hsame transport, displayed Cont replay, Pkg provenance, local naming, and one terminal RealUp seal before the seal is consumed.

Independence witness: regulated-function, streamname, dyadicratcore, regseqrat, real: RegulatedCauchyStepEnv is not bijective to any listed sibling because it jointly carries a regulated-function source, a finite step-envelope schedule, finite stream windows, a dyadic tolerance ledger, regular rational readback, a terminal Real seal, transport, replay, provenance, and local NameCert in one packet.

Closure status for $\mathsf{NameCert}_{\mathsf{RegulatedCauchyStepEnvelope}^{\uparrow}}$.

Constructive story: A $\mathsf{RegulatedCauchyStepEnvelope}^{\uparrow}$ packet is generated from a regulated-function source row, finite step-envelope schedule, StreamName windows, DyadicRatCore tolerance ledger, RegSeqRat readback, RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RegulatedCauchyStepEnvelope}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 9108.1, Definition 9108.2, and Definition 9108.3 seed the finite route from regulated step approximants to regular rational readback and the Real seal.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RegulatedCauchyStepEnvelope}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim quotient functions, selected limits, measure completion, host step functions, trichotomy, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked source admission, step-envelope schedule admission, finite-window exposure, dyadic tolerance exactness, RegSeqRat readback, Real-seal nonescape, transport stability, replay stability, provenance, and local naming for BEDC.Derived.RegulatedCauchyStepEnvelopeUp.

Chapter 9109

A Concrete Naming Certificate for $\mathsf{CauchyCompactnessCriterion}^{\uparrow}$

Following Bishop and Bridges constructive compactness criteria, the $\mathsf{CauchyCompactnessCriterion}^{\uparrow}$ packet records the finite route by which Cauchy real data are admitted to a compactness read through explicit net evidence. It sits beside the finite-window naming surface of chapter 126, the regular rational readback of chapter 301, the dyadic tolerance core of chapter 291, the terminal real-name seal of chapter 38, the compact-metric surface of chapter 129, the interval finite-net row of chapter 1379, the finite-net selection principle of chapter 9078, and the regular Cauchy criterion of chapter 8437. The packet names the handoff from regular Cauchy windows to finite nets; it does not import open-cover compactness, sequential compactness without explicit data, quotient-stream equality, countable choice, or ambient Real completeness.

Definition 9109.1 (Cauchy compactness criterion carrier)**.** *A* $\mathsf{CauchyCompactnessCriterion}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (S, Q, D, R, M, I, F, G, H, P, N)$$

with the following displayed rows:

1. S *is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row that records the inspected name windows.*
2. Q *is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the regular rational data exposed by those windows.*
3. D *is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row controlling mesh size, Cauchy radius, and comparison budget.*
4. R *is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached only after* S, Q, D *have been displayed.*
5. M *is the* $\mathsf{CompactMetric}^{\uparrow}$ *compact-metric row read by the finite-net consumer.*
6. I *is the* $\mathsf{HeineBorelInterval}^{\uparrow}$ *interval-net row supplying bounded interval net cells.*
7. F *is the* $\mathsf{FiniteNetSelectionPrinciple}^{\uparrow}$ *row selecting the displayed finite net from the available compact-metric and interval data.*
8. G *is the* $\mathsf{RegularCauchyCompactnessCriterion}^{\uparrow}$ *handoff row that records compatibility with regular Cauchy compactness data.*
9. H *records componentwise* hsame *transport for* $S, Q, D, R, M, I, F, G, P, N$.

10. *P is the displayed* Cont *replay and* Pkg *provenance over* $\mathsf{CauchyCompactnessCriterion}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{HeineBorelInterval}^{\uparrow}$, $\mathsf{FiniteNetSelectionPrinciple}^{\uparrow}$, $\mathsf{RegularCauchyCompactnessCriterion}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{CauchyCompactnessCriterion}^{\uparrow}}$ *row.*

The carrier predicate asserts exactly that compactness is read through these finite rows. It has no coordinate for open-cover compactness, sequential compactness without explicit finite-window data, quotient equality of streams, countable choice, selected representatives, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 9109.2 (Cauchy compactness criterion NameCert obligations)**.** *For every accepted* $\mathsf{CauchyCompactnessCriterion}^{\uparrow}$ *carrier* $K = (S, Q, D, R, M, I, F, G, H, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{CauchyCompactnessCriterio}}$ *surface consists exactly of carrier admission for the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row,* $\mathsf{Real}^{\uparrow}$ *seal row,* $\mathsf{CompactMetric}^{\uparrow}$ *compact-metric row,* $\mathsf{HeineBorelInterval}^{\uparrow}$ *interval-net row,* $\mathsf{FiniteNetSelectionPrinciple}^{\uparrow}$ *finite-net selection row,* RegularCauchyCompactness *handoff row, componentwise* hsame *transport, displayed* Cont *replay with* Pkg *provenance, and local naming. No obligation row may be discharged by host open-cover compactness, sequential compactness without displayed data, quotient-stream equality, countable choice, selected representatives, or ambient Real completeness.*

Proof. Project the carrier of Definition 9109.1. Its displayed coordinates are exactly $S, Q, D, R, M, I, F, G, H, P, N$, so carrier admission and local naming can inspect only those rows.

Read the Cauchy side first. The finite windows S expose the regular rational readback Q, the dyadic tolerance row D controls the Cauchy and mesh budgets, and the terminal seal R is downstream of those displayed rows.

Now read the compactness side. The compact-metric row M, interval-net row I, finite-net selection row F, and regular Cauchy handoff G provide the complete finite-net route consumed by the criterion. Transport, replay, provenance, and local naming preserve the same finite packet, so the excluded compactness and choice principles have no carrier coordinate. □

Theorem 9109.3 (Cauchy compactness criterion finite-net handoff)**.** *Every compactness read of an accepted* $\mathsf{CauchyCompactnessCriterion}^{\uparrow}$ *carrier factors through the finite-net route*

$$S, Q, D, R, M, I, F, G, H, P, N.$$

In particular, the read consumes StreamName windows, RegSeqRat readback, DyadicRatCore tolerance, the Real seal, CompactMetric finite data, Heine–Borel interval nets, FiniteNetSelectionPrinciple selection data, the RegularCauchyCompactnessCriterion handoff, transport, replay, provenance, and local naming before it can expose compactness data. It is therefore a finite-net handoff, not open-cover compactness, not sequential compactness without explicit data, and not an appeal to ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start with the NameCert obligations of Definition 9109.2. They identify the complete local surface of an accepted carrier, so a compactness read cannot leave the rows $S, Q, D, R, M, I, F, G, H, P, N$.

Use the Real-facing route next. Rows S, Q, D provide finite observation, regular rational readback, and tolerance accounting before the terminal seal R is available.

Finally apply the finite-net rows M, I, F, G. The compact-metric and interval rows provide the net cells, the selection-principle row records the finite choice already displayed in the packet, and the regular Cauchy handoff keeps the read compatible with regular Cauchy compactness data. Since none of these rows contains an open-cover subcover choice, a sequence-only compactness

principle, quotient stream equality, countable choice, or an ambient completeness theorem, the compactness read is exactly the stated finite-net handoff. □

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyCompactnessCriterion}^{\uparrow}}$.

Constructive story: A $\mathsf{CauchyCompactnessCriterion}^{\uparrow}$ packet is generated from StreamName windows, RegSeqRat readback, DyadicRatCore tolerance, a terminal RealUp seal, CompactMetric finite data, Heine–Borel interval nets, FiniteNetSelectionPrinciple selection data, RegularCauchyCompactnessCriterion handoff, componentwise hsame transport, displayed Cont replay with Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CauchyCompactnessCriterion}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 9109.1, Definition 9109.2, and Definition 9109.3 seed the finite-net compactness criterion route over StreamName, RegSeqRat, DyadicRatCore, Real, CompactMetric, Heine–Borel interval, finite-net selection, and regular Cauchy compactness data.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CauchyCompactnessCriterion}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim open-cover compactness, sequential compactness without explicit data, quotient-stream equality, countable choice, selected representatives, Lean verification, or ambient Real completeness.

Upgrade path: Obligation closure requires checked carrier admission, finite-net exactness, regular rational readback, dyadic tolerance accounting, Real seal routing, CompactMetric handoff, Heine–Borel interval handoff, finite-net selection handoff, regular Cauchy compactness handoff, transport, replay, provenance, and local naming for BEDC.Derived.CauchyCompactnessCriterion

Chapter 9110

A Concrete Naming Certificate for $\mathsf{NearestPointProjection}^{\uparrow}$

Following Bishop–Bridges metric constructions and Kelley-style metric neighbourhoods, the $\mathsf{NearestPointProjection}^{\uparrow}$ packet records a displayed nearest-point projection witness only when the metric source, located candidate surface, finite distance comparisons, endpoint row, dyadic comparison ledger, and $\mathsf{Real}^{\uparrow}$ distance seal are all present. It sits after the metric source of chapter 57, the terminal real-distance naming discipline of chapter 38, the finite projection table of chapter 7348, and the finite selector boundary of chapter 7761. The packet is a finite displayed projection certificate; it does not assert a global nearest-point choice principle, hidden minimizers, quotient subset equality, compactness, or ambient completion.

Definition 9110.1 (Nearest-point projection carrier)**.** *A* $\mathsf{NearestPointProjection}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$P = (M, S, T, Q, E, R, H, C, G, N)$$

with the following displayed rows:

1. *M is the ambient* $\mathsf{Met}^{\uparrow}$ *source row naming the metric space in which the projection question is posed.*
2. *S is the located candidate-surface row naming the finite visible candidate family and its membership ledger.*
3. *T is the consumed* $\mathsf{FiniteMetricProjection}^{\uparrow}$ *table row, recording the displayed distances from the query point to the visible candidates.*
4. *Q is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *comparison ledger used to compare all distance entries in T.*
5. *E is the endpoint row naming the candidate whose distance row is certified minimal by Q.*
6. *R is the terminal* $\mathsf{Real}^{\uparrow}$ *distance seal attached to the endpoint row after the finite comparisons have been replayed.*
7. *H records componentwise* hsame *transport for the metric source, candidate surface, finite table, comparison ledger, endpoint, distance seal, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from a projection request through the finite table, comparison ledger, endpoint row, and terminal distance seal.*
9. *G is the* Pkg *provenance over* $\mathsf{NearestPointProjection}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{FiniteMetricProjection}^{\uparrow}$, $\mathsf{FiniteMetricProjectionSelector}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.

10. N is the local $\mathsf{NameCert}_{\mathsf{NearestPointProjection}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through these rows. It has no coordinate for a host projection function, selected minimizer outside the displayed table, quotient subset equality, compactness theorem, countable selection schedule, or ambient completion.

Theorem 9110.2 (Nearest-point projection NameCert obligations)**.** *For every accepted* $\mathsf{NearestPointProjection}^{\uparrow}$ *carrier* $P = (M, S, T, Q, E, R, H, C, G, N)$*, the local* $\mathsf{NameCert}_{\mathsf{NearestPointProjection}^{\uparrow}}$ *surface consists exactly of carrier admission, metric-source exposure, located candidate-surface exposure, finite projection-table exposure, dyadic comparison admission, endpoint handoff, terminal distance sealing, componentwise stability transport, displayed replay, provenance, local naming, and refusal of global nearest-point choice, hidden minimizers, quotient subset equality, compactness, and ambient completion.*

Proof. Project the carrier of Definition 9110.1. Its public rows are exactly $M, S, T, Q, E, R, H, C, G, N$, so admission exposes only the displayed metric source, candidate surface, finite distance table, comparison ledger, endpoint row, distance seal, and structural rows.

The finite projection-table obligation is inherited from chapter 7348. The row T supplies displayed candidate-distance entries, while Q supplies the dyadic comparison route that can certify one endpoint row against the visible table.

The endpoint and refusal obligations follow from the absence of any additional coordinate. Since the packet stores no host projection map, no quotient subset object, no compactness theorem, and no completion row, the local NameCert surface can export only the displayed endpoint and terminal $\mathsf{Real}^{\uparrow}$ distance seal. □

Theorem 9110.3 (Nearest-point projection distance minimality)**.** *Let* $P = (M, S, T, Q, E, R, H, C, G, N)$ *be an accepted* $\mathsf{NearestPointProjection}^{\uparrow}$ *packet. Every visible candidate row s in the located surface S is compared with the endpoint row E by the finite route*

$$M, S, T, Q \longmapsto E, R \longmapsto H, C, G, N.$$

The terminal read therefore certifies the displayed inequality

$$d_M(x, E) \leq d_M(x, s)$$

only for candidates whose distance rows occur in T.

Proof. Start with the visible candidate surface S and the finite table T. The table contains exactly the distance rows available to the packet, so a candidate s can be compared with E only when its distance entry is displayed in T.

Read the dyadic ledger Q. It performs the finite comparison between the endpoint entry and each displayed candidate entry, and the endpoint row E is accepted only after those comparisons have been replayed.

Finally read the terminal seal R and structural rows H, C, G, N. They preserve the comparison route as BEDC data and expose the inequality as a finite displayed fact, not as an ambient minimization principle over an unbounded subset. □

Theorem 9110.4 (Nearest-point projection completion handoff)**.** *Every completion-facing consumer that reads an accepted* $\mathsf{NearestPointProjection}^{\uparrow}$ *packet must first expose the metric row M, candidate surface S, finite projection table T, dyadic comparison ledger Q, endpoint row E, terminal* $\mathsf{Real}^{\uparrow}$ *seal R, and structural rows H, C, G, N. The handoff supplies a finite endpoint witness and its displayed distance; it does not import ambient completion, quotient subset equality, compactness, or a global projection selector.*

Proof. Begin with the metric and real-distance dependencies. The rows M and R place the packet inside the metric and $\mathsf{Real}^{\uparrow}$ naming surfaces referenced by chapter 57 and chapter 38.

Next read the finite projection table and selector boundary. The row T is the finite projection table admitted by chapter 7348, and the endpoint read is constrained by the finite selector discipline of chapter 7761.

It remains to pass the endpoint to the consumer. The continuation row C replays M, S, T, Q, E, R, while H, G, N preserve transport, provenance, and local naming. Because no completion carrier or quotient subset coordinate is present, the consumer receives only the displayed endpoint witness and distance seal. □

Closure status for $\mathsf{NameCert}_{\mathsf{NearestPointProjection}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{NearestPointProjection}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 9110.1, Definition 9110.2, Definition 9110.3, and Definition 9110.4 seed the finite displayed nearest-point projection certificate over MetricUp, RealUp, FiniteMetricProjectionUp, FiniteMetricProjectionSelectorUp, DyadicRatCoreUp, BHist, hsame, Cont, Pkg, and NameCert rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{NearestPointProjection}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close global nearest-point choice, hidden minimizers, quotient subset equality, compactness, ambient completion, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, located candidate-surface exposure, finite comparison exactness, endpoint handoff, Real distance sealing, transport, replay, provenance, and local naming for BEDC.Derived.NearestPointProjectionUp.

Constructive story: A $\mathsf{NearestPointProjection}^{\uparrow}$ packet is generated from a Metric row, a located candidate-surface row, a FiniteMetricProjection table row, a DyadicRatCore comparison ledger, an endpoint row, a Real distance seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 9111

A Concrete Naming Certificate for $\mathsf{MetricApartnessCompletion}^{\uparrow}$

Following Bishop–Bridges constructive metric and apartness completion, the $\mathsf{MetricApartnessCompletion}^{\uparrow}$ packet records the finite route by which a separated metric completion keeps positive apartness data visible while it accepts Cauchy names. It sits after the metric carrier of chapter 57, the abstract completion packet of chapter 95, the apartness-space surface of chapter 1514, the regular Cauchy criterion of chapter 1611, and the Cauchy completion criterion of chapter 1476. The packet makes the separated completion consume displayed apartness evidence directly; it does not treat apartness as a side condition stored outside the completion carrier.

Definition 9111.1 (Metric apartness completion carrier)**.** *A* $\mathsf{MetricApartnessCompletion}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M = (S, C, A, R, Q, E, H, T, P, N)$$

with the following displayed rows:

1. *S is the* $\mathsf{Met}^{\uparrow}$ *source row whose distance reads supply the Cauchy and separation data.*
2. *C is the* $\mathsf{Completion}^{\uparrow}$ *row naming the completion request and its finite target surface.*
3. *A is the* $\mathsf{ApartnessSpace}^{\uparrow}$ *row that displays positive apartness before separated completion reads are accepted.*
4. *R is the* $\mathsf{RegularCauchyCriterion}^{\uparrow}$ *row recording the regular Cauchy schedule consumed by the completion request.*
5. *Q is the* $\mathsf{CauchyCompletionCriterion}^{\uparrow}$ *row that admits the Cauchy-name handoff into the completion carrier.*
6. *E is the separation ledger, recording that apartness transport and zero-distance refusal are replayed along the Cauchy-name route.*
7. *H records componentwise* hsame *transport for the metric source, completion target, apartness row, Cauchy criteria, separation ledger, replay, provenance, and local naming rows.*
8. *T records displayed* Cont *replay from the metric source and Cauchy criteria through the apartness row and separation ledger before the completion name is exposed.*
9. *P is the* Pkg *provenance over* $\mathsf{MetricApartnessCompletion}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{Completion}^{\uparrow}$, $\mathsf{ApartnessSpace}^{\uparrow}$, $\mathsf{RegularCauchyCriterion}^{\uparrow}$, $\mathsf{CauchyCompletionCriterion}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.

10. N is the local $\mathsf{NameCert}_{\mathsf{MetricApartnessCompletion}^{\uparrow}}$ *row.*
The classifier compares accepted packets only through $S, C, A, R, Q, E, H, T, P, N$. It has no coordinate for host equality of completion classes, selected Cauchy representatives, untracked apartness, real trichotomy, or an ambient completeness theorem.

Theorem 9111.2 (MetricApartnessCompletion NameCert obligations)**.** *For every accepted* MetricApartnessComple *carrier $M = (S, C, A, R, Q, E, H, T, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{MetricApartnessCompletion}^{\uparrow}}$ *surface consists exactly of carrier admission for the displayed metric source, completion target, apartness row, regular Cauchy criterion, Cauchy completion criterion, separation ledger, componentwise transport, displayed replay, provenance, and local naming rows. A completion-facing consumer may read the completed name only after the route*

$$S, R, Q \longmapsto A, E \longmapsto C, H, T, P, N$$

has been displayed.

Proof. Project the carrier of Definition 9111.1. Its only rows are $S, C, A, R, Q, E, H, T, P, N$, so every accepted read must use those coordinates.

The Cauchy side is exposed by R and Q over the metric source S. The apartness side is exposed by A, and the separation ledger E records the replay that keeps zero-distance refusal and positive apartness attached to the Cauchy-name route.

The structural rows then close the local certificate. Componentwise transport H, displayed replay T, provenance P, and local naming N preserve the same finite packet, while C is available only downstream of the displayed criteria and apartness ledger. Since no hidden coordinate stores representatives or host equality, the listed rows exhaust the NameCert surface. □

Theorem 9111.3 (MetricApartnessCompletion apartness transport)**.** *Every accepted* $\mathsf{MetricApartnessCompletion}^{\uparrow}$ *read transports apartness through the displayed* $\mathsf{ApartnessSpace}^{\uparrow}$ *row A and separation ledger E. If a consumer reads the completed name without exposing A, E, H, T, P, N, then the read is outside the carrier of Definition 9111.1.*

Proof. The carrier contains apartness information only in the displayed row A and its separation ledger E. The transport row H and replay row T preserve those rows componentwise along the completion route.

Apply Definition 9111.2. It places A, E between the Cauchy criteria and the exposed completion name, with H, T, P, N stabilizing the same packet.

Thus an apartness-free read cannot be a read of the accepted carrier. It would require a coordinate for hidden apartness or host equality, and the carrier has neither. □

Theorem 9111.4 (MetricApartnessCompletion Cauchy separation)**.** *For every accepted* MetricApartnessCompletio *carrier $M = (S, C, A, R, Q, E, H, T, P, N)$, the regular Cauchy row R and Cauchy completion row Q are separated by the displayed apartness row A and separation ledger E before the completion row C becomes public. The packet therefore refuses a completion route that identifies Cauchy names by hidden representative equality.*

Proof. Project R, Q, A, E, C from the carrier. The rows R, Q provide the Cauchy schedule and admission criterion, while A, E carry the positive apartness and separation replay attached to that schedule.

Use the obligation theorem above. Its route displays S, R, Q before A, E, and only then exposes the completion-facing rows C, H, T, P, N.
