Because representative equality is not a carrier coordinate, no consumer can replace the displayed apartness separation with hidden equality of Cauchy names. The only public route to C is the separated route listed in the carrier. □

Theorem 9111.5 (MetricApartnessCompletion public boundary)**.** *The public boundary of an accepted* $\mathsf{MetricApartnessCompletion}^{\uparrow}$ *packet is exactly the metric source S, completion row C, apartness row A, regular Cauchy row R, Cauchy completion row Q, separation ledger E, componentwise* hsame *transport H, displayed* Cont *replay T,* Pkg *provenance P, and local* $\mathsf{NameCert}_{\mathsf{MetricApartnessCompletion}^{\uparrow}}$ *row N. It exports no host equality of completion classes, selected representative, untracked apartness predicate, trichotomy, or ambient completeness principle.*

Proof. The carrier definition lists the public packet as $S, C, A, R, Q, E, H, T, P, N$. No other coordinate is available to the classifier.

The NameCert obligations force a read of the completion row through the metric source, Cauchy criteria, apartness row, and separation ledger. The apartness-transport and Cauchy-separation theorems keep that route visible for every completion-facing consumer.

Therefore the public boundary is exactly the displayed packet. The excluded host equality, selected representative, untracked apartness predicate, trichotomy, and ambient completeness data have no row from which they could be exported. □

Falsifiable prediction: Every accepted $\mathsf{MetricApartnessCompletion}^{\uparrow}$ read displays a MetricUp source, Completion row, ApartnessSpace row, RegularCauchyCriterion row, CauchyCompletion-Criterion row, separation ledger, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming before the completion name is exposed.

Independence witness: metric, completion, apartnessspace, regularcauchycriterion, cauchy-completioncriterion: $\mathsf{MetricApartnessCompletion}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries metric source data, a completion target, apartness evidence, regular Cauchy scheduling, Cauchy completion admission, separation replay, transport, continuation, provenance, and local NameCert rows in one packet.

Closure status for $\mathsf{NameCert}_{\mathsf{MetricApartnessCompletion}^{\uparrow}}$**.**

Constructive story: A $\mathsf{MetricApartnessCompletion}^{\uparrow}$ packet is generated from a MetricUp source row, CompletionUp target row, ApartnessSpace row, RegularCauchyCriterion row, CauchyCompletionCriterion row, separation ledger, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{MetricApartnessCompletion}^{\uparrow}}$, seed)

Scope closed: Definition 9111.1, Definition 9111.2, Definition 9111.3, Definition 9111.4, and Definition 9111.5 seed the finite separated metric completion surface that keeps apartness data on the completion route.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{MetricApartnessCompletion}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close host equality of completion classes, selected Cauchy representatives, quotient completion semantics, real trichotomy, ambient completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, apartness transport, Cauchy separation, completion-boundary nonescape, transport stability, replay stability, provenance, and local naming for BEDC.Derived.MetricApartnessCompletio

Chapter 9112

A Concrete Naming Certificate for $\mathsf{ApartnessCompletionReflector}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{ApartnessCompletionReflector}^{\uparrow}$ packet records the finite route by which a regular Cauchy source carrying displayed apartness evidence is reflected into the separated comparison surface of the Real completion route. It sits after the tail-diameter witness of chapter 1746, the regular rational readback of chapter 301, the finite stream-window surface of chapter 126, the dyadic tolerance ledger of chapter 291, and the terminal real-name seal of chapter 38. The packet names a reflector from apartness-stable regular Cauchy data to a separated Real-facing comparison row; it does not select a completed limit, quotient a Cauchy name, assert countable choice, or invoke ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 9112.1 (Apartness completion reflector carrier)**.** *An* $\mathsf{ApartnessCompletionReflector}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$A = (S, T, W, D, R, X, E, H, C, P, N)$$

with the following displayed rows:

1. *S is the regular Cauchy source row, read through the* $\mathsf{RegSeqRat}^{\uparrow}$ *discipline and carrying the source observations used by the reflector.*
2. *T is the* $\mathsf{CauchyTailDiameter}^{\uparrow}$ *row witnessing that the displayed tail window has the requested dyadic diameter bound.*
3. *W is the* $\mathsf{StreamName}^{\uparrow}$ *window row that exposes the finite observations used by S and T.*
4. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row recording the dyadic request, tail budget, and comparison scale.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row obtained from the same finite windows and tolerance data.*
6. *X is the displayed apartness witness row, recording the separated comparison branch that survives the regular Cauchy reflection.*
7. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row, available only after S, T, W, D, R, X have been displayed.*
8. *H records componentwise* hsame *transport for the source, tail-diameter, window, tolerance, readback, apartness, Real-seal, replay, provenance, and local naming rows.*
9. *C records displayed* Cont *replay through the same reflector route.*

10. *P is the* Pkg *provenance over* $\mathsf{ApartnessCompletionReflector}^{\uparrow}$, $\mathsf{CauchyTailDiameter}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

11. *N is the local* $\mathsf{NameCert}_{\mathsf{ApartnessCompletionReflector}^{\uparrow}}$ *row.*

The classifier accepts only packets whose separated completion read is exhausted by $S, T, W, D, R, X, E, H, C, P, N$. It has no coordinate for quotient Cauchy equality, selected representatives, selected limits, countable choice, trichotomy, host real equality, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 9112.2 (Apartness completion carrier obligation)**.** *For every accepted* $\mathsf{ApartnessCompletionReflector}^{\uparrow}$ *carrier*

$$A = (S, T, W, D, R, X, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{ApartnessCompletionReflector}^{\uparrow}}$ *surface consists exactly of carrier admission for the displayed packet; regular Cauchy source exposure through S; tail-diameter exposure through T; finite StreamName window exposure through W; DyadicRatCore tolerance exposure through D; RegSeqRat readback through R; displayed apartness witness exposure through X; terminal Real sealing through E; componentwise transport through H; displayed replay through C; provenance through P; and local naming through N.*

Proof. Project the carrier of Definition 9112.1. The analytic rows are the regular source, tail-diameter row, finite window, dyadic tolerance, regular readback, apartness witness, and Real seal.

The structural rows H, C, P, N transport, replay, source, and name exactly those analytic rows. They do not add an external completion endpoint or a quotient equality.

Thus the local certificate surface is exhausted by $S, T, W, D, R, X, E, H, C, P, N$. The excluded objects are absent from the carrier inventory, so they cannot become local obligations of the reflector. □

Theorem 9112.3 (Apartness completion separated readback)**.** *Every separated Real-facing read of an accepted* $\mathsf{ApartnessCompletionReflector}^{\uparrow}$ *carrier factors through*

$$S \longmapsto T, W, D \longmapsto R, X \longmapsto E \longmapsto H, C, P, N.$$

The displayed apartness witness X is read after the same tail-diameter, StreamName, DyadicRatCore, and RegSeqRat rows that serve the regular Cauchy source. Hence the separated comparison is a reflected finite route, not a selected completed real or a quotient of Cauchy names.

Proof. Start from the source row S. It supplies only the displayed regular Cauchy observations and must be inspected through the finite windows W.

Read the control rows next. The tail-diameter row T and dyadic ledger D fix the requested tolerance before the regular readback row R is consumed.

The apartness witness X is then attached to the same finite route. Since X is downstream of T, W, D, R, it cannot be replaced by a detached trichotomy decision or host real inequality.

Finally the terminal Real seal E and structural rows H, C, P, N preserve the same route. The separated readback therefore remains finite and displayed. □

Theorem 9112.4 (Apartness completion reflector nonescape)**.** *No accepted* $\mathsf{ApartnessCompletionReflector}^{\uparrow}$ *packet exports quotient Cauchy equality, a selected representative, a selected limit, countable choice, trichotomy, host real equality, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness. Every consumer that reads the terminal* $\mathsf{Real}^{\uparrow}$ *seal or the separated apartness witness must first read the rows $S, T, W, D, R, X, E, H, C, P, N$.*

Proof. Use the obligation surface of Definition 9112.2. It lists all rows that a local NameCert read may inspect.

Apply the separated readback theorem Definition 9112.3. It places the apartness witness and Real seal after the displayed tail-diameter, window, tolerance, and regular readback rows.

The excluded principles are not rows of the carrier. Since transport, replay, provenance, and local naming preserve only the displayed packet, no consumer can obtain those principles from an accepted reflector read. □

Falsifiable prediction: Every accepted ApartnessCompletionReflectorUp read that reaches a separated Real-facing comparison displays the regular Cauchy source, tail-diameter row, StreamName window, DyadicRatCore tolerance, RegSeqRat readback, apartness witness, RealUp seal, componentwise hsame transport, Cont replay, Pkg provenance, and local NameCert row.

Independence witness: cauchy-tail-diameter, regseqrat, streamname, dyadicratcore, real: no listed sibling alone binds a regular Cauchy source, tail-diameter control, finite stream window, dyadic tolerance, regular readback, displayed apartness witness, Real seal, transport, replay, provenance, and local naming into one completion reflector packet.

Closure status for $\mathsf{NameCert}_{\mathsf{ApartnessCompletionReflector}^{\uparrow}}$.

Constructive story: An $\mathsf{ApartnessCompletionReflector}^{\uparrow}$ packet is generated from a regular Cauchy source, CauchyTailDiameter row, StreamName window, DyadicRatCore tolerance, RegSeqRat readback, displayed apartness witness, RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{ApartnessCompletionReflector}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 9112.1, Definition 9112.2, Definition 9112.3, and Definition 9112.4 seed the L10 route from apartness-stable regular Cauchy data to a separated Real-facing comparison surface.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{ApartnessCompletionReflector}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient Cauchy equality, selected representatives, selected limits, countable choice, trichotomy, host real equality, ambient RealUp completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, tail-diameter exactness, finite-window readback, displayed apartness preservation, Real sealing, transport, replay, provenance, and local naming for BEDC.Derived.ApartnessCompletionReflector

Chapter 9113

A Concrete Naming Certificate for $\mathsf{StreamNameRealizer}^{\uparrow}$

Following Bishop and Bridges and Troelstra–van Dalen on lawlike choice sequences, the $\mathsf{StreamNameRealizer}^{\uparrow}$ packet records finite realization data for observed stream names without converting the stream into a quotient object or a countable-choice schedule. It sits over the finite stream-name surface of chapter 126, the regular rational readback of chapter 301, the dyadic tolerance ledger of chapter 291, and the terminal real-name seal of chapter 38. The packet is a lawlike finite admission route for Real and Completion consumers: it tells the consumer which finite observations are available, how they are replayed, and where regular-rational and dyadic checks enter before any $\mathsf{Real}^{\uparrow}$ seal can be read.

Definition 9113.1 (StreamNameRealizer carrier)**.** *A* $\mathsf{StreamNameRealizer}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$R = (S, W, Q, D, E, H, C, P, N)$$

with the following displayed rows:

1. *S is the* $\mathsf{StreamName}^{\uparrow}$ *source row, naming the observed stream and the finite request discipline by which windows are opened.*
2. *W is the lawlike window-realization row, recording a finite request list, its returned observations, and the monotone extension discipline for later requests.*
3. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row attached to those realized windows.*
4. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row, carrying dyadic radii, comparison budgets, and endpoint arithmetic for the realized observations.*
5. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row, readable only after S, W, Q, D have been displayed.*
6. *H records componentwise* hsame *transport for source streams, realized windows, regular readback rows, dyadic tolerance rows, real seals, replay rows, provenance rows, and local naming rows.*
7. *C records displayed* Cont *replay from a finite observation request through S, W, Q, D, E, H, P, N.*
8. *P is the* Pkg *provenance over* $\mathsf{StreamNameRealizer}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* NameCert.
9. *N is the local* $\mathsf{NameCert}_{\mathsf{StreamNameRealizer}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through $S, W, Q, D, E, H, C, P, N$. It has no coordinate for a completed infinite stream, quotient stream equality, countable choice, a host modulus selector, ambient $\mathsf{Real}^{\uparrow}$ *completeness, or an external oracle for future observations.*

Theorem 9113.2 (StreamNameRealizer window admission)**.** *Every finite observation request admitted by an accepted* $\mathsf{StreamNameRealizer}^{\uparrow}$ *carrier*

$$R = (S, W, Q, D, E, H, C, P, N)$$

must first expose the $\mathsf{StreamName}^{\uparrow}$ *source row S and the lawlike window-realization row W. Any downstream regular-rational or real-facing read must then pass through the* $\mathsf{RegSeqRat}^{\uparrow}$ *row Q, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row D, the terminal* $\mathsf{Real}^{\uparrow}$ *seal row E, componentwise* hsame *transport H, displayed* Cont *replay C,* Pkg *provenance P, and local* NameCert *naming N. The admission route exports only finite realized windows and refuses quotient stream equality, countable choice, host-side future observation, and ambient Real completeness.*

Proof. Project the carrier of Definition 9113.1. The rows S and W are the only source and window-realization entrances, so an admitted finite request cannot be read before those rows are displayed.

The completion-facing part of the route is ordered by the carrier. Regular-rational readback is Q, dyadic tolerance and endpoint arithmetic are D, and the real-name seal is E. Thus a consumer cannot skip directly from a stream observation to a $\mathsf{Real}^{\uparrow}$ row.

Finally use the structural rows. Transport through H, replay through C, provenance through P, and local naming through N preserve the same finite route. Since no carrier coordinate stores a completed stream, quotient equality, countable choice, or a host oracle, those claims are outside the admission theorem. □

Theorem 9113.3 (StreamNameRealizer NameCert obligations)**.** *For every accepted* $\mathsf{StreamNameRealizer}^{\uparrow}$ *carrier*

$$R = (S, W, Q, D, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{StreamNameRealizer}^{\uparrow}}$ *surface consists exactly of carrier admission for the finite* BHist *packet,* $\mathsf{StreamName}^{\uparrow}$ *source exposure through S, lawlike finite-window realization through W,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback through Q,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance exactness through D,* $\mathsf{Real}^{\uparrow}$ *seal nonescape through E, componentwise* hsame *transport through H, displayed* Cont *replay through C,* Pkg *provenance through P, and local naming through N.*

Proof. Read the accepted carrier of Definition 9113.1. Its displayed rows are exactly $S, W, Q, D, E, H, C, P, N$.

Apply the window-admission theorem Definition 9113.2. It fixes the order in which source, finite window realization, regular readback, dyadic tolerance, and real seal rows may be consumed.

The remaining rows are structural. Componentwise hsame transports the same finite realization data, Cont replays the displayed request, Pkg records the provenance, and the local NameCert row names the packet. No other obligation can be projected from the carrier. □

Closure status for $\mathsf{NameCert}_{\mathsf{StreamNameRealizer}^{\uparrow}}$**.**

Constructive story: A $\mathsf{StreamNameRealizer}^{\uparrow}$ packet is generated from a StreamName source row, a lawlike finite-window realization row, RegSeqRat readback, DyadicRatCore tolerance data, a Real seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{StreamNameRealizer}^{\uparrow}}$, obligation)

Scope closed: Definition 9113.1, Definition 9113.2, and Definition 9113.3 bind the finite lawlike realization route from StreamName observations to RegSeqRat, DyadicRatCore, and Real-facing consumers.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{StreamNameRealizer}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim completed streams, quotient stream equality, countable choice, host-side future observation, ambient $\mathrm{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Lean closure requires carrier admission, window admission, readback exactness, tolerance exactness, Real seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.StreamNameRealizerUp.

Chapter 9114

A Concrete Naming Certificate for $\mathsf{ObserverCenteredConstructorCertificate}^{\uparrow}$

The $\mathsf{ObserverCenteredConstructorCertificate}^{\uparrow}$ packet realizes the observer-centered constructor certificate of section 9421.6 as finite NameCert data. It packages the OCLSD constructor packet of Definition 9421.21 together with the orthogonal section handoff of Definition 9421.23, so the projection residual is a displayed ledger row rather than an implicit Hilbert-space afterthought.

The carrier consumes the Hilbert source of chapter 91, the displayed projection route of chapter 2356, and the local-trivialization rows of chapter 97. These sibling rows make the projection residual a visible ledger entry before the orthogonal handoff, instead of treating the Hilbert bundle and projection data as ambient structure.

Falsifiable prediction: Removing the projection residual row prevents the NameCert obligations from deriving the orthogonal section handoff.

Independence witness: hilbert, projection, bundle, observer-centered-dynamics, ledger: no listed sibling is bijective to $\mathsf{ObserverCenteredConstructorCertificate}^{\uparrow}$ because this packet jointly carries frame selection, Hilbert bundle data, reshaping rows, closed ledger rows, projection residual rows, orthogonal section handoff, transport, replay, provenance, and local naming.

Definition 9114.1 (Observer-centered constructor certificate carrier)**.** *An* $\mathsf{ObserverCenteredConstructorCertificate}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$O = (F, B, S, L, P, R, E, H, C, G, N)$$

with the following displayed rows:

1. *F is the adjacent frame-selection row naming the displayed frame edge and successor frame.*
2. *B is the Hilbert-bundle row naming the source and successor Hilbert spaces used by the observer-centered step.*
3. *S is the isometric reshaping row carrying the section transport between the two frames.*
4. *L is the closed ledger row naming the prior ledger subspace and its rewritten closed image.*
5. *P is the orthogonal projection row against the rewritten ledger.*
6. *R is the projection residual row naming the vector subtracted from the projection row.*
7. *E is the orthogonal section handoff row, recording the residual line and accepted ledger sum.*

8. *H records componentwise* hsame *transport for frame, bundle, reshaping, ledger, projection, residual, handoff, replay, provenance, and local naming rows.*
9. *C records displayed* Cont *replay through the constructor packet and the orthogonal handoff.*
10. *G is the* TasteGate *readiness row for the later* Nontrivial *and* FieldFaithful *instances.*
11. *N is the local* $\mathsf{NameCert}_{\mathsf{ObserverCenteredConstructorCertificate}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through $F, B, S, L, P, R, E, H, C, G, N$. It has no coordinate for a hidden observer, an untyped Hilbert-space completion, a projection theorem detached from the displayed ledger, or a residual-free section handoff.

Theorem 9114.2 (Observer-centered constructor certificate obligations)**.** *For every accepted* ObserverCenteredCons *carrier*

$$O = (F, B, S, L, P, R, E, H, C, G, N),$$

the local $\mathsf{NameCert}_{\mathsf{ObserverCenteredConstructorCertificate}^{\uparrow}}$ *surface consists exactly of adjacent frame selection through F, Hilbert-bundle exposure through B, isometric reshaping through S, closed ledger retention through L, projection against the rewritten ledger through P, projection residual exposure through R, orthogonal section handoff through E, componentwise* hsame *transport through H, displayed* Cont *replay through C,* TasteGate *readiness through G, and local naming through N.*

Proof. Project the carrier of Definition 9114.1. The rows F, B, S, L reproduce the typed inputs of the OCLSD constructor packet, and P, R, E are the projection, residual, and accepted orthogonal section rows.

Apply Definition 9421.23. The theorem forces the residual row to be orthogonal to the rewritten ledger, so the handoff row E cannot be derived if R is absent.

The structural rows H, C, G, N preserve, replay, reserve TasteGate readiness for, and name the same packet. Since the carrier has no hidden observer, detached projection theorem, or residual-free handoff coordinate, the listed rows exhaust the local NameCert obligations. □

Theorem 9114.3 (Observer-centered projection handoff nonescape)**.** *Every consumer of an accepted* $\mathsf{ObserverCenteredConstructorCertificate}^{\uparrow}$ *packet that reads the orthogonal section handoff must factor through*

$$F, B, S, L, P, R, E, H, C, G, N.$$

In particular, the consumer must read the projection residual row R before using the handoff row E. The route exports a finite observer-centered constructor certificate, not an ambient Hilbert projection oracle, a hidden observer state, or an unledgered dynamics theorem.

Proof. Start from the carrier of Definition 9114.1. The handoff row E is listed after frame, bundle, reshaping, ledger, projection, and residual rows.

Use the NameCert obligations of Definition 9114.2. They identify the residual row as part of the local certificate surface before the orthogonal handoff can be exported.

The replay and transport rows keep the same finite order under consumer reads. Therefore any handoff consumer factors through the displayed route and receives no detached projection oracle or unledgered dynamics theorem. □

The Lean follow-up file `lean4/BEDC/Derived/ObserverCenteredConstructorCertificateUp/TasteGate.le` must supply `Nontrivial ObserverCenteredConstructorCertificateUp` and `FieldFaithful ObserverCentere` These instances preserve the rows $F, B, S, L, P, R, E, H, C, G, N$ and keep the projection residual row visible before the orthogonal section handoff is exported.

Closure status for $\mathsf{NameCert}_{\mathsf{ObserverCenteredConstructorCertificate}^{\uparrow}}$.

Constructive story: An $\mathsf{ObserverCenteredConstructorCertificate}^{\uparrow}$ packet is generated from adjacent frame selection, Hilbert bundle data, isometric reshaping, closed ledger rows, projection rows, residual rows, orthogonal handoff rows, componentwise hsame transport, displayed Cont replay, TasteGate readiness, and local naming.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{ObserverCenteredConstructorCertificate}^{\uparrow}}, \text{obligation})$

Scope closed: Definition 9114.1, Definition 9114.2, Definition 9114.3, the falsifiable prediction, and the independence witness expose the finite constructor certificate for observer-centered orthogonal ledger steps.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{ObserverCenteredConstructorCertificate}^{\uparrow}}, \text{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim a hidden observer state, ambient Hilbert projection oracle, untyped dynamics theorem, Lean verification, or bridge checking.

Upgrade path: Lean closure requires Nontrivial ObserverCenteredConstructorCertificateUp and FieldFaithful ObserverCenteredConstructorCertificateUp instances in `lean4/BEDC/Derived/ObserverCenteredConstructorCertificateUp/TasteGate.le`

Chapter 9115

A Concrete Naming Certificate for $\mathsf{FiniteCoverMesh}^{\uparrow}$

Following Bishop and Bridges on constructive compactness and finite covers, the $\mathsf{FiniteCoverMesh}^{\uparrow}$ packet records the finite mesh carrier consumed by compact-completion handoffs. It sits after the compact-metric source of chapter 129, the total-bounded finite-net row of chapter 127, the metric-space source of chapter 4230, the Real seal of chapter 38, the regular rational readback of chapter 301, and the dyadic tolerance core of chapter 291. The mesh ledger is the finite-cover consumer of the dyadic interval net and compact finite-net surfaces, so its carrier should be read together with chapter 5966 and chapter 129. The packet names the finite mesh data that compact and completion routes can consume; it is not the mesh-chain uniform-modulus theorem and it does not assert open-cover compactness.

Definition 9115.1 (Finite cover mesh carrier)**.** *A* $\mathsf{FiniteCoverMesh}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$F = (C, T, M, R, Q, D, L, U, H, E, P, N)$$

with the following displayed rows:

1. *C is the* $\mathsf{CompactMetric}^{\uparrow}$ *compact-metric source row whose finite-cover data are being meshed.*
2. *T is the* $\mathsf{TotallyBounded}^{\uparrow}$ *finite-net row supplying the finite mesh cells.*
3. *M is the* $\mathsf{Met}^{\uparrow}$ *row used for radius comparison, triangle transport, and mesh containment checks.*
4. *R is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row consumed by completion-facing readers.*
5. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *rational readback row for the inspected mesh radii.*
6. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row controlling mesh size, cover radius, and completion budget.*
7. *L is the finite mesh ledger, recording which displayed mesh cells refine which displayed cover rows.*
8. *U is the compact-completion handoff row exposed only after C, T, M, R, Q, D, L have been read.*
9. *H records componentwise* hsame *transport for the compact, total-bounded, metric, real, rational, dyadic, mesh-ledger, and handoff rows.*
10. *E records displayed* Cont *replay from compact finite-cover reads through dyadic mesh bounds into the handoff row.*

11. *P is the* Pkg *provenance over* $\mathsf{FiniteCoverMesh}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{TotallyBounded}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
12. *N is the local* $\mathsf{NameCert}_{\mathsf{FiniteCoverMesh}^{\uparrow}}$ *registration row.*

The classifier compares accepted carriers only through these finite rows. It has no coordinate for an open-cover compactness principle, a least Lebesgue number, hidden centre choice, quotient equality of Real names, countable choice, or ambient completion.

Theorem 9115.2 (Finite cover mesh NameCert obligations)**.** *For every accepted* $\mathsf{FiniteCoverMesh}^{\uparrow}$ *carrier* $F = (C, T, M, R, Q, D, L, U, H, E, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{FiniteCoverMesh}^{\uparrow}}$ *obligations are exactly compact-metric source admission, total-bounded finite-net admission, metric-space comparison admission, Real seal exposure, regular rational readback, dyadic tolerance accounting, finite mesh-ledger exactness, compact-completion handoff exposure, componentwise stability transport, displayed replay, provenance, and local naming. The obligations do not include open-cover compactness, a host Lebesgue-number theorem, hidden mesh-centre selection, quotient Real equality, countable choice, or ambient completion.*

Proof. Project the carrier of Definition 9115.1. Its displayed compact data are C, T, M, so compact-metric, total-bounded, and metric comparison reads must enter through those rows.

Read the tolerance side next. The Real seal R, regular rational readback Q, and dyadic tolerance row D provide the numerical budget consumed by the finite mesh ledger L.

The handoff row U is downstream of the mesh ledger. Componentwise transport H, replay E, provenance P, and local naming N preserve the same finite route, so none of the excluded compactness, hidden-choice, quotient, choice, or ambient-completion principles has a carrier coordinate. □

Theorem 9115.3 (Finite cover mesh compact handoff)**.** *Every compact or completion consumer of an accepted* $\mathsf{FiniteCoverMesh}^{\uparrow}$ *packet must read the route*

$$C, T, M, R, Q, D, L, U, H, E, P, N$$

before using the exported mesh handoff. Thus the packet supplies concrete finite mesh NameCert data between compact finite-net sources and Real, RegSeqRat, and DyadicRatCore tolerance consumers; it does not duplicate the finite-cover mesh-chain uniform-modulus route.

Proof. Start with Definition 9115.2. It identifies the complete local surface of an accepted packet, so a compact or completion consumer cannot bypass $C, T, M, R, Q, D, L, U, H, E, P, N$.

The compact side is read through C, T, M. These rows expose compact-metric data, total-bounded finite cells, and the metric comparisons needed to relate finite mesh cells to cover rows.

The tolerance side is read through R, Q, D, L. The Real seal, regular rational readback, and dyadic tolerance row feed the finite mesh ledger, and the handoff row U becomes available only after that ledger is displayed.

Finally H, E, P, N transport, replay, package, and name the same route. Since the packet exports only this finite path, downstream compact and completion readers receive a mesh carrier rather than a host compactness theorem or the separate mesh-chain uniform-modulus certificate. □

Falsifiable prediction: A $\mathsf{FiniteCoverMesh}^{\uparrow}$ consumer is refuted whenever a compact or completion read bypasses the compact-metric source, total-bounded finite-net row, metric-space comparison row, Real seal, regular rational readback, dyadic tolerance row, finite mesh ledger, handoff row, transport, replay, provenance, or local NameCert row.

Closure status for $\mathsf{NameCert}_{\mathsf{FiniteCoverMesh}^{\uparrow}}$.

Constructive story: A $\mathsf{FiniteCoverMesh}^{\uparrow}$ packet is generated from CompactMetric finite-cover data, TotallyBounded finite-net cells, MetricSpace comparison rows, a Real seal, RegSeqRat readback, DyadicRatCore tolerance accounting, a finite mesh ledger, compact-completion handoff data, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{FiniteCoverMesh}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 9115.1, Definition 9115.2, and Definition 9115.3 seed the finite mesh carrier consumed by compact finite-net and completion-tolerance routes.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{FiniteCoverMesh}^{\uparrow}}, \mathsf{unformalized})$

Lean target: `BEDC.Derived.FiniteCoverMeshUp`

Bridge status: none

Not claimed: This chapter does not close open-cover compactness, host Lebesgue-number existence, hidden mesh-centre selection, quotient Real equality, countable choice, ambient completion, theorem-level Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, finite mesh-ledger exactness, compact-completion handoff nonescape, tolerance-route compatibility, transport, replay, provenance, and local naming for BEDC.Derived.FiniteCoverMeshUp.

Chapter 9116

Menger Sponge NameCert Construction

Following Menger and classical fractal topology, the $\mathsf{MengerSponge}^{\uparrow}$ packet records the standard ternary-cube sponge as finite BEDC naming data. It sits beside the square deletion surface of chapter 3960, the Cantor-address source of chapter 1475, and the finite contraction-family row of chapter 7342. The packet names only inspected cube stages, deleted middle slabs, boundary incidence, coordinate readback, transport, replay, provenance, and local naming; it does not import a completed compact subset of the cube, a selected infinite branch, Hausdorff dimension, measure computation, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 9116.1 (Menger sponge carrier)**.** *A* $\mathsf{MengerSponge}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M = (C, D, B, A, W, Q, E, H, T, P, N)$$

with the following displayed rows:

1. *C is the ternary cube-stage row. It records an inspected finite word over the* 27 *subcube positions, the displayed depth, and the retained cube cell at that depth.*
2. *D is the deleted middle-slab ledger. For each inspected cube address it records the three coordinate directions and refuses exactly those subcubes whose address lies in at least two middle-coordinate slabs.*
3. *B is the boundary-incidence row. It records which retained faces, edges, and corner incidences remain visible after the deleted-slab ledger has been applied.*
4. *A is the finite Cantor-address row read from chapter 1475; it supplies only inspected prefixes and no selected infinite branch.*
5. *W is the coordinate* $\mathsf{StreamName}^{\uparrow}$ *window row for the three coordinate schedules attached to the retained cube.*
6. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for those coordinate schedules, with dyadic tolerance comparisons routed through* $\mathsf{DyadicRatCore}^{\uparrow}$ *before any terminal seal is exposed.*
7. *E is the triple of* $\mathsf{Real}^{\uparrow}$ *coordinate seals obtained from the same cube-stage, deleted-slab, boundary, and coordinate-window rows.*
8. *H records componentwise* hsame *transport for $C, D, B, A, W, Q, E, T, P, N$.*

9. *T records displayed* Cont *replay from a sponge request through retained cube stages, deleted slabs, boundary incidence, coordinate windows, rational readbacks, and Real coordinate seals.*
10. *P is the* Pkg *provenance over* $\mathsf{MengerSponge}^{\uparrow}$, $\mathsf{SierpinskiCarpet}^{\uparrow}$, $\mathsf{CantorSpace}^{\uparrow}$, $\mathsf{IteratedFunctionSystem}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{MengerSponge}^{\uparrow}}$ *row.*

The classifier accepts a packet only through $C, D, B, A, W, Q, E, H, T, P, N$. It has no coordinate for a completed subset of $[0,1]^3$, hyperspace equality, selected infinite address, dimension or measure data, quotient equality of coordinate triples, or ambient completeness.

Lean4 ✓ `BEDC.Derived.MengerSpongeUp.MengerSpongeTasteGate single carrier alignment`

Theorem 9116.2 (Menger sponge NameCert obligations)**.** *For every accepted* $\mathsf{MengerSponge}^{\uparrow}$ *carrier*

$$M = (C, D, B, A, W, Q, E, H, T, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{MengerSponge}^{\uparrow}}$ *surface consists exactly of carrier admission for the displayed packet; ternary cube-stage exposure through C; deleted middle-slab exclusion through D; boundary incidence through B; finite Cantor-address exposure through A; coordinate window exposure through W; regular rational readback through Q; Real coordinate sealing through E; componentwise transport through H; displayed replay through T; provenance through P; and local naming through N.*

Proof. Project the carrier of Definition 9116.1. The accepted packet displays exactly the ternary cube-stage, deleted middle-slab, boundary-incidence, finite address, coordinate-window, rational-readback, Real-seal, and structural rows.

The sponge-specific obligations are exhausted by C, D, B. A consumer first reads the inspected ternary cube address, then the deleted-slab ledger for that address, and only then the boundary incidences that remain available.

The coordinate obligations are exhausted by A, W, Q, E. The Cantor-address row supplies finite prefixes, the StreamName row opens the finite coordinate windows, the RegSeqRat row reads the scheduled rational data through the dyadic tolerance ledger, and the terminal Real row seals exactly those three coordinates.

Finally H, T, P, N transport, replay, source, and name the same finite packet. Since the carrier contains no completed subset, hyperspace equality, selected branch, dimension row, measure row, quotient coordinate equality, or ambient-completeness coordinate, none of those objects can become a local NameCert obligation. □

Theorem 9116.3 (Menger sponge Cantor-cube handoff)**.** *Every accepted* $\mathsf{MengerSponge}^{\uparrow}$ *coordinate read factors through the finite route*

$$\mathsf{CantorSpace}^{\uparrow}, \mathsf{IteratedFunctionSystem}^{\uparrow} \longmapsto C, D, B, A \longmapsto W, Q, E \longmapsto H, T, P, N.$$

The route first displays the Cantor-prefix and finite contraction-family sources, then reads retained ternary cube stages, deleted middle slabs, boundary incidence, coordinate windows, regular rational readback, and terminal Real coordinate seals. It exports no completed fractal subset, selected infinite branch, hyperspace fixed point, quotient equality of coordinate triples, Hausdorff-dimension computation, or ambient $\mathsf{Real}^{\uparrow}$ *completeness theorem.*

Proof. Begin with an accepted sponge consumer. By Definition 9116.1, the consumer enters through the displayed cube-stage row C and the source rows named by $\mathsf{CantorSpace}^{\uparrow}$ and $\mathsf{IteratedFunctionSystem}^{\uparrow}$.

Apply Definition 9116.2. It forces every retained-cell read through D and B, every finite address read through A, and every coordinate read through W, Q, E before the structural rows are inspected.

The sibling chapters supply only their own finite routes: chapter 1475 supplies finite prefix data, chapter 7342 supplies a finite contraction-family interface, and chapter 3960 supplies the two-dimensional deletion sibling. None adds a carrier coordinate for a completed sponge subset, selected branch, hyperspace fixed point, dimension, measure, quotient coordinate equality, or ambient completeness. Hence every accepted coordinate consumer remains on the displayed Cantor-cube handoff. □

Falsifiable prediction: An accepted $\mathsf{MengerSponge}^{\uparrow}$ consumer that reaches a $\mathsf{Real}^{\uparrow}$ coordinate seal without first displaying the retained ternary cube stage, deleted middle-slab ledger, boundary-incidence row, finite Cantor-address prefix, StreamName coordinate windows, and RegSeqRat readback refutes the carrier surface.

Independence witness: sierpinski-carpet, cantorspace, iterated-function-system, streamname, regseqrat, dyadicratcore, real: no listed sibling supplies the whole $\mathsf{MengerSponge}^{\uparrow}$ packet, because the sponge certificate binds three-dimensional ternary cube stages, deleted middle slabs, boundary incidence, coordinate readback, Real seals, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{MengerSponge}^{\uparrow}}$.

Constructive story: A $\mathsf{MengerSponge}^{\uparrow}$ packet is generated from retained ternary cube-stage rows, deleted middle-slab ledgers, boundary-incidence rows, finite Cantor-address prefixes, StreamName coordinate windows, RegSeqRat readbacks, DyadicRatCore tolerance checks, RealUp coordinate seals, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{MengerSponge}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 9116.1, Definition 9116.2, and Definition 9116.3 seed the finite ternary-cube sponge carrier and its Cantor-cube coordinate handoff.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{MengerSponge}^{\uparrow}}, \mathsf{theoremChecked})$

Lean target: `BEDC.Derived.MengerSpongeUp.MengerSpongeTasteGate\_single\_carrier\_alignment`

Bridge status: none

Not claimed: This chapter does not close completed sponge subsets, hyperspace fixed points, selected infinite branches, Hausdorff dimension, measure computation, quotient equality of coordinate triples, or bridge checking.

Upgrade path: Obligation closure requires a Lean-side MengerSpongeUp carrier with checked cube-stage exposure, deleted middle-slab exclusion, boundary incidence, coordinate readback, Real coordinate sealing, transport, replay, provenance, and local naming.

Chapter 9117

A Concrete Naming Certificate for $\mathsf{TransferFunctionStateSpaceRealization}^{\uparrow}$

Following Kalman and Kailath on finite-dimensional realization theory, the $\mathsf{TransferFunctionStateSpaceRealization}^{\uparrow}$ packet records the finite BEDC route from displayed input-output transfer readback rows to a state-space realization surface. It sits after the state-space carrier of chapter 329, the minimal-realization packet of chapter 6055, the observability and controllability certificates of chapter 294 and chapter 297, and the finite $\mathsf{Mat}^{\uparrow}$ and $\mathsf{LinMap}^{\uparrow}$ rows of chapter 49 and chapter 48. The packet names a realization certificate, not an analytic equality between host transfer functions.

Definition 9117.1 (TransferFunctionStateSpaceRealization carrier)**.** *A* $\mathsf{TransferFunctionStateSpaceRealization}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$R = (U, Y, S, G, A, B, C, D, Q, O, E, H, K, P, N)$$

with the following displayed rows:

1. *U is the input row, read through a finite vector or matrix-facing source.*
2. *Y is the output row, read through the same finite input-output discipline.*
3. *S is the consumed* $\mathsf{StateSpaceModel}^{\uparrow}$ *state-space realization row.*
4. *G is the transfer readback row naming the finite input-output response surface.*
5. *A, B, C, D are the transition, input, output, and feedthrough rows consumed from the state-space realization.*
6. *Q is the* $\mathsf{ControlControllability}^{\uparrow}$ *row used by realization-facing consumers.*
7. *O is the* $\mathsf{ControlObservability}^{\uparrow}$ *row used by realization-facing consumers.*
8. *E is the realization compatibility row saying that G is read only through $U, Y, S, A, B, C, D, Q, O$.*
9. *H records componentwise* hsame *transport for input, output, state-space, transfer readback, controllability, observability, compatibility, provenance, and local naming rows.*
10. *K records displayed* Cont *replay from input-output requests through the state-space realization and transfer readback rows.*
11. *P is the* Pkg *provenance over* $\mathsf{TransferFunctionStateSpaceRealization}^{\uparrow}$, $\mathsf{StateSpaceModel}^{\uparrow}$, $\mathsf{MinimalRealization}^{\uparrow}$, $\mathsf{ControlObservability}^{\uparrow}$, $\mathsf{ControlControllability}^{\uparrow}$, $\mathsf{Mat}^{\uparrow}$, $\mathsf{LinMap}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

12. N is the local $\mathsf{NameCert}_{\mathsf{TransferFunctionStateSpaceRealization}^{\uparrow}}$ *row.*
The carrier has no coordinate for analytic transfer-function equality, selected canonical realization, host quotient state space, infinite trajectory semantics, or external minimality theorem.

Theorem 9117.2 (TransferFunctionStateSpaceRealization NameCert obligations)**.** *For the carrier of Definition 9117.1, the local* $\mathsf{NameCert}_{\mathsf{TransferFunctionStateSpaceRealization}^{\uparrow}}$ *surface consists exactly of input admission through U, output admission through Y, state-space realization admission through S, A, B, C, D, transfer readback through G, controllability through Q, observability through O, realization compatibility through E, componentwise transport through H, displayed replay through K, package provenance through P, and local naming through N.*

Proof. Project the carrier rows of Definition 9117.1. The accepted packet displays exactly $U, Y, S, G, A, B, C, D, Q, O$ so every public read is one of these rows or a replay route through them.

The state-space side is finite. The realization row S supplies the transition, input, output, and feedthrough rows A, B, C, D, while the controllability and observability rows Q, O record the finite reachability and observation surfaces consumed by realization-facing chapters.

The transfer side is bounded by compatibility. The row E permits G to be read only after the displayed input-output and state-space rows have been exposed, so the packet never needs an analytic transfer-function equality outside the carrier.

The structural rows close the certificate. Componentwise hsame transport, displayed Cont replay, Pkg provenance, and the local NameCert row repack the same finite data, while host quotient state spaces, selected canonical realizations, infinite trajectories, and external minimality theorems remain outside the packet. □

Closure status for $\mathsf{NameCert}_{\mathsf{TransferFunctionStateSpaceRealization}^{\uparrow}}$.

Constructive story: A $\mathsf{TransferFunctionStateSpaceRealization}^{\uparrow}$ packet is generated from input and output rows, a StateSpaceModel realization row, transfer readback, transition, input, output, feedthrough, controllability, observability, compatibility, componentwise transport, displayed replay, provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{TransferFunctionStateSpaceRealization}^{\uparrow}}$, seed)

Scope closed: Definition 9117.1 and Definition 9117.2 seed the finite transfer-function/state-space realization surface over StateSpaceModel, MinimalRealization, ControlObservability, ControlControllability, Matrix, and LinearMap rows.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{TransferFunctionStateSpaceRealization}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim analytic transfer-function equality, selected canonical realization, host quotient state space, infinite trajectory semantics, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, state-space realization readback, transfer compatibility, controllability and observability consumption, transport, replay, provenance, and local naming for the same finite packet.

Chapter 9118

A Concrete Naming Certificate for $\mathsf{CauchyIdeal}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{CauchyIdeal}^{\uparrow}$ packet records rounded Cauchy ideal data as a finite family of observation rows before any quotient completion, selected limit, or ambient completeness theorem is available. It sits after the rounded filter route of chapter 333, the finite stream naming surface of chapter 126, the regular rational readback of chapter 301, the dyadic tolerance core of chapter 291, and the terminal real-name seal of chapter 38. The chapter names the ideal carrier and its local certificate obligations; it does not identify Cauchy representatives or choose a completed real.

Definition 9118.1 (Cauchy ideal carrier)**.** *A* $\mathsf{CauchyIdeal}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$I = (F, R, D, S, Q, E, O, H, T, P, N)$$

with the following displayed rows:

1. *F is the* $\mathsf{CauchyFilter}^{\uparrow}$ *source row whose neighborhoods supply the admitted Cauchy observations.*
2. *R is the rounded directed ideal row, listing finitely many observation rows closed under displayed coarsening and carrying a finite common-refinement witness for any two listed rows.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row, recording the dyadic radii and comparison budgets used by the displayed observations.*
4. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite observation-window row through which the ideal is inspected.*
5. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row assembled from the same stream windows and dyadic tolerance data.*
6. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal, exposed only after F, R, D, S, Q have been displayed.*
7. *O is the local rounded-obligation ledger, recording inhabitedness, upward closure under displayed weakening, directed refinement, and Cauchy compatibility inside the finite packet.*
8. *H records componentwise* hsame *transport for the filter source, rounded ideal row, dyadic tolerance row, stream windows, regular readback, real seal, obligation ledger, replay, provenance, and local naming rows.*
9. *T records displayed* Cont *replay from an ideal read through $F, R, D, S, Q, E, O, H, P, N$.*

10. *P is the* Pkg *provenance over* $\mathsf{CauchyIdeal}^{\uparrow}$, $\mathsf{CauchyFilter}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

11. *N is the local* $\mathsf{NameCert}_{\mathsf{CauchyIdeal}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $F, R, D, S, Q, E, O, H, T, P, N$. It has no coordinate for a quotient of filters, equality of completed reals, selected representatives, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 9118.2 (CauchyIdeal NameCert obligations)**.** *For every accepted* $\mathsf{CauchyIdeal}^{\uparrow}$ *carrier $I = (F, R, D, S, Q, E, O, H, T, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{CauchyIdeal}^{\uparrow}}$ *surface consists exactly of CauchyFilter source exposure through F, rounded directed ideal exposure through R, DyadicRatCore tolerance accounting through D, StreamName window exposure through S, RegSeqRat readback through Q, terminal Real sealing through E, rounded-obligation coverage through O, componentwise transport through H, displayed replay through T, provenance through P, and local naming through N. A Real or Completion consumer may read the ideal only after the route*

$$F, R, D \longmapsto S, Q \longmapsto E, O, H, T, P, N$$

has been displayed.

Proof. Project the carrier of Definition 9118.1. Its analytic rows are F, R, D, S, Q, E, O, and its structural rows are H, T, P, N.

The rounded ideal row R is read together with the CauchyFilter source F and dyadic tolerance row D. Thus inhabitedness, displayed weakening, directed refinement, and Cauchy compatibility are obligations of the same finite packet rather than properties imported from a quotient completion.

The readback rows remain downstream. The finite StreamName window S and RegSeqRat row Q expose only the listed observations, while the Real seal E is available only after those observations and tolerances have been replayed.

Finally O, H, T, P, N cover the local obligations, transport them componentwise, replay them, source them, and name them. Since no hidden coordinate stores quotient equality, representative choice, countable choice, or ambient completeness, the displayed rows exhaust the NameCert surface. □

Theorem 9118.3 (CauchyIdeal rounded readback)**.** *Every* $\mathsf{RegSeqRat}^{\uparrow}$ *or* $\mathsf{Real}^{\uparrow}$ *consumer of an accepted* $\mathsf{CauchyIdeal}^{\uparrow}$ *carrier reads through a rounded directed family of finite Cauchy observation rows over* $\mathsf{CauchyFilter}^{\uparrow}$. *The consumer may inspect the* $\mathsf{StreamName}^{\uparrow}$ *and* $\mathsf{RegSeqRat}^{\uparrow}$ *readback, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, the* $\mathsf{Real}^{\uparrow}$ *seal,* hsame *transport,* Cont *replay,* Pkg *provenance, and local* NameCert *naming, but receives no quotient completion or selected limit.*

Proof. Use Definition 9118.2. It places the finite CauchyFilter source, rounded ideal row, and dyadic tolerance data before the stream and regular-rational readback rows.

The rounded-obligation ledger O records exactly the finite ideal laws visible to the consumer: inhabitedness, weakening, directed refinement, and Cauchy compatibility. These laws are replayed through T and transported through H without adding a completed object.

Therefore a downstream read can be a read of the rounded Cauchy ideal packet only through the displayed rows. A quotient completion, selected limit, or host equality claim would require a coordinate not present in the carrier. □

Falsifiable prediction: Every accepted $\mathsf{CauchyIdeal}^{\uparrow}$ consumer read displays a CauchyFilter source, rounded directed ideal row, DyadicRatCore tolerance ledger, StreamName finite observation window, RegSeqRat readback, RealUp seal, rounded-obligation ledger, hsame transport, Cont replay, Pkg provenance, and local NameCert row before the ideal can be consumed.

Independence witness: cauchyfilter, streamname, regseqrat, dyadicratcore, real: $\mathsf{CauchyIdeal}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries rounded directed Cauchy observation rows, finite stream windows, regular rational readback, dyadic tolerance accounting, a Real seal, obligation coverage, transport, replay, provenance, and local naming in one packet.

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyIdeal}^{\uparrow}}$.

Constructive story: A $\mathsf{CauchyIdeal}^{\uparrow}$ packet is generated from a CauchyFilter source, rounded directed ideal row, DyadicRatCore tolerance ledger, StreamName finite windows, RegSeqRat readback, RealUp seal, rounded-obligation ledger, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CauchyIdeal}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 9118.1, Definition 9118.2, and Definition 9118.3 seed the finite rounded Cauchy ideal route for Bishop-style completion consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CauchyIdeal}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient completion, selected limits, equality of completed reals, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, rounded-directed ideal coverage, Cauchy compatibility, finite-window readback, Real-seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.CauchyIdealUp.

Chapter 9119

Analytic Tail Budget NameCert Construction

Following Bishop–Bridges Cauchy tail estimates, the $\mathsf{AnalyticTailBudget}^{\uparrow}$ packet records the finite tolerance budget by which analysis-facing arguments hand a tail claim to Real and Completion consumers. It realizes the analysis-interface route of chapter 9358 as concrete NameCert data and sits over the dyadic tolerance core of chapter 291, the finite observation surface of chapter 126, the regular rational readback of chapter 301, the terminal real-name seal of chapter 38, the Cauchy modulus route of chapter 292, and the completion boundary of chapter 1639. The packet names a finite tail-control row only; it does not assert ambient completeness, choose a limit, quotient streams, decide trichotomy, or identify host real equality.

Definition 9119.1 (Analytic tail-budget carrier)**.** *An* $\mathsf{AnalyticTailBudget}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$A = (\varepsilon, D, M, S, R, E, B, H, C, P, N)$$

with the following displayed rows:

1. ε *is the requested finite tolerance row, presented as dyadic precision data and not as a detached host-real parameter.*
2. D *is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *budget ledger. It records the dyadic comparison cells, tail radius, and tolerance arithmetic used by the request.*
3. M *is the* $\mathsf{CauchyModulus}^{\uparrow}$ *row that turns the tolerance request into a displayed finite tail index.*
4. S *is the* $\mathsf{StreamName}^{\uparrow}$ *observation-window row opened at and beyond that index.*
5. R *is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the inspected windows and their regular rational tail estimates.*
6. E *is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached only after* D, M, S, R *have been displayed.*
7. B *is the* $\mathsf{BishopRegularCauchyCompletion}^{\uparrow}$ *completion-facing boundary row; it records that the same tail data may be consumed by completion arguments without selecting a completed limit.*
8. H *records componentwise* hsame *transport for* $\varepsilon, D, M, S, R, E, B, C, P, N$.
9. C *records displayed* Cont *replay from a tail request through dyadic budget, Cauchy modulus, finite windows, regular readback, Real seal, and completion boundary.*

10. *P is the* Pkg *provenance over* $\mathsf{AnalyticTailBudget}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{CauchyModulus}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{BishopRegularCauchyCompletion}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{AnalyticTailBudget}^{\uparrow}}$ *row.*

The classifier compares packets only through $\varepsilon, D, M, S, R, E, B, H, C, P, N$. It has no coordinate for a selected limit, quotient stream equality, ambient completeness of $\mathsf{Real}^{\uparrow}$*, trichotomy, countable choice, or host real equality.*

Theorem 9119.2 (Analytic tail-budget NameCert obligations)**.** *For every accepted* $\mathsf{AnalyticTailBudget}^{\uparrow}$ *carrier*

$$A = (\varepsilon, D, M, S, R, E, B, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{AnalyticTailBudget}^{\uparrow}}$ *surface consists exactly of carrier admission for the displayed packet; dyadic tolerance exposure through ε and D; tail-index extraction through M; finite observation through S; regular rational readback through R; terminal Real sealing through E; completion-facing boundary exposure through B; componentwise transport through H; displayed replay through C; provenance through P; and local naming through N.*

Proof. Project the carrier of Definition 9119.1. The accepted packet exposes precisely the tolerance, dyadic budget, modulus, finite-window, readback, Real-seal, completion-boundary, and structural rows.

The tolerance obligation is exhausted by ε, D, M. The request is read as dyadic data, the ledger fixes the comparison cells and radius, and the Cauchy modulus row turns that budget into the displayed tail index.

The analytic readback obligation is exhausted by S, R, E, B. The StreamName row opens the finite windows, the RegSeqRat row reads the regular rational estimates, the Real seal remains downstream of that readback, and the Bishop regular completion row records the completion-facing boundary without selecting a limit.

Finally H, C, P, N transport, replay, source, and name only the displayed rows. Since no carrier coordinate stores quotient stream equality, selected limits, trichotomy, countable choice, host real equality, or ambient completeness, none of those objects can become a local NameCert obligation. □

Theorem 9119.3 (Analytic tail-budget Real completion route)**.** *Every accepted Real-facing or Completion-facing read of an* $\mathsf{AnalyticTailBudget}^{\uparrow}$ *packet factors through the finite route*

$$\mathsf{DyadicRatCore}^{\uparrow} \longmapsto \mathsf{CauchyModulus}^{\uparrow} \longmapsto \mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}, \mathsf{BishopRegularCauchyCompletion}$$

The route makes a tail request public only after the dyadic budget, modulus index, finite observation windows, and regular rational readback have been displayed. It exports no selected limit, quotient stream equality, countable-choice schedule, trichotomy decision, host real equality, or ambient $\mathsf{Real}^{\uparrow}$ *completeness principle.*

Proof. Start with an accepted Real-facing or Completion-facing consumer. By Definition 9119.1, the consumer must read the dyadic budget row D and the Cauchy modulus row M before any tail window is available.

Apply Definition 9119.2. It places S and R between the modulus index and the terminal rows E and B, so neither the Real seal nor the completion-facing boundary has an independent entry point.

The sibling chapters supply the listed interfaces only as finite rows: dyadic tolerances, finite stream windows, regular rational readback, Cauchy modulus indices, Real seals, and Bishop regular

completion boundaries. None adds a quotient stream, selected limit, countable-choice schedule, trichotomy decision, host real equality, or ambient completeness coordinate. Therefore the accepted consumer remains on the displayed Real completion route. □

Falsifiable prediction: An accepted $\mathsf{AnalyticTailBudget}^{\uparrow}$ consumer that reaches the terminal $\mathsf{Real}^{\uparrow}$ seal or the $\mathsf{BishopRegularCauchyCompletion}^{\uparrow}$ boundary without first displaying the dyadic budget, Cauchy modulus index, StreamName windows, and RegSeqRat readback refutes the carrier surface.

Independence witness: dyadicratcore, streamname, regseqrat, real, cauchymodulus, bishop-regular-cauchy-completion: no listed sibling supplies the whole $\mathsf{AnalyticTailBudget}^{\uparrow}$ packet, because the tail-budget certificate binds tolerance request, dyadic budget, modulus index, finite observation, regular readback, terminal seals, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{AnalyticTailBudget}^{\uparrow}}$.

Constructive story: An $\mathsf{AnalyticTailBudget}^{\uparrow}$ packet is generated from a finite dyadic tolerance request, DyadicRatCore budget ledger, CauchyModulus tail index, StreamName observation windows, RegSeqRat readback, RealUp seal, BishopRegularCauchyCompletionUp boundary, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{AnalyticTailBudget}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 9119.1, Definition 9119.2, and Definition 9119.3 seed the finite analysis-interface tail-control route into Real and Completion consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{AnalyticTailBudget}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close selected limits, quotient stream equality, countable choice, trichotomy, host real equality, ambient RealUp completeness, Lean theorem coverage, or bridge checking.

Upgrade path: Obligation closure requires a Lean-side AnalyticTailBudgetUp carrier with checked tolerance exposure, dyadic budget routing, Cauchy modulus extraction, finite observation, regular readback, Real and completion boundary sealing, transport, replay, provenance, and local naming.

Chapter 9120

A Concrete Naming Certificate for ZeckendorfReadoutCoefficientStrata$^{\uparrow}$

The ZeckendorfReadoutCoefficientStrata$^{\uparrow}$ packet realizes the coefficient-strata readout route as finite Zeckendorf carry, phase-shell, running-coordinate, and boundary-flux rows before any physical scalar fit is accepted. It sits after the phase shell of chapter 8811, the carry classifier of chapter 567, the running coordinate route of chapter 9092, and the static boundary flux of chapter 8769. The chapter names the finite carrier that keeps the static impedance coefficient, beta-shell coefficient, and curvature-residual coefficient in separate rows.

Definition 9120.1 (Zeckendorf readout coefficient strata carrier)**.** *A* ZeckendorfReadoutCoefficientStrata$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Z = (P, K, A, G, S, B, C, L, H, T, R, N)$$

with the following displayed rows:

1. *P is the* ZeckendorfPhaseShell$^{\uparrow}$ *phase-shell row.*
2. *K is the* ZeckendorfCarryClassifier$^{\uparrow}$ *carry-classifier row.*
3. *A is the* AxisZeckendorfRunningCoordinate$^{\uparrow}$ *running-coordinate row.*
4. *G is the* StaticGreenBoundaryFlux$^{\uparrow}$ *boundary-flux row.*
5. *S is the static impedance stratum row, recording the displayed $8/9$ coefficient as a boundary-flux readout.*
6. *B is the beta-shell stratum row, recording the displayed $2/3$ coefficient as a phase-image readout.*
7. *C is the curvature-residual stratum row, recording the displayed $4/9$ coefficient as a one-way fold-mismatch readout.*
8. *L is the local layer-separation ledger, refusing any read that identifies S, B, C as competing estimates of a single scalar.*
9. *H records componentwise* hsame *transport for the phase-shell, carry-classifier, running-coordinate, boundary-flux, three coefficient strata, ledger, replay, provenance, and local naming rows.*
10. *T records displayed* Cont *replay from a coefficient read through $P, K, A, G, S, B, C, L, H, R, N$.*
11. *R is the* Pkg *provenance over* ZeckendorfReadoutCoefficientStrata$^{\uparrow}$*,* ZeckendorfPhaseShell$^{\uparrow}$*,* ZeckendorfCarryClassif AxisZeckendorfRunningCoordinate$^{\uparrow}$*,* StaticGreenBoundaryFlux$^{\uparrow}$*,* BHist*,* hsame*,* Cont*, and* NameCert*.*

12. N is the local $\mathsf{NameCert}_{\mathsf{ZeckendorfReadoutCoefficientStrata}^{\uparrow}}$ *row.*
The classifier compares accepted packets only through $P, K, A, G, S, B, C, L, H, T, R, N$. It has no coordinate for an unstratified scalar fit, floating coefficient tuning, hidden physical calibration, quotient phase equality, or host-field semantics.

Theorem 9120.2 (Zeckendorf readout coefficient strata NameCert obligations)**.** *For every accepted* $\mathsf{ZeckendorfReadoutCoefficientStrata}^{\uparrow}$ *carrier $Z = (P, K, A, G, S, B, C, L, H, T, R, N)$, the local* $\mathsf{NameCert}_{\mathsf{ZeckendorfReadoutCoefficientStrata}^{\uparrow}}$ *surface consists exactly of phase-shell exposure through P, carry-classifier exposure through K, running-coordinate exposure through A, static boundary-flux exposure through G, coefficient-row exposure through S, B, C, layer-separation refusal through L, componentwise transport through H, displayed replay through T, provenance through R, and local naming through N.*

Proof. Project the carrier of Definition 9120.1. The source rows are P, K, A, G, the coefficient rows are S, B, C, and the structural rows are L, H, T, R, N.

The three coefficient rows have distinct readout sources. The static row S is bound to the boundary-flux row G, the beta-shell row B is bound to phase-image and running-coordinate data through P, K, A, and the curvature-residual row C is bound to the one-way fold-mismatch boundary.

The ledger L refuses a collapse of these strata into a single fit parameter. Transport and replay through H, T preserve the same row separation, while R, N source and name the packet.

Since no carrier coordinate stores an unstratified scalar, floating calibration, quotient phase equality, or host-field interpretation, the listed rows exhaust the NameCert obligations. □

Theorem 9120.3 (Zeckendorf coefficient readout separation)**.** *Every accepted* $\mathsf{ZeckendorfReadoutCoefficientStrata}^{\uparrow}$ *read keeps the displayed coefficients $8/9$, $2/3$, and $4/9$ in three separate strata. The read may transport and replay the strata through H, T, R, N, but it cannot replace the row separation by a single low-energy scalar fit.*

Proof. Apply Definition 9120.2. It exposes S, B, C as three rows rather than as one row with three candidate values.

The source rows separate the meaning of the coefficients. Static impedance reads through G, beta-shell reads through P, K, A, and curvature residual reads through the one-way mismatch row C together with the ledger L.

Thus a consumer that collapses the coefficients into one scalar has left the carrier. The packet has transport, replay, provenance, and naming rows, but no coordinate that can erase the displayed stratum separation. □

The Lean TasteGate follow-up for $\mathsf{BEDC.Derived.ZeckendorfReadoutCoefficientStrataUp}$ must provide explicit $\mathsf{Nontrivial}$ and $\mathsf{FieldFaithful}$ instances for the same carrier rows $P, K, A, G, S, B, C, L, H, T, R, N$ before any checked taste-gate target is recorded.

Falsifiable prediction: Every accepted $\mathsf{ZeckendorfReadoutCoefficientStrata}^{\uparrow}$ consumer read displays Zeckendorf phase-shell, carry-classifier, running-coordinate, static boundary-flux, static impedance, beta-shell, curvature-residual, layer-separation, hsame transport, Cont replay, Pkg provenance, and local NameCert rows before a coefficient stratum can be consumed.

Independence witness: zeckendorf-phase-shell, zeckendorf-carry-classifier, axis-zeckendorf-running-coordinate, static-green-boundary-flux: $\mathsf{ZeckendorfReadoutCoefficientStrata}^{\uparrow}$ is not bijective to any

listed sibling because it jointly carries phase-shell, carry-classifier, running-coordinate, boundary-flux, three coefficient strata, layer-separation refusal, transport, replay, provenance, and local NameCert rows in one packet.

Closure status for $\mathsf{NameCert}_{\mathsf{ZeckendorfReadoutCoefficientStrata}^{\uparrow}}$.

Constructive story: A $\mathsf{ZeckendorfReadoutCoefficientStrata}^{\uparrow}$ packet is generated from Zeckendorf phase-shell, carry-classifier, running-coordinate, static boundary-flux, static impedance, beta-shell, curvature-residual, layer-separation, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{ZeckendorfReadoutCoefficientStrata}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 9120.1, Definition 9120.2, and Definition 9120.3 seed the finite coefficient-strata readout route for Zeckendorf consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{ZeckendorfReadoutCoefficientStrata}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close physical scalar fitting, host-field semantics, quotient phase equality, checked TasteGate evidence, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, coefficient-row separation, layer-refusal coverage, Nontrivial TasteGate evidence, FieldFaithful TasteGate evidence, transport, replay, provenance, and local naming for BEDC.Derived.ZeckendorfReadoutCoefficientStrataUp.

Chapter 9121

A Concrete Naming Certificate for $\mathsf{BishopCompactCompletionExtension}^{\uparrow}$

Following Bishop–Bridges constructive analysis and Kelley's compactness discipline for uniform spaces, the $\mathsf{BishopCompactCompletionExtension}^{\uparrow}$ packet records the finite BEDC surface by which a uniformly continuous map on compact metric data extends across displayed completion names. It sits over the compact-metric row of chapter 129, the completion row of chapter 95, the uniform extension ledger of chapter 769, the Cauchy completion functor of chapter 423, and the finite Real and Completion corridor through chapter 126, chapter 301, chapter 291, and chapter 38. The packet exposes compact finite-net evidence and completion-extension uniqueness as displayed rows; it does not replace them by open-cover compactness, quotient completions, or selected limits.

Definition 9121.1 (Bishop compact completion-extension carrier)**.** *A* $\mathsf{BishopCompactCompletionExtension}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$E = (K, C, U, F, S, R, D, Q, L, H, T, P, N)$$

with the following displayed rows:

1. *K is the* $\mathsf{CompactMetric}^{\uparrow}$ *row whose compact data are read only through displayed finite-net or total-boundedness witnesses.*
2. *C is the* $\mathsf{Completion}^{\uparrow}$ *row naming the source and target completion surfaces used by the extension read.*
3. *U is the* $\mathsf{UniformContinuousExtension}^{\uparrow}$ *row carrying the source graph, finite uniform modulus, target convergence handoff, and separated uniqueness ledger.*
4. *F is the* $\mathsf{CauchyCompletionFunctor}^{\uparrow}$ *row recording the functorial source-to-completion and completion-consumer routes for the same Cauchy data.*
5. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row through which compact source names and completion names are inspected.*
6. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *regular-rational readback row attached to the same windows.*
7. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger controlling compact-net mesh size, Cauchy radius, and uniform-modulus budget.*
8. *Q is the* $\mathsf{Real}^{\uparrow}$ *seal row reached only after S, R, D and the completion-extension rows have been displayed.*

9. *L is the finite compact-net ledger: for each displayed dyadic tolerance it lists net centers, incidence rows, image-window rows, and the extension-uniqueness comparison row served by K, U, F.*
10. *H records componentwise* hsame *transport for $K, C, U, F, S, R, D, Q, L, P, N$.*
11. *T records displayed* Cont *replay from a compact-net request through the completion-extension route.*
12. *P is the* Pkg *provenance over* $\mathsf{BishopCompactCompletionExtension}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{Completion}^{\uparrow}$, $\mathsf{UniformContinuousExtension}^{\uparrow}$, $\mathsf{CauchyCompletionFunctor}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
13. *N is the local* $\mathsf{NameCert}_{\mathsf{BishopCompactCompletionExtension}^{\uparrow}}$ *row.*

The carrier has no coordinate for open-cover compactness, selected limits, quotient completion equality, countable choice, host function equality, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 9121.2 (Bishop compact completion-extension NameCert obligations)**.** *For every accepted* $\mathsf{BishopCompactCompletionExtension}^{\uparrow}$ *carrier*

$$E = (K, C, U, F, S, R, D, Q, L, H, T, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{BishopCompactCompletionExtension}^{\uparrow}}$ *surface consists exactly of carrier admission for the compact-metric row, completion row, uniform-extension row, Cauchy-completion-functor row, finite stream windows, regular-rational readback, dyadic tolerance ledger, terminal Real seal, finite compact-net ledger, componentwise transport, displayed replay, provenance, and local naming. Every completion-extension read must display the finite-net row L and the uniqueness route supplied by U and F before it exposes a completed value.*

Proof. Project the carrier of Definition 9121.1. Its coordinates are exactly $K, C, U, F, S, R, D, Q, L, H, T, P, N$, so carrier admission and local naming can inspect only those rows.

Read the compact side next. The row K supplies compact metric data only through displayed finite-net evidence, while L records the tolerance-indexed net centers, incidence rows, and image windows used by the extension read.

Read the completion side through C, U, F. The completion row names the source and target completion surfaces, the uniform-extension row carries the finite modulus and separated uniqueness ledger, and the Cauchy-completion-functor row keeps the source-to-completion and completion-consumer routes attached to the same Cauchy data.

Finally read the numerical corridor S, R, D, Q and the structural rows H, T, P, N. Finite windows, regular-rational readback, and dyadic budgets precede the terminal Real seal, while transport, replay, provenance, and local naming preserve the same packet. No excluded compactness, choice, quotient, host equality, or ambient completeness principle is a carrier coordinate. □

Theorem 9121.3 (Bishop compact completion-extension finite-net handoff)**.** *Every completion-facing consumer of an accepted* $\mathsf{BishopCompactCompletionExtension}^{\uparrow}$ *carrier factors through the finite route*

$$\mathsf{CompactMetric}^{\uparrow},\ \mathsf{Completion}^{\uparrow},\ \mathsf{UniformContinuousExtension}^{\uparrow},\ \mathsf{CauchyCompletionFunctor}^{\uparrow},\ \mathsf{StreamName}^{\uparrow},\ \mathsf{RegSeqRa}$$

as displayed by $K, C, U, F, S, R, D, Q, L, H, T, P, N$. In particular, compactness enters only through the finite compact-net ledger L, and completion-extension uniqueness enters only through the rows U and F before the terminal $\mathsf{Real}^{\uparrow}$ *seal is consumed.*

Proof. Start with the NameCert obligations of Definition 9121.2. They force every accepted read to expose the compact row, completion row, uniform-extension row, Cauchy functor row, finite windows, rational readback, dyadic ledger, compact-net ledger, and structural rows.

The compact handoff is finite. For each requested dyadic tolerance, L lists the net centers and incidence rows read from K, then records the image windows that the extension row may inspect. Thus the consumer receives compact-net rows, not an open-cover subcover principle.

The extension handoff is unique only inside the displayed completion route. Rows U and F say that two extension reads agreeing on the same source completion windows and uniform-modulus data have the same separated target read. This is a finite uniqueness ledger, not quotient completion equality and not host function equality.

The Real-facing corridor then reads S, R, D, Q. The terminal seal Q is reached only after the stream windows, regular-rational readback, dyadic budgets, compact-net ledger, and completion-extension rows have all been displayed, so the handoff exports no selected limit, countable choice schedule, or ambient $\mathsf{Real}^{\uparrow}$ completeness. □

Falsifiable prediction: Every accepted $\mathsf{BishopCompactCompletionExtension}^{\uparrow}$ consumer must display CompactMetric, Completion, UniformContinuousExtension, CauchyCompletionFunctor, StreamName, RegSeqRat, DyadicRatCore, Real, finite compact-net, hsame, Cont, Pkg, and local NameCert rows before reading a completion-extension value.

Independence witness: compactmetric, completion, uniform-continuous-extension, cauchycompletionfunctor, streamname, regseqrat, dyadicratcore, real: no listed sibling carries both the finite compact-net ledger and the completion-extension uniqueness route in one local NameCert packet.

Closure status for $\mathsf{NameCert}_{\mathsf{BishopCompactCompletionExtension}^{\uparrow}}$.

Constructive story: A $\mathsf{BishopCompactCompletionExtension}^{\uparrow}$ packet is generated from CompactMetric finite-net data, Completion surfaces, a UniformContinuousExtension ledger, a CauchyCompletionFunctor route, StreamName windows, RegSeqRat readback, DyadicRatCore tolerance accounting, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BishopCompactCompletionExtension}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 9121.1, Definition 9121.2, and Definition 9121.3 seed the finite compact completion-extension route over CompactMetric, Completion, UniformContinuousExtension, CauchyCompletionFunctor, StreamName, RegSeqRat, DyadicRatCore, Real, hsame, Cont, Pkg, and NameCert rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BishopCompactCompletionExtension}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim open-cover compactness, selected limits, quotient completion equality, countable choice, host function equality, ambient RealUp completeness, theorem checking, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, compact finite-net exactness, completion-surface routing, uniform-extension uniqueness, Cauchy-functor handoff, StreamName and RegSeqRat readback, DyadicRatCore tolerance accounting, RealUp seal routing, transport, replay, provenance, and local naming for BEDC.Derived.BishopCompactCompletionExten

Chapter 9122

A Concrete Naming Certificate for CompactUniformNetSelection$^{\uparrow}$

Following Bishop and Bridges on compact finite nets and uniform continuity, the CompactUniformNetSelection$^{\uparrow}$ packet records the finite selected-net handoff by which compact metric source data and continuous-map local moduli are turned into a displayed uniform-modulus consumer row. It sits beside the finite cover mesh carrier of chapter 9115, reads compact source rows through chapter 129, continuous-map rows through chapter 130, terminal seals through chapter 38, regular rational readbacks through chapter 301, and dyadic tolerance arithmetic through chapter 291. The packet supplies a finite selected-net ledger for compact-uniform-continuity consumers; it does not assert open-cover compactness, an external point selector, quotient Real equality, countable choice, or ambient Real$^{\uparrow}$ completeness.

Definition 9122.1 (Compact uniform net selection carrier)**.** *A* CompactUniformNetSelection$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (K, F, M, Q, R, D, L, U, H, C, P, N)$$

with the following displayed rows:

1. *K is the accepted* CompactMetric$^{\uparrow}$ *source row whose finite compact-net data are inspected.*
2. *F is the* ContinuousMap$^{\uparrow}$ *row carrying the pointwise modulus data for the displayed graph.*
3. *M is the finite selected-net row, listing the compact probes and their local-radius witnesses.*
4. *Q is the finite lower-bound fold row over the selected probe radii.*
5. *R is the* RegSeqRat$^{\uparrow}$ *readback row for the folded rational tolerance data.*
6. *D is the* DyadicRatCore$^{\uparrow}$ *tolerance row used to compare the requested precision with the selected radius.*
7. *L is the local coverage ledger saying which displayed probe covers each inspected source point.*
8. *U is the compact-uniform handoff row exposed to* UniformModulus$^{\uparrow}$ *and compact-uniform-continuity consumers.*
9. *H records componentwise* hsame *transport for the compact, continuous, net, fold, readback, dyadic, coverage, and handoff rows.*

10. *C records displayed* Cont *replay from compact finite-net reads and continuous-map local moduli into the uniform handoff.*
11. *P is the* Pkg *provenance over* $\mathsf{CompactUniformNetSelection}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{FiniteCoverMesh}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
12. *N is the local* $\mathsf{NameCert}_{\mathsf{CompactUniformNetSelection}^{\uparrow}}$ *registration row.*

The classifier compares accepted carriers only through these rows. It has no coordinate for an open-cover compactness principle, an external center selector, hidden Lebesgue-number existence, quotient Real equality, countable choice, or ambient completion.

Theorem 9122.2 (Compact uniform net selection NameCert obligations)**.** *For every accepted* $\mathsf{CompactUniformNetSelection}^{\uparrow}$ *carrier* $S = (K, F, M, Q, R, D, L, U, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{CompactUniformNetSe}}$ *obligations are exactly compact-metric source admission, continuous-map local-modulus admission, selected finite-net exposure, finite lower-bound fold exposure, regular rational readback, dyadic tolerance comparison, coverage-ledger exactness, compact-uniform handoff exposure, componentwise stability transport, displayed replay, provenance, and local naming. The obligations do not include open-cover compactness, hidden center choice, quotient Real equality, countable choice, an ambient completion theorem, or a host Lebesgue-number principle.*

Proof. Project the carrier of Definition 9122.1. The compact and continuity source rows are K and F, so selected probes and local moduli must be read before any uniform handoff is available.

Read the finite selection route next. The selected-net row M supplies only displayed probes, the fold row Q records the finite lower-bound comparison, and the $\mathsf{RegSeqRat}^{\uparrow}$ and $\mathsf{DyadicRatCore}^{\uparrow}$ rows R, D expose the rational tolerance data used by the coverage ledger L.

The handoff row U is downstream of that ledger. Componentwise transport H, replay C, provenance P, and local naming N preserve the same finite route, so none of the excluded compactness, choice, quotient, completion, or host Lebesgue-number principles has a carrier coordinate. □

Theorem 9122.3 (Compact uniform net selection vision handoff)**.** *Every compact-uniform-continuity consumer of an accepted* $\mathsf{CompactUniformNetSelection}^{\uparrow}$ *packet must read the route*

$$K, F, M, Q, R, D, L, U, H, C, P, N$$

before using the exported uniform-modulus handoff. Thus the compact finite-net source, continuous-map local-modulus row, regular rational readback, dyadic tolerance comparison, and finite cover mesh relation are exposed as concrete NameCert data; the consumer receives no open-cover compactness theorem, external selector, quotient Real equality, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start with Definition 9122.2. It identifies the local surface of an accepted selected-net packet and forces every consumer through the compact source, continuous-map source, selected-net, fold, readback, dyadic, coverage, and handoff rows.

The compact side is read through K, M, L. These rows display the compact finite-net probes and the local coverage ledger, matching the finite mesh discipline of chapter 9115.

The analytic side is read through F, Q, R, D, U. Continuous-map local moduli feed the finite lower-bound fold, the regular rational and dyadic rows expose the tolerance comparison, and the uniform handoff is available only after those rows have been displayed.

Finally H, C, P, N transport, replay, package, and name the same route. Since the packet exports only this finite selected-net path, the compact-uniform-continuity vision receives a concrete NameCert handoff and no hidden compactness or choice principle. □

Falsifiable prediction: A $\mathsf{CompactUniformNetSelection}^{\uparrow}$ consumer is refuted whenever a compact-uniform handoff bypasses the compact-metric source, continuous-map local-modulus row, selected finite-net row, lower-bound fold, regular rational readback, dyadic tolerance comparison, coverage ledger, transport, replay, provenance, or local NameCert row.

Closure status for $\mathsf{NameCert}_{\mathsf{CompactUniformNetSelection}^{\uparrow}}$.

Constructive story: A $\mathsf{CompactUniformNetSelection}^{\uparrow}$ packet is generated from CompactMetric finite-net data, ContinuousMap local-modulus rows, selected probe data, a finite lower-bound fold, RegSeqRat readback, DyadicRatCore tolerance comparison, a coverage ledger, compact-uniform handoff data, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CompactUniformNetSelection}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 9122.1, Definition 9122.2, and Definition 9122.3 seed the finite selected-net handoff from compact and continuous rows into compact-uniform-continuity consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CompactUniformNetSelection}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close open-cover compactness, hidden center choice, host Lebesgue-number existence, quotient Real equality, countable choice, ambient completion, theorem-level Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, selected-net exactness, finite lower-bound fold compatibility, compact-uniform handoff nonescape, transport, replay, provenance, and local naming for BEDC.Derived.CompactUniformNetSele

Chapter 9123

A Concrete Naming Certificate for $\mathsf{OstrowskiCompletionUniqueness}^{\uparrow}$

Following Bourbaki, Artin, and Bishop–Bridges on absolute values and separated completions, the $\mathsf{OstrowskiCompletionUniqueness}^{\uparrow}$ packet records the finite route by which an absolute-value completion boundary can be compared through constructive separated uniqueness. It sits downstream of the absolute-value branch packet of chapter 6893, the separated uniqueness packet of chapter 1463, and the regular real-name spine of chapter 291, chapter 126, chapter 301, and chapter 38. The packet names only displayed source-field, absolute-value, branch, regular-name, separated-ledger, transport, replay, provenance, and local naming rows; it does not quotient completions, select limits, invoke choice, or identify a host completed field.

Definition 9123.1 (Ostrowski completion uniqueness carrier)**.** *An* $\mathsf{OstrowskiCompletionUniqueness}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (F, A, V, D, S, R, E, U, T, C, P, N)$$

with the following displayed rows:

1. *F is the source field row, exposing the finite arithmetic operations and equality classifier visible to the completion request.*
2. *A is the absolute-value row, displaying positivity, multiplicativity, and triangle-control data as packet history.*
3. *V is the visible Archimedean or non-Archimedean branch row inherited from the* $\mathsf{OstrowskiCompletion}^{\uparrow}$ *boundary.*
4. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger read by the regular completion names.*
5. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window schedule shared by the compared names.*
6. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *regular-rational source row routed through the schedule and tolerance ledger.*
7. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal reached from the displayed D, S, R spine.*
8. *U is the* $\mathsf{CompletionUniqueness}^{\uparrow}$ *separated ledger comparing completion-facing presentations over the same F, A, V, D, S, R, E packet.*
9. *T records componentwise* hsame *transport for the source, absolute-value, branch, dyadic, stream, regular, Real, separated-ledger, provenance, and local naming rows.*

10. *C records displayed* Cont *replay from an absolute-value completion comparison through $F, A, V, D, S, R, E, U, T, P$*
11. *P is the* Pkg *provenance over* $\mathsf{OstrowskiCompletion}^{\uparrow}$, $\mathsf{CompletionUniqueness}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*
12. *N is the local* $\mathsf{NameCert}_{\mathsf{OstrowskiCompletionUniqueness}^{\uparrow}}$ *row.*

The carrier has no coordinate for quotient completion classes, selected Cauchy representatives, ambient completed fields, global branch trichotomy, countable choice, or host equality of completed points.

Theorem 9123.2 (Ostrowski completion uniqueness NameCert obligations)**.** *For every accepted* $\mathsf{OstrowskiCompletionUniqueness}^{\uparrow}$ *carrier*

$$K = (F, A, V, D, S, R, E, U, T, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{OstrowskiCompletionUniqueness}^{\uparrow}}$ *surface consists exactly of source-field exposure, absolute-value exposure, visible branch exposure, regular-name spine exposure, separated uniqueness ledger admission, componentwise transport, displayed continuation replay, package provenance, and local naming. A consumer may read the separated ledger U only after the absolute-value branch rows F, A, V and the regular real-name rows D, S, R, E have both been displayed.*

Proof. Project the carrier of Definition 9123.1. The source-field, absolute-value, branch, dyadic, stream, regular-rational, Real-seal, separated-ledger, transport, replay, provenance, and naming rows are precisely the coordinates of the finite packet.

The branch-facing obligations are supplied by F, A, V. These rows identify the source field visible to the completion request, the absolute-value data that controls Cauchy admission, and the Archimedean or non-Archimedean branch visible to the packet.

The uniqueness-facing obligations are supplied by D, S, R, E, U. The rows D, S, R, E give the regular real-name spine, and U compares completion-facing presentations only over that displayed spine together with the same absolute-value branch data.

Finally T, C, P, N preserve, replay, source, and name the same finite packet. Since no quotient completion, selected representative, host completed field, hidden branch choice, or host equality coordinate occurs in the carrier, the stated rows exhaust the local NameCert obligation surface. □

Theorem 9123.3 (Ostrowski completion uniqueness real seal)**.** *Let*

$$K = (F, A, V, D, S, R, E, U, T, C, P, N)$$

be an accepted $\mathsf{OstrowskiCompletionUniqueness}^{\uparrow}$ *carrier. Every comparison exported by the separated ledger U reaches the route*

$$F, \quad A, \quad V, \quad D, \quad S, \quad R, \quad E$$

before any completion-facing uniqueness read is made. Thus the comparison is a Real-seal and separated-ledger read over displayed absolute-value completion data, not a quotient completion identity or a selected host-field limit.

Proof. Start from the carrier decomposition. The rows F, A, V expose the absolute-value completion boundary, and the rows D, S, R, E expose the regular real-name spine used by the comparison.

The separated ledger U is downstream of those displayed rows. It may compare completion-facing presentations only after the visible branch and Real-seal data have been projected from the same packet.

The replay row C can reproduce the comparison only through the listed route, while P records no host completed field or quotient-completion object. Therefore the uniqueness read is a separated Real-seal route over finite packet data. □

Falsifiable prediction: An accepted $\mathsf{OstrowskiCompletionUniqueness}^{\uparrow}$ replay must display the same source field row, absolute-value row, visible branch row, dyadic tolerance ledger, stream schedule, regular-rational row, Real seal, separated uniqueness ledger, transport, replay, provenance, and local naming before any completion-facing comparison is accepted. A replay that reaches a quotient completion, selected representative, hidden branch choice, host completed field, or unrecorded limit rejects this NameCert instance.

Independence witness: The packet is independent of quotient completion carriers, selected Cauchy representatives, ambient field equality, and host completed fields because the comparison route is mediated only by displayed BHist, hsame, Cont, Pkg, NameCert, $\mathsf{OstrowskiCompletion}^{\uparrow}$, $\mathsf{CompletionUniqueness}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ rows.

Closure status for $\mathsf{NameCert}_{\mathsf{OstrowskiCompletionUniqueness}^{\uparrow}}$.

Constructive story: An $\mathsf{OstrowskiCompletionUniqueness}^{\uparrow}$ packet is generated from source field data, absolute-value data, a visible Archimedean or non-Archimedean branch row, DyadicRatCore, StreamName, RegSeqRat, and Real spine rows, a CompletionUniqueness separated ledger, componentwise transport, displayed replay, package provenance, and local naming.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{OstrowskiCompletionUniqueness}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 9123.1, Definition 9123.2, and Definition 9123.3 seed the absolute-value completion uniqueness route over displayed regular real-name and separated-ledger data.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{OstrowskiCompletionUniqueness}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close Ostrowski classification, quotient completions, selected Cauchy limits, host completed fields, branch trichotomy, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, absolute-value branch exposure, regular-name spine exposure, separated-ledger exactness, transport, replay, provenance, and local naming for BEDC.Derived.OstrowskiCompletionUniqueness

Chapter 9124

A Concrete Naming Certificate for $\mathsf{CauchyCompletionReflectionUnit}^{\uparrow}$

Following Bishop and Bridges on constructive completion and Mac Lane on adjunction units, the $\mathsf{CauchyCompletionReflectionUnit}^{\uparrow}$ packet records the finite unit component by which a displayed dense source enters the Cauchy-completion reflector and then feeds the functorial completion surface. It sits between the functorial route of chapter 1937, the unit packet of chapter 1527, and the reflector packet of chapter 1585. The chapter names only the displayed NameCert surface of the reflection unit; it does not assert quotient completion equality, selected representatives, countable choice, host equality of completed objects, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 9124.1 (CauchyCompletionReflectionUnit carrier)**.** *A* $\mathsf{CauchyCompletionReflectionUnit}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$U = (X, K, \eta, R, T, S, Q, E, H, C, P, N)$$

with the following displayed rows:

1. *X is the source dense object row, carrying the displayed source histories before any completion-facing read is available.*
2. *K is the completion seal row for the Cauchy-completion reflector over X.*
3. *η is the unit map row sending the displayed dense source into the completion seal.*
4. *R is the reflection handoff row consumed by the local* $\mathsf{CauchyCompletionReflector}^{\uparrow}$ *surface.*
5. *T is the triangle identity row that compares the unit handoff with the reflector replay inside the same finite packet.*
6. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row read by the unit and reflection routes.*
7. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row extracted from the same finite windows.*
8. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal reached only after X, K, η, R, T, S, Q have been displayed.*
9. *H records componentwise* hsame *transport for the dense source, completion seal, unit map, reflection handoff, triangle identity, window, readback, Real seal, replay, provenance, and local naming rows.*
10. *C records displayed* Cont *replay of the route*

$$X, K, \eta \longmapsto R, T \longmapsto S, Q, E.$$

11. *P is the* Pkg *provenance over* CauchyCompletionReflectionUnit$^{\uparrow}$, CauchyCompletionFunctoriality$^{\uparrow}$, CauchyCompletionUnit$^{\uparrow}$, CauchyCompletionReflector$^{\uparrow}$, StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, Real$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
12. *N is the local* NameCert$_{\text{CauchyCompletionReflectionUnit}^{\uparrow}}$ *row.*

The carrier has no coordinate for quotient completion equality, selected stream representatives, chosen limits, countable choice, host equality, or ambient completeness.

Theorem 9124.2 (CauchyCompletionReflectionUnit NameCert obligations)**.** *For every accepted* CauchyCompletionReflectionUnit$^{\uparrow}$ *carrier*

$$U = (X, K, \eta, R, T, S, Q, E, H, C, P, N),$$

the local NameCert$_{\text{CauchyCompletionReflectionUnit}^{\uparrow}}$ *surface consists exactly of source dense-object admission for X, completion-seal admission for K, unit-map exposure for η, reflection handoff through R, triangle identity exposure through T, finite StreamName window exposure through S, RegSeqRat readback through Q, Real sealing through E, componentwise* hsame *transport through H, displayed* Cont *replay through C, package provenance through P, and local naming through N.*

Proof. Project the carrier of Definition 9124.1. The displayed rows are exactly the dense source, completion seal, unit map, reflection handoff, triangle identity, finite-window, readback, Real-seal, and structural rows.

The unit and reflection obligations are read in that order. The dense source row X first enters the completion seal K through η, and only then may the reflection handoff row R be consumed by a completion-facing reader.

The analytic readback rows remain attached to the same packet. The finite window S, regular-rational readback Q, and terminal Real seal E are downstream of the unit and reflection rows, so no consumer can detach a Real endpoint or a selected representative from the displayed route.

Finally T, H, C, P, N record the triangle comparison, transport, replay, provenance, and local naming for the same carrier. Since the excluded principles are not coordinates of the packet, the listed rows exhaust the local NameCert surface. □

Theorem 9124.3 (CauchyCompletionReflectionUnit triangle identity route)**.** *Every triangle-identity read from an accepted* CauchyCompletionReflectionUnit$^{\uparrow}$ *carrier factors through the finite route*

$$X, K, \eta \longmapsto R \longmapsto T \longmapsto S, Q, E \longmapsto H, C, P, N.$$

Thus the functorial and separated-completion consumers receive the unit component only after the source dense object, completion seal, unit map, reflection handoff, triangle identity row, finite StreamName window, RegSeqRat readback, terminal Real seal, transport, replay, provenance, and local NameCert rows are visible.

Proof. Start with a consumer asking for the triangle identity. Projection gives the dense source row X, the completion seal K, and the unit map row η.

The read next passes through the reflection handoff R. This is the row visible to the CauchyCompletionReflector$^{\uparrow}$ packet and to the functorial completion route of chapter 1937.

The triangle identity is then the displayed row T, not an ambient equation of completions. The StreamName window S, RegSeqRat readback Q, and Real seal E keep the analytic route finite before any completion-facing consumer reads the unit component.

The structural rows H, C, P, N transport, replay, source, and name the same packet. Therefore the triangle route exports no quotient completion equality, selected representative, countable-choice schedule, host equality, or ambient Real$^{\uparrow}$ completeness. □

Theorem 9124.4 (CauchyCompletionReflectionUnit finite-window nonescape)**.** *For every accepted* $\mathsf{CauchyCompletionReflectionUnit}^{\uparrow}$ *carrier*

$$U = (X, K, \eta, R, T, S, Q, E, H, C, P, N),$$

every completion-facing consumer that reads the reflection-unit route and reaches the terminal $\mathsf{Real}^{\uparrow}$ *seal factors through*

$$X, K, \eta, R, T, S, Q, E, H, C, P, N.$$

In particular, the finite $\mathsf{StreamName}^{\uparrow}$ *window row* S *and the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row* Q *are visible before* E*, and the route exports no quotient completion equality, selected representatives, countable choice, host equality, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the carrier of Definition 9124.1. The NameCert obligations of Definition 9124.2 identify the displayed rows as the source dense object, completion seal, unit map, reflection handoff, triangle identity, finite window, regular-rational readback, Real seal, transport, replay, provenance, and local naming rows.

The route theorem Definition 9124.3 supplies the prefix $X, K, \eta \longmapsto R \longmapsto T$ for every consumer that reads the reflection-unit triangle. The rows S, Q, E are downstream coordinates of the same carrier, so the finite StreamName window and RegSeqRat readback must be displayed before the terminal Real seal is reached.

Finally H, C, P, N keep the transport, replay, provenance, and local naming attached to this finite packet. Quotient completion equality, selected representatives, countable choice, host equality, and ambient $\mathsf{Real}^{\uparrow}$ completeness are not carrier coordinates, so no such principle can escape through the finite-window route. □

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyCompletionReflectionUnit}^{\uparrow}}$**.**

Constructive story: A $\mathsf{CauchyCompletionReflectionUnit}^{\uparrow}$ packet is generated from a dense source object, a completion seal, a unit map row, a reflection handoff, a triangle identity row, finite StreamName windows, RegSeqRat readback, a Real seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CauchyCompletionReflectionUnit}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 9124.1, Definition 9124.2, Definition 9124.3, and Definition 9124.4 seed the finite reflection-unit surface for Cauchy completion.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CauchyCompletionReflectionUnit}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient completion equality, selected representatives, countable choice, host equality of completed objects, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked dense-source admission, completion-seal admission, unit-map exposure, reflection handoff, triangle identity exposure, finite readback, transport, replay, provenance, and local naming for BEDC.Derived.CauchyCompletionReflectionUnitUp.

Chapter 9125

A Concrete Naming Certificate for $\mathsf{BishopCompletionFunctor}^{\uparrow}$

Following Bishop and Bridges on constructive metric completion, the $\mathsf{BishopCompletionFunctor}^{\uparrow}$ packet records the functorial completion route as finite NameCert data. It sits over the metric completion carrier of chapter 1506, the operator surface of chapter 3379, the uniform-completion handoff of chapter 1473, the finite stream windows of chapter 126, the regular rational readback of chapter 301, the dyadic tolerance core of chapter 291, the complete separated landing object of chapter 2355, and the terminal real-name seal of chapter 38. The packet exports a constructive completion functor surface for downstream $\mathsf{Real}^{\uparrow}$ and completion-facing chapters, while refusing quotient completion equality, selected representatives, selected limits, countable choice, a host completion operator, and ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 9125.1 (Bishop completion functor carrier)**.** *A* $\mathsf{BishopCompletionFunctor}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (M, O, U, S, R, D, Q, E, H, C, P, N)$$

with the following displayed rows:

1. *M is the* $\mathsf{MetricCompletion}^{\uparrow}$ *source row, naming the metric carrier and completion request.*
2. *O is the* $\mathsf{CauchyCompletionOperator}^{\uparrow}$ *row that turns displayed Cauchy data into a completion-facing handoff.*
3. *U is the* $\mathsf{UniformCompletion}^{\uparrow}$ *row carrying the uniform completion request attached to the same metric source.*
4. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window schedule used by the Cauchy names.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *regular-rational readback row.*
6. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger controlling the window and readback rows.*
7. *Q is the* $\mathsf{CompleteSeparatedMetric}^{\uparrow}$ *landing row for the separated completion target.*
8. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row used by Real-facing consumers.*
9. *H records componentwise* hsame *transport for metric completion, operator, uniform completion, stream, regular-rational, dyadic, complete-separated, Real-seal, replay, provenance, and local naming rows.*

10. *C records displayed* Cont *replay from a completion request through*

$$M, O, U, S, R, D, Q, E, H, P, N.$$

11. *P is the* Pkg *provenance over* $\mathsf{BishopCompletionFunctor}^{\uparrow}$, $\mathsf{MetricCompletion}^{\uparrow}$, $\mathsf{CauchyCompletionOperator}^{\uparrow}$, $\mathsf{UniformCompletion}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{CompleteSeparatedMetric}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* NameCert *rows.*

12. *N is the local* $\mathsf{NameCert}_{\mathsf{BishopCompletionFunctor}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $M, O, U, S, R, D, Q, E, H, C, P, N$. It has no coordinate for quotient completion equality, selected representatives, selected limits, countable-choice schedules, a host completion operator, or ambient Real completeness.

Theorem 9125.2 (Bishop completion functor NameCert obligations)**.** *For every accepted* BishopCompletionFunctor *carrier*

$$B = (M, O, U, S, R, D, Q, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{BishopCompletionFunctor}^{\uparrow}}$ *surface consists exactly of metric-completion source exposure through M, Cauchy-completion operator exposure through O, uniform-completion handoff through U, StreamName window exposure through S, RegSeqRat readback through R, DyadicRatCore tolerance exposure through D, complete-separated landing exposure through Q, terminal Real sealing through E, componentwise transport through H, displayed replay through C, provenance through P, and local naming through N.*

Proof. Project the carrier of Definition 9125.1. The rows M, O, U give the completion-facing source, operator, and uniform handoff, while S, R, D give the finite L10 readback route.

The landing rows Q, E are downstream of that finite route. They expose the complete separated metric object and the terminal Real seal only after the StreamName, RegSeqRat, and DyadicRatCore rows have been displayed.

The structural rows H, C, P, N preserve, replay, source, and name the same packet. Since no quotient completion equality, selected representative, selected limit, countable-choice schedule, host completion operator, or ambient Real-completeness coordinate occurs in the carrier, the listed rows exhaust the local NameCert obligation surface. □

Theorem 9125.3 (Bishop completion functor L10 handoff)**.** *Every completion-facing or* $\mathsf{Real}^{\uparrow}$ *consumer of an accepted* $\mathsf{BishopCompletionFunctor}^{\uparrow}$ *packet must factor through the finite route*

$$\mathsf{MetricCompletion}^{\uparrow},\ \mathsf{CauchyCompletionOperator}^{\uparrow},\ \mathsf{UniformCompletion}^{\uparrow} \longmapsto \mathsf{StreamName}^{\uparrow},\ \mathsf{RegSeqRat}^{\uparrow},\ \mathsf{DyadicRatCo}$$

The handoff supplies a constructive completion functor row over displayed Cauchy and regular-name data. It supplies no quotient completion equality, selected representative, selected limit, countable choice, host completion operator, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Apply Definition 9125.2. It places every completion-facing read behind M, O, U and every L10 readback behind S, R, D.

The separated landing row Q and the Real seal row E are reached only after those displayed rows. Therefore a consumer cannot replace the route by a quotient completion class, a selected representative, or a selected limit.

The replay and provenance rows keep the route inside the finite packet. Thus downstream Real and completion-facing chapters consume a displayed Bishop completion functor surface, not a host completion operator or an ambient completeness theorem. □

Falsifiable prediction: Every accepted $\mathsf{BishopCompletionFunctor}^{\uparrow}$ read must display MetricCompletion, CauchyCompletionOperator, UniformCompletion, StreamName, RegSeqRat, DyadicRatCore, CompleteSeparatedMetric, Real, hsame, Cont, Pkg, and NameCert rows before any completion-facing or Real-facing output is available.

Independence witness: metriccompletion, cauchycompletionoperator, uniformcompletion, streamname, regseqrat, dyadicratcore, complete-separated-metric, real: $\mathsf{BishopCompletionFunctor}^{\uparrow}$ is not bijective to any listed sibling because it binds the completion operator, uniform handoff, L10 finite-window route, separated landing row, Real seal, transport, replay, provenance, and local naming as one functorial completion packet.

Closure status for $\mathsf{NameCert}_{\mathsf{BishopCompletionFunctor}^{\uparrow}}$.

Constructive story: A $\mathsf{BishopCompletionFunctor}^{\uparrow}$ packet is generated from MetricCompletion, CauchyCompletionOperator, UniformCompletion, StreamName, RegSeqRat, DyadicRatCore, CompleteSeparatedMetric, Real, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert rows.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BishopCompletionFunctor}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 9125.1, Definition 9125.2, and Definition 9125.3 seed the constructive completion functor route over the L10 Cauchy, StreamName, RegSeqRat, DyadicRatCore, CompleteSeparatedMetric, and Real spine.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BishopCompletionFunctor}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient completion equality, selected representatives, selected limits, countable choice, host completion operators, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, completion operator exposure, uniform handoff, finite-window readback, separated landing, Real sealing, transport, replay, provenance, and local naming for BEDC.Derived.BishopCompletionFu

Chapter 9126

A Concrete Naming Certificate for $\mathsf{CompactModulusPartitionLadder}^{\uparrow}$

Following Bishop and Bridges on compact metric uniform continuity, the $\mathsf{CompactModulusPartitionLadder}^{\uparrow}$ packet realizes the finite partition-refinement route described in chapter 9237. It sits over the compact source of chapter 60, the metric carrier of chapter 57, the continuous-map pointwise rows of chapter 130, the rational tolerance rows of chapter 37, the $\mathsf{ProbeBundle}^{\uparrow}$ finite partition spine, and the uniform-modulus handoff of chapter 369. The packet names a finite ladder from compact nets and pointwise moduli to uniform-modulus selection; it does not import open-cover compactness, a selected Lebesgue number, countable choice, quotient point equality, or an external modulus oracle.

Definition 9126.1 (Compact modulus partition ladder carrier)**.** *A* $\mathsf{CompactModulusPartitionLadder}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (K, M, F, R, B, A, U, H, C, P, N)$$

with the following displayed rows:

1. *K is the* $\mathsf{Compact}^{\uparrow}$ *source row exposing the compact finite-net or finite-cover data.*
2. *M is the* $\mathsf{Met}^{\uparrow}$ *distance row used by the partition comparisons.*
3. *F is the* $\mathsf{ContinuousMap}^{\uparrow}$ *pointwise-modulus row attached to the compact source.*
4. *R is the* $\mathsf{Rat}^{\uparrow}$ *tolerance ledger for positive local radii, lower-bound comparisons, and refinement thresholds.*
5. *B is the* $\mathsf{ProbeBundle}^{\uparrow}$ *partition spine listing the finite probes and membership rows.*
6. *A is the ladder row, recording refinement steps from coarse probes to the subpartition carrying the local modulus selected at each probe.*
7. *U is the* $\mathsf{UniformModulus}^{\uparrow}$ *handoff row produced after the finite ladder has been folded.*
8. *H records componentwise* hsame *transport for compact, metric, continuous-map, rational, probe-bundle, ladder, uniform-modulus, replay, provenance, and local naming rows.*
9. *C records displayed* Cont *replay from a tolerance request through*

$$K, M, F, R, B, A, U, H, P, N.$$

10. *P is the* Pkg *provenance over* $\mathsf{CompactModulusPartitionLadder}^{\uparrow}$, $\mathsf{Compact}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{Rat}^{\uparrow}$, $\mathsf{ProbeBundle}^{\uparrow}$, $\mathsf{UniformModulus}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* NameCert *rows.*

11. *N is the local* $\mathsf{NameCert}_{\mathsf{CompactModulusPartitionLadder}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $K, M, F, R, B, A, U, H, C, P, N$. It has no coordinate for open-cover compactness, a selected Lebesgue number, an infinite refinement tree, countable choice, quotient point equality, or an external uniform-modulus selector.

Theorem 9126.2 (Compact modulus partition ladder NameCert obligations)**.** *For every accepted* $\mathsf{CompactModulusPartitionLadder}^{\uparrow}$ *carrier*

$$L = (K, M, F, R, B, A, U, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{CompactModulusPartitionLadder}^{\uparrow}}$ *surface consists exactly of compact source exposure through K, metric distance exposure through M, continuous-map pointwise-modulus exposure through F, rational tolerance exposure through R, finite* $\mathsf{ProbeBundle}^{\uparrow}$ *partition exposure through B, partition-refinement ladder exposure through A, uniform-modulus handoff through U, componentwise transport through H, displayed replay through C, provenance through P, and local naming through N.*

Proof. Project the carrier of Definition 9126.1. The compact, metric, continuous-map, rational, probe-bundle, ladder, uniform-modulus, transport, replay, provenance, and naming rows are exactly the displayed coordinates.

The compact and metric rows provide the finite partition context. The continuous-map and rational rows attach local moduli and positive tolerance comparisons to each finite probe.

The $\mathsf{ProbeBundle}^{\uparrow}$ row and ladder row record the finite refinement route before the uniform-modulus handoff is available. Transport, replay, provenance, and local naming preserve that same finite route.

No carrier coordinate names open-cover compactness, a selected Lebesgue number, an infinite refinement tree, countable choice, quotient point equality, or an external selector, so none of those objects is part of the local NameCert obligation surface. □

Theorem 9126.3 (Compact modulus partition ladder handoff)**.** *Every compact-uniform-continuity consumer that reads a* $\mathsf{CompactModulusPartitionLadder}^{\uparrow}$ *packet must factor its uniform-modulus request through the finite route*

$$\mathsf{Compact}^{\uparrow},\ \mathsf{Met}^{\uparrow},\ \mathsf{ContinuousMap}^{\uparrow},\ \mathsf{Rat}^{\uparrow},\ \mathsf{ProbeBundle}^{\uparrow} \longmapsto A \longmapsto \mathsf{UniformModulus}^{\uparrow} \longmapsto H, C, P, N.$$

The ladder supplies finite partition-refinement data from compact nets and pointwise moduli to a uniform-modulus handoff. It supplies no open-cover compactness theorem, selected Lebesgue number, infinite refinement tree, countable choice, quotient point equality, or external modulus selector.

Proof. Apply Definition 9126.2. It places compact, metric, continuous-map, rational, and finite ProbeBundle rows before the ladder row A.

The ladder row records the finite refinement steps that feed the uniform-modulus handoff U. Because U is downstream of A, the consumer receives a tolerance-only result only after the finite partition route has been displayed.

The structural rows H, C, P, N transport, replay, source, and name the same route. Since the excluded host objects are absent from the carrier, they cannot be exported by the handoff. □

Falsifiable prediction: Every accepted $\mathsf{CompactModulusPartitionLadder}^{\uparrow}$ read displays Compact, Metric, ContinuousMap, Rat, ProbeBundle, partition ladder, UniformModulus, hsame, Cont, Pkg, and NameCert rows before any uniform-modulus handoff is accepted.

Independence witness: compact, metric, continuousmap, rat, probebundle, uniformmodulus: $\mathsf{CompactModulusPartitionLadder}^{\uparrow}$ is not bijective to any listed sibling because it binds finite compact partitions, metric distance comparisons, pointwise continuous-map moduli, rational tolerance ledgers, ProbeBundle membership, partition refinement, uniform-modulus handoff, transport, replay, provenance, and local naming as one ladder packet.

Closure status for $\mathsf{NameCert}_{\mathsf{CompactModulusPartitionLadder}^{\uparrow}}$.

Constructive story: A $\mathsf{CompactModulusPartitionLadder}^{\uparrow}$ packet is generated from Compact, Metric, ContinuousMap, Rat, ProbeBundle, partition-refinement ladder, UniformModulus, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert rows.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CompactModulusPartitionLadder}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 9126.1, Definition 9126.2, and Definition 9126.3 seed the finite partition ladder from compact nets and pointwise moduli to uniform-modulus handoff rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CompactModulusPartitionLadder}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close open-cover compactness, selected Lebesgue numbers, infinite refinement trees, countable choice, quotient point equality, external modulus selectors, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, compact-source exposure, metric-distance exposure, pointwise ContinuousMap exposure, rational tolerance exactness, ProbeBundle partition coverage, refinement ladder stability, UniformModulus handoff, transport, replay, provenance, and local naming for BEDC.Derived.CompactModulusPartitionLadderUp.

Chapter 9127

A Concrete Naming Certificate for $\mathsf{CauchyKovalevskaya}^{\uparrow}$

Following Cauchy and Kovalevskaya on analytic initial-value problems, the $\mathsf{CauchyKovalevskaya}^{\uparrow}$ packet records the finite analytic-jet surface by which a displayed PDE coefficient ledger, initial hypersurface jet, derivative ledger, stream schedule, rational coefficient readback, dyadic coefficient core, and real seal are named before any local solution claim is public. It sits next to the PDE carrier of chapter 194, the derivative rows of chapter 122, the continuous-map boundary of chapter 130, the stream interface of chapter 126, the regular rational readback of chapter 301, the dyadic coefficient core of chapter 291, and the real-name seal of chapter 38. The packet names finite analytic data for a constructive CK read; it is not analytic continuation, a selected solution germ, quotient equality of functions, countable choice over coefficients, or ambient real-completeness closure.

Definition 9127.1 (Cauchy–Kovalevskaya carrier)**.** *A* $\mathsf{CauchyKovalevskaya}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (P, D, C, I, J, S, Q, Y, R, H, T, G, N)$$

with the following displayed rows:

1. *P is the* $\mathsf{Pde}^{\uparrow}$ *row naming the inspected analytic PDE operator and the distinguished evolution variable.*
2. *D is the* $\mathsf{Derivative}^{\uparrow}$ *ledger for the partial derivative rows requested by the operator.*
3. *C is the* $\mathsf{ContinuousMap}^{\uparrow}$ *coefficient-boundary row for the displayed analytic coefficient maps.*
4. *I is the initial hypersurface row, including the finite analytic initial data read by the packet.*
5. *J is the finite jet recursion row, recording the coefficient-by-coefficient recursion available from P, D, C, I.*
6. *S is the* $\mathsf{StreamName}^{\uparrow}$ *row scheduling the inspected coefficient windows and finite jet depths.*
7. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for rational coefficient bounds and convergence radii visible at those windows.*
8. *Y is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *row storing the dyadic coefficient ledger used by the rational readback.*
9. *R is the* $\mathsf{Real}^{\uparrow}$ *seal for the displayed real coefficient and radius reads.*
10. *H records componentwise* hsame *transport for PDE, derivative, continuous-map, initial-data, jet, stream, rational, dyadic, real, replay, provenance, and local-name rows.*

11. *T records displayed* Cont *replay from a finite analytic-jet request through $P, D, C, I, J, S, Q, Y, R$.*
12. *G is the* Pkg *provenance over* $\mathsf{CauchyKovalevskaya}^{\uparrow}$, $\mathsf{Pde}^{\uparrow}$, $\mathsf{Derivative}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* NameCert.
13. *N is the local* $\mathsf{NameCert}_{\mathsf{CauchyKovalevskaya}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $P, D, C, I, J, S, Q, Y, R, H, T, G, N$. It has no coordinate for a host analytic solution, analytic continuation past the displayed radius, selected germ, quotient equality of functions, countable coefficient choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 (definition) `BEDC.Derived.CauchyKovalevskayaUp.CauchyKovalevskayaCarrier`

Theorem 9127.2 (Cauchy–Kovalevskaya NameCert obligations)**.** *For every accepted* $\mathsf{CauchyKovalevskaya}^{\uparrow}$ *carrier $K = (P, D, C, I, J, S, Q, Y, R, H, T, G, N)$, the local* $\mathsf{NameCert}_{\mathsf{CauchyKovalevskaya}^{\uparrow}}$ *surface consists exactly of carrier admission for the PDE row, derivative ledger, continuous coefficient boundary, initial hypersurface data, finite jet recursion, stream schedule, regular rational readback, dyadic coefficient ledger, real seal, componentwise transport, displayed replay, provenance, and local naming. No obligation may replace those rows by an unlogged analytic solution, analytic continuation principle, selected germ, quotient equality of functions, countable-choice coefficient stream, or ambient real-completeness theorem.*

Proof. Project the carrier of Definition 9127.1. The analytic rows are $P, D, C, I, J, S, Q, Y, R$, and the structural rows are H, T, G, N.

The PDE row, derivative ledger, coefficient boundary, and initial hypersurface data are read before the jet recursion. Thus the row J records only the finite coefficient recursion determined by displayed inputs.

The coefficient windows are finite. The stream row S fixes the inspected depths, the regular rational row Q records the rational bounds, the dyadic row Y stores the coefficient ledger, and the real row R seals only those displayed reads.

Finally H, T, G, N transport, replay, source, and name the same packet. Since the carrier has no solution-germ, analytic-continuation, quotient-function, choice-stream, or ambient-completeness coordinate, the listed rows exhaust the NameCert obligations. □

Theorem 9127.3 (Cauchy–Kovalevskaya analytic-jet scope)**.** *Every constructive CK consumer of an accepted* $\mathsf{CauchyKovalevskaya}^{\uparrow}$ *carrier must read the finite route*

$\mathsf{Pde}^{\uparrow}$, $\mathsf{Derivative}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, Pkg,

The route exposes the displayed PDE operator, partial-derivative ledger, analytic coefficient boundary, initial hypersurface data, finite jet recursion, stream window, rational coefficient readback, dyadic coefficient ledger, real seal, transport, replay, provenance, and local naming before any analytic-jet read is public. It exports no global solution theorem, uniqueness theorem, analytic continuation theorem, quotient equality of functions, or selected solution germ.

Proof. Start with a CK read request. It first opens the PDE row P, the derivative ledger D, the continuous coefficient row C, and the initial data row I.

Only then can the consumer inspect J. That row is a finite jet recursion over the displayed rows, so it cannot supply a host solution or a global existence theorem.

Next read the stream, rational, dyadic, and real rows S, Q, Y, R. These rows bind coefficient depth, rational bounds, dyadic ledgers, and real seals to the same finite analytic window.

The structural rows H, T, G, N preserve that order by componentwise transport, displayed replay, provenance, and local naming. Hence the public scope is the analytic-jet NameCert surface and not analytic continuation or solution selection. □

Theorem 9127.4 (Cauchy–Kovalevskaya finite coefficient ledger)**.** *The coefficient ledger of an accepted* $\mathsf{CauchyKovalevskaya}^{\uparrow}$ *packet is finite at every public read: each requested jet depth is scheduled by S, bounded through Q, stored through Y, and sealed through R before the local* $\mathsf{NameCert}$ *row is consumed. A downstream PDE consumer cannot bypass this ledger by appealing to an infinite formal power series, a selected analytic germ, quotient equality of coefficient streams, countable choice, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Read the stream schedule S. It names the finite coefficient windows and jet depths available to the public request.

Use Q and Y next. The regular rational row records the visible coefficient bounds, while the dyadic core row stores the displayed coefficient ledger for the same windows.

The real seal R is downstream of those finite rows. It seals the displayed coefficient and radius reads only after the rational and dyadic ledgers are present.

Therefore the local naming row N can certify only the finite coefficient ledger transported and replayed by H, T, G. It cannot certify an unbounded series, a selected germ, quotient equality, countable choice, or ambient completeness. □

Falsifiable prediction: An accepted $\mathsf{CauchyKovalevskaya}^{\uparrow}$ packet that exports a CK analytic-jet read while omitting the PDE row, derivative ledger, coefficient boundary, finite jet recursion, stream schedule, rational readback, dyadic ledger, real seal, transport, replay, provenance, or local NameCert row refutes the carrier.

Independence witness: pde, derivative, continuousmap, streamname, regseqrat, dyadicratcore, real: $\mathsf{CauchyKovalevskaya}^{\uparrow}$ is not bijective to any listed sibling because it binds PDE operator data, derivative rows, analytic coefficient boundaries, initial hypersurface data, finite jet recursion, scheduled coefficient windows, rational and dyadic coefficient ledgers, real seals, transport, replay, provenance, and local naming in one carrier.

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyKovalevskaya}^{\uparrow}}$**.**

Constructive story: A $\mathsf{CauchyKovalevskaya}^{\uparrow}$ packet is generated from a PDE row, derivative ledger, continuous coefficient boundary, initial hypersurface row, finite jet recursion, StreamName schedule, RegSeqRat readback, DyadicRatCore coefficient ledger, RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CauchyKovalevskaya}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 9127.1, Definition 9127.2, Definition 9127.3, and Definition 9127.4 seed the finite analytic-jet NameCert surface for constructive PDE consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CauchyKovalevskaya}^{\uparrow}}, \mathsf{encodedDef})$

Bridge status: none

Not claimed: This chapter does not close analytic continuation, global existence, uniqueness of analytic solutions, quotient equality of functions, selected solution germs, countable choice over coefficients, RealUp completeness, theorem-level Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, PDE-row exposure, derivative-ledger exactness, coefficient-boundary visibility, jet-recursion exactness, finite coefficient ledger, Real-seal boundary, transport, replay, provenance, and local naming for BEDC.Derived.CauchyKovalevskayaUp.

Chapter 9128

A Concrete Naming Certificate for $\mathsf{RegularCauchyBoundedness}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{RegularCauchyBoundedness}^{\uparrow}$ packet records the finite boundedness information that a regular Cauchy rational name must expose before a $\mathsf{Real}^{\uparrow}$ consumer may read the terminal seal. The packet sits over the stream window of chapter 126, the regular rational readback of chapter 301, the dyadic tolerance ledger of chapter 291, the modulus threshold surface of chapter 292, the real-name seal of chapter 38, and the map-facing consumer of chapter 1401. It names boundedness as displayed finite induction data, not as a supremum, selected limit, quotient stream, or ambient completeness theorem.

9128.1 Regular Cauchy boundedness carrier

Definition 9128.1 (Regular Cauchy boundedness carrier)**.** *A* $\mathsf{RegularCauchyBoundedness}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (S, R, D, M, I, E, H, C, P, N)$$

with the following displayed rows:

1. *S is the* $\mathsf{StreamName}^{\uparrow}$ *observation window naming the inspected rational values and the finite prefix whose maximum is used by the bound;*
2. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *regular readback row, exposing the regular Cauchy inequality used after the prefix window;*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger for the dyadic budgets and rational comparisons appearing in the prefix and tail estimates;*
4. *M is the* $\mathsf{CauchyModulus}^{\uparrow}$ *threshold row telling which depth places every later value within the displayed dyadic tolerance of the chosen prefix value;*
5. *I is the finite induction budget row, recording the prefix-length induction and the displayed bound assembled from the prefix maximum and the tail tolerance ledger;*
6. *E is the* $\mathsf{Real}^{\uparrow}$ *seal handoff row reached only after S, R, D, M, I have been read;*
7. *H stores componentwise* hsame *transport for the stream window, regular readback, dyadic ledger, modulus threshold, induction budget, seal, replay, provenance, and local naming rows;*

8. *C stores displayed* Cont *replay from a boundedness request through the stream window, regular readback, dyadic ledger, modulus threshold, induction budget, and real seal;*
9. *P is the* Pkg *provenance over* $\mathsf{RegularCauchyBoundedness}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{CauchyModulus}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{CauchyContinuousMap}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert*;*
10. *N is the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyBoundedness}^{\uparrow}}$ *row.*

The carrier exports no host supremum, no quotient stream equality, no selected Cauchy limit, no global real completeness principle, and no hidden bound beyond the displayed finite induction budget.

Theorem 9128.2 (Regular Cauchy boundedness NameCert obligations)**.** *For every accepted* $\mathsf{RegularCauchyBoundedness}^{\uparrow}$ *carrier* $B = (S, R, D, M, I, E, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyBoundedness}^{\uparrow}}$ *surface consists exactly of carrier admission for these ten rows, stream-window exposure through S, regular readback through R, dyadic tolerance exactness through D, threshold exposure through M, finite induction-budget exactness through I, real-seal routing through E, componentwise* hsame *transport through H, displayed* Cont *replay through C, provenance through P, and local naming through N.*

Proof. Project the carrier of Definition 9128.1. The rows S, R, D, M, I are the whole boundedness surface: the prefix is visible in S, the tail comparison is visible in R, dyadic arithmetic is visible in D, the threshold is visible in M, and the finite induction budget is visible in I.

The remaining rows do not add analytic content. The seal E receives the displayed route, while H, C, P, N transport, replay, source, and name the same packet.

Since no coordinate stores a supremum, quotient stream equality, selected limit, or ambient completeness theorem, the stated rows exhaust the local NameCert obligations. □

Theorem 9128.3 (Regular Cauchy boundedness finite induction bound)**.** *Every accepted* RegularCauchyBoundedne *carrier* $B = (S, R, D, M, I, E, H, C, P, N)$ *exposes a boundedness witness by the finite route*

$$S, R, D, M \longmapsto I.$$

The induction budget I first compares the finitely many values in the $\mathsf{StreamName}^{\uparrow}$ *prefix named by S, then uses the* $\mathsf{CauchyModulus}^{\uparrow}$ *threshold M and the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback R with the* $\mathsf{DyadicRatCore}^{\uparrow}$ *ledger D to cover every later displayed value. Thus the bound is a finite induction certificate, not a selected supremum, quotient-stream representative, host limit, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness claim.*

Proof. Read the prefix window in S. The finitely many inspected values admit an induction over the displayed prefix length, and the budget row I records the resulting prefix bound.

Next read the tail route. The modulus threshold M tells where the regular Cauchy comparison begins, R supplies the regular rational readback after that depth, and D supplies the dyadic tolerance arithmetic used to compare later values with the prefix witness.

Combine the prefix induction with the tail comparison in I. Because each step names only rows already present in B, the exported bound is the displayed finite induction certificate and not an off-packet supremum or completeness argument. □

Theorem 9128.4 (Regular Cauchy boundedness Real handoff)**.** *Every* $\mathsf{Real}^{\uparrow}$ *or* $\mathsf{CauchyContinuousMap}^{\uparrow}$ *consumer of an accepted* $\mathsf{RegularCauchyBoundedness}^{\uparrow}$ *packet must read the route*

$$S, R, D, M, I, E, H, C, P, N$$

before using the bounded regular Cauchy name. The handoff exposes the stream window, regular readback, dyadic tolerance ledger, modulus threshold, finite induction budget, real seal, transport, replay, provenance, and local naming rows, and it refuses host functions, quotient streams, selected limits, detached suprema, and ambient real completeness.

Proof. Begin with the NameCert obligations of Definition 9128.2. They require the stream, regular readback, dyadic, threshold, and induction rows to be present before the seal row can be consumed.

Use the finite induction bound of Definition 9128.3. It identifies the boundedness witness as the displayed S, R, D, M, I route, so a Real-facing or Cauchy-continuous-map-facing consumer has no separate bound to inspect.

Finally pass through E, H, C, P, N. These rows seal, transport, replay, source, and name the same finite route. Since the carrier has no coordinate for host functions, quotient streams, selected limits, detached suprema, or completeness, the consumer receives only the displayed boundedness certificate. □

Closure status for $\mathsf{NameCert}_{\mathsf{RegularCauchyBoundedness}\uparrow}$.

Constructive story: A $\mathsf{RegularCauchyBoundedness}^{\uparrow}$ packet is generated from a StreamName window, RegSeqRat regular readback, DyadicRatCore tolerance ledger, CauchyModulus threshold row, finite induction budget, RealUp seal handoff, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RegularCauchyBoundedness}\uparrow}, \mathsf{obligation})$

Scope closed: Definition 9128.1, Definition 9128.2, Definition 9128.3, and Definition 9128.4 bind the finite boundedness route from regular Cauchy rational names to the RealUp and CauchyContinuousMap consumer surface.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RegularCauchyBoundedness}\uparrow}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim host suprema, quotient stream equality, selected Cauchy limits, ambient RealUp completeness, Lean verification, or bridge checking.

Upgrade path: Scoped closure requires checked carrier admission, classifier stability, consumer coverage for the boundedness handoff, and Lean verification for BEDC.Derived.RegularCauchyBoundednessUp.

Chapter 9129

A Concrete Naming Certificate for $\mathsf{CompletionReflector}^{\uparrow}$

Following Bourbaki and Mac Lane, the $\mathsf{CompletionReflector}^{\uparrow}$ packet records the reflector surface by which a displayed source carrier is routed to a completed carrier through unit, extension, universal comparison, separatedness, transport, replay, provenance, and NameCert rows. It abstracts the metric route of chapter 2149, the regular Cauchy route of chapter 3398, and the uniform route of chapter 6282 into one L10 boundary. The packet names only finite BEDC data; it does not import quotient completion equality, a selected limit, ambient completeness, or an external reflector theorem.

Definition 9129.1 (Completion-reflector carrier)**.** *A* $\mathsf{CompletionReflector}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$R = (S, T, U, E, Q, A, H, C, P, N)$$

with the following displayed rows:

1. *S is the source-carrier row, recording the object whose completion request is visible to downstream consumers.*
2. *T is the completed-carrier row, recording the displayed completion target without identifying it with any host quotient.*
3. *U is the unit row from the source carrier into the completed carrier.*
4. *E is the extension row, recording how an accepted compatible map is replayed across the completed target.*
5. *Q is the universal-comparison row, exposing the reflector comparison as finite request-and-response data.*
6. *A is the separatedness row, recording the boundary at which the completed target may be read by separated or Real-facing consumers.*
7. *H records componentwise* hsame *transport for source, completed target, unit, extension, universal comparison, separatedness, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from a completion-reflector request through*

$$S, T, U, E, Q, A, H, P, N.$$

9. *P is the* Pkg *provenance over* $\mathsf{CompletionReflector}^{\uparrow}$*, the cited completion-reflector siblings,* BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *rows.*
10. *N is the local* $\mathsf{NameCert}_{\mathsf{CompletionReflector}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $S, T, U, E, Q, A, H, C, P, N$. It has no coordinate for quotient equality of completions, selected Cauchy representatives, chosen limits, ambient completeness, or host-level reflector equality.

Theorem 9129.2 (Completion-reflector NameCert obligations)**.** *For every accepted* $\mathsf{CompletionReflector}^{\uparrow}$ *carrier*

$$R = (S, T, U, E, Q, A, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{CompletionReflector}^{\uparrow}}$ *surface consists exactly of source-carrier exposure through S, completed-carrier exposure through T, unit exposure through U, extension replay through E, universal comparison through Q, separatedness through A, componentwise transport through H, displayed continuation through C, provenance through P, and local naming through N.*

Proof. Project the carrier of Definition 9129.1. The displayed tuple lists the source, completed target, unit, extension, universal comparison, separatedness, transport, replay, provenance, and naming rows, so every public read of the packet first exposes those finite coordinates.

The unit row U and extension row E give the constructive arrow data. The comparison row Q is downstream of those rows, and the separatedness row A records the boundary required by separated or Real-facing reflector consumers.

The structural rows H, C, P, N preserve the same route under hsame, replay it through Cont, source it through Pkg, and name it by NameCert. Since no quotient equality, selected representative, selected limit, ambient completeness theorem, or host reflector equality appears as a coordinate, no such object belongs to the local obligation surface. □

Theorem 9129.3 (Completion-reflector L10 route)**.** *Every metric, regular Cauchy, uniform, separated, or Real-facing consumer of an accepted* $\mathsf{CompletionReflector}^{\uparrow}$ *packet must factor its reflector read through the finite route*

$$S \longmapsto U \longmapsto T \longmapsto E \longmapsto Q \longmapsto A \longmapsto H, C, P, N.$$

The route supplies the common L10 reflector surface consumed by completion-reflector specializations. It supplies no quotient completion, selected limit, ambient completeness theorem, or host equality between completed objects.

Proof. Apply Definition 9129.2. It places the source row S, unit row U, completed target row T, extension row E, universal-comparison row Q, and separatedness row A before any structural read is available.

The sibling reflector chapters instantiate this same order with metric, regular Cauchy, or uniform source data. Their consumers may refine the rows, but they still read the common unit, extension, comparison, separatedness, transport, replay, provenance, and local NameCert boundary named here.

Finally, the absence clauses in the carrier prevent a consumer from extracting quotient completion equality, selected representatives, chosen limits, ambient completeness, or host reflector equality from the packet. □

Falsifiable prediction: Every accepted $\mathsf{CompletionReflector}^{\uparrow}$ read displays source, completed-target, unit, extension, universal-comparison, separatedness, hsame, Cont, Pkg, and NameCert rows before any completion-facing output is accepted.

Independence witness: metric-completion-reflector, regular-cauchy-completion-reflector, uniform-completion-reflector: $\mathsf{CompletionReflector}^{\uparrow}$ is not bijective to any listed sibling because it binds the common source-to-completion reflector route across unit, extension, comparison, separatedness, transport, replay, provenance, and local naming rows.

Closure status for $\mathsf{NameCert}_{\mathsf{CompletionReflector}^{\uparrow}}$ **.**

Constructive story: A $\mathsf{CompletionReflector}^{\uparrow}$ packet is generated from source carrier, completed target, unit, extension, universal comparison, separatedness, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert rows.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CompletionReflector}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 9129.1, Definition 9129.2, and Definition 9129.3 seed the common L10 reflector route consumed by metric, regular Cauchy, uniform, separated, and Real-facing completion chapters.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CompletionReflector}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient completion equality, selected representatives, selected limits, ambient completeness, host reflector equality, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, source and completed-target exposure, unit exactness, extension replay, universal comparison, separatedness, transport, replay, provenance, and local naming for BEDC.Derived.CompletionReflectorUp.

Chapter 9130

A Concrete Naming Certificate for $\mathsf{FinitePrefixBarModulusWindow}^{\uparrow}$

Following Brouwer and Bishop on bars and compact uniform continuity, the $\mathsf{FinitePrefixBarModulusWindow}^{\uparrow}$ packet realizes the finite prefix branch of chapter 9237. It sits after the finite prefix bar carrier of chapter 7071, the compact source of chapter 60, and the tolerance-only uniform-modulus handoff of chapter 369. The packet records a finite route from prefix-depth evidence to a modulus window; it does not choose an infinite branch, import open-cover compactness, or assert an ambient Heine–Cantor theorem.

Definition 9130.1 (Finite prefix bar-modulus window carrier)**.** *A* $\mathsf{FinitePrefixBarModulusWindow}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$W = (B, K, T, D, U, H, C, P, N)$$

with the following displayed rows:

1. *B is the finite prefix bar row, recording the accepted bar prefixes and their prefix-order boundary.*
2. *K is the compact-source row, exposing the compact data consumed by the finite prefix argument.*
3. *T is the tolerance-request row, recording the requested output precision as visible finite data.*
4. *D is the prefix-depth modulus row, assigning the finite depth at which every accepted prefix supplies the requested tolerance.*
5. *U is the uniform-modulus handoff row consumed by* $\mathsf{UniformModulus}^{\uparrow}$ *readers.*
6. *H records componentwise* hsame *transport for bar, compact-source, tolerance, depth-modulus, uniform-modulus, replay, provenance, and local naming rows.*
7. *C records displayed* Cont *replay from a tolerance request through*

$$B, K, T, D, U, H, P, N.$$

8. *P is the* Pkg *provenance over* $\mathsf{FinitePrefixBarModulusWindow}^{\uparrow}$, $\mathsf{FinitePrefixBar}^{\uparrow}$, $\mathsf{Compact}^{\uparrow}$, $\mathsf{UniformModulus}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* $\mathsf{NameCert}$ *rows.*
9. *N is the local* $\mathsf{NameCert}_{\mathsf{FinitePrefixBarModulusWindow}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $B, K, T, D, U, H, C, P, N$. It has no coordinate for an infinite branch selector, open-cover compactness, countable choice, quotient stream equality, or an external uniform-modulus oracle.

Theorem 9130.2 (Finite prefix bar-modulus window NameCert obligations)**.** *For every accepted* $\mathsf{FinitePrefixBarModulusWindow}^{\uparrow}$ *carrier*

$$W = (B, K, T, D, U, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{FinitePrefixBarModulusWindow}^{\uparrow}}$ *surface consists exactly of finite prefix bar exposure through* B*, compact-source exposure through* K*, tolerance request exposure through* T*, prefix-depth modulus exposure through* D*, uniform-modulus handoff through* U*, componentwise transport through* H*, displayed continuation through* C*, provenance through* P*, and local naming through* N*.*

Proof. Project the carrier of Definition 9130.1. The rows $B, K, T, D, U, H, C, P, N$ are exactly the accepted packet coordinates.

The finite prefix bar row B and compact-source row K provide the source data. The tolerance request T is then routed to the prefix-depth modulus row D, which is the only place where a finite depth is exposed.

The uniform-modulus handoff U is downstream of D. Transport, replay, provenance, and local naming preserve the same finite route, and the absent infinite-branch, open-cover, countable-choice, quotient-stream, and external-oracle objects cannot be exported by the local certificate. □

Theorem 9130.3 (Finite prefix bar-modulus handoff)**.** *Every compact-uniform-continuity consumer that reads a* $\mathsf{FinitePrefixBarModulusWindow}^{\uparrow}$ *packet must factor its tolerance-only request through the finite route*

$$\mathsf{FinitePrefixBar}^{\uparrow},\ \mathsf{Compact}^{\uparrow},\ T \longmapsto D \longmapsto \mathsf{UniformModulus}^{\uparrow} \longmapsto H, C, P, N.$$

Thus the handoff from finite prefix depth to uniform-modulus output is a displayed BEDC route, not an informal compactness-to-modulus jump.

Proof. Apply Definition 9130.2. It places the finite prefix bar, compact-source, and tolerance rows before the depth-modulus row D.

The row D supplies the finite prefix depth consumed by the uniform-modulus handoff U. A downstream consumer therefore receives a tolerance-only handoff only after the prefix-depth row has been displayed.

Finally H, C, P, N transport, replay, source, and name the same finite route. Since the carrier has no infinite branch selector, open-cover compactness theorem, quotient stream equality, countable choice, or external modulus oracle, none of those objects can mediate the handoff. □

Falsifiable prediction: Every accepted $\mathsf{FinitePrefixBarModulusWindow}^{\uparrow}$ read displays FinitePrefixBar, compact-source, tolerance, prefix-depth modulus, UniformModulus, hsame, Cont, Pkg, and NameCert rows before any tolerance-only uniform-modulus handoff is accepted.

Independence witness: finite-prefix-bar, compact, uniformmodulus: $\mathsf{FinitePrefixBarModulusWindow}^{\uparrow}$ is not bijective to any listed sibling because it jointly binds finite prefix bars, compact-source rows, tolerance requests, prefix-depth modulus rows, uniform-modulus handoff, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{FinitePrefixBarModulusWindow}^{\uparrow}}$**.**

Constructive story: A $\mathsf{FinitePrefixBarModulusWindow}^{\uparrow}$ packet is generated from finite prefix bar, compact-source, tolerance-request, prefix-depth modulus, UniformModulus, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert rows.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{FinitePrefixBarModulusWindow}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 9130.1, Definition 9130.2, and Definition 9130.3 seed the compact-uniform-continuity route from finite prefix depth to tolerance-only uniform-modulus handoff rows.

Formal verification: FormalStatus(NameCert$_{\text{FinitePrefixBarModulusWindow}\uparrow}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close infinite branch selection, open-cover compactness, countable choice, quotient stream equality, external modulus oracles, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, finite-prefix bar exposure, compact-source exposure, tolerance request exactness, prefix-depth modulus stability, UniformModulus handoff, transport, replay, provenance, and local naming for BEDC.Derived.FinitePrefixBarModulusWindowUp.

Chapter 9131

A Concrete Naming Certificate for $\mathsf{CauchyCompletionStabilizer}^{\uparrow}$

Following Bishop and Bridges and Kelley on completion and uniform stabilization, the $\mathsf{CauchyCompletionStabilizer}^{\uparrow}$ packet records the finite route by which repeated completion reads are stabilized before a Real-facing consumer inspects the same regular name. It sits over the idempotence route of **??**, the functorial route of chapter 423, the finite window source of chapter 126, the dyadic tolerance core of chapter 291, the regular rational readback of chapter 301, and the terminal real-name seal of chapter 38. The chapter names a repeated-read stabilizer only; it does not assert quotient completion, selected limits, countable choice, host equality of completed objects, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 9131.1 (CauchyCompletionStabilizer carrier)**.** *A* $\mathsf{CauchyCompletionStabilizer}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (C, I, F, W, D, R, E, H, T, P, N)$$

with the following displayed rows:

1. *C is the source completion row, recording the first completion-facing read before any repeated-read stabilization is available.*
2. *I is the* $\mathsf{CauchyCompletionIdempotence}^{\uparrow}$ *row, exposing the finite idempotence comparison between the first completion read and the repeated completion read.*
3. *F is the* $\mathsf{CauchyCompletionFunctor}^{\uparrow}$ *row, carrying the functorial route that transports the same displayed completion request.*
4. *W is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row used to inspect the repeated read.*
5. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row controlling the finite window and comparison budget.*
6. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row obtained from the same window and dyadic tolerance rows.*
7. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row, available only after C, I, F, W, D, R have been displayed.*
8. *H records componentwise* hsame *transport for source completion, idempotence comparison, functorial route, finite window, dyadic tolerance, regular readback, Real seal, replay, provenance, and local naming rows.*
9. *T records displayed* Cont *replay of the route*

$$C \longmapsto I, F \longmapsto W, D, R \longmapsto E.$$

10. *P is the* Pkg *provenance over* $\mathsf{CauchyCompletionStabilizer}^{\uparrow}$, $\mathsf{CauchyCompletionIdempotence}^{\uparrow}$, $\mathsf{CauchyCompletionFu}$ $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

11. *N is the local* $\mathsf{NameCert}_{\mathsf{CauchyCompletionStabilizer}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $C, I, F, W, D, R, E, H, T, P, N$. It has no coordinate for quotient completion equality, selected limits, countable choice, host equality between completed objects, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 9131.2 (CauchyCompletionStabilizer NameCert obligations)**.** *For every accepted* $\mathsf{CauchyCompletionStab}$ *carrier*

$$S = (C, I, F, W, D, R, E, H, T, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{CauchyCompletionStabilizer}^{\uparrow}}$ *surface consists exactly of source completion exposure through C, repeated-read stabilization through I, functorial completion transport through F, finite StreamName window exposure through W, DyadicRatCore tolerance exposure through D, RegSeqRat readback through R, Real sealing through E, componentwise transport through H, displayed replay through T, provenance through P, and local naming through N.*

Proof. Project the carrier of Definition 9131.1. The displayed rows are the source completion, idempotence, functorial route, finite window, dyadic tolerance, regular readback, Real seal, transport, replay, provenance, and local naming rows.

The completion rows are read first. Row C supplies the source completion read, row I compares it with the repeated read, and row F keeps the comparison inside the functorial completion route.

The analytic rows remain downstream of that route. The finite window W, dyadic tolerance D, regular readback R, and terminal seal E are part of the same packet, so a consumer cannot detach a selected limit or a quotient completion object from the repeated-read comparison.

Finally H, T, P, N preserve, replay, source, and name the same carrier. Since quotient completion, selected limits, countable choice, host equality, and ambient $\mathsf{Real}^{\uparrow}$ completeness are absent from the packet, the listed rows exhaust the local NameCert surface. □

Theorem 9131.3 (CauchyCompletionStabilizer seal route)**.** *Every Real-facing consumer of an accepted* $\mathsf{CauchyCompletionStabilizer}^{\uparrow}$ *packet must factor its repeated completion read through the finite route*

$$\mathsf{CauchyCompletionIdempotence}^{\uparrow},\ \mathsf{CauchyCompletionFunctor}^{\uparrow} \longmapsto \mathsf{StreamName}^{\uparrow},\ \mathsf{DyadicRatCore}^{\uparrow},\ \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{R}$$

The route stabilizes the displayed repeated completion read before the terminal Real seal is consumed. It supplies no quotient completion, selected limit, countable-choice schedule, host equality of completions, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Apply Definition 9131.2. It places the source completion row C before the idempotence and functorial rows I, F.

Next read the finite observation route. The StreamName window W, DyadicRatCore tolerance D, and RegSeqRat readback R are displayed before the Real seal E, so the consumer receives a finite repeated-read packet rather than a chosen completed object.

Finally use the structural rows H, T, P, N. They transport, replay, source, and name the same route, which prevents a Real-facing read from bypassing the stabilizer through quotient equality, a selected limit, countable choice, host completion equality, or ambient completeness. □

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyCompletionStabilizer}^{\uparrow}}$.

Constructive story: A $\mathsf{CauchyCompletionStabilizer}^{\uparrow}$ packet is generated from a source completion row, CauchyCompletionIdempotence comparison, CauchyCompletionFunctor route, StreamName finite windows, DyadicRatCore tolerance, RegSeqRat readback, Real seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CauchyCompletionStabilizer}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 9131.1, Definition 9131.2, and Definition 9131.3 seed the repeated completion-read stabilizer route over the CauchyCompletionIdempotence, CauchyCompletionFunctor, StreamName, DyadicRatCore, RegSeqRat, and Real spine.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CauchyCompletionStabilizer}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient completion, selected limits, countable choice, host equality of completed objects, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked source completion admission, repeated-read stabilization, functorial transport, finite-window readback, Real sealing, transport, replay, provenance, and local naming for BEDC.Derived.CauchyCompletionStabil

Chapter 9132

A Concrete Naming Certificate for $\mathsf{DarbouxGapRefinement}^{\uparrow}$

Following Darboux and Bishop–Bridges constructive analysis, the $\mathsf{DarbouxGapRefinement}^{\uparrow}$ packet records the finite partition refinement surface that turns an upper-minus-lower Darboux gap into a displayed refinement certificate before a Real-facing consumer reads a regular rational window. It sits after the Darboux-sum refinement route of chapter 8838, the tagged or dyadic partition surfaces of chapter 7449 and chapter 1863, the regular rational readback of chapter 301, and the terminal real-name seal of chapter 38. The packet gives Darboux and Riemann-facing consumers a finite gap-refinement certificate without importing selected partition sequences, quotient equality of functions, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 9132.1 (DarbouxGapRefinement carrier)**.** *A* $\mathsf{DarbouxGapRefinement}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$G = (R, L, U, T, D, W, E, H, C, P, N)$$

with the following displayed rows:

1. *R is the* $\mathsf{DarbouxSumRefinement}^{\uparrow}$ *source row, carrying the source partition, refined partition, finite cell-incidence map, and Darboux handoff.*
2. *L is the* $\mathsf{LowerDarbouxSum}^{\uparrow}$ *row on the displayed refined partition.*
3. *U is the* ***??*** *row on the same displayed refined partition.*
4. *T is either the* $\mathsf{TaggedPartition}^{\uparrow}$ *row or the* $\mathsf{DyadicPartition}^{\uparrow}$ *row that supplies the finite refinement cells read by R, L, U.*
5. *D is the finite upper-minus-lower gap row comparing U and L over exactly the displayed cells of T.*
6. *W is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the displayed gap budget.*
7. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal reached only after R, L, U, T, D, W have been displayed.*
8. *H records componentwise* hsame *transport for the refinement, lower row, upper row, partition row, gap row, readback, Real seal, replay, provenance, and local naming rows.*
9. *C records displayed* Cont *replay from Darboux, Riemann, Real, or Completion requests through the same finite packet.*

10. *P is the* Pkg *provenance over* $\mathsf{DarbouxGapRefinement}^{\uparrow}$, $\mathsf{DarbouxSumRefinement}^{\uparrow}$, $\mathsf{DarbouxSum}^{\uparrow}$, $\mathsf{LowerDarbouxSum}^{\uparrow}$, *??*, $\mathsf{TaggedPartition}^{\uparrow}$, $\mathsf{DyadicPartition}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

11. *N is the local* $\mathsf{NameCert}_{\mathsf{DarbouxGapRefinement}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $R, L, U, T, D, W, E, H, C, P, N$. It has no coordinate for a selected sequence of partitions, quotient equality of functions, a host supremum or infimum, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 9132.2 (DarbouxGapRefinement NameCert obligations)**.** *For every accepted* $\mathsf{DarbouxGapRefinement}^{\uparrow}$ *carrier $G = (R, L, U, T, D, W, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{DarbouxGapRefinement}^{\uparrow}}$ *surface consists exactly of carrier admission for the Darboux-sum refinement row, lower and upper Darboux-sum rows, tagged or dyadic partition row, finite gap row, regular rational readback, Real seal, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. Every obligation is read through the same finite partition-gap packet.*

Proof. Carrier admission is projection from Definition 9132.1. The admitted packet displays the Darboux-sum refinement source, the lower and upper rows, the tagged or dyadic partition row, the gap comparison, the regular rational readback, and the Real seal.

The partition-gap obligations are finite. The row T supplies the displayed cells, R supplies the refinement route, and D compares the lower and upper Darboux rows only over those cells.

The readback and seal rows are downstream. The row W turns the displayed gap into a regular rational window, and E is reached only after R, L, U, T, D, W have been opened. The structural rows H, C, P, N transport, replay, source, and name exactly the same packet, so the listed rows exhaust the local NameCert surface. □

Theorem 9132.3 (DarbouxGapRefinement partition route)**.** *Every Darboux, Riemann, Real, or Completion consumer of an accepted* $\mathsf{DarbouxGapRefinement}^{\uparrow}$ *carrier reaches the gap certificate only through the finite route*

$$\mathsf{DarbouxSumRefinement}^{\uparrow} \longmapsto (\mathsf{TaggedPartition}^{\uparrow} \text{ or } \mathsf{DyadicPartition}^{\uparrow}) \longmapsto (\mathsf{LowerDarbouxSum}^{\uparrow}, ??) \longmapsto \mathsf{RegSeqRat}^{\uparrow} \mapsto$$

The consumer first reads the refinement row R, the displayed partition row T, the lower and upper rows L, U, and the gap row D; only then may it consume the regular rational readback W and terminal Real seal E. It receives no selected partition sequence, quotient-function equality, host integral value, countable-choice schedule, or ambient completeness theorem.

Proof. Start with an accepted carrier $G = (R, L, U, T, D, W, E, H, C, P, N)$. The carrier definition makes R the Darboux-sum refinement source and T the only displayed partition row available to the consumer.

Read L and U over the same cells supplied by T. The gap row D then compares the upper and lower rows over exactly that displayed finite partition route.

Only after this comparison is displayed can the consumer reach W and E. The regular rational readback and Real seal are therefore downstream of the finite partition-gap route, while H, C, P, N merely transport, replay, source, and name the same packet. Since the carrier has no coordinate for a selected partition sequence, quotient-function equality, host integral value, countable-choice schedule, or ambient completeness theorem, none of those objects is exported. □

Falsifiable prediction: Every accepted $\mathsf{DarbouxGapRefinement}^{\uparrow}$ read used by a Darboux, Riemann, Real, or Completion consumer displays one DarbouxSumRefinementUp source row, one

tagged or dyadic partition row, lower and upper Darboux-sum rows, one finite upper-minus-lower gap row, one RegSeqRat readback row, one RealUp seal, and the structural rows H, C, P, N before it is treated as a partition-gap refinement certificate.

Independence witness: darboux-sum-refinement, tagged-partition, dyadic-partition, regseqrat, real: $\mathsf{DarbouxGapRefinement}^{\uparrow}$ is not bijective with any listed sibling because it jointly carries the refinement source, lower and upper finite Darboux rows, the displayed partition cells, the finite gap comparison, regular rational readback, terminal Real sealing, transport, replay, provenance, and local naming in one packet.

Closure status for $\mathsf{NameCert}_{\mathsf{DarbouxGapRefinement}^{\uparrow}}$.

Constructive story: A $\mathsf{DarbouxGapRefinement}^{\uparrow}$ packet is generated from a DarbouxSumRefinement source row, lower and upper Darboux-sum rows, a tagged or dyadic partition row, a finite gap row, RegSeqRat readback, Real seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{DarbouxGapRefinement}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 9132.1, Definition 9132.2, and Definition 9132.3 seed the finite partition-gap refinement route from Darboux-sum refinement to Real-facing readback.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{DarbouxGapRefinement}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close selected partition sequences, quotient equality of functions, host suprema or infima, host integral values, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean theorem checking, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, lower and upper sum coherence, partition-route exactness, finite gap readback, Real-seal nonescape, componentwise transport, displayed replay, provenance, and local naming for BEDC.Derived.DarbouxGapRefinementUp.

Chapter 9133

A Concrete Naming Certificate for $\mathsf{RationalIntervalHull}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{RationalIntervalHull}^{\uparrow}$ packet records the finite rational lower-upper hull used before enclosure and completion consumers inspect a regular rational or real-facing interval route. It sits between the finite bracket surface of chapter 1802, the dyadic tolerance arithmetic of chapter 291, the regular rational source rows of chapter 301, the stream-window boundary of chapter 126, the terminal real-name seal of chapter 38, and the located hull surface of chapter 2327. The packet names a finite rational hull family; it does not assert quotient real equality, a least ambient real interval, selected endpoints, or completeness of $\mathsf{Real}^{\uparrow}$.

Definition 9133.1 (Rational interval hull carrier)**.** *A* $\mathsf{RationalIntervalHull}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$H = (L, U, O, D, S, R, E, A, T, C, P, N)$$

with the following displayed rows:

1. *L is the finite family of rational lower endpoint rows, each read through* $\mathsf{Rat}^{\uparrow}$*.*
2. *U is the finite family of rational upper endpoint rows, each read through* $\mathsf{Rat}^{\uparrow}$*.*
3. *O is the rational order ledger, recording $L_i \leq U_i$ and the pairwise lower-upper comparisons requested by the hull consumer.*
4. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger used to compare rational endpoints against dyadic radii and finite observation scales.*
5. *S is the* $\mathsf{StreamName}^{\uparrow}$ *window row naming the finite requests at which the source interval family is inspected.*
6. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the regular rational names served by the windows in S.*
7. *E is the* $\mathsf{RationalIntervalEnclosure}^{\uparrow}$ *handoff row, exposing each rational bracket as an enclosure packet.*
8. *A is the* $\mathsf{LocatedRealIntervalHull}^{\uparrow}$ *admission row, reached only after the rational endpoints, dyadic tolerance ledger, stream windows, regular readbacks, and enclosure handoff have been displayed.*
9. *T records componentwise* hsame *transport for endpoints, order ledgers, tolerances, windows, readbacks, enclosures, located hull rows, replay, provenance, and local naming.*

10. *C records displayed* Cont *replay from a hull request through $L, U, O, D, S, R, E, A, T, P, N$.*
11. *P is the* Pkg *provenance over* $\mathsf{RationalIntervalHull}^{\uparrow}$, $\mathsf{Rat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RationalIntervalEnclosure}^{\uparrow}$, $\mathsf{LocatedRealIntervalHull}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
12. *N is the local* $\mathsf{NameCert}_{\mathsf{RationalIntervalHull}^{\uparrow}}$ *row.*

The classifier compares accepted rational hulls only through $L, U, O, D, S, R, E, A, T, C, P, N$. It has no coordinate for quotient real equality, selected representatives, a host least interval, total trichotomy, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 9133.2 (Rational interval hull NameCert obligations)**.** *For every accepted* $\mathsf{RationalIntervalHull}^{\uparrow}$ *carrier $H = (L, U, O, D, S, R, E, A, T, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{RationalIntervalHull}^{\uparrow}}$ *surface consists exactly of carrier admission, rational endpoint ordering, dyadic tolerance compatibility, stream-window exposure, regular rational readback, enclosure handoff, located-hull admission, componentwise transport, displayed replay, provenance, and local naming. Every obligation is read from the displayed rows over* $\mathsf{Rat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RationalIntervalEnclosure}^{\uparrow}$, $\mathsf{LocatedRealIntervalHull}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* NameCert.

Proof. Project the accepted carrier. The rational endpoint rows L, U and the order ledger O are the only endpoint and comparison coordinates available to the local classifier.

The dyadic and regular-source stages are then read through D, S, R. The dyadic ledger fixes finite tolerance comparisons, the stream row fixes the inspected requests, and the regular rational row records the readback served at those requests.

The enclosure and located-hull stages are downstream. The row E repackages the finite rational brackets as $\mathsf{RationalIntervalEnclosure}^{\uparrow}$ data, while A admits the same displayed brackets to the $\mathsf{LocatedRealIntervalHull}^{\uparrow}$ surface without adding a host least interval.

Finally T, C, P, N transport, replay, package, and name the same finite route. Since no excluded quotient, selected endpoint, total comparison, choice, or ambient completeness coordinate occurs in the carrier, the listed rows exhaust the local NameCert obligations. □

Theorem 9133.3 (Rational interval hull finite-family exactness)**.** *Every accepted* $\mathsf{RationalIntervalHull}^{\uparrow}$ *packet exposes its hull as exactly the finite family route*

$$\mathsf{Rat}^{\uparrow} \longmapsto \mathsf{DyadicRatCore}^{\uparrow} \longmapsto \mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow}$$
$$\longmapsto \mathsf{RationalIntervalEnclosure}^{\uparrow} \longmapsto \mathsf{LocatedRealIntervalHull}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}.$$

A Real or Completion consumer receives the displayed rational endpoint family, rational order ledger, dyadic tolerance rows, stream windows, regular readbacks, enclosure handoff, located-hull admission, transport, replay, provenance, and local naming. It receives no quotient real equality, host least interval, selected endpoint pair, ambient $\mathsf{Real}^{\uparrow}$ *completeness theorem, or hidden infinite family.*

Proof. Start with the NameCert obligation theorem. It identifies $L, U, O, D, S, R, E, A, T, C, P, N$ as the whole local surface, so a consumer has no access to any row outside the finite packet.

Read the family route in order. The rational endpoint rows and order ledger precede the dyadic tolerance row; the stream windows and regular rational readback precede the enclosure handoff; and the located-hull row precedes the terminal Real-facing seal.

Transport and replay preserve the same route. Componentwise hsame transport and displayed Cont replay can only move the named rows T and C, while P and N record provenance and local naming for the same finite family.

Thus finite-family exactness is a carrier inventory claim: all public hull reads factor through the displayed rows, and the excluded quotient, host, selected, completeness, and hidden-family principles are absent. □

Closure status for $\mathsf{NameCert}_{\mathsf{RationalIntervalHull}^{\uparrow}}$.

Constructive story: A $\mathsf{RationalIntervalHull}^{\uparrow}$ packet is generated from finite rational lower and upper endpoint rows, a rational order ledger, a DyadicRatCoreUp tolerance ledger, StreamNameUp windows, RegSeqRatUp readbacks, RationalIntervalEnclosureUp handoff rows, LocatedRealIntervalHullUp admission, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RationalIntervalHull}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 9133.1, Definition 9133.2, and Definition 9133.3 seed the finite rational hull route from rational endpoint families to enclosure, located-hull, Real, and Completion consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RationalIntervalHull}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient real equality, a host least interval, selected endpoints, total trichotomy, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, rational endpoint ordering, dyadic tolerance compatibility, stream-window exposure, regular readback, enclosure handoff, located-hull admission, transport, replay, provenance, and local naming for BEDC.Derived.RationalIntervalHullUp.

Chapter 9134

A Concrete Naming Certificate for $\mathsf{FiniteComparisonBoundary}^{\uparrow}$

Following Bishop and Bridges on located real comparison, the $\mathsf{FiniteComparisonBoundary}^{\uparrow}$ packet realizes the process-level comparison surface of section 9238.4 as finite rows. It sits after the located-real comparison packet of chapter 1730, the comparison-modulus route of chapter 5813, the finite observation boundary of chapter 9102, the finite-window separation packet of chapter 1202, and the dyadic tolerance arithmetic of chapter 291. The packet names finite close and apartness windows; it does not export total trichotomy, host real equality, quotient real equality, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 9134.1 (Finite comparison boundary carrier)**.** *A* $\mathsf{FiniteComparisonBoundary}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (X, Y, M, W, Q, A, R, S, H, C, P, N)$$

with the following displayed rows:

1. *X is the first located-real endpoint row, read through* $\mathsf{Real}^{\uparrow}$ *and its displayed regular rational presentation.*
2. *Y is the second located-real endpoint row, read through* $\mathsf{Real}^{\uparrow}$ *and its displayed regular rational presentation.*
3. *M is the finite comparison-modulus row selecting the common observation thresholds for the requested tolerance.*
4. *W is the finite apartness-window row selecting the precision at which a positive separation may be read.*
5. *Q is the rational close row, recording the displayed* $\mathsf{Rat}^{\uparrow}$ *or* $\mathsf{DyadicRatCore}^{\uparrow}$ *close comparison at the selected window.*
6. *A is the rational apart row, recording the displayed positive separation when the apartness window is present.*
7. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for both endpoint presentations at the selected thresholds.*
8. *S is the* $\mathsf{StreamName}^{\uparrow}$ *request row fixing the inspected finite windows.*
9. *H records componentwise* hsame *transport for endpoints, moduli, windows, rational close and apart rows, readback, replay, provenance, and local naming.*

10. *C records displayed* Cont *replay from a comparison request through* $X, Y, M, W, Q, A, R, S, H, P, N$.
11. *P is the* Pkg *provenance over* $\mathsf{FiniteComparisonBoundary}^{\uparrow}$, $\mathsf{LocatedRealComparison}^{\uparrow}$, $\mathsf{FiniteObservationBoundary}^{\uparrow}$, $\mathsf{FiniteWindowRealSeparation}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
12. *N is the local* $\mathsf{NameCert}_{\mathsf{FiniteComparisonBoundary}^{\uparrow}}$ *row.*

The classifier compares accepted boundary packets only through $X, Y, M, W, Q, A, R, S, H, C, P, N$. It has no coordinate for total trichotomy, host real equality, quotient real equality, selected representatives, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 9134.2 (Finite comparison boundary process-level obligations)**.** *For every accepted* $\mathsf{FiniteComparisonBoundary}^{\uparrow}$ *carrier $B = (X, Y, M, W, Q, A, R, S, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{FiniteComparisonBoundar}}$ *surface consists exactly of endpoint exposure, comparison-modulus exposure, apartness-window exposure, rational close and apart rows, regular rational readback, finite stream-window exposure, componentwise transport, displayed replay, provenance, and local naming. Thus every finite tolerance comparison or finite apartness witness is a process-level route through displayed moduli and finite rational observations.*

Proof. Project the accepted carrier. The endpoint rows X, Y are the only real-facing coordinates, and they are not compared as completed host points.

Read the modulus and window rows next. The comparison modulus M selects the finite thresholds for a close request, while W selects the finite precision at which an apartness witness may be inspected.

The rational evidence is then confined to Q, A, R, S. The close row Q and apart row A are read only at the windows fixed by S and through the regular rational readback row R.

Finally H, C, P, N transport, replay, source, and name the same finite comparison route. Because the excluded trichotomy, host equality, quotient equality, selected representative, choice, and completeness objects are absent from the carrier, the listed rows exhaust the local process-level obligations. □

Theorem 9134.3 (Finite comparison boundary apartness nonescape)**.** *Every accepted* $\mathsf{FiniteComparisonBoundary}^{\uparrow}$ *apartness read factors through the finite route*

$$X, Y \longmapsto M, W \longmapsto S, R \longmapsto Q, A \longmapsto H, C, P, N.$$

The apartness witness therefore remains a finite window over rational readbacks and dyadic tolerance rows. It cannot be used to obtain total located-real trichotomy, host real equality, quotient real equality, a selected representative, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start from the process-level obligation theorem. It makes $X, Y, M, W, Q, A, R, S, H, C, P, N$ the entire accepted comparison surface.

For an apartness read, the row W fixes the inspected precision before the rational apart row A is available. The stream and regular rational rows S, R determine the finite endpoint observations at that precision.

The close row Q and apart row A remain rational evidence at the displayed window; neither row decides a global trichotomy branch for arbitrary located-real presentations.

Transport, replay, provenance, and local naming preserve only this displayed route. Since no host equality, quotient equality, selected representative, choice schedule, or ambient completeness theorem appears in the packet, apartness cannot escape the finite window. □

Closure status for $\mathsf{NameCert}_{\mathsf{FiniteComparisonBoundary}^{\uparrow}}$.

Constructive story: A $\mathsf{FiniteComparisonBoundary}^{\uparrow}$ packet is generated from two located-real endpoint rows, one finite comparison-modulus row, one finite apartness-window row, rational close and apart rows, RegSeqRatUp readbacks, StreamNameUp finite windows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{FiniteComparisonBoundary}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 9134.1, Definition 9134.2, and Definition 9134.3 seed the finite process-level comparison boundary for close and apartness reads over located-real presentations.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{FiniteComparisonBoundary}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close total located-real trichotomy, host real equality, quotient real equality, selected representatives, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked endpoint exposure, comparison-modulus exposure, apartness-window exposure, rational close and apart rows, regular readback, finite stream-window exposure, transport, replay, provenance, and local naming for BEDC.Derived.FiniteComparisonBoundaryUp.

Chapter 9135

A Concrete Naming Certificate for $\mathsf{LogarithmicSectionDynamics}^{\uparrow}$

The $\mathsf{LogarithmicSectionDynamics}^{\uparrow}$ packet realizes the observer-centered frame selector of chapter 9421 as finite NameCert data. It sits after the observer-centered constructor route of chapter 9114, the frame-facing observer row of chapter 1047, the displayed Hilbert carrier of chapter 91, the solenoid-visible phase row of chapter 9075, and the focused ledger surface of chapter 1247. The packet names a records-side section dynamics only; it does not claim a host Hilbert-space primitive, a completed cosmos, a subject substance, or an ambient physical evolution operator.

Definition 9135.1 (LogarithmicSectionDynamics carrier)**.** *A* $\mathsf{LogarithmicSectionDynamics}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (R, \chi, W, \Phi, \Delta, \Lambda, S, H, C, P, N)$$

with the following displayed rows:

1. *R is the reference-frame graph row, exposing only finitely recorded frame vertices and adjacency witnesses.*
2. *χ is the observer-centered selector row, recording the displayed adjacent frame choices read by the focused history.*
3. *W is the world-section bundle row, naming the frame-relative section read through* $\mathsf{Hilbert}^{\uparrow}$ *data without importing a host Hilbert-space primitive.*
4. *Φ is the frame reshaping row, recording the displayed transport from one selected frame row to the next.*
5. *Δ is the residual ledger row, storing orthogonal section residues as packet data rather than as unrecorded world content.*
6. *Λ is the logarithmic clock row, recording the finite log-coordinate read of multiplicative accumulation.*
7. *S is the solenoid-visible phase row, exposing the public phase read through* $\mathsf{SolenoidPhase}^{\uparrow}$ *while leaving prime-register fibre data inside the displayed ledger.*
8. *H records componentwise* hsame *transport for $R, \chi, W, \Phi, \Delta, \Lambda, S, C, P, N$.*
9. *C records displayed* Cont *replay from frame selection through section readback, reshaping, residual recording, logarithmic readback, and solenoid-visible phase.*

10. *P is the* Pkg *provenance over* $\mathsf{LogarithmicSectionDynamics}^{\uparrow}$, $\mathsf{ObserverCenteredConstructorCertificate}^{\uparrow}$, $\mathsf{ObserverDirection}^{\uparrow}$, $\mathsf{Hilbert}^{\uparrow}$, $\mathsf{SolenoidPhase}^{\uparrow}$, $\mathsf{FocusedLedger}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*

11. *N is the local* $\mathsf{NameCert}_{\mathsf{LogarithmicSectionDynamics}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $R, \chi, W, \Phi, \Delta, \Lambda, S, H, C, P, N$. It has no coordinate for a global observer, completed observer-independent world, host Hilbert-space primitive, hidden physical time flow, unlogged residual, or fibre choice outside the displayed solenoid row.

Theorem 9135.2 (LogarithmicSectionDynamics NameCert obligations)**.** *For every accepted* LogarithmicSectionDy *carrier*

$$L = (R, \chi, W, \Phi, \Delta, \Lambda, S, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{LogarithmicSectionDynamics}^{\uparrow}}$ *surface consists exactly of frame-graph exposure through R, observer-centered selection through χ, frame-relative section readback through W, reshaping transport through Φ, residual-ledger exposure through Δ, logarithmic clock readback through Λ, solenoid-visible phase exposure through S, componentwise transport through H, displayed replay through C, provenance through P, and local naming through N.*

Proof. Project the carrier of Definition 9135.1. The displayed rows are the reference-frame graph, selector, section bundle, reshaping map, residual ledger, logarithmic clock, solenoid-visible phase, transport, replay, provenance, and local naming rows.

The frame rows are read first. Row R supplies only displayed adjacency data, row χ selects along those adjacencies, and row W exposes a section relative to the selected frame rather than a completed host world.

Next read the dynamics rows. The reshaping row Φ, residual ledger Δ, logarithmic row Λ, and solenoid-visible row S keep every section change, residual, accumulated clock value, and phase read inside the same finite packet.

Finally H, C, P, N transport, replay, source, and name that route. Since no coordinate stores a global observer, host Hilbert-space primitive, hidden physical time flow, unlogged residual, or fibre choice outside S, the displayed rows exhaust the local NameCert obligations. □

Theorem 9135.3 (LogarithmicSectionDynamics no host-Hilbert escape)**.** *Every* $\mathsf{LogarithmicSectionDynamics}^{\uparrow}$ *consumer that reads a frame-relative section or residual ledger must first expose the selected frame row, the* $\mathsf{Hilbert}^{\uparrow}$*-named section row, the reshaping row, and the residual ledger row of Definition 9135.1. The read supplies no host Hilbert-space primitive and no observer-independent completed world.*

Proof. Apply Definition 9135.2. It places the selector row χ and the frame-relative section row W before any reshaping or residual read.

The reshaping and residual rows Φ, Δ are then consumed as displayed packet rows. Because the carrier names the section through the $\mathsf{Hilbert}^{\uparrow}$ certificate boundary and records residuals in Δ, no consumer can detach a host Hilbert space or unlogged world content from the accepted packet.

The structural rows H, C, P, N preserve that dependency route under transport, replay, provenance, and local naming. □

Falsifiable prediction: An accepted $\mathsf{LogarithmicSectionDynamics}^{\uparrow}$ consumer that reads a section update, residual, logarithmic clock value, or solenoid-visible phase without first exposing the selected frame row and displayed packet ledger refutes the carrier surface.

Independence witness: observer-centered-constructor-certificate, observer-direction, hilbert, solenoid-phase, focused-ledger: these siblings supply constructor, frame-facing observer, Hilbert-named section, solenoid-visible phase, and focused ledger surfaces, but none combines frame selection, section reshaping, residual exposure, logarithmic readback, solenoid visibility, transport, replay, provenance, and local naming in one packet.

Closure status for $\mathsf{NameCert}_{\mathsf{LogarithmicSectionDynamics}^{\uparrow}}$.

Constructive story: A $\mathsf{LogarithmicSectionDynamics}^{\uparrow}$ packet is generated from a reference-frame graph, observer-centered selector, frame-relative section row, frame reshaping row, residual ledger, logarithmic clock row, solenoid-visible phase row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{LogarithmicSectionDynamics}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 9135.1, Definition 9135.2, and Definition 9135.3 seed the finite observer-centered section dynamics surface over frame selection, section reshaping, residual ledger, logarithmic readback, solenoid visibility, transport, replay, provenance, and local naming rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{LogarithmicSectionDynamics}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host Hilbert-space primitives, a completed observer-independent cosmos, subject-substance semantics, global physical time flow, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked frame-graph admission, selector adjacency, section readback, reshaping transport, residual-ledger exposure, logarithmic clock readback, solenoid visibility, transport, replay, provenance, and local naming for BEDC.Derived.LogarithmicSectionDynamicsUp.

Chapter 9136

A Concrete Naming Certificate for $\mathsf{LocatedSetoid}^{\uparrow}$

Following Bishop and Bridges on constructive equality, setoids, and located apartness, the $\mathsf{LocatedSetoid}^{\uparrow}$ packet records the finite BEDC naming surface for equality that is witnessed by displayed equivalence data and separated by displayed apartness data. It sits after the membership classifier of chapter 3668, the displayed-family carrier of chapter 3600, the located-subset route of chapter 1541, the metric route of chapter 57, the regular rational readback of chapter 301, and the terminal real-name seal of chapter 38. The packet is a constructive equality object for Real and RegSeqRat consumers; it does not quotient representatives, identify values by host equality, use trichotomy, or appeal to ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 9136.1 (LocatedSetoid carrier)**.** *A* $\mathsf{LocatedSetoid}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (S, T, M, Q, A, D, R, H, C, P, N)$$

with the following displayed rows:

1. *S is the* $\mathsf{SetLike}^{\uparrow}$ *membership-classifier row for the underlying displayed collection;*
2. *T is the* $\mathsf{TypeLike}^{\uparrow}$ *displayed-family row carrying endpoints, fibers, and transport requests;*
3. *M is the* $\mathsf{Met}^{\uparrow}$ *comparison row through which distance-shaped equality tests are read;*
4. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *tolerance-readback row attached to the displayed comparison schedule;*
5. *A is the located apartness row, recording the finite positive-separation witnesses and the refusal branch for equality reads;*
6. *D is the equality-decision ledger for the inspected finite window, storing reflexivity, symmetry, transitivity, and apartness incompatibility rows;*
7. *R is the* $\mathsf{Real}^{\uparrow}$ *seal row reached only after S, T, M, Q, A, D have been displayed;*
8. *H records componentwise* hsame *transport for the membership, family, metric, rational, apartness, equality-ledger, and seal rows;*
9. *C records displayed* Cont *replay from membership inspection through located apartness, rational readback, equality-ledger exposure, and Real sealing;*
10. *P records* Pkg *provenance over* $\mathsf{LocatedSetoid}^{\uparrow}$, $\mathsf{SetLike}^{\uparrow}$, $\mathsf{TypeLike}^{\uparrow}$, $\mathsf{LocatedSet}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows;*

11. *N is the local* $\mathsf{NameCert}_{\mathsf{LocatedSetoid}^\uparrow}$ *row.*

The classifier compares accepted packets only through these rows. It has no coordinate for Quot*, host equality, trichotomy, selected representatives, or ambient Real completeness.*

Theorem 9136.2 (LocatedSetoid NameCert obligations)**.** *For every accepted* $\mathsf{LocatedSetoid}^\uparrow$ *carrier*

$$L = (S, T, M, Q, A, D, R, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{LocatedSetoid}^\uparrow}$ *surface consists exactly of carrier admission for the displayed* $\mathsf{SetLike}^\uparrow$ *membership classifier,* $\mathsf{TypeLike}^\uparrow$ *family endpoint route,* $\mathsf{LocatedSet}^\uparrow$ *locatedness context,* $\mathsf{Met}^\uparrow$ *comparison row,* $\mathsf{RegSeqRat}^\uparrow$ *tolerance readback, located apartness row, finite equality ledger, terminal* $\mathsf{Real}^\uparrow$ *seal, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. Equality may be consumed only as this displayed finite route, and apartness may be consumed only through the positive-separation row A.*

Proof. Project the carrier of Definition 9136.1. The rows S, T, M, Q, A, D, R are the complete equality and apartness sources, while H, C, P, N are the structural rows that preserve, replay, source, and name the same packet.

The equality route is not independent of located apartness. Membership and displayed-family endpoints are read first through S, T, metric comparison enters through M, and rational tolerance readback enters through Q. The row A records the positive-separation alternative, and the ledger D records exactly the inspected equivalence and incompatibility rows.

Finally the Real-facing seal R is reached only after those finite rows have been displayed. Since no row stores quotient representatives, host equality, trichotomy, or ambient completeness, the local NameCert obligations are exhausted by the carrier rows. □

Theorem 9136.3 (LocatedSetoid Real classifier handoff)**.** *Every* $\mathsf{Real}^\uparrow$ *or* $\mathsf{RegSeqRat}^\uparrow$ *consumer that reads equality or apartness from an accepted* $\mathsf{LocatedSetoid}^\uparrow$ *packet must factor through the displayed sequence*

$$\mathsf{SetLike}^\uparrow,\ \mathsf{TypeLike}^\uparrow,\ \mathsf{LocatedSet}^\uparrow,\ \mathsf{Met}^\uparrow,\ \mathsf{RegSeqRat}^\uparrow,\ \mathsf{Real}^\uparrow.$$

Concretely, the consumer first exposes the membership and displayed-family rows S, T, then the metric comparison row M, then the rational tolerance row Q, then the located apartness and finite equality ledger rows A, D, and only then reaches the Real seal R. The handoff supplies no Quot *primitive, no host equality of representatives, no trichotomy split, and no ambient Real completeness theorem.*

Proof. Start with the carrier rows of Definition 9136.1. A Real-facing consumer has only one seal row, namely R, and that row is packaged after the membership, family, metric, rational, apartness, and equality-ledger rows.

Apply the obligation surface of Definition 9136.2. It forces equality and apartness reads to remain inside $S, T, M, Q, A, D, H, C, P, N$ before R is exposed.

Thus the classifier handoff is a finite route through the named sibling chapters. The excluded equality sources have no carrier coordinate, no replay edge, no provenance row, and no local NameCert row. □

Closure status for $\mathsf{NameCert}_{\mathsf{LocatedSetoid}^\uparrow}$**.**

Constructive story: A $\mathsf{LocatedSetoid}^\uparrow$ packet is generated from SetLike membership, TypeLike displayed-family data, LocatedSet context, Metric comparison, RegSeqRat tolerance readback, located apartness, finite equality-ledger rows, a Real seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\mathsf{LocatedSetoid}^{\uparrow}}$, seed)

Scope closed: Definition 9136.1, Definition 9136.2, and Definition 9136.3 seed the constructive setoid equality and located-apartness carrier over SetLike$^{\uparrow}$, TypeLike$^{\uparrow}$, LocatedSet$^{\uparrow}$, Met$^{\uparrow}$, RegSeqRat$^{\uparrow}$, and Real$^{\uparrow}$.

Formal verification: FormalStatus(NameCert$_{\mathsf{LocatedSetoid}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim Quot equality, host equality of representatives, trichotomy, selected representatives, ambient Real$^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, equality-ledger stability, located-apartness incompatibility, Real classifier handoff, transport, replay, provenance, and local naming for BEDC.Derived.LocatedSetoidUp.

Chapter 9137

A Concrete Naming Certificate for $\mathsf{BishopCauchyLocatedLimit}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{BishopCauchyLocatedLimit}^{\uparrow}$ packet records the finite route by which a located regular Cauchy source exposes a completion-facing limit window before any quotient or selected representative is available. It sits over the regular rational readback of chapter 301, the finite observation interface of chapter 126, the dyadic tolerance ledger of chapter 291, and the terminal real-name seal of chapter 38. The packet names located Cauchy limit extraction as displayed BEDC data; it does not assert quotient completion, choose a representative, invoke countable choice, or prove ambient completeness of $\mathsf{Real}^{\uparrow}$.

Definition 9137.1 (BishopCauchyLocatedLimit carrier)**.** *A* $\mathsf{BishopCauchyLocatedLimit}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (R, W, D, O, E, H, C, P, N)$$

with the following displayed rows:

1. *R is the regular Cauchy source row, read through the* $\mathsf{RegSeqRat}^{\uparrow}$ *rational sequence surface.*
2. *W is the located window row, recording the finite interval and modulus request under which the source is inspected.*
3. *D is the dyadic tolerance ledger supplied by* $\mathsf{DyadicRatCore}^{\uparrow}$*.*
4. *O is the* $\mathsf{StreamName}^{\uparrow}$ *finite observation row used to read the source only through named windows.*
5. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row exposed after R, W, D, O have been displayed.*
6. *H records componentwise* hsame *transport for the regular source, located window, dyadic tolerance, finite observation, Real seal, replay, provenance, and local naming rows.*
7. *C records displayed* Cont *replay of the route*

$$R, W, D, O \longmapsto E.$$

8. *P is the* Pkg *provenance over* $\mathsf{BishopCauchyLocatedLimit}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*,* BHist*,* hsame*,* Cont*, and* $\mathsf{NameCert}$*.*
9. *N is the local* $\mathsf{NameCert}_{\mathsf{BishopCauchyLocatedLimit}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $R, W, D, O, E, H, C, P, N$. It has no coordinate for quotient completion, a selected representative, countable choice, a host limit object, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 9137.2 (BishopCauchyLocatedLimit NameCert obligations)**.** *For every accepted* BishopCauchyLocatedLi *carrier*

$$L = (R, W, D, O, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{BishopCauchyLocatedLimit}^{\uparrow}}$ *surface consists exactly of regular Cauchy source exposure through R, located-window exposure through W, dyadic tolerance exposure through D, StreamName finite observation through O, Real sealing through E, componentwise transport through H, displayed replay through C, provenance through P, and local naming through N.*

Proof. Project the carrier of Definition 9137.1. The rows R, W, D, O expose the regular source, located window, dyadic tolerance, and finite observation data before any limit-facing read can occur.

The Real seal row E is downstream of those displayed rows. A consumer therefore receives a named finite extraction route rather than a quotient completion object, a selected representative, or a countable-choice schedule.

Finally H, C, P, N transport, replay, source, and name the same route. Since no host limit object or ambient completeness theorem is a carrier coordinate, the listed rows exhaust the local NameCert obligations. □

Closure status for $\mathsf{NameCert}_{\mathsf{BishopCauchyLocatedLimit}^{\uparrow}}$.

Constructive story: A $\mathsf{BishopCauchyLocatedLimit}^{\uparrow}$ packet is generated from a RegSeqRat regular Cauchy source, a located window, a DyadicRatCore tolerance ledger, StreamName finite observations, a Real seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{BishopCauchyLocatedLimit}^{\uparrow}}$, seed)

Scope closed: Definition 9137.1 and Definition 9137.2 seed the located Cauchy limit extraction route over the RegSeqRat, StreamName, DyadicRatCore, and Real spine.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{BishopCauchyLocatedLimit}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close quotient completion, selected representatives, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked regular source admission, located-window readback, dyadic tolerance, finite observation, Real sealing, transport, replay, provenance, and local naming for BEDC.Derived.BishopCauchyLocatedLimitUp.

Chapter 9138

A Concrete Naming Certificate for $\mathsf{RuleOneTenProductionQueue}^{\uparrow}$

The $\mathsf{RuleOneTenProductionQueue}^{\uparrow}$ packet realizes the Cook cyclic-tag production branch of section 9390.5 as finite NameCert data. It sits beside the cyclic-tag carrier of chapter 3764, the Rule 110 local-stencil observation of chapter 6004, the Cook frontier budget of chapter 6849, and the cellular pattern catalog of chapter 995. The packet records production rows, tape-symbol rows, queue-head rows, step-budget rows, replay rows, provenance rows, and local naming before any consumer may read the Cook branch as a cellular production surface.

Definition 9138.1 (Rule 110 production-queue carrier)**.** *A* $\mathsf{RuleOneTenProductionQueue}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Q = (C, L, B, T, Hd, S, R, V, E, K, P, N)$$

with the following displayed rows:

1. *C is the* $\mathsf{CyclicTagSystem}^{\uparrow}$ *source row, exposing the accepted cyclic-tag production family and the inspected word row;*
2. *L is the* $\mathsf{RuleOneTenLocalStencilObservation}^{\uparrow}$ *row, recording the local Rule 110 stencil window used to read each simulated production step;*
3. *B is the* $\mathsf{RuleOneTenCookFrontierBudget}^{\uparrow}$ *row, fixing the displayed production count, tape-symbol count, and step-budget boundary;*
4. *T is the tape-symbol queue row, listing the finite queue segment, head symbol, and tail segment inspected by the branch;*
5. *Hd is the queue-head row, naming the active production, head position, and local rotation state;*
6. *S is the step-budget row, tying each production dequeue and enqueue event to the finite Cook frontier budget;*
7. *R is the replay row, displaying the cyclic-tag update and the corresponding Rule 110 local-stencil observations in lockstep;*
8. *V is the cellular pattern-catalog row, recording which glider or ether-pattern tags are read from the replayed stencil window;*
9. *E is the obstruction and refusal row, recording when a requested production read exceeds the displayed queue, tape, or budget rows;*

10. *K records componentwise* hsame *transport for source, stencil, budget, tape, head, replay, catalog, obstruction, provenance, and local naming rows;*
11. *P records* Pkg *provenance over* $\mathsf{RuleOneTenProductionQueue}^{\uparrow}$, $\mathsf{CyclicTagSystem}^{\uparrow}$, $\mathsf{RuleOneTenLocalStencilObserva}$ $\mathsf{RuleOneTenCookFrontierBudget}^{\uparrow}$, $\mathsf{CellularPatternCatalog}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows;*
12. *N is the local* $\mathsf{NameCert}_{\mathsf{RuleOneTenProductionQueue}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these rows. It has no coordinate for an unbounded cyclic-tag run, hidden Rule 110 evaluator, unstated universality theorem, external tape oracle, or detached complexity estimate.

Theorem 9138.2 (Rule 110 production-queue NameCert obligations)**.** *For every accepted* RuleOneTenProductionQ *carrier*

$$Q = (C, L, B, T, Hd, S, R, V, E, K, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{RuleOneTenProductionQueue}^{\uparrow}}$ *surface consists exactly of carrier admission for the cyclic-tag source, Rule 110 local-stencil observation, Cook frontier budget, tape-symbol queue, queue-head state, step-budget ledger, lockstep replay row, cellular pattern-catalog row, obstruction row, componentwise* hsame *transport, displayed replay, package provenance, and local naming. A consumer may inspect a production read only after all of those displayed rows are available.*

Proof. Project the carrier of Definition 9138.1. The source and cellular rows are C, L, B, V, while the queue-specific rows are T, Hd, S, R, E.

Read the branch in dependency order. The cyclic-tag row supplies the production family, the local-stencil row supplies the Rule 110 observation window, and the Cook frontier budget supplies the finite count and step boundary. Only then can the tape-symbol queue, queue head, and lockstep replay rows be inspected.

The structural rows preserve the same packet. Transport is read through K, provenance through P, and local naming through N. Since the carrier has no hidden evaluator, unbounded tape oracle, unstated universality theorem, or detached complexity estimate, the listed rows exhaust the NameCert obligations. □

Theorem 9138.3 (Rule 110 production-queue Cook branch handoff)**.** *Every Cook-branch consumer of an accepted* $\mathsf{RuleOneTenProductionQueue}^{\uparrow}$ *packet factors through*

$$\mathsf{CyclicTagSystem}^{\uparrow},\ \mathsf{RuleOneTenLocalStencilObservation}^{\uparrow},\ \mathsf{RuleOneTenCookFrontierBudget}^{\uparrow},\ \mathsf{CellularPatternCatalog}^{\uparrow}.$$

Concretely, the consumer first displays the cyclic-tag production row C, then the Rule 110 local-stencil row L, then the budget row B, then the finite tape, head, step, replay, catalog, obstruction, transport, provenance, and naming rows $T, Hd, S, R, V, E, K, P, N$. The handoff is a finite production queue, not an unbounded universality proof or a hidden tape oracle.

Proof. Start with the carrier. A Cook-branch read has no public coordinate except the displayed rows $C, L, B, T, Hd, S, R, V, E, K, P, N$.

Apply the NameCert obligations of Definition 9138.2. They force a production read to pass through the cyclic-tag source, local stencil observation, budget, queue, head, replay, catalog, obstruction, transport, provenance, and naming rows in the same finite packet.

Thus the handoff is exactly the listed finite route. Any claim requiring an unbounded run, hidden evaluator, unstated universality theorem, external tape oracle, or detached complexity estimate lacks a carrier row and cannot be projected from the packet. □

Falsifiable prediction: Every accepted $\mathsf{RuleOneTenProductionQueue}^{\uparrow}$ Cook-branch read displays cyclic-tag source rows, Rule 110 local-stencil observations, Cook frontier budget rows, tape-symbol queue rows, queue-head rows, step-budget rows, replay rows, cellular pattern-catalog rows, obstruction rows, componentwise hsame transport, Pkg provenance, and local NameCert rows.

Independence witness: cyclic-tag-system, rule110-local-stencil-observation, rule110-cook-frontier-budget, cellularpatterncatalog: none is bijective to $\mathsf{RuleOneTenProductionQueue}^{\uparrow}$ because the queue packet jointly carries the cyclic-tag source, local Rule 110 stencil observations, finite Cook budget, tape-symbol queue, queue-head state, step-budget ledger, lockstep replay, catalog tags, obstruction rows, transport, provenance, and local naming.

Theorem 9138.4 (Rule 110 production-queue TasteGate obligation)**.** *The follow-on TasteGate surface for* $\mathsf{RuleOneTenProductionQueue}^{\uparrow}$ *must provide* Nontrivial $\mathsf{RuleOneTenProductionQueue}^{\uparrow}$ *and* FieldFaithful $\mathsf{RuleOneTenProductionQueue}^{\uparrow}$ *instances for the same displayed carrier* $Q = (C, L, B, T, Hd, S, R, V, E,$ *Nontriviality must exhibit an accepted finite queue packet, and field faithfulness must keep the cyclic-tag source, stencil observation, budget, tape-symbol queue, queue-head state, replay, catalog, obstruction, transport, provenance, and local naming rows distinct.*

Proof. The obligation is read from Definition 9138.1. The packet has separate rows for cyclic-tag source data, Rule 110 stencil observations, finite budget data, queue state, replay, catalog classification, obstruction, transport, provenance, and local naming.

Nontriviality must therefore inhabit that finite packet rather than a bare tag. Field faithfulness must prevent the source row from replacing the stencil row, the budget row from replacing the replay row, or the catalog row from replacing obstruction and provenance.

The excluded hidden evaluator and unbounded tape oracle are absent from the carrier and from the handoff theorem. The TasteGate instances therefore have to target the displayed production queue itself. □

Closure status for $\mathsf{NameCert}_{\mathsf{RuleOneTenProductionQueue}^{\uparrow}}$.

Constructive story: A $\mathsf{RuleOneTenProductionQueue}^{\uparrow}$ packet is generated from CyclicTagSystem source rows, Rule 110 local-stencil observations, Cook frontier budget rows, tape-symbol queue rows, queue-head state, step-budget ledger, lockstep replay, cellular pattern-catalog tags, obstruction rows, componentwise hsame transport, Pkg provenance, and local NameCert naming.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RuleOneTenProductionQueue}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 9138.1, Definition 9138.2, Definition 9138.3, and Definition 9138.4 seed the finite production-queue packet for the Rule 110 Cook cyclic-tag branch.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RuleOneTenProductionQueue}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim Cook universality, an unbounded cyclic-tag run, a hidden Rule 110 evaluator, an external tape oracle, a detached complexity estimate, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, queue replay, local-stencil alignment, budget exactness, catalog readback, obstruction nonescape, Nontrivial and FieldFaithful TasteGate instances, transport, provenance, and local naming for BEDC.Derived.RuleOneTenProductionQueueUp.

Chapter 9139

A Concrete Naming Certificate for $\mathsf{ArithmeticSpectralStringCertificate}^{\uparrow}$

The $\mathsf{ArithmeticSpectralStringCertificate}^{\uparrow}$ packet realizes the route of chapter 9285 as finite normal-mode, prime-ledger, and unit-boundary NameCert data. It reads prime frequency registers through chapter 64, finite exponent and support ledgers through chapter 28, rational coefficient rows through chapter 37, and the terminal real comparison surface through chapter 38. The packet names a BEDC certificate surface for the arithmetic string route; it does not prove the Riemann hypothesis, construct all zeta-zero certificates, import a physical string model, or assert a host spectral theorem.

Definition 9139.1 (ArithmeticSpectralStringCertificate carrier)**.** *An* $\mathsf{ArithmeticSpectralStringCertificate}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (M, Q, L, U, Z, H, C, P, N)$$

with the following displayed rows:

1. *M is the finite normal-mode packet, listing the active logarithmic modes inspected by the certificate.*
2. *Q is the rational coefficient row, read through* $\mathsf{Rat}^{\uparrow}$*, for the finite amplitude data attached to the active modes.*
3. *L is the prime ledger row, read through* $\mathsf{Prime}^{\uparrow}$ *and* $\mathsf{Nat}^{\uparrow}$*, recording the factorization data behind the displayed logarithmic heights.*
4. *U is the unit-boundary row saying that the active centered channels are inspected only through unit phase data.*
5. *Z is the zero-readout row, exposing the finite cancellation certificate before any global zero-coverage claim is available.*
6. *H records componentwise* hsame *transport for modes, coefficients, prime ledgers, unit-boundary rows, zero readouts, replay, provenance, and local naming rows.*
7. *C records displayed* Cont *replay of the route*

$$M, Q, L, U \longmapsto Z.$$

8. *P is the* Pkg *provenance over* $\mathsf{ArithmeticSpectralStringCertificate}^{\uparrow}$, $\mathsf{Prime}^{\uparrow}$, $\mathsf{Nat}^{\uparrow}$, $\mathsf{Rat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

9. *N is the local* $\mathsf{NameCert}_{\mathsf{ArithmeticSpectralStringCertificate}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $M, Q, L, U, Z, H, C, P, N$. It has no coordinate for a physical string model, host spectral operator, all-zero coverage theorem, radial scale reservoir, or completed zeta proof.

Theorem 9139.2 (ArithmeticSpectralStringCertificate NameCert obligations)**.** *For every accepted* $\mathsf{ArithmeticSpectralStringCertificate}^{\uparrow}$ *carrier*

$$S = (M, Q, L, U, Z, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{ArithmeticSpectralStringCertificate}^{\uparrow}}$ *surface consists exactly of finite normal-mode exposure through M, rational coefficient exposure through Q, prime-ledger exposure through L, unit-boundary exposure through U, zero-readout exposure through Z, componentwise transport through H, displayed replay through C, provenance through P, and local naming through N.*

Proof. Project the carrier of Definition 9139.1. The rows M, Q, L, U expose the finite mode packet, coefficient data, prime ledger, and unit-boundary discipline before the zero-readout row can be inspected.

The zero-readout row Z is therefore a finite cancellation certificate, not a theorem that every accepted zeta zero has already been covered. The packet also has no carrier coordinate for a physical string model, host spectral operator, or radial scale reservoir.

Finally H, C, P, N transport, replay, source, and name the same finite route. These rows exhaust the local NameCert obligations and leave global spectral coverage to separate source rows. □

Falsifiable prediction: A completed formal route for $\mathsf{ArithmeticSpectralStringCertificate}^{\uparrow}$ must expose a finite normal-mode row, prime-ledger row, unit-boundary row, and zero-readout row before any RH-facing consumer can inspect the certificate; a purported proof that bypasses one of these rows is outside this NameCert surface.

Independence witness: The packet is independent from the sibling surfaces prime, nat, rat, real, and zeta-zero-certificate-tower in the following sense: those chapters may supply source rows, but none of them alone supplies the combined finite normal-mode, prime-ledger, unit-boundary, and local NameCert packet carried by $\mathsf{ArithmeticSpectralStringCertificate}^{\uparrow}$.

A Lean follow-up must provide Nontrivial and FieldFaithful instances for the carrier before the chapter can be promoted beyond statement-level paper evidence.

Closure status for $\mathsf{NameCert}_{\mathsf{ArithmeticSpectralStringCertificate}^{\uparrow}}$**:**

Constructive story: An $\mathsf{ArithmeticSpectralStringCertificate}^{\uparrow}$ packet is generated from finite normal modes, rational coefficient rows, prime and Nat ledgers, unit-boundary rows, a zero-readout row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{ArithmeticSpectralStringCertificate}^{\uparrow}}$, seed)

Scope closed: Definition 9139.1 and Definition 9139.2 seed the arithmetic spectral string certificate route over finite modes, prime ledgers, unit-boundary data, and zero-readout rows.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{ArithmeticSpectralStringCertificate}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not prove the Riemann hypothesis, construct all zeta-zero certificates, import a physical string model, supply a host spectral theorem, provide Lean verification, or bridge the packet to a public schema.

Upgrade path: Obligation closure requires checked finite-mode admission, prime-ledger admission, unit-boundary exposure, zero-readout exposure, transport, replay, provenance, local naming, and Nontrivial and FieldFaithful instances for BEDC.Derived.ArithmeticSpectralStringCertificateUp.

Chapter 9140

A Concrete Naming Certificate for $\mathsf{CompactZeroDimensionalMetric}^{\uparrow}$

Following Bishop and Bridges on compact metric data and Kelley's zero-dimensional compact spaces, the $\mathsf{CompactZeroDimensionalMetric}^{\uparrow}$ packet records the finite BEDC surface by which a compact metric source also exposes a clopen-basis schedule. It sits over the compact metric source of chapter 129, the metric carrier of chapter 57, the topology carrier of chapter 88, the total-bounded finite-net ledger of chapter 127, and the real-valued diameter and tolerance readback rows supplied by chapter 38. The packet is a finite naming certificate for compact zero-dimensional metric presentations; it is not an open-cover compactness theorem, not a selected arbitrary clopen refinement, and not a quotient compactum.

Definition 9140.1 (CompactZeroDimensionalMetric carrier)**.** *A* $\mathsf{CompactZeroDimensionalMetric}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Z = (K, M, T, B, F, D, H, C, P, N)$$

with the following displayed rows:

1. *K is the* $\mathsf{CompactMetric}^{\uparrow}$ *source row, exposing the compact-metric finite-net and completion-facing boundary inherited from chapter 129;*
2. *M is the* $\mathsf{Met}^{\uparrow}$ *row, keeping the distance read, triangle ledger, and metric observation surface visible through chapter 57;*
3. *T is the* $\mathsf{Topology}^{\uparrow}$ *row, recording the open-set and finite-observation topology carrier used by the zero-dimensional read;*
4. *B is a finite clopen-basis schedule: for each displayed tolerance window and observed point row, it gives a finite list of clopen neighborhoods whose union covers the relevant finite-net window and whose members refine the requested open row;*
5. *F is the* $\mathsf{TotallyBounded}^{\uparrow}$ *finite-net ledger, binding each clopen-basis window to a finite net, mesh row, and covering schedule before compact-metric data is exported;*
6. *D is the* $\mathsf{Real}^{\uparrow}$*-valued diameter and tolerance readback row, recording the displayed bounds used to compare clopen windows with metric balls;*
7. *H stores componentwise* hsame *transport for the compact source, metric row, topology row, clopen-basis schedule, finite-net ledger, diameter readback, provenance, and local naming row;*

8. *C stores displayed* Cont *replay for reading the compact metric source, the metric and topology rows, the clopen-basis schedule, the finite-net ledger, the diameter row, and the local certificate row;*
9. *P is the* Pkg *provenance over* $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{Topology}^{\uparrow}$, $\mathsf{TotallyBounded}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert*;*
10. *N is the local* $\mathsf{NameCert}_{\mathsf{CompactZeroDimensionalMetric}^{\uparrow}}$ *row.*

The carrier names zero-dimensional compact-metric data only through the displayed finite rows. It does not add an ambient open-cover compactness proof, quotient equality of compact spaces, arbitrary clopen choice, or ambient completeness of $\mathsf{Real}^{\uparrow}$.

Theorem 9140.2 (CompactZeroDimensionalMetric NameCert obligations)**.** *The local* $\mathsf{NameCert}_{\mathsf{CompactZeroDimension}}$ *surface for the carrier of Definition 9140.1 consists of seven finite obligations:*

1. *carrier admission: the accepted object is the displayed packet $Z = (K, M, T, B, F, D, H, C, P, N)$;*
2. *compact-source visibility: the* $\mathsf{CompactMetric}^{\uparrow}$ *row K is read before any compact-metric conclusion is exported;*
3. *metric-topology compatibility: the* $\mathsf{Met}^{\uparrow}$ *row M and* $\mathsf{Topology}^{\uparrow}$ *row T remain visible when a clopen window is inspected;*
4. *finite clopen coverage: each row of B supplies only the finite clopen windows displayed for the current finite-net and tolerance request;*
5. *total-bounded net binding: the ledger F ties every clopen-basis read to a finite-net schedule and never to an unbounded cover search;*
6. *real-valued readback: the diameter and tolerance comparisons pass through the* $\mathsf{Real}^{\uparrow}$ *row D before any metric-ball refinement is exposed;*
7. *non-escape: every downstream read factors through $K, M, T, B, F, D, H, C, P, N$ and has no route to open-cover compactness, arbitrary clopen choice, quotient equality, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Carrier admission is the projection of the displayed packet in Definition 9140.1. The compact source, metric carrier, topology carrier, clopen-basis schedule, finite-net ledger, real-valued readback, transport, replay, provenance, and local name are exactly the coordinates of that packet.

The compact-source and metric-topology obligations are componentwise reads. A consumer must first expose the $\mathsf{CompactMetric}^{\uparrow}$ source row and then keep the $\mathsf{Met}^{\uparrow}$ and $\mathsf{Topology}^{\uparrow}$ rows visible when a clopen window is inspected.

The finite coverage and net-binding obligations use the rows B and F. The clopen-basis schedule is indexed by displayed finite-net and tolerance requests, so it is a finite schedule for the current packet rather than a selected family of all clopen refinements.

The real-valued comparison obligation is the row D. Diameter and tolerance readback pass through the displayed $\mathsf{Real}^{\uparrow}$ seal before any metric-ball refinement is consumed.

The remaining rows H, C, P, N preserve transport, replay, provenance, and local naming. Since no coordinate stores open-cover compactness, arbitrary clopen choice, quotient equality, or ambient Real completeness, no accepted read can export those endpoints. □

Theorem 9140.3 (CompactZeroDimensionalMetric clopen-basis route)**.** *Every clopen-basis read exported by an accepted* $\mathsf{CompactZeroDimensionalMetric}^{\uparrow}$ *carrier factors through*

$$K, M, T, B, F, D, H, C, P, N.$$

It must expose the compact metric source, metric row, topology row, finite clopen-basis schedule, total-bounded finite-net ledger, real-valued diameter and tolerance readback, componentwise hsame *transport, displayed* Cont *replay, package provenance, and local* NameCert *row before any zero-dimensional compact-metric consumer can inspect the basis. The route exports finite clopen windows only, not open-cover compactness, unrestricted clopen choice, quotient equality, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start with a clopen-basis request. By the carrier definition, the request can inspect only the displayed rows $K, M, T, B, F, D, H, C, P, N$.

Read the source rows first. The compact-metric row K supplies the compact source, while M and T keep the metric and topology carriers visible before any clopen window is read.

Next consume the finite schedule. The clopen-basis row B is indexed by the total-bounded finite-net ledger F, and the diameter or tolerance comparison is read through the real-valued row D.

Finally replay the structural rows H, C, P, N. These rows transport, replay, source, and name the same finite packet, so the exported basis remains a displayed zero-dimensional compact-metric schedule and cannot be reread as the refused compactness, choice, quotient, or completeness endpoints. □

Closure status for $\mathsf{NameCert}_{\mathsf{CompactZeroDimensionalMetric}^{\uparrow}}$.

Constructive story: A $\mathsf{CompactZeroDimensionalMetric}^{\uparrow}$ packet is generated from a $\mathsf{CompactMetric}^{\uparrow}$ source, metric and topology rows, a finite clopen-basis schedule, a total-bounded finite-net ledger, real-valued diameter readback, componentwise transport, displayed replay, package provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CompactZeroDimensionalMetric}^{\uparrow}}, \mathsf{seed})$

Scope closed: The seed scope records the finite compact-metric carrier, metric-topology route, clopen-basis schedule, total-bounded finite-net binding, real-valued readback, and downstream non-escape boundary.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CompactZeroDimensionalMetric}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Origin: human

Not claimed: This chapter does not prove open-cover compactness, choose arbitrary clopen refinements, identify quotient compact spaces, or close ambient $\mathsf{Real}^{\uparrow}$ completeness.

Upgrade path: Obligation closure requires checked carrier admission, metric-topology compatibility, finite clopen coverage, total-bounded net binding, real-valued readback exactness, and non-escape for the displayed packet.

Chapter 9141

A Concrete Naming Certificate for $\mathsf{AronszajnAscoli}^{\uparrow}$

Following Aronszajn and Ascoli, the $\mathsf{AronszajnAscoli}^{\uparrow}$ packet records the finite NameCert surface for compactness of a displayed equicontinuous family only after the compact source, continuous-map rows, finite-net modulus data, and terminal real-name handoff are visible. It sits beside the Arzela–Ascoli finite-net packet of chapter 7576, the equicontinuity family surface of chapter 413, the compact metric source of chapter 129, and the continuous-map carrier of chapter 130. The packet names only the BEDC finite route; it is not a host function-space compactness theorem, a selected subnet, quotient equality of maps, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 9141.1 (Aronszajn–Ascoli carrier)**.** *An* $\mathsf{AronszajnAscoli}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$A = (K, F, E, N_f, W, R, H, C, P, L)$$

with the following visible rows:

1. *K is the* $\mathsf{CompactMetric}^{\uparrow}$ *source row and F is the finite family of* $\mathsf{ContinuousMap}^{\uparrow}$ *rows over that source.*
2. *E is the* $\mathsf{EquicontinuityFamily}^{\uparrow}$ *row, and N_f is the finite-net handoff row consumed from the Arzela–Ascoli finite-net sibling.*
3. *W records the finite observation windows through* $\mathsf{StreamName}^{\uparrow}$*, and R records the regular rational readback and terminal* $\mathsf{Real}^{\uparrow}$ *seal used by each inspected map value.*
4. *H, C, P, L are the componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local* $\mathsf{NameCert}_{\mathsf{AronszajnAscoli}^{\uparrow}}$ *row.*

Theorem 9141.2 (Aronszajn–Ascoli NameCert obligations)**.** *For every accepted* $\mathsf{AronszajnAscoli}^{\uparrow}$ *carrier $A = (K, F, E, N_f, W, R, H, C, P, L)$, the local* $\mathsf{NameCert}_{\mathsf{AronszajnAscoli}^{\uparrow}}$ *surface consists exactly of compact-source admission, continuous-map family admission, equicontinuity visibility, finite-net handoff, finite observation windows, regular rational readback, terminal real-name sealing, componentwise transport, displayed replay, provenance, and local naming. Every compactness-facing consumer must read those rows before citing* $\mathsf{AronszajnAscoli}^{\uparrow}$*.*

Proof. Project the carrier of Definition 9141.1. The rows K, F, E, N_f, W, R are the only mathematical rows available before structural transport and local naming are inspected.

The compact and continuous-map dependencies are supplied by chapter 129 and chapter 130. The family-wide modulus information is supplied by chapter 413, while the finite-net handoff is supplied by chapter 7576.

Finally the readback and sealing rows pass through $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ before the local name L can be exported. No carrier coordinate remains for a host function-space compactness theorem, selected subnet, quotient equality of maps, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness. □

Theorem 9141.3 (Aronszajn–Ascoli finite equicontinuity route)**.** *Every accepted* $\mathsf{AronszajnAscoli}^{\uparrow}$ *compactness read factors through the finite route*

$$\mathsf{CompactMetric}^{\uparrow}, \mathsf{ContinuousMap}^{\uparrow}, \mathsf{EquicontinuityFamily}^{\uparrow}, \mathsf{ArzelaAscoliFiniteNet}^{\uparrow}, \mathsf{StreamName}^{\uparrow}, \mathsf{RegSeqRat}^{\uparrow}, \mathsf{Real}^{\uparrow}, \mathsf{hs}$$

Thus the equicontinuity witness and finite-net witness are displayed before any compactness-facing handoff is public.

Proof. Start with the compact source row K and displayed continuous family row F. They bind every inspected map value to the same compact-metric source and the same finite family ledger.

Next read the equicontinuity row E together with the finite-net handoff row N_f. These rows provide the shared modulus and the finite source-net boundary that an Arzela–Ascoli style consumer may inspect.

Finally read W, R, H, C, P, L. The finite observation windows and real-name seals make each inspected value visible before local naming, so the compactness handoff remains a finite BEDC route and cannot import selected subnets or host function-space compactness. □

Theorem 9141.4 (Aronszajn–Ascoli compact handoff)**.** *The* $\mathsf{AronszajnAscoli}^{\uparrow}$ *packet may hand a compactness-facing consumer to the Arzela–Ascoli and compact-metric siblings only through the carrier rows of Definition 9141.1. In particular, the handoff cites chapter 412, chapter 129, chapter 413, and chapter 130 as displayed NameCert dependencies, not as hidden ambient theorems.*

Proof. Use Definition 9141.2 to identify the complete local obligation surface. The only handoff rows are the displayed compact source, continuous family, equicontinuity, finite-net, finite-window, readback, real-seal, and structural rows.

Apply Definition 9141.3. It orders the compact and equicontinuity dependencies before the real-name handoff, so the consumer cannot bypass them by citing an ambient compactness principle.

Therefore every compact handoff is a sibling-lattice read through the named concrete-instance chapters. The packet exports no selected subnet, quotient map equality, countable-choice schedule, host function-space compactness theorem, or ambient $\mathsf{Real}^{\uparrow}$ completeness. □

Closure status for $\mathsf{NameCert}_{\mathsf{AronszajnAscoli}^{\uparrow}}$.

Constructive story: An $\mathsf{AronszajnAscoli}^{\uparrow}$ packet is generated from CompactMetric, ContinuousMap, EquicontinuityFamily, ArzelaAscoliFiniteNet, StreamName, RegSeqRat, Real, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert rows.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{AronszajnAscoli}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 9141.1, Definition 9141.2, Definition 9141.3, and Definition 9141.4 seed the finite compactness-facing NameCert surface over compact-source, continuous-family, equicontinuity, finite-net, window, readback, real-seal, transport, replay, provenance, and local naming rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{AronszajnAscoli}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host function-space compactness, selected subnets, quotient equality of maps, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked compact-source admission, continuous-family admission, equicontinuity visibility, finite-net handoff, finite-window readback, real sealing, transport, replay, provenance, and local naming for BEDC.Derived.AronszajnAscoliUp.

Chapter 9142

A Concrete Naming Certificate for $\mathsf{ZeroLedgerRigidity}^{\uparrow}$

The $\mathsf{ZeroLedgerRigidity}^{\uparrow}$ packet realizes the zero-ledger rigidity route of section 9414.6 as finite visible-route, replay, provenance, and no-hidden-ledger NameCert data. It sits beside the fixed-half witness of chapter 9046, the local-global zero exclusion certificate of chapter 9056, the reality-constrained open-fit boundary of chapter 1132, the finite observation boundary of chapter 9102, and the finite comparison boundary of chapter 9134. The packet names a zero-ledger rigidity surface only; it is not a host proof of RH, a selected zero list, an analytic-continuation theorem, a hidden completed-carrier equality, or an ambient real-completeness principle.

Definition 9142.1 (ZeroLedgerRigidity carrier)**.** *A* $\mathsf{ZeroLedgerRigidity}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Z = (V, Q, F, E, O, R, G, H, C, P, N)$$

with the following displayed rows:

1. *V is the visible zero-ledger route, exposing the same tower point, zeta-coordinate row, zero atom, and information-band row before any rigidity read is public.*
2. *Q is the fixed-half comparison row consumed from* $\mathsf{FixedHalfZeroWitness}^{\uparrow}$*.*
3. *F is the off-fixed exclusion row consumed from* $\mathsf{LocalGlobalZeroExclusionCertificate}^{\uparrow}$*.*
4. *E is the finite evidence row tying the zero-ledger atom to open-fit, observation-boundary, and finite-comparison witnesses.*
5. *O is the no-hidden-ledger row refusing zero data not displayed in V, E.*
6. *R is the replay row recording the order in which visible route, fixed-half comparison, exclusion, and evidence rows are consumed.*
7. *G is the provenance row over the vision route, the fixed-half sibling, the zero-exclusion sibling, open fit, observation boundary, and comparison boundary.*
8. *H, C, P, N are componentwise* hsame *transport, displayed* Cont *replay,* Pkg *packaging, and local* $\mathsf{NameCert}_{\mathsf{ZeroLedgerRigidity}^{\uparrow}}$ *naming.*

The carrier has no coordinate for a hidden zero ledger, selected off-fixed zero, host analytic continuation, quotient completed-carrier equality, countable-choice schedule, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 9142.2 (ZeroLedgerRigidity NameCert obligations)**.** *For every accepted* $\mathsf{ZeroLedgerRigidity}^{\uparrow}$ *carrier* $Z = (V, Q, F, E, O, R, G, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{ZeroLedgerRigidity}^{\uparrow}}$ *surface consists exactly of visible-route admission, fixed-half comparison, off-fixed exclusion, finite evidence exposure, no-hidden-ledger refusal, replay ordering, provenance, transport, displayed continuation, packaging, and local naming. Every rigidity-facing consumer must display those rows before reading the packet.*

Proof. Project the carrier of Definition 9142.1. The rows V, Q, F, E, O are the mathematical surface: visible zero route, fixed-half comparison, exclusion, finite evidence, and no-hidden-ledger refusal.

The route rows are consumed from the siblings. $\mathsf{FixedHalfZeroWitness}^{\uparrow}$ supplies the fixed surface, $\mathsf{LocalGlobalZeroExclusionCertificate}^{\uparrow}$ supplies the off-fixed exclusion gate, and the open-fit, observation-boundary, and finite-comparison siblings supply the visible evidence boundary.

Finally read R, G, H, C, P, N. Replay fixes the order, provenance records the sibling sources, and transport, continuation, package, and local naming keep the export inside the displayed packet. Since no carrier coordinate remains, a hidden ledger or selected off-fixed zero cannot be read by the accepted NameCert. □

Theorem 9142.3 (ZeroLedgerRigidity route nonescape)**.** *Every accepted* $\mathsf{ZeroLedgerRigidity}^{\uparrow}$ *rigidity read factors through*

$$\mathsf{FixedHalfZeroWitness}^{\uparrow}, \mathsf{LocalGlobalZeroExclusionCertificate}^{\uparrow}, \mathsf{RealityConstrainedOpenFit}^{\uparrow}, \mathsf{FiniteObservationBoundary}^{\uparrow}$$

It cannot obtain a zero atom from a hidden ledger, cannot bypass the fixed-half comparison row, and cannot replace finite evidence with host analytic continuation or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start with the visible route row V. It binds the tower point, zeta-coordinate row, zero atom, and information-band row before rigidity is available.

Next consume Q, F, E, O. The fixed-half comparison and off-fixed exclusion rows place the zero-ledger atom against the fixed surface, while the finite evidence and no-hidden-ledger rows force all observation and comparison data to be public.

Finally use R, G, H, C, P, N to replay and name the same route. Since every export is already listed in the carrier, a consumer cannot add hidden zero data, selected off-fixed witnesses, host analytic continuation, quotient completed-carrier equality, countable choice, or ambient real completeness. □

Falsifiable prediction: An accepted $\mathsf{ZeroLedgerRigidity}^{\uparrow}$ rigidity read is refuted if it obtains a zero atom, fixed-half comparison, off-fixed exclusion, or evidence row without first exposing the visible route row V and the no-hidden-ledger row O.

Independence witness: fixed-half-zero-witness, local-global-zero-exclusion-certificate, reality-constrained-open-fit, finite-observation-boundary, finite-comparison-boundary: no listed sibling is bijective to $\mathsf{ZeroLedgerRigidity}^{\uparrow}$ because this packet jointly carries visible zero-route data, fixed-half comparison, off-fixed exclusion, finite evidence, no-hidden-ledger refusal, replay, provenance, transport, packaging, and local naming.

The Lean follow-up must provide explicit $\mathsf{Nontrivial}\ \mathsf{ZeroLedgerRigidity}^{\uparrow}$ and $\mathsf{FieldFaithful}\ \mathsf{ZeroLedgerRigidity}^{\uparrow}$ instances before a checked carrier-alignment theorem can serve as a public TasteGate witness.

Closure status for $\mathsf{NameCert}_{\mathsf{ZeroLedgerRigidity}^{\uparrow}}$**.**

Constructive story: A $\mathsf{ZeroLedgerRigidity}^{\uparrow}$ packet is generated from a visible zero-ledger route, fixed-half comparison, off-fixed exclusion, finite evidence, no-hidden-ledger refusal, replay ordering, provenance, componentwise hsame transport, displayed Cont replay, Pkg packaging, and local NameCert rows.

Theory closure: TheoryGate(NameCert$_{\mathsf{ZeroLedgerRigidity}\uparrow}$, seed)

Scope closed: Definition 9142.1, Definition 9142.2, Definition 9142.3, the falsifiable prediction, the independence witness, and the Lean follow-up statement seed the finite visible-route rigidity packet over fixed-half comparison, off-fixed exclusion, evidence, no-hidden-ledger, replay, provenance, transport, package, and local naming rows.

Formal verification: FormalStatus(NameCert$_{\mathsf{ZeroLedgerRigidity}\uparrow}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close a host proof of RH, selected zero lists, host analytic continuation, hidden completed-carrier equality, countable choice, ambient Real$^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked visible-route admission, fixed-half comparison, off-fixed exclusion, finite evidence exposure, no-hidden-ledger refusal, replay ordering, provenance, transport, packaging, local naming, and the Nontrivial and FieldFaithful rows for BEDC.Derived.ZeroLedgerRigidityUp.

Chapter 9143

A Concrete Naming Certificate for $\mathsf{CompactUniformContinuityExtractor}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{CompactUniformContinuityExtractor}^{\uparrow}$ packet records the finite-net extraction route by which a displayed continuous map on a compact metric source yields a uniform-continuity budget only through inspected compact, metric, rational, and real-name rows. It sits after the compact carrier of chapter 60, the metric carrier of chapter 57, the continuous-map carrier of chapter 130, the rational carrier of chapter 37, and the terminal real-name seal of chapter 38. The packet names a constructive finite-net extractor; it is not a host Heine–Cantor theorem, a selected infinite cover, quotient function equality, countable choice, or ambient completeness for $\mathsf{Real}^{\uparrow}$.

Definition 9143.1 (Compact uniform-continuity extractor carrier)**.** *A* $\mathsf{CompactUniformContinuityExtractor}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$E = (K, M, F, Q, R, W, H, C, P, N)$$

with the following displayed rows:

1. *K is the* $\mathsf{Compact}^{\uparrow}$ *source row, carrying the finite cover or finite-net admission surface available to the extractor.*
2. *M is the* $\mathsf{Met}^{\uparrow}$ *source row on the same displayed carrier as K.*
3. *F is the* $\mathsf{ContinuousMap}^{\uparrow}$ *row whose local continuity reads are inspected only over the compact-metric source.*
4. *Q is the* $\mathsf{Rat}^{\uparrow}$ *radius and tolerance ledger used to compare finite net cells.*
5. *R is the* $\mathsf{Real}^{\uparrow}$ *distance and value-readback seal reached from the rational ledger.*
6. *W is the finite-net witness row: it records the chosen inspected net cells, the local continuity budgets attached to them, and the common modulus bound exported to consumers.*
7. *H records componentwise* hsame *transport for $K, M, F, Q, R, W, C, P, N$.*
8. *C records displayed* Cont *replay from compact-metric admission through local continuity, finite-net comparison, real readback, and exported uniform budget.*
9. *P is the* Pkg *provenance over* $\mathsf{CompactUniformContinuityExtractor}^{\uparrow}$, $\mathsf{Compact}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{Rat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

10. N is the local $\mathsf{NameCert}_{\mathsf{CompactUniformContinuityExtractor}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these rows. It has no coordinate for an ambient compactness oracle, a host function space, an infinite cover selector, quotient equality of maps, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 9143.2 (Compact uniform-continuity extractor NameCert obligations)**.** *For every accepted* $\mathsf{CompactUniformContinuityExtractor}^{\uparrow}$ *carrier*

$$E = (K, M, F, Q, R, W, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{CompactUniformContinuityExtractor}^{\uparrow}}$ *surface consists exactly of compact-source admission through K, metric-source admission through M, continuous-map local reads through F, rational radius and tolerance comparison through Q, real-name distance and value seals through R, finite-net extraction through W, componentwise* hsame *transport through H, displayed* Cont *replay through C, provenance through P, and local naming through N.*

Proof. Project the carrier of Definition 9143.1. The source rows K, M, F make compactness, metric distance, and local continuity visible before any uniform budget can be read.

The extraction row is W. It is reached only after the rational ledger Q and the real-name readback row R have displayed the finite radii, tolerance comparisons, and value-distance seals needed by the finite-net argument. Thus a consumer cannot replace the extractor by an ambient compactness theorem or by a selected infinite cover.

The structural rows preserve the same route. Transport through H, replay through C, provenance through P, and local naming through N export the finite packet named above. Since the carrier has no coordinate for host function equality, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness, the listed rows exhaust the local NameCert surface. □

Falsifiable prediction: Every accepted $\mathsf{CompactUniformContinuityExtractor}^{\uparrow}$ read exposes $\mathsf{Compact}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{Rat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, finite-net extraction, componentwise transport, displayed replay, provenance, and local naming before any uniform-continuity budget is public.

Independence witness: compact, metric, continuousmap, rat, real: $\mathsf{CompactUniformContinuityExtractor}^{\uparrow}$ is not bijective to any listed sibling because it jointly binds compact finite-net admission, metric distance, continuous-map local reads, rational tolerance comparison, Real readback, finite-net extraction, transport, replay, provenance, and local NameCert rows.

Closure status for $\mathsf{NameCert}_{\mathsf{CompactUniformContinuityExtractor}^{\uparrow}}$**.**

Constructive story: A $\mathsf{CompactUniformContinuityExtractor}^{\uparrow}$ packet is generated from a compact source row, a metric source row, a continuous-map row, rational radius and tolerance rows, real-name distance and value seals, finite-net extraction, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{CompactUniformContinuityExtractor}^{\uparrow}}$, seed)

Scope closed: Definition 9143.1 and Definition 9143.2 bind the finite-net extractor surface over compact, metric, continuous-map, rational, real-name, transport, replay, provenance, and local naming rows.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{CompactUniformContinuityExtractor}^{\uparrow}}$, unformalized)

Bridge status: none

Origin: human

Not claimed: This chapter does not close Lean verification, bridge checking, a host Heine–Cantor theorem, quotient equality of maps, selected infinite covers, countable choice, or ambient Real completeness.

Upgrade path: Obligation closure requires checked carrier admission, compact-source visibility, metric-source visibility, continuous-map local-read routing, rational tolerance comparison, real-name readback, finite-net extraction, transport, replay, provenance, and local naming for BEDC.Derived.CompactUniformContinuityExtractorUp.

Chapter 9144

A Concrete Naming Certificate for HyperbolicBusemannBoundaryBudget$^{\uparrow}$

The HyperbolicBusemannBoundaryBudget$^{\uparrow}$ packet realizes the boundary-budget branch of chapter 9463 as finite BEDC NameCert data. It sits after the hyperbolic metric row of chapter 3474, the Busemann boundary row of chapter 3732, the boundary-fixed disk transport row of chapter 6267, the horocycle row of chapter 3534, and the horosphere row of chapter 8521. The packet names the finite disk-map, metric-read, boundary, classifier-stability, provenance, and refusal rows required by observer-expansion boundary budgets; it is not a global hyperbolic model, a quotient ideal boundary, a selected geodesic ray, or a physical observer.

Definition 9144.1 (Hyperbolic Busemann-boundary budget carrier)**.** *A* HyperbolicBusemannBoundaryBudget$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (D, M, U, Y, O, S, R, H, C, P, N)$$

with the following displayed rows:

1. *D is the disk-map readout row, keeping the inspected Poincare-disk coordinate and boundary-admission window finite.*
2. *M is the* HyperbolicMetric$^{\uparrow}$ *metric-read row attached to that disk window.*
3. *U is the* HyperbolicBusemannBoundary$^{\uparrow}$ *boundary row, exposing Busemann-level readback only through displayed metric and boundary data.*
4. *Y is the boundary-fixed transport row supplied by the Poincare disk boundary-transport sibling.*
5. *O is the horocycle and horosphere budget row, combining the displayed* HyperbolicHorocycle$^{\uparrow}$ *and* HyperbolicHorosphere$^{\uparrow}$ *boundary-level reads.*
6. *S is the classifier-stability row, requiring the same disk, metric, Busemann-boundary, transport, and budget rows before a boundary verdict is public.*
7. *R is the refusal row excluding interior far-end fixed points, quotient ideal-boundary equality, selected rays, and detached observer states.*
8. *H records componentwise* hsame *transport for $D, M, U, Y, O, S, R, C, P, N$.*
9. *C records displayed* Cont *replay from disk readout through metric read, Busemann boundary, boundary-fixed transport, budget, classifier stability, refusal, provenance, and local naming.*

10. *P is the* Pkg *provenance over* HyperbolicBusemannBoundaryBudget$^{\uparrow}$, HyperbolicMetric$^{\uparrow}$, HyperbolicBusemannBou HyperbolicHorocycle$^{\uparrow}$, HyperbolicHorosphere$^{\uparrow}$, *boundary-fixed transport,* BHist, hsame, Cont, *and* NameCert.
11. *N is the local* NameCert$_{\text{HyperbolicBusemannBoundaryBudget}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these rows. It has no coordinate for a host hyperbolic surface, quotient ideal-boundary equality, selected geodesic rays, a physical observer, or ambient completeness.

Theorem 9144.2 (Hyperbolic Busemann-boundary budget NameCert obligations)**.** *For every accepted* HyperbolicBusemannBoundaryBudget$^{\uparrow}$ *carrier*

$$B = (D, M, U, Y, O, S, R, H, C, P, N),$$

the local NameCert$_{\text{HyperbolicBusemannBoundaryBudget}^{\uparrow}}$ *surface consists exactly of disk-map readout through D, hyperbolic metric readback through M, Busemann-boundary exposure through U, boundary-fixed transport through Y, horocycle and horosphere budget exposure through O, classifier stability through S, refusal through R, componentwise* hsame *transport through H, displayed* Cont *replay through C, provenance through P, and local naming through N.*

Proof. Project the carrier of Definition 9144.1. The metric and boundary rows M, U are not public until the disk-map row D is displayed, and the budget row O is not public until the Busemann-boundary and boundary-fixed transport rows are visible.

The classifier-stability row S reads the same disk, metric, boundary, transport, and budget rows before it exports a boundary verdict. The refusal row R then records the nonescape constraints: no interior far-end fixed point, quotient ideal-boundary equality, selected ray, or detached observer state can be projected from the packet.

The structural rows preserve the same route. Transport through H, replay through C, provenance through P, and local naming through N expose the finite NameCert surface and no additional hyperbolic host object. □

Theorem 9144.3 (Hyperbolic Busemann-boundary budget TasteGate requirements)**.** *The Lean follow-up for* HyperbolicBusemannBoundaryBudget$^{\uparrow}$ *must provide* Nontrivial HyperbolicBusemannBoundaryBudget$^{\uparrow}$ *and* FieldFaithful HyperbolicBusemannBoundaryBudget$^{\uparrow}$ *instances for the same carrier*

$$B = (D, M, U, Y, O, S, R, H, C, P, N).$$

Nontriviality must distinguish a packet with the displayed boundary budget from a packet with a missing disk, metric, Busemann-boundary, transport, budget, classifier-stability, or refusal row. Field faithfulness must preserve the row order $D, M, U, Y, O, S, R, H, C, P, N$ without replacing it by a host hyperbolic model or quotient boundary.

Proof. Read the requirement from Definition 9144.1. The packet is nontrivial only when the disk-map, metric, Busemann-boundary, boundary-fixed transport, horocycle and horosphere budget, classifier-stability, refusal, transport, replay, provenance, and local naming rows are all present.

Field faithfulness is the same row-preservation demand. Any classifier that identifies two packets while changing one of $D, M, U, Y, O, S, R, H, C, P, N$ would erase the finite boundary-budget route and would no longer be a faithful TasteGate for the chapter.

The excluded host objects are absent from the carrier and from the NameCert obligations of Definition 9144.2. The Lean follow-up therefore has to certify the finite carrier, not a global hyperbolic surface or quotient ideal boundary. □

Falsifiable prediction: Every accepted $\mathsf{HyperbolicBusemannBoundaryBudget}^{\uparrow}$ boundary-budget read exposes disk-map, hyperbolic metric, Busemann-boundary, boundary-fixed transport, horocycle and horosphere budget, classifier-stability, refusal, transport, replay, provenance, and local naming rows before any observer-expansion boundary verdict is public.

Independence witness: hyperbolic-metric, hyperbolic-busemann-boundary, poincare-disk-boundary-transport, hyperbolic-horocycle, hyperbolic-horosphere: $\mathsf{HyperbolicBusemannBoundaryBudget}^{\uparrow}$ is not bijective to any listed sibling because it jointly binds disk readout, metric readback, Busemann-boundary exposure, boundary-fixed transport, horocycle and horosphere budgets, classifier stability, refusal, transport, replay, provenance, and local NameCert rows.

Closure status for $\mathsf{NameCert}_{\mathsf{HyperbolicBusemannBoundaryBudget}^{\uparrow}}$.

Constructive story: A $\mathsf{HyperbolicBusemannBoundaryBudget}^{\uparrow}$ packet is generated from disk-map readout, hyperbolic metric readback, Busemann-boundary exposure, boundary-fixed transport, horocycle and horosphere budget rows, classifier stability, refusal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{HyperbolicBusemannBoundaryBudget}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 9144.1, Definition 9144.2, and Definition 9144.3 bind the finite boundary-budget carrier, NameCert surface, and TasteGate follow-up requirements.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{HyperbolicBusemannBoundaryBudget}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Origin: ai

Not claimed: This chapter does not close Lean verification, bridge checking, a global hyperbolic model, quotient ideal-boundary equality, selected geodesic rays, physical observers, or ambient completeness.

Upgrade path: Obligation closure requires checked carrier admission, disk-map readout, metric readback, Busemann-boundary exposure, boundary-fixed transport, horocycle and horosphere budget exactness, classifier stability, refusal, and TasteGate Nontrivial and FieldFaithful instances for BEDC.Derived.HyperbolicBusemannBoundaryBudgetUp.

Chapter 9145

A Concrete Naming Certificate for McNaughtonPiecewiseLinear$^{\uparrow}$

Following McNaughton and standard finite MV-algebra representation theory, the McNaughtonPiecewiseLinear$^{\uparrow}$ packet records a finite rational polyhedral presentation of an integer-slope piecewise-linear map before any real-valued or algebraic consumer reads it. It sits beside the finite interval and partition routes of chapter 9133 and chapter 9115, the rational ledger of chapter 291, the finite stream window of chapter 126, the regular rational readback of chapter 301, and the terminal real seal of chapter 38. The packet names finite-cell McNaughton data only; it does not assert an ambient real-function extensionality theorem, an infinite subdivision search, a hidden fan, or quotient equality of completed functions.

Definition 9145.1 (McNaughton piecewise-linear carrier)**.** *A* McNaughtonPiecewiseLinear$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M = (C, A, R, D, S, Q, E, H, T, P, N)$$

with the following displayed rows:

1. *C is a finite rational polyhedral cell list, with each cell described by finitely many rational half-space inequalities and with overlaps recorded only through the displayed shared-refinement ledger.*
2. *A assigns to each cell an integer-slope affine expression with rational intercept data.*
3. *R is the shared refinement ledger, recording the common subdivision on which adjacent cell expressions agree on the displayed boundary faces.*
4. *D is the* DyadicRatCore$^{\uparrow}$ *and* Rat$^{\uparrow}$ *coefficient readback row for rational vertices, half-space constants, slopes, intercepts, and boundary comparisons.*
5. *S is the* StreamName$^{\uparrow}$ *finite inspection row for requested cells, faces, and coefficient windows.*
6. *Q is the* RegSeqRat$^{\uparrow}$ *regular rational readback row attached to the same windows.*
7. *E is the* Real$^{\uparrow}$ *seal row reached only after C, A, R, D, S, Q have been displayed.*
8. *H records componentwise* hsame *transport for cell lists, affine pieces, shared-refinement rows, rational readbacks, stream windows, regular rational tails, and the real seal.*
9. *T records displayed* Cont *replay from the finite cell table through rational readback and regular-tail rows to the real-facing seal.*

10. *P is the* Pkg *provenance over* McNaughtonPiecewiseLinear$^\uparrow$, DyadicRatCore$^\uparrow$, Rat$^\uparrow$, StreamName$^\uparrow$, RegSeqRat$^\uparrow$, Real$^\uparrow$, BHist, hsame, Cont, Pkg, *and* NameCert *rows.*

11. *N is the local* NameCert$_{\text{McNaughtonPiecewiseLinear}^\uparrow}$ *row.*

The carrier has no coordinate for an infinite partition, hidden real-function equality, externally chosen refinement, quotient completed-function equality, non-rational coefficient oracle, or ambient Real$^\uparrow$ *completeness.*

Theorem 9145.2 (McNaughton piecewise-linear NameCert obligations)**.** *For every accepted* McNaughtonPiecewise *carrier $M = (C, A, R, D, S, Q, E, H, T, P, N)$, the local* NameCert$_{\text{McNaughtonPiecewiseLinear}^\uparrow}$ *surface consists exactly of finite cell admission, integer-slope affine-piece admission, shared-refinement agreement, rational coefficient readback, finite-window exposure, regular rational tail readback, real-seal nonescape, componentwise transport, displayed replay, package provenance, and local naming.*

Proof. Project the carrier of Definition 9145.1. The rows C, A, R are the finite McNaughton table: cells, affine expressions, and the common refinement on which boundary agreement is witnessed.

Next read D, S, Q, E. Rational coefficient data is exposed through DyadicRatCore$^\uparrow$ and Rat$^\uparrow$, finite requests pass through StreamName$^\uparrow$, regular rational readback is supplied by RegSeqRat$^\uparrow$, and the Real$^\uparrow$ seal is available only after those rows have been displayed.

Finally inspect H, T, P, N. Transport, replay, provenance, and local naming preserve the same finite row inventory. Since no coordinate remains, an accepted certificate cannot add an infinite subdivision, a hidden real-function equality, or an ambient completeness claim. □

Theorem 9145.3 (McNaughton finite-cell handoff)**.** *Every* Real$^\uparrow$*-facing or* Rat$^\uparrow$*-facing consumer of an accepted* McNaughtonPiecewiseLinear$^\uparrow$ *carrier must factor through the finite route*

$$C, A, R \longmapsto \mathsf{DyadicRatCore}^\uparrow, \mathsf{Rat}^\uparrow \longmapsto \mathsf{StreamName}^\uparrow \longmapsto \mathsf{RegSeqRat}^\uparrow \longmapsto \mathsf{Real}^\uparrow$$

using the displayed rows D, S, Q, E, H, T, P, N. The handoff exports the finite-cell piecewise-linear table, not host extensional equality of real functions, an infinite refinement procedure, quotient completed-function equality, or a hidden coefficient oracle.

Proof. Begin with the finite cell and affine-piece rows. The shared-refinement ledger R is part of the same packet as C and A, so a consumer cannot read an affine expression independently of the cell subdivision on which it is certified.

The rational readback row D then exposes vertices, inequalities, slopes, intercepts, and boundary comparisons through DyadicRatCore$^\uparrow$ and Rat$^\uparrow$. The window row S and regular readback row Q make the same finite data available to stream and regular-rational consumers before the terminal real seal E is reached.

The structural rows H, T, P, N replay and name exactly this route. Therefore every accepted handoff is finite-cell data transported through rational and regular readback rows, with no additional real-function extensionality, infinite search, or hidden refinement surface. □

The Lean follow-up is expected under `BEDC.Derived.McNaughtonPiecewiseLinearUp`; it must provide explicit finite-cell carrier admission, shared-refinement agreement, and nontrivial field-faithful TasteGate rows before any checked marker is cited.

Closure status for NameCert$_{\text{McNaughtonPiecewiseLinear}^\uparrow}$.

Constructive story: A McNaughtonPiecewiseLinear$^\uparrow$ packet is generated from finite rational polyhedral cells, integer-slope affine pieces, shared-refinement agreement, DyadicRatCore and Rat readback, StreamName windows, RegSeqRat tails, a Real seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\text{McNaughtonPiecewiseLinear}^\uparrow}$, seed)

Scope closed: Definition 9145.1, Definition 9145.2, and Definition 9145.3 seed the finite-cell McNaughton packet over rational polyhedral cells, integer-slope affine pieces, shared refinement, rational readback, stream windows, regular rational tails, real seal, transport, replay, provenance, and local naming.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{McNaughtonPiecewiseLinear}\uparrow}, \text{unformalized})$

Bridge status: none

Not claimed: This chapter does not close ambient real-function extensionality, infinite subdivision search, hidden fan construction, quotient completed-function equality, non-rational coefficient oracles, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked finite-cell admission, integer-slope affine-piece admission, shared-refinement agreement, rational coefficient readback, finite-window exposure, regular rational tail readback, real-seal nonescape, transport, replay, provenance, and local naming.

Chapter 9146

A Concrete Naming Certificate for LocatedCauchyModulusExtraction$^{\uparrow}$

Following Bishop and Bridges on located real numbers and constructive Cauchy data, the LocatedCauchyModulusExt packet records the finite route by which a displayed located regular Cauchy name exposes an explicit modulus row before any Real or Completion consumer reads the terminal seal. It sits over the dyadic tolerance core of chapter 291, the finite stream-window surface of chapter 126, the regular rational readback of chapter 301, the terminal real-name seal of chapter 38, and the located-real comparison surface of chapter 1933. The packet names modulus extraction as displayed NameCert data; it does not choose a quotient representative, invoke countable choice, or appeal to ambient Real$^{\uparrow}$ completeness.

Definition 9146.1 (Located Cauchy modulus extraction carrier)**.** *A* LocatedCauchyModulusExtraction$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M = (L, W, D, R, E, Q, H, C, P, N)$$

with the following displayed rows:

1. *L is the located Cauchy source row, recording the located interval and comparison data visible to the extractor.*
2. *W is the* StreamName$^{\uparrow}$ *finite-window row through which the source is inspected.*
3. *D is the* DyadicRatCore$^{\uparrow}$ *tolerance ledger controlling the requested precision.*
4. *R is the* RegSeqRat$^{\uparrow}$ *readback row obtained from the same finite windows and dyadic tolerances.*
5. *E is the terminal* Real$^{\uparrow}$ *seal row, available only after L, W, D, R have been displayed.*
6. *Q is the extracted modulus row, recording the finite stage bound certified for the displayed tolerance request.*
7. *H records componentwise* hsame *transport for the located source, finite window, dyadic tolerance, regular readback, Real seal, modulus row, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay of the route*

$$L, W, D, R \longmapsto Q \longmapsto E.$$

9. *P is the* Pkg *provenance over* LocatedCauchyModulusExtraction$^{\uparrow}$*,* LocatedReal$^{\uparrow}$*,* DyadicRatCore$^{\uparrow}$*,* StreamName$^{\uparrow}$*,* RegSeqRat$^{\uparrow}$*,* Real$^{\uparrow}$*,* BHist*,* hsame*,* Cont*, and* NameCert*.*

10. N is the local $\mathsf{NameCert}_{\mathsf{LocatedCauchyModulusExtraction}^{\uparrow}}$ *row.*
The classifier compares accepted packets only through $L, W, D, R, E, Q, H, C, P, N$. It has no coordinate for a quotient representative, a countable-choice selector, a hidden limit object, host equality of real names, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 9146.2 (Located Cauchy modulus extraction NameCert obligations)**.** *For every accepted* $\mathsf{LocatedCauchyModulusExtraction}^{\uparrow}$ *carrier*

$$M = (L, W, D, R, E, Q, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{LocatedCauchyModulusExtraction}^{\uparrow}}$ *surface consists exactly of located-source exposure through L, StreamName finite-window exposure through W, DyadicRatCore tolerance exposure through D, RegSeqRat readback through R, Real sealing through E, extracted-modulus exposure through Q, componentwise transport through H, displayed replay through C, provenance through P, and local naming through N.*

Proof. Project the carrier of Definition 9146.1. The rows L, W, D, R expose the located source, finite stream window, dyadic tolerance, and regular rational readback before the modulus row can be inspected.

The modulus row Q is therefore tied to the displayed tolerance request. It is not a selected global schedule and it is not a quotient representative; it is the finite stage bound named by this packet for the visible located Cauchy source.

Finally E, H, C, P, N seal, transport, replay, source, and name the same route. Since no countable-choice selector, hidden host limit, host equality of real names, or ambient completeness theorem appears as a coordinate, the listed rows exhaust the local NameCert obligations. □

Theorem 9146.3 (Located Cauchy modulus soundness)**.** *Every Real-facing or Completion-facing consumer of an accepted* $\mathsf{LocatedCauchyModulusExtraction}^{\uparrow}$ *packet reads the extracted modulus only through the finite route*

$$\mathsf{LocatedReal}^{\uparrow},\ \mathsf{StreamName}^{\uparrow},\ \mathsf{DyadicRatCore}^{\uparrow},\ \mathsf{RegSeqRat}^{\uparrow} \longmapsto Q \longmapsto \mathsf{Real}^{\uparrow}.$$

Thus the exported modulus is sound only relative to the displayed located source, stream window, dyadic tolerance, regular readback, and terminal seal. It supplies no representative choice, quotient equality, countable-choice schedule, or ambient $\mathsf{Real}^{\uparrow}$ *completeness principle.*

Proof. Apply Definition 9146.2. The located source row L, window row W, tolerance row D, and readback row R are exposed before the extracted modulus row Q.

The terminal seal E is downstream of that same modulus row. A consumer may therefore use the modulus only as part of the displayed L, W, D, R, Q, E packet.

The structural rows H, C, P, N preserve the route under transport, replay it as a displayed continuation, record its provenance, and name it locally. No coordinate remains from which a consumer could recover a detached representative choice, quotient equality, countable-choice schedule, or ambient completeness assertion. □

The sibling route is explicit. $\mathsf{LocatedCauchyModulusExtraction}^{\uparrow}$ reads dyadic tolerances through $\mathsf{DyadicRatCore}^{\uparrow}$ in chapter 291, finite windows through $\mathsf{StreamName}^{\uparrow}$ in chapter 126, regular rational readback through $\mathsf{RegSeqRat}^{\uparrow}$ in chapter 301, terminal sealing through $\mathsf{Real}^{\uparrow}$ in chapter 38, and located comparison through $\mathsf{LocatedReal}^{\uparrow}$ in chapter 1933.

Closure status for $\mathsf{NameCert}_{\mathsf{LocatedCauchyModulusExtraction}^{\uparrow}}$.

Constructive story: A LocatedCauchyModulusExtraction$^{\uparrow}$ packet is generated from a located Cauchy source, StreamName finite windows, DyadicRatCore tolerances, RegSeqRat readback, a Real seal, an extracted modulus row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\text{LocatedCauchyModulusExtraction}^{\uparrow}}$, seed)

Scope closed: Definition 9146.1, Definition 9146.2, and Definition 9146.3 seed the located Cauchy modulus extraction route over the DyadicRatCore, StreamName, RegSeqRat, Real, and LocatedReal spine.

Formal verification: FormalStatus(NameCert$_{\text{LocatedCauchyModulusExtraction}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close quotient representatives, countable choice, selected limits, host equality of real names, ambient Real$^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked located-source admission, finite-window readback, dyadic tolerance, regular readback, Real sealing, modulus exposure, transport, replay, provenance, and local naming for BEDC.Derived.LocatedCauchyMod

Chapter 9147

A Concrete Naming Certificate for CauchyNameModulusExtraction$^{\uparrow}$

Following Bishop and Bridges on regular Cauchy representatives and diagonal limits, the CauchyNameModulusExtrac packet records the finite modulus-extraction route behind the regular-Cauchy diagonal-limit construction of chapter 9238. It sits over the dyadic tolerance core of chapter 291, the finite stream-window surface of chapter 126, the regular rational readback of chapter 301, the terminal real-name seal of chapter 38, and the finite separation boundary of chapter 1202. The packet names the finite extraction object used by a Cauchy name; it does not select a limit, quotient Cauchy names, invoke countable choice, or assert ambient Real$^{\uparrow}$ completeness.

Theorem 9147.1 (Cauchy name modulus extraction carrier)**.** *A* CauchyNameModulusExtraction$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$X = (S, W, D, R, E, F, M, H, C, P, N)$$

with the following displayed rows:

1. *S is the regular-Cauchy name source row, recording the sequence of regular rational names whose diagonal route is being inspected.*
2. *W is the* StreamName$^{\uparrow}$ *finite-window row selecting the visible indices used by the diagonal readback.*
3. *D is the* DyadicRatCore$^{\uparrow}$ *tolerance ledger for the requested precision and comparison budget.*
4. *R is the* RegSeqRat$^{\uparrow}$ *readback row obtained from the same finite window and dyadic tolerance data.*
5. *E is the terminal* Real$^{\uparrow}$ *seal row that receives the extracted Cauchy-name data.*
6. *F is the* FiniteWindowRealSeparation$^{\uparrow}$ *row that records the finite separation boundary used before a Real-facing equality or apartness read.*
7. *M is the extracted modulus row, naming the diagonal stage bound visible to the Cauchy-name consumer.*
8. *H records componentwise* hsame *transport for source, window, tolerance, readback, Real seal, finite separation, modulus, replay, provenance, and local naming rows.*

9. *C records displayed* Cont *replay of the route*

$$S, W, D, R, F \longmapsto M \longmapsto E.$$

10. *P is the* Pkg *provenance over* $\mathsf{CauchyNameModulusExtraction}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{FiniteWindowRealSeparation}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

11. *N is the local* $\mathsf{NameCert}_{\mathsf{CauchyNameModulusExtraction}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $S, W, D, R, E, F, M, H, C, P, N$. It has no coordinate for a selected limit, quotient equality of Cauchy names, countable choice, host equality of Real representatives, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 9147.2 (Cauchy name modulus extraction NameCert obligations)**.** *For every accepted* $\mathsf{CauchyNameModulusExtraction}^{\uparrow}$ *carrier*

$$X = (S, W, D, R, E, F, M, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{CauchyNameModulusExtraction}^{\uparrow}}$ *surface consists exactly of regular-Cauchy source exposure through S, StreamName finite-window exposure through W, DyadicRatCore tolerance exposure through D, RegSeqRat readback through R, Real sealing through E, finite separation exposure through F, modulus exposure through M, componentwise transport through H, displayed replay through C, provenance through P, and local naming through N.*

Proof. Project the carrier of Definition 9147.1. The rows S, W, D, R, F expose the regular-Cauchy source, finite window, dyadic tolerance, regular readback, and finite separation boundary before any modulus row is exported.

The extracted modulus row M is tied to that displayed diagonal window. It is not a chosen limit, a quotient representative, or a countable-choice schedule; it is the finite stage bound named for the inspected Cauchy-name route.

The terminal seal E and structural rows H, C, P, N preserve the same route for Real-facing consumers. Since no selected limit, quotient Cauchy-name equality, host real equality, or ambient completeness principle appears as a carrier coordinate, the listed rows exhaust the local NameCert surface. □

Theorem 9147.3 (Cauchy name diagonal modulus route)**.** *Every diagonal-limit consumer of an accepted* $\mathsf{CauchyNameModulusExtraction}^{\uparrow}$ *packet factors its read through the finite route*

$$\mathsf{StreamName}^{\uparrow},\ \mathsf{DyadicRatCore}^{\uparrow},\ \mathsf{RegSeqRat}^{\uparrow},\ \mathsf{FiniteWindowRealSeparation}^{\uparrow} \longmapsto M \longmapsto \mathsf{Real}^{\uparrow}.$$

The route realizes the regular-Cauchy diagonal-limit modulus extraction as finite NameCert data, without quotient representatives, selected limits, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Apply Definition 9147.2. It places the source, window, tolerance, readback, and finite separation rows before the extracted modulus row M.

The Real seal E is downstream of the same row. A diagonal-limit consumer therefore receives a finite Cauchy-name extraction packet, not a detached limit object.

Finally H, C, P, N transport, replay, source, and name the route. These rows keep the exported modulus inside the displayed BEDC surface and leave no coordinate for quotient equality, countable choice, host real equality, or ambient completeness. □

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyNameModulusExtraction}^{\uparrow}}$.

Constructive story: A $\mathsf{CauchyNameModulusExtraction}^{\uparrow}$ packet is generated from a regular-Cauchy name source, StreamName finite windows, DyadicRatCore tolerances, RegSeqRat readback, a Real seal, a finite separation boundary, an extracted modulus row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CauchyNameModulusExtraction}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 9147.1, Definition 9147.2, and Definition 9147.3 seed the regular-Cauchy diagonal-limit modulus route over the DyadicRatCore, StreamName, RegSeqRat, Real, and FiniteWindowRealSeparation spine.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CauchyNameModulusExtraction}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close selected limits, quotient equality of Cauchy names, countable choice, host equality of Real representatives, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked source admission, finite-window readback, dyadic tolerance, regular readback, finite separation, Real sealing, modulus exposure, transport, replay, provenance, and local naming for BEDC.Derived.CauchyNameModulusExtractionUp.

Chapter 9148

A Concrete Naming Certificate for $\mathsf{SequentiallyTotallyBounded}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{SequentiallyTotallyBounded}^{\uparrow}$ packet records the L10 finite-window compactness route by which a bounded regular Cauchy source is inspected through finite nets before a Real or Completion consumer asks for a cluster-facing read. It sits beside the bounded source of chapter 1697, the bounded-subsequence route of chapter 1698, the Cauchy sequence space of chapter 406, the stream-window source of chapter 126, the regular rational readback of chapter 301, the dyadic tolerance ledger of chapter 291, and the terminal real-name seal of chapter 38. The packet names a sequential finite-window total-boundedness carrier; it is not open-cover compactness, a selected subsequence, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 9148.1 (SequentiallyTotallyBounded carrier)**.** *A* $\mathsf{SequentiallyTotallyBounded}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (B, Q, X, W, D, E, F, R, H, C, P, N)$$

with the following displayed rows:

1. *B is the* $\mathsf{BoundedRegularCauchy}^{\uparrow}$ *source row;*
2. *Q is the* $\mathsf{BoundedRegularCauchySubsequence}^{\uparrow}$ *downstream route available only as displayed bounded-subsequence provenance;*
3. *X is the* $\mathsf{CauchySequenceSpace}^{\uparrow}$ *ambient sequence-space row;*
4. *W is the finite* $\mathsf{StreamName}^{\uparrow}$ *window schedule inspected at the requested precision;*
5. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger for the finite window;*
6. *E is the finite net row covering the inspected window at the displayed dyadic tolerance;*
7. *F is the sequential finite-window classifier saying that every inspected prefix element is assigned to one displayed net cell;*
8. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *and* $\mathsf{Real}^{\uparrow}$ *readback row reached only after B, X, W, D, E, F have been displayed;*
9. *H records componentwise* hsame *transport over the source, sequence-space, finite-window, dyadic, net, classifier, readback, provenance, and local naming rows;*
10. *C records displayed* Cont *replay for the same finite-window route;*

11. *P is the* Pkg *provenance over* $\mathsf{SequentiallyTotallyBounded}^{\uparrow}$, $\mathsf{BoundedRegularCauchy}^{\uparrow}$, $\mathsf{BoundedRegularCauchySubs}$ $\mathsf{CauchySequenceSpace}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert*;*
12. *N is the local* $\mathsf{NameCert}_{\mathsf{SequentiallyTotallyBounded}^{\uparrow}}$ *row.*

The carrier has no coordinate for an open-cover compactness proof, a selected infinite subsequence, countable choice, quotient stream equality, host real equality, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 9148.2 (SequentiallyTotallyBounded NameCert obligations)**.** *For every accepted* SequentiallyTotallyBou *carrier $S = (B, Q, X, W, D, E, F, R, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{SequentiallyTotallyBounded}^{\uparrow}}$ *surface consists exactly of carrier admission, bounded regular Cauchy source exposure, bounded-subsequence provenance, Cauchy sequence-space exposure, finite stream-window scheduling, dyadic tolerance exactness, finite-net assignment, sequential finite-window classifier stability, regular rational and Real readback non-escape, componentwise transport, displayed replay, package provenance, and local naming.*

Proof. Carrier admission is projection from Definition 9148.1. The accepted packet exposes only the rows $B, Q, X, W, D, E, F, R, H, C, P, N$.

The finite-window route reads the bounded source B, the sequence-space row X, the stream schedule W, and the dyadic ledger D before the finite net E and classifier F are available. Thus total boundedness is inspected through displayed finite windows rather than through an open-cover or host compactness principle.

Finally R, H, C, P, N preserve the same route for regular rational readback, Real sealing, transport, replay, provenance, and local naming. Since selected subsequences, countable choice, quotient stream equality, host real equality, and ambient completeness are absent from the carrier, no accepted consumer can project them from the certificate surface. □

Theorem 9148.3 (SequentiallyTotallyBounded L10 finite-window compactness route)**.** *Every L10 compactness-facing consumer of an accepted* $\mathsf{SequentiallyTotallyBounded}^{\uparrow}$ *packet factors through*

$\mathsf{BoundedRegularCauchy}^{\uparrow}$, $\mathsf{BoundedRegularCauchySubsequence}^{\uparrow}$, $\mathsf{CauchySequenceSpace}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, DyadicRatC

The consumer first reads bounded regular Cauchy data, bounded-subsequence provenance, and the Cauchy sequence-space row; then it inspects a finite stream window and dyadic tolerance ledger; then it reads the finite net classifier; only then may it reach the regular rational and Real seal rows. The route does not claim open-cover compactness, selected subsequences, countable choice, quotient stream equality, host real equality, or $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start with the NameCert obligations of Definition 9148.2. They require the bounded source, bounded-subsequence provenance, sequence-space row, stream schedule, dyadic ledger, finite net, and classifier to be displayed before readback.

Use the carrier ordering from Definition 9148.1. The readback row R is available only after B, X, W, D, E, F, and the bounded-subsequence row Q is provenance rather than a selected infinite subsequence.

The structural rows H, C, P, N transport, replay, source, and name the same finite-window packet. Because the forbidden compactness and choice coordinates are absent, the exported L10 route is a finite-window total-boundedness certificate, not a classical compactness or completeness theorem. □

Closure status for $\mathsf{NameCert}_{\mathsf{Sequentially TotallyBounded}^{\uparrow}}$.

Constructive story: A $\mathsf{SequentiallyTotallyBounded}^{\uparrow}$ packet is generated from a BoundedRegularCauchy source, bounded-subsequence provenance, a CauchySequenceSpace row, finite StreamName windows, a DyadicRatCore tolerance ledger, finite net rows, a sequential finite-window classifier, RegSeqRat and Real readback, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{SequentiallyTotallyBounded}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 9148.1, Definition 9148.2, and Definition 9148.3 seed the L10 finite-window compactness route over bounded regular Cauchy, bounded-subsequence, CauchySequenceSpace, StreamName, DyadicRatCore, RegSeqRat, and Real rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{SequentiallyTotallyBounded}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim open-cover compactness, selected subsequences, countable choice, quotient stream equality, host real equality, Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, finite-window scheduling, dyadic tolerance exactness, finite-net classifier stability, bounded-subsequence provenance, readback non-escape, transport, replay, and local naming for BEDC.Derived.SequentiallyTotallyBoundedUp.

Chapter 9149

A Concrete Naming Certificate for InnovationSolderingMetricInterface$^{\uparrow}$

The InnovationSolderingMetricInterface$^{\uparrow}$ packet concretizes the soldering target of chapter 9423 as finite BEDC data. It names the interface where a ledger innovation row determines a soldering one-form, and the soldering one-form determines the metric row. The packet sits beside LogarithmicSectionDynamics$^{\uparrow}$ in chapter 9135, SolenoidPhase$^{\uparrow}$ in chapter 9075, ObserverCenteredConstructorCertificat in chapter 9114, and FiniteObservationBoundary$^{\uparrow}$ in chapter 9102. Those siblings provide section dynamics, phase transport, observer-centered construction, or finite observation boundaries; this packet binds the metric-facing soldering interface itself.

Definition 9149.1 (InnovationSolderingMetricInterface carrier)**.** *An* InnovationSolderingMetricInterface$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M = (L, O, D, B, Q, \Theta, G, g, F, A, H, C, P, N)$$

with the following displayed rows:

1. *L is the ledger-field row;*
2. *O is the displayed orthogonal innovation row;*
3. *D is the frame-reshaping connection row;*
4. *B is the finite section-bundle boundary row named by the source vision;*
5. *Q is the innovation projector row;*
6. *Θ is the soldering one-form row, read as QDB in finite carrier notation;*
7. *G is the displayed signature row on the effective innovation bundle;*
8. *g is the metric row read from $G(\Theta, \Theta)$;*
9. *F is the field-faithfulness row requiring changes in L, O, D, Q, Θ, G to be visible at the metric interface when the carrier admits such a change;*
10. *A is the audit row refusing product-only coexistence, independent metric insertion, Hilbert-norm-as-Lorentz-metric replacement, hidden rank assumptions, hidden signature assumptions, and unledgered curvature dynamics;*
11. *H records componentwise* hsame *transport over the ledger, innovation, connection, boundary, projector, soldering, signature, metric, faithfulness, audit, provenance, and local naming rows;*

12. *C records displayed* Cont *replay for the same interface;*
13. *P is the* Pkg *provenance over* InnovationSolderingMetricInterface$^{\uparrow}$, LogarithmicSectionDynamics$^{\uparrow}$, SolenoidPhase$^{\uparrow}$, ObserverCenteredConstructorCertificate$^{\uparrow}$, FiniteObservationBoundary$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert*;*
14. *N is the local* NameCert$_{\text{InnovationSolderingMetricInterface}^{\uparrow}}$ *row.*

The carrier requires Lean-side Nontrivial InnovationSolderingMetricInterface$^{\uparrow}$ *and* FieldFaithful InnovationSolderingMe *instances before any checked discovery or bridge claim may use the interface as a non-smoke metric row.*

Theorem 9149.2 (InnovationSolderingMetricInterface NameCert obligations)**.** *For every accepted* InnovationSolderingMetricInterface$^{\uparrow}$ *carrier $M = (L, O, D, B, Q, \Theta, G, g, F, A, H, C, P, N)$, the local* NameCert$_{\text{InnovationSolderingMetricInterface}^{\uparrow}}$ *surface consists exactly of carrier admission, ledger-field exposure, orthogonal innovation exposure, connection exposure, section-bundle boundary exposure, innovation-projector exactness, soldering one-form exactness, signature-row exposure, metric-row exactness, field-faithfulness visibility, audit-row exactness, componentwise transport, displayed replay, package provenance, and local naming.*

Proof. Carrier admission is projection from Definition 9149.1. The rows $L, O, D, B, Q, \Theta, G, g, F, A, H, C, P, N$ are the whole accepted interface.

The soldering route reads L, O, D, B, Q before Θ, and reads Θ and G before g. Thus the metric row is not inserted independently and the positive Hilbert norm is not treated as a Lorentz metric.

Finally the field-faithfulness row and audit row constrain the export. The structural rows H, C, P, N transport, replay, source, and name the same finite interface, while the required Lean Nontrivial and FieldFaithful instances are the formal hooks that prevent the carrier from becoming a vacuous metric label. □

Theorem 9149.3 (InnovationSolderingMetricInterface metric dependency)**.** *Every metric-facing consumer of an accepted* InnovationSolderingMetricInterface$^{\uparrow}$ *packet must read the metric row through the displayed dependency chain*

$$L, O, D, B, Q, \Theta, G, g.$$

The carrier may be consumed as an interface only when the Nontrivial and FieldFaithful instance surface for InnovationSolderingMetricInterface$^{\uparrow}$ *is available on the Lean side; the paper route itself does not claim Einstein dynamics, empirical matter coupling, quantum gravity, unledgered curvature equations, or a metric inserted independently of the ledger innovation.*

Proof. Project the carrier and the NameCert obligations. They order the ledger, innovation, connection, boundary, projector, soldering, signature, and metric rows before any public metric read.

Use the audit row A. It refuses the product-only route, independent metric insertion, Hilbert-norm replacement, hidden rank data, hidden signature data, and unledgered curvature dynamics.

The sibling provenance row P locates the section-dynamics, solenoid-phase, observer-centered construction, and finite-observation boundary packets without merging their carriers into the metric interface. Thus the exported metric dependency is exactly the displayed soldering route, with Nontrivial and FieldFaithful Lean instances required for checked non-vacuity and field sensitivity. □

Falsifiable prediction: Every accepted InnovationSolderingMetricInterface$^{\uparrow}$ consumer that reaches a metric row while omitting one of L, O, D, B, Q, Θ, G refutes the packet.

Independence witness: logarithmicsectiondynamics, solenoidphase, observercenteredconstructorcertificate, finiteobservationboundary: none is bijective with $\mathsf{InnovationSolderingMetricInterface}^{\uparrow}$ because each omits the full ledger-innovation-projector-soldering-signature-metric route or the field-faithfulness audit row.

Closure status for $\mathsf{NameCert}_{\mathsf{InnovationSolderingMetricInterface}^{\uparrow}}$.

Constructive story: An $\mathsf{InnovationSolderingMetricInterface}^{\uparrow}$ packet is generated from a ledger-field row, orthogonal innovation row, frame-reshaping connection row, section-bundle boundary row, innovation projector, soldering one-form, signature row, metric row, field-faithfulness row, audit row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{InnovationSolderingMetricInterface}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 9149.1, Definition 9149.2, and Definition 9149.3 seed the finite soldering metric interface over ledger innovation, projector, soldering, signature, metric, audit, and field-faithfulness rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{InnovationSolderingMetricInterface}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim Einstein dynamics, empirical matter coupling, quantum gravity, unledgered curvature equations, checked Nontrivial or FieldFaithful Lean instances, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, soldering one-form exactness, signature-row exactness, metric-row dependency, Nontrivial and FieldFaithful instances, audit exactness, transport, replay, and local naming for BEDC.Derived.InnovationSolderingMetricInterfaceUp.

Chapter 9150

A Concrete Naming Certificate for Window6 Forward Deliverable Shapes

The Window6 forward-math package realizes six Fibonacci-cube proof-object shapes as finite NameCert data: a closed-zero count identity, a seam-gluing law, a sharp saturation-deficit inequality, a live-tail congruence with exact finite-state memory, a signed involution with a fixed block, and a zero-mark Galois closure. Each shape is recorded here as a bounded Window6 surface over Boolean words, local six-letter windows, and the no-adjacent-1 Fibonacci-cube constraint.

9150.1 Closed-Zero Flattening Count Identity

Theorem 9150.1 (Closed-zero interior flattening)**.** *For Window6 Fibonacci-cube words, a closed-zero endpoint window is insulated from the no-adjacent interior between its two displayed zero guards. Replacing that interior by any other no-adjacent interior preserves the surrounding no-adjacent read. In the concrete enumerated windows this yields the checked count identity*

$$C_m = 8Z_m$$

for the displayed finite lengths $m = 6, \ldots, 12$.

Lean4 ✓ `BEDC.Derived.Window6ClosedZeroFlattenBijection.window6 closed zero flatten bijection`

Lean target: `BEDC.Derived.Window6ZeroMarkGaloisClosure.window6\_galois\_adjunction`

Bridge status: none

Not claimed: This anchor does not claim a topological closure space over an infinite carrier or a complete symbolic classification of every closed finite set outside the checked Window6 mark interface.

Upgrade path: A broader closure would expose fixed-point interval-union normal forms as a single checked classifier theorem.

Chapter 9151

A Finite Window6 Skew/Neutral Certificate for the RH No-Neutral-Leak Obligation

The zeta-to-Zeckendorf residual route sends an off-mirror zeta zero event into a Zeckendorf residual tower over the Fibonacci-cube projections $X_m = \{0,1\}^m_{\text{no}\,11}$, with residual carrier $V_m = \mathbb{Q}[X_m]$. One of the load-bearing obligations of that route is a no-neutral-leak condition: the residual must live in the skew sector of a return operator R_m, with $1 \notin \operatorname{spec}(R_m|_{\text{skew}})$, since the attractive computation $R_6 r = -\frac{1}{2} r$ eliminates a residual only after its neutral 1-eigenmode has been excluded. This chapter records a finite Window6-level certificate for the shape of that obligation: an explicit mirror involution whose fixed set is the neutral support and whose free orbits are the skew sector, so that the skew/neutral split of X_6 is exhibited as a checked ± 1-eigenspace decomposition. This is a finite residual-surface certificate, not a proof of RH.

9151.1 The Window6 Mirror Involution

Let X_6 be the Fibonacci-cube surface of six-letter Boolean words with no adjacent 1. The mirror is the letter reversal

$$\mu(b_0 b_1 b_2 b_3 b_4 b_5) = b_5 b_4 b_3 b_2 b_1 b_0.$$

Theorem 9151.1 (Mirror is a no-adjacent involution)**.** *The reversal μ is an involution, $\mu \circ \mu = \mathrm{id}$, and it preserves the no-adjacent-1 constraint: if a six-letter word has no adjacent 1, then so does its reversal. Hence μ acts on X_6.*

```
Lean4 ✓  BEDC.Derived.Window6MirrorSkewNeutralSplit.mirror6 involutive
  ↪ variant  BEDC.Derived.Window6MirrorSkewNeutralSplit.mirror6 preserves noAdj
```

9151.2 Fixed Points Are the Neutral Support

Theorem 9151.2 (Fixed iff palindrome)**.** *A word of X_6 is fixed by μ if and only if it is a palindrome. On the no-adjacent surface the palindromes are exactly*

$$000000, \qquad 010010, \qquad 100001,$$

so the mirror-fixed set has size 3*. These fixed words are the finite neutral support: they are the words the mirror cannot move, the Window6 analogue of the* 1*-eigenmode that the no-neutral-leak obligation must exclude from the skew sector.*

Lean4 ✓ `BEDC.Derived.Window6MirrorSkewNeutralSplit.mirror6 fixed iff palindrome`

9151.3 The Skew/Neutral Split Certificate

Every non-palindrome pairs with its distinct reversal, so the non-fixed words of X_6 partition into free two-element mirror orbits, the finite skew sector. Choosing the lexicographically smaller representative of each orbit counts those orbits.

Theorem 9151.3 (Finite skew/neutral decomposition)**.** *The Fibonacci-cube surface X_6 decomposes under the mirror into the neutral fixed set and the free skew orbits:*

$$|X_6| = |X_6^{\text{neutral}}| + 2\,|X_6^{\text{skew}}|, \qquad 21 = 3 + 2 \cdot 9.$$

The neutral part has dimension 3*; the skew part has* 9 *free mirror orbits, spanning the remaining* 18 *words. This is the checked* ± 1*-eigenspace split of the mirror on the Window6 residual surface.*

Lean4 ✓ `BEDC.Derived.Window6MirrorSkewNeutralSplit.window6 mirror skew neutral split certificate`
↪ variant `BEDC.Derived.Window6MirrorSkewNeutralSplit.neutral count`
↪ variant `BEDC.Derived.Window6MirrorSkewNeutralSplit.skew pair count`

9151.4 Relation to the No-Neutral-Leak Obligation

The zeta-to-Zeckendorf route asks, at each layer, that a certified residual carry no component in the 1-eigenmode of the return operator, so that the $-\frac{1}{2}$ contraction can drive it to zero. Definition 9151.3 realizes the finite instance of that split explicitly: the mirror supplies a concrete involution on X_6 whose $+1$-eigenspace is spanned by the three palindromic neutral words and whose -1-eigenspace is spanned by the nine skew orbit differences. A residual placed in the skew span is, at this Window6 layer, provably free of the neutral mode, because the neutral mode is exactly the fixed-point span, which the skew span meets only in zero.

This is a finite residual-surface certificate. It does not prove RH, and it does not by itself discharge the all-layer spectral obligation $1 \notin \operatorname{spec}(R_m|_{\text{skew}})$ for every m; it exhibits the combinatorial shape of that obligation on the sixth Fibonacci-cube projection and gives an axiom-free finite witness of the skew/neutral separation there.

Closure status for NameCert$_{Window6MirrorSkewNeutralSplit}$.

Theory closure: TheoryGate(NameCert$_{Window6MirrorSkewNeutralSplit}$, scopedClosed)

Scope closed: Definition 9151.3 closes the finite Window6 mirror skew/neutral decomposition $21 = 3 + 2 \cdot 9$ with the mirror-fixed palindromes as the neutral support.

Formal verification: FormalStatus(NameCert$_{Window6MirrorSkewNeutralSplit}$, theoremChecked)

Lean target: `BEDC.Derived.Window6MirrorSkewNeutralSplit.window6\_mirror\_skew\_neutral\_split\_certificate`

Bridge status: none

Not claimed: This does not prove RH; it is a finite Window6-layer skew/neutral separation certificate only, and it does not discharge the all-layer spectral no-neutral-leak obligation.

Upgrade path: An RH-route upgrade would extend the finite mirror split to the all-layer Zeckendorf tower and connect the mirror-fixed neutral support to the 1-eigenmode of the return operator R_m on V_m.

Chapter 9152

The Fibonacci–Polya Jensen Kernel

Following Polya and Griffin–Ono–Rolen–Zagier, this chapter records a finite Fibonacci smoothing of the actual Riemann ξ Jensen criterion. Let

$$J^{d,n}(X) = \sum_{j=0}^{d} \binom{d}{j} \gamma_{n+j} X^j$$

be the Jensen polynomial of the Taylor coefficients of ξ. Polya's criterion places the Riemann Hypothesis inside the assertion that all such Jensen polynomials are hyperbolic, while Griffin–Ono–Rolen–Zagier prove unconditionally that, for each fixed d, $J^{d,n}$ is hyperbolic for all sufficiently large n.

For a Fibonacci cube of length m, set

$$W_m(T) = \sum_k \binom{m-k+1}{k} T^k.$$

Its coefficients count binary words of length m with no adjacent 1s and exactly k entries equal to 1. The real-rootedness of W_m places $W_m(D)$, with $D = d/dX$, among the finite Polya–Schur hyperbolicity preservers. Applied to the reciprocal Jensen polynomial

$$\widehat{J}^{d,n}(X) = X^d J^{d,n}(1/X) = \sum_{j=0}^{d} \binom{d}{j} \gamma_{n+j} X^{d-j},$$

the packet studies the finite window

$$F_{m,d,n}(X) = W_m(D) \widehat{J}^{d,n}(X).$$

Thus hyperbolicity of $J^{d,n}$ implies hyperbolicity of $F_{m,d,n}$, and the GORZ theorem gives an unconditional large-n hyperbolicity shadow for every fixed m, d.

9152.1 Degree-Two Discriminant Window

In degree two write

$$\widehat{J}^{2,n}(X) = aX^2 + 2bX + c,$$

where $a = \gamma_n$, $b = \gamma_{n+1}$, and $c = \gamma_{n+2}$. Since

$$W_m(D) = 1 + mD + \frac{(m-1)(m-2)}{2} D^2$$

on degree-two polynomials, the smoothed polynomial is

$$F_{m,2,n}(X) = aX^2 + (2am + 2b)X + (am^2 - 3am + 2a + 2bm + c).$$

Its discriminant is the finite identity

$$\operatorname{disc} F_{m,2,n} = 4\left((b^2 - ac) + (3m - 2)a^2\right).$$

Equivalently,

$$\operatorname{disc} F_{m,2,n} - 4(b^2 - ac) = 4(3m - 2)a^2.$$

For $m \geq 1$, the added Fibonacci-kernel term is nonnegative. The Fibonacci window therefore preserves and strengthens the degree-two Turan margin $b^2 - ac$; it does not replace the xi coefficient problem by a Fibonacci counting problem.

Theorem 9152.1 (Fibonacci–Polya degree-two Jensen certificate)**.** *The degree-two Fibonacci–Polya smoothing has the symbolic discriminant certificate*

$$\operatorname{disc} F_{m,2,n} = 4\left((\gamma_{n+1}^2 - \gamma_n\gamma_{n+2}) + (3m - 2)\gamma_n^2\right),$$

and the concrete $m = 5$ differential kernel satisfies

$$W_5(D)X^0 = 1, \quad W_5(D)X = X+5, \quad W_5(D)X^2 = X^2+10X+12, \quad W_5(D)X^3 = X^3+15X^2+36X+6.$$

Lean4 ✓ `BEDC.Derived.FibonacciPolyaJensenKernel.fibonacci polya jensen kernel certificate`

9152.2 Honest Scope

This is a hyperbolicity-preserving Fibonacci smoothing of the Jensen criterion, a genuine finite RH-shadow, not a sharper attack on RH, not a claim that ξ coefficients are Zeckendorf or Fibonacci counts, and not a proof of the Riemann Hypothesis. The Lean certificate treats $\gamma_n, \gamma_{n+1}, \gamma_{n+2}$ as symbolic coefficients. It proves the finite algebraic normal-form identity behind the displayed degree-two discriminant and checks the $W_5(D)$ monomial action; it does not assume numerical values of the Riemann ξ coefficients and does not discharge any analytic zero-location theorem.

The analytic bridge is external and classical: Polya identifies RH with total hyperbolicity of the Jensen family, and GORZ gives unconditional eventual hyperbolicity in each fixed degree. The BEDC content here is the finite kernel interface placed inside that classical criterion: applying a Fibonacci-cube Laguerre–Polya kernel to the actual ξ Jensen window adds a visible nonnegative degree-two margin term while preserving the honest distinction between finite hyperbolicity shadows and RH itself.

Falsifiable prediction: A recomputation of the symbolic degree-two smoothing that changes the coefficient tuple $(a, 2am + 2b, am^2 - 3am + 2a + 2bm + c)$, the discriminant term $4((b^2 - ac) + (3m - 2)a^2)$, or the $W_5(D)$ monomial actions listed in Definition 9152.1, refutes this packet.

Independence witness: riemann-hypothesis, zeckendorf-coefficient-models: this packet is a finite hyperbolicity-preserving smoothing of the actual Riemann ξ Jensen criterion, not a proof of RH and not a model identifying ξ coefficients with Fibonacci or Zeckendorf counts.

Closure status for $\mathsf{NameCert}_{FibonacciPolyaJensenKernel}$.

Theory closure: TheoryGate($\mathsf{NameCert}_{FibonacciPolyaJensenKernel}$, scopedClosed)

Scope closed: degree-2 discriminant identity and Fibonacci-kernel margin preservation for symbolic γ coefficients.

Formal verification: FormalStatus(NameCert$_{FibonacciPolyaJensenKernel}$, theoremChecked)

Lean target: `BEDC.Derived.FibonacciPolyaJensenKernel.fibonacci\_polya\_jensen\_kernel\_certificate`

Bridge status: none

Not claimed: not a proof of RH; a hyperbolicity-preserving Fibonacci Polya-Schur smoothing of the actual xi Jensen criterion, degree-2 discriminant identity only; not a Zeckendorf model of xi coefficients.

Upgrade path: lift to general degree d via the full Polya-Schur preservation, and add the deformation parameter λ in $W_m(\lambda D)$ to certify a Jensen stability margin over rational λ-intervals.

Chapter 9153

The Fibonacci–Polya Jensen Deformation

This chapter records a finite lambda-deformation of the Fibonacci–Polya Jensen kernel. Let

$$\widehat{J}^{d,n}(X) = X^d J^{d,n}(1/X)$$

be the reciprocal Jensen polynomial attached to the Taylor coefficients γ_n of the Riemann ξ function. For a Fibonacci cube of length m, set

$$W_m(T) = \sum_k \binom{m-k+1}{k} T^k.$$

The deformation is

$$F^{(\lambda)}_{m,d,n}(X) = W_m(\lambda D)\widehat{J}^{d,n}(X),$$

where $D = d/dX$. At $\lambda = 0$ this is the actual reciprocal xi Jensen polynomial. At $\lambda = 1$ this is the Fibonacci-smoothed window. The parameter therefore embeds the actual degree window into a finite Polya–Schur smoothing family without replacing the xi coefficients by a Fibonacci counting model.

9153.1 Degree-Two Lambda Discriminant

In degree two write

$$\widehat{J}^{2,n}(X) = aX^2 + 2bX + c,$$

where $a = \gamma_n$, $b = \gamma_{n+1}$, and $c = \gamma_{n+2}$. Since

$$W_m(\lambda D) = 1 + m\lambda D + \frac{(m-1)(m-2)}{2}\lambda^2 D^2$$

on degree-two polynomials, the deformed window is

$$F^{(\lambda)}_{m,2,n}(X) = aX^2 + (2am\lambda + 2b)X + \left(a\lambda^2 m^2 - 3a\lambda^2 m + 2a\lambda^2 + 2bm\lambda + c\right).$$

Its discriminant is the finite identity

$$\operatorname{disc} F^{(\lambda)}_{m,2,n} = 4\left((b^2 - ac) + (3m-2)\lambda^2 a^2\right).$$

Equivalently,

$$\operatorname{disc} F^{(\lambda)}_{m,2,n} - 4(b^2 - ac) = 4(3m-2)\lambda^2 a^2.$$

For $m \geq 1$, the Fibonacci term is nonnegative after the usual shift $m \mapsto m+1$. Thus the deformation certifies a continuous hyperbolicity stability margin from the actual Jensen discriminant at $\lambda = 0$ to the Fibonacci-smoothed margin at $\lambda = 1$.

Theorem 9153.1 (Fibonacci–Polya lambda-deformation Jensen certificate)**.** *The degree-two lambda-deformed Fibonacci–Polya Jensen window has the symbolic discriminant certificate*

$$\operatorname{disc} F^{(\lambda)}_{m,2,n} = 4\left((\gamma_{n+1}^2 - \gamma_n\gamma_{n+2}) + (3m-2)\lambda^2\gamma_n^2\right).$$

The specialization $\lambda = 0$ gives the actual reciprocal Jensen discriminant $4(\gamma_{n+1}^2 - \gamma_n\gamma_{n+2})$, the specialization $\lambda = 1$ gives the Fibonacci-smoothed degree-two window, and the difference from the actual Jensen discriminant is the explicit lambda-square margin.

Lean4 ✓ `BEDC.Derived.FibonacciPolyaJensenDeformation.fibonacci polya jensen deformation certificate`

9153.2 Honest Scope

This is a finite Jensen stability-margin certificate under Fibonacci Polya–Schur deformation, interpolating the actual reciprocal xi Jensen polynomial at $\lambda = 0$ and the Fibonacci-smoothed window at $\lambda = 1$. It is a genuine finite RH-shadow, not a sharper attack on RH, not a Zeckendorf model of xi, and not a proof of the Riemann Hypothesis. The coefficients $\gamma_n, \gamma_{n+1}, \gamma_{n+2}$ remain symbolic throughout.

The Lean certificate proves the algebraic normal-form identity for the lambda discriminant, the $\lambda = 0$ and $\lambda = 1$ specializations, and the lambda-square margin identity. It does not evaluate xi coefficients, does not assert global hyperbolicity for all Jensen degrees, and does not discharge any analytic zero-location theorem. Its role is to place the actual degree-two Jensen discriminant inside a finite hyperbolicity-preserving deformation whose extra Fibonacci contribution is visible and nonnegative in the certified margin.

Falsifiable prediction: A recomputation of the symbolic degree-two deformation that changes the coefficient tuple $(a, 2am\lambda + 2b, a\lambda^2m^2 - 3a\lambda^2m + 2a\lambda^2 + 2bm\lambda + c)$, the lambda discriminant term $4((b^2 - ac) + (3m-2)\lambda^2a^2)$, the $\lambda = 0$ Turan specialization, or the $\lambda = 1$ Fibonacci-window specialization refutes this packet.

Independence witness: riemann-hypothesis, zeckendorf-coefficient-models: this packet is a finite Jensen stability-margin certificate under Fibonacci Polya–Schur deformation, interpolating the actual reciprocal xi Jensen polynomial at $\lambda = 0$ and the Fibonacci-smoothed window at $\lambda = 1$; it is not a proof of RH and not a model identifying xi coefficients with Fibonacci or Zeckendorf counts.

Closure status for NameCert$_{FibonacciPolyaJensenDeformation}$.

Theory closure: TheoryGate(NameCert$_{FibonacciPolyaJensenDeformation}$, scopedClosed)

Scope closed: degree-2 λ-discriminant identity plus $\lambda = 0$ and $\lambda = 1$ specializations and margin, with symbolic γ coefficients.

Formal verification: FormalStatus(NameCert$_{FibonacciPolyaJensenDeformation}$, theoremChecked)

Lean target: `BEDC.Derived.FibonacciPolyaJensenDeformation.fibonacci\_polya\_jensen\_deformation\_certificate`

Bridge status: none

Not claimed: not a proof of RH; a finite Jensen stability-margin certificate under Fibonacci deformation, degree-2 discriminant identity interpolating lambda=0 (actual Jensen) and lambda=1 (Fibonacci window); not a Zeckendorf model of xi.

Upgrade path: certify hyperbolicity and root separation over rational lambda-intervals for higher degree d.

Chapter 9154

The Zeckendorf Mobius Sieve Certificate

This chapter records a finite Mobius and squarefree arithmetic packet over Fibonacci–Zeckendorf windows. Let $F_0 = 0$, $F_1 = 1$, and $F_{n+2} = F_{n+1} + F_n$. For each $0 \le N < F_{m+2}$, the Zeckendorf representation writes N uniquely as a sum of nonadjacent Fibonacci numbers, and $s_Z(N)$ denotes the number of summands in that representation.

9154.1 Squarefree Zeckendorf-Hamming Polynomials

For each window length m, define the squarefree Zeckendorf-Hamming polynomial

$$SQ_m(u) = \sum_{1 \le N < F_{m+2}} \mu(N)^2 u^{s_Z(N)}$$

and its signed companion

$$M_m(u) = \sum_{1 \le N < F_{m+2}} \mu(N) u^{s_Z(N)}.$$

The certificate computes these polynomials as finite integer coefficient lists, with coefficient degree equal to Zeckendorf Hamming weight. The Lean carrier uses only finite recursion over natural numbers and integer lists: Fibonacci values, greedy Zeckendorf weights, squarefree testing, the Mobius value, and polynomial accumulation are all closed computations.

The squarefree arithmetic core is the finite sieve identity

$$\mu(n)^2 = \sum_{d^2 \mid n} \mu(d).$$

Inside the certificate this is checked for $1 \le n \le 20$ by the same Mobius and divisibility routines used by the window polynomials. The squarefree polynomial is therefore not merely a count of selected examples; it is tied to the classical squarefree sieve in the bounded arithmetic range recorded by the certificate.

9154.2 Finite Mertens Cancellation

The signed companion has evaluation

$$M_m(1) = \sum_{1 \le N < F_{m+2}} \mu(N).$$

The certificate records, for $1 \le m \le 12$, an explicit nonnegative slack witnessing the finite Mertens-cancellation inequality

$$\left(\sum_{1\le N<F_{m+2}} \mu(N)\right)^2 \le F_{m+2}.$$

In Lean this bound is carried as a natural-number slack equality

$$|M_m(1)|^2 + \mathrm{slack}_m = F_{m+2},$$

which avoids importing any analytic argument or any classical inequality principle. The theorem target also records the concrete polynomial window $m \le 8$, the squarefree sieve checks through $n = 20$, and the representative terminal Mertens slack certificate at $m = 12$.

Theorem 9154.1 (Zeckendorf Mobius sieve certificate)**.** *The finite Zeckendorf-window packet computes $SQ_m(u)$ and $M_m(u)$ for $1 \le m \le 8$, checks the squarefree sieve identity $\mu(n)^2 = \sum_{d^2|n} \mu(d)$ for $1 \le n \le 20$, and records explicit Mertens-cancellation slack certificates $|M_m(1)|^2 + \mathrm{slack}_m = F_{m+2}$ for $1 \le m \le 12$.*

Lean4 ✓ `BEDC.Derived.ZeckendorfMobiusSieve.zeckendorf mobius sieve certificate`

9154.3 Honest Scope

This is a finite Mobius/squarefree and Mertens-cancellation certificate over Zeckendorf windows. It places classical Mobius arithmetic inside finite Fibonacci windows and mirrors the RH-equivalent Mertens bound $M(x) = O(x^{1/2})$, but it is finite computed evidence, not a proof of that bound for all x, not an analytic zeta statement, and not a proof of the Riemann Hypothesis.

The squarefree polynomial is classically adjacent to the squarefree summatory structure behind $1/\zeta(2s)$, and the signed window is adjacent to the Mertens summatory function. The BEDC content here is the finite arithmetic interface: Zeckendorf weight supplies the Fibonacci window coordinate, Mobius values supply the signed arithmetic, the squarefree sieve supplies the bounded divisor check, and the slack equations supply finite cancellation witnesses. No Euler product, analytic continuation, zero-free region, or asymptotic estimate is claimed.

Falsifiable prediction: A recomputation of the finite Lean carrier that changes the greedy Zeckendorf weights for 6, 7, or 12, the squarefree status of 4 or 6, the Mobius values of 4, 6, or 30, the SQ_m and M_m coefficient lists through $m = 8$, the squarefree sieve checks through $n = 20$, or the Mertens slack certificates through $m = 12$, refutes this packet.

Independence witness: riemann-hypothesis, global-mertens-bound, analytic-zeta-claims: this packet is a finite Mobius/squarefree and Mertens-cancellation certificate over Zeckendorf windows only; it does not prove RH, does not prove $M(x) = O(x^{1/2})$ for all x, and does not assert an analytic zeta theorem.

Closure status for NameCert$_{ZeckendorfMobiusSieve}$.

Theory closure: TheoryGate(NameCert$_{ZeckendorfMobiusSieve}$, scopedClosed)

Scope closed: SQ_m/M_m concrete $m \le 8$, squarefree sieve $n \le 20$, Mertens bound $m \le 12$.

Formal verification: FormalStatus(NameCert$_{ZeckendorfMobiusSieve}$, theoremChecked)

Lean target: `BEDC.Derived.ZeckendorfMobiusSieve.zeckendorf\_mobius\_sieve\_certificate`

Bridge status: none

Not claimed: not a proof of RH or of the Mertens bound for all x; a finite Mobius/squarefree and Mertens-cancellation certificate over Zeckendorf windows only; the analytic zeta connection is heuristic.

Upgrade path: prove the squarefree residue-transfer sieve identity $SQ_m = \sum_d \mu(d)(C_{m,d^2,0} - 1)$ universally via the Zeckendorf residue recurrence, and extend the Mertens bound beyond the finite table.

Chapter 9155

Fibonacci-Cube Ihara Zeta

This chapter records a finite Ihara zeta computation for the Fibonacci-cube graphs. For $m \geq 1$, let Γ_m be the graph whose vertices are the binary words of length m with no adjacent 1s, with an edge between two words exactly when their Hamming distance is 1. Thus $|V(\Gamma_m)| = F_{m+2}$, and the first non-tree case is Γ_3.

Let A_m be the adjacency matrix of Γ_m, and let D_m be the diagonal degree matrix. Bass' determinant formula gives the reciprocal Ihara zeta expression

$$Z_{\Gamma_m}(u)^{-1} = (1-u^2)^{|E|-|V|} \det\bigl(I - A_m u + (D_m - I)u^2\bigr).$$

The Lean certificate works at the polynomial determinant layer:

$$\det\bigl(I - A_m u + (D_m - I)u^2\bigr).$$

It avoids encoding negative powers of $(1-u^2)$ as rational functions. For Γ_1 and Γ_2, the graphs are trees; the determinant is $1-u^2$, and the Bass prefactor cancels it in the reciprocal zeta. For Γ_3, the exponent $|E|-|V|$ is 0, so the reciprocal zeta is exactly the determinant.

9155.1 Finite Bass Determinants

The verified vertex orders are the lexicographic no-adjacent-1 orders

$$\Gamma_1 : \ 0, 1,$$

$$\Gamma_2 : \ 00, 01, 10,$$

and

$$\Gamma_3 : \ 000, 001, 010, 100, 101.$$

For these orders, the certificate evaluates the concrete Bass matrices with entries

$$\bigl(I - A_m u + (D_m - I)u^2\bigr)_{ij} = \delta_{ij} - A_{ij}u + (\deg(i) - 1)\delta_{ij}u^2.$$

The determinant identities are

$$\det\bigl(I - A_1 u + (D_1 - I)u^2\bigr) = 1 - u^2,$$

$$\det\bigl(I - A_2 u + (D_2 - I)u^2\bigr) = 1 - u^2,$$

and

$$\det(I - A_3u + (D_3 - I)u^2) = 1 - 2u^4 + u^8.$$

Equivalently, the first non-tree case factors as

$$1 - 2u^4 + u^8 = (u-1)^2(u+1)^2(u^2+1)^2.$$

Theorem 9155.1 (Fibonacci-cube Ihara determinant certificate)**.** *For the Fibonacci-cube graphs $\Gamma_1, \Gamma_2, \Gamma_3$, the polynomial Bass determinants are*

$$\det(I - A_1u + (D_1 - I)u^2) = 1 - u^2,$$

$$\det(I - A_2u + (D_2 - I)u^2) = 1 - u^2,$$

and

$$\det(I - A_3u + (D_3 - I)u^2) = 1 - 2u^4 + u^8 = (u-1)^2(u+1)^2(u^2+1)^2.$$

For Γ_3, since $|E| - |V| = 0$, this is also $Z_{\Gamma_3}(u)^{-1}$.

Lean4 ✓ `BEDC.Derived.FibonacciCubeIharaZeta.fibonacci cube ihara zeta certificate`

9155.2 Honest Scope

This packet is a finite Ihara (graph) zeta of the Fibonacci-cube graphs computed by the Bass determinant; it belongs to graph and dynamical zeta theory and to the graph-RH (Ramanujan) analogy, not to the actual Riemann xi or its Jensen criterion, and it is not a proof of the Riemann Hypothesis. The Lean object is a concrete polynomial determinant calculation over integer coefficient lists. It does not encode analytic continuation, the critical strip, the nontrivial zeros of $\zeta(s)$, the Riemann ξ function, or any Jensen-polynomial criterion for RH.

The finite analogy is still mathematically legitimate. Ihara zeta functions attach Euler-product-style zeta data to finite graphs, and their pole geometry is governed by graph spectra. In regular graph families, the Ramanujan condition is commonly expressed as a graph-theoretic RH analogue. The Fibonacci-cube calculation here stays inside that finite graph-zeta world: it verifies the Bass determinant data through Γ_3 and marks the first non-tree determinant explicitly, while leaving any uniform spectral theorem for all Γ_m outside the closed scope.

Falsifiable prediction: A recomputation of the listed Bass matrices for $\Gamma_1, \Gamma_2, \Gamma_3$ that changes the determinant coefficient lists $[1, 0, -1]$, $[1, 0, -1]$, or $[1, 0, 0, 0, -2, 0, 0, 0, 1]$ refutes this packet.

Independence witness: riemann-hypothesis, riemann-xi-jensen-criterion: this packet is a finite Ihara graph zeta computation for Fibonacci-cube graphs, not a statement about the actual Riemann ξ function, not a Jensen criterion certificate, and not a proof of RH.

Closure status for NameCert$_{FibonacciCubeIharaZeta}$.

Theory closure: TheoryGate(NameCert$_{FibonacciCubeIharaZeta}$, scopedClosed)

Scope closed: Bass det identity for Γ_1 through Γ_3.

Formal verification: FormalStatus(NameCert$_{FibonacciCubeIharaZeta}$, theoremChecked)

Lean target: `BEDC.Derived.FibonacciCubeIharaZeta.fibonacci\_cube\_ihara\_zeta\_certificate`

Bridge status: none

Not claimed: not a proof of RH; a finite Ihara graph zeta of the Fibonacci cube (graph-RH/Ramanujan analogy) only, not the actual Riemann xi.

Upgrade path: extend the Bass determinant to all Γ_m and connect the graph-RH (Ramanujan) property to the Fibonacci-cube spectral gap.

Chapter 9156

The Finite-Window Fibonacci–RH Program

The Riemann Hypothesis has several equivalent finite-window formulations: hyperbolicity of the Jensen polynomials of ξ, positivity of Li's coefficients, positivity of Weil's explicit-formula quadratic form, and cancellation bounds such as $M(x) = O(x^{1/2+\varepsilon})$ for the Mertens function. This chapter is the organizing summary of a finite, axiom-free program that places Fibonacci and Zeckendorf structure inside these finite-window criteria. It proves no new theorem; it records which finite certificates were built, how each touches a genuine RH criterion, and where the exact-arithmetic frontier honestly ends.

9156.1 The Certificates

Each certificate below is a finite, 0-axiom object verified in the Lean development. None is a proof of the Riemann Hypothesis; each is a finite shadow of, or a finite carrier for, a genuine RH-equivalent criterion.

Certificate	**Finite content**	**Genuine RH**
Fibonacci–Pólya Jensen kernel	$\operatorname{disc} F_{m,2,n} = 4[(\gamma_{n+1}^2 - \gamma_n\gamma_{n+2}) + (3m-2)\gamma_n^2]$	the actual ξ Je
Jensen kernel deformation	$\operatorname{disc} F_{m,2,n}^{(\lambda)}$, $\lambda = 0$ the exact ξ Jensen window	Jensen stability
Zeckendorf–Möbius sieve	$\left(\sum_{N<F_{m+2}} \mu(N)\right)^2 \le F_{m+2}$	the Mertens bo
Fibonacci-cube Ihara zeta	Bass $\det(I - Au + (D-I)u^2)$, $\Gamma_3 = (u-1)^2(u+1)^2(u^2+1)^2$	the graph-theor

The first two are the hyperbolicity flavor: the Fibonacci-cube weight polynomial W_m is real-rooted, so $W_m(D)$ is a finite Pólya–Schur hyperbolicity preserver, and the Griffin–Ono–Rolen–Zagier theorem gives unconditional large-n hyperbolicity of the smoothed windows. The third is the arithmetic flavor: it places Möbius and squarefree arithmetic inside Fibonacci windows and records a finite Mertens cancellation certificate. The fourth is the graph-zeta flavor: it computes the Ihara zeta of the Fibonacci-cube graphs through the Bass determinant and marks the first non-tree case.

Theorem 9156.1 (Program summary)**.** *The four finite certificates above are verified in Lean as axiom-free, propext-free objects. Together they realize the hyperbolicity, arithmetic, and graph-zeta flavors of the finite-window Fibonacci–RH program on exact integer and polynomial data.*

↪ variant `BEDC.Derived.FibonacciPolyaJensenKernel.fibonacci polya jensen kernel certificate`
↪ variant `BEDC.Derived.ZeckendorfMobiusSieve.zeckendorf mobius sieve certificate`
↪ variant `BEDC.Derived.FibonacciCubeIharaZeta.fibonacci cube ihara zeta certificate`

9156.2 The Program Boundary

This program is complete as a finite, exact-arithmetic certificate program. The three flavors above exhaust the finite-window RH criteria that reduce to exact integer, polynomial, or $\mathbb{Z}[\varphi]$ arithmetic: Jensen hyperbolicity through symbolic ξ coefficients, Mertens cancellation through exact Möbius sums, and the graph zeta through an exact Bass determinant.

The one genuinely distinct criterion not reduced here is Weil's explicit-formula positivity: the finite Galerkin quadratic form of the Weil functional on Fibonacci-windowed test functions. That object is real and central, but its matrix entries are transcendental, involving the Euler–Mascheroni constant, $\log 4\pi$, archimedean integrals, and von Mangoldt evaluations at logarithms of integers. It is therefore not an exact-arithmetic 0-axiom object; a certificate would require certified interval arithmetic together with a rational positive-semidefinite (Cholesky) certificate, a different and substantially harder formalization. It is recorded here as the honest open direction, not as a completed certificate.

Falsifiable prediction: A recomputation of any listed finite certificate that contradicts its displayed identity or inequality at the enumerated parameters refutes the corresponding packet and this summary's placement of it.

Independence witness: finite-window-fib-rh-program: these are finite axiom-free shadows and carriers of genuine RH-equivalent criteria (Jensen hyperbolicity, the Mertens bound, and the graph-RH analogy); none is a proof of the Riemann Hypothesis, none evaluates the analytic ξ or its zeros, and the Weil explicit-formula positivity criterion is left as an honest open direction outside the exact-arithmetic scope.

Closure status for NameCert$_{FiniteWindowFibRHProgramHub}$.

Theory closure: TheoryGate(NameCert$_{FiniteWindowFibRHProgramHub}$, scopedClosed)

Scope closed: Definition 9156.1 records the four finite axiom-free certificates and section 9156.2 states the exact-arithmetic boundary; the program is complete as a finite exact-arithmetic certificate program.

Formal verification: FormalStatus(NameCert$_{FiniteWindowFibRHProgramHub}$, theoremChecked)

Lean target: `BEDC.Derived.FibonacciPolyaJensenKernel.fibonacci\_polya\_jensen\_kernel\_certificate`

Bridge status: none

Not claimed: not a proof of RH; a finite exact-arithmetic certificate program of shadows/carriers of RH-equivalent criteria; the Weil explicit-formula positivity criterion is an honest open direction requiring certified interval arithmetic, not a completed certificate.

Upgrade path: formalize the Fibonacci-windowed Weil positivity matrix with certified interval-arithmetic entries and a rational Cholesky certificate, or prove a density/fundamentality theorem for a Fibonacci/Zeckendorf restriction of a finite-window RH criterion.

Chapter 9157

A Concrete Naming Certificate for Euler's Pentagonal Number Theorem

Following Euler and Franklin, the Euler pentagonal number theorem packet records a finite BEDC reconstruction of the classical partition-theory identity

$$\prod_{n\geq 1}(1-q^n) = \sum_{k=-\infty}^{\infty}(-1)^k q^{k(3k-1)/2}.$$

The generalized pentagonal numbers are

$$g_k = \frac{k(3k-1)}{2}$$

for $k \in \mathbb{Z}$, and the attached sign is $(-1)^k$. The BEDC carrier does not assert analytic convergence of the infinite product or a completed infinite formal power series. It records an exact finite reconstruction of Euler's pentagonal number theorem and Franklin's sign-reversing involution as finite NameCert data; the generating-function identity is truncated to a finite polynomial coefficient identity.

Definition 9157.1 (Euler–Franklin finite carrier)**.** *An Euler–Franklin finite carrier consists of the following displayed rows:*

1. *a low-degree q-polynomial row for the product $\prod_{n=1}^{30}(1-q^n)$;*
2. *a coefficient window row exposing the coefficients of q^d for $0 \leq d \leq 26$;*
3. *a generalized pentagonal sign row, computed by the finite searches $d = k(3k-1)/2$ and $d = k(3k+1)/2$ for $0 \leq k \leq d$;*
4. *a distinct-partition enumerator row for strict decreasing positive parts summing to n;*
5. *a signed partition-count row computing $\sum_{\lambda\in D(n)}(-1)^{\#\lambda}$ for $0 \leq n \leq 12$;*
6. *a local NameCert row naming the finite Euler coefficient window and the finite Franklin cancellation count as the same pentagonal-sign packet.*

The classifier has no coordinate for convergence, infinite products, infinite sums over all integers, quotient power series, or a host-side partition theorem outside the displayed finite data.

Theorem 9157.2 (Finite Euler coefficient certificate)**.** *For the finite product*

$$P_{30}(q) = \prod_{n=1}^{30}(1-q^n),$$

the coefficient row through degree 26 *is*

$$1, -1, -1, 0, 0, 1, 0, 1, 0, 0, 0, 0, -1, 0, 0, -1, 0, 0, 0, 0, 0, 0, 1, 0, 0, 0, 1.$$

Equivalently, the nonzero entries in this window occur at

$$(0, +1), (1, -1), (2, -1), (5, +1), (7, +1), (12, -1), (15, -1), (22, +1), (26, +1),$$

matching the generalized pentagonal data

$$(0, 0, +), (1, 1, -), (-1, 2, -), (2, 5, +), (-2, 7, +), (3, 12, -), (-3, 15, -), (4, 22, +), (-4, 26, +).$$

Proof. The Lean certificate computes the coefficient window by a finite coefficient recurrence for multiplication by $1-q^n$. The resulting row is compared by Boolean list equality with the displayed coefficient table, and the pentagonal-sign row is computed independently by finite search over generalized pentagonal shapes. □

Theorem 9157.3 (Finite Franklin signed-count certificate)**.** *Let $D(n)$ be the finite set of partitions of n into distinct positive parts, represented as strict decreasing lists. Then the finite signed count*

$$\sum_{\lambda \in D(n)} (-1)^{\#\lambda}$$

agrees with the pentagonal sign for every $0 \le n \le 12$. In particular the checked rows include

$$n = 0 : +1, \quad n = 1 : -1, \quad n = 2 : -1, \quad n = 5 : +1, \quad n = 7 : +1, \quad n = 12 : -1.$$

Proof. The Lean certificate enumerates distinct-part partitions by bounded recursion over the largest permitted part. Each listed partition contributes $+1$ or -1 according to the parity of its length. The signed count is then compared by kernel reduction with the same finite pentagonal-sign row used in the coefficient certificate. □

Theorem 9157.4 (Euler–Franklin finite NameCert reconstruction)**.** *The Euler–Franklin packet is a finite NameCert reconstruction of the classical theorem: the Euler side verifies the product $\prod_{n=1}^{30}(1-q^n)$ through degree* 26*, while the Franklin side verifies the distinct-partition signed count through $n = 12$. Franklin's sign-reversing involution is represented at this scope by its finite cancellation consequence: all non-pentagonal signed rows in the checked range cancel, and only the pentagonal fixed rows remain.*

`Lean4 ✓ BEDC.Derived.EulerPentagonalNumberTheorem.euler pentagonal number theorem certificate`

Proof. Combine the finite Euler coefficient table, the independent pentagonal-sign computation, and the Franklin signed-count rows. The Lean target records these rows as a single conjunction. It is a finite certificate of the displayed reconstruction, not an analytic assertion about the infinite product. □

Falsifiable prediction: Every accepted Euler–Franklin finite carrier exposes the finite product row, coefficient window through degree 26, generalized pentagonal sign search, distinct-partition enumeration, signed count through $n = 12$, and local NameCert row before exporting an Euler pentagonal-number theorem conclusion.

Independence witness: q-series, distinct partitions, pentagonal sign: this packet is not bijective to a generic polynomial row or a generic partition row because it jointly binds the truncated Euler product, the generalized pentagonal sign search, and the finite Franklin signed cancellation count.

Closure status for NameCert$_{EulerPentagonalNumberTheoremUp}$.

Constructive story: The packet is generated from a finite coefficient window for $\prod_{n=1}^{30}(1-q^n)$, a bounded generalized-pentagonal sign search, a distinct-partition enumerator, a signed-count row through $n = 12$, and a local NameCert row tying the Euler and Franklin surfaces together.

Theory closure: TheoryGate(NameCert$_{EulerPentagonalNumberTheoremUp}$, scopedClosed)

Scope closed: finite truncation $\prod_{n=1}^{30}(1 - q^n)$ coefficient identity through degree 26 + Franklin signed distinct-partition count through $n = 12$

Formal verification: FormalStatus(NameCert$_{EulerPentagonalNumberTheoremUp}$, theoremChecked)

Lean target: `BEDC.Derived.EulerPentagonalNumberTheorem.euler\_pentagonal\_number\_theorem\_certificate`

Bridge status: none

Not claimed: a finite reconstruction of Euler's pentagonal number theorem and Franklin's involution; the generating-function identity is verified as a finite truncated polynomial coefficient identity, not as an infinite product convergence statement

Upgrade path: extend to the Jacobi triple product and the Rogers–Ramanujan identities as further finite q-series NameCert reconstructions

Chapter 9158

A Concrete Naming Certificate for Euler's Distinct–Odd Partition Identity

Following Euler and Glaisher, the Euler distinct–odd partition packet records a finite BEDC reconstruction of the classical identity

$$\prod_{n\geq 1}(1+q^n) = \prod_{n\geq 1}\frac{1}{1-q^{2n-1}}.$$

Equivalently, the number of partitions of n into distinct positive parts equals the number of partitions of n into odd positive parts. The BEDC carrier does not assert analytic convergence of either infinite product, nor does it close an all-n formal-power-series proof. It records an exact finite reconstruction of Euler's distinct-equals-odd partition identity and Glaisher's bijection as finite NameCert data.

Definition 9158.1 (Euler–Glaisher finite carrier)**.** *An Euler–Glaisher finite carrier consists of the following displayed rows:*

1. *a distinct-partition row, enumerating strict decreasing positive-part lists summing to n;*
2. *an odd-partition row, enumerating positive odd-part lists summing to n;*
3. *a count-comparison row verifying the equality of the two finite lists for $1 \leq n \leq 12$;*
4. *a low-degree q-polynomial row for the product $\prod_{n=1}^{12}(1+q^n)$;*
5. *a coefficient-window row exposing the coefficients of q^d for $0 \leq d \leq 12$;*
6. *a Glaisher row sending an odd partition to a distinct partition by binary expansion of the multiplicity of each odd part;*
7. *a reverse Glaisher row sending a distinct part $2^a u$ with u odd to 2^a copies of u;*
8. *a local NameCert row tying the finite count table, the generating-function coefficient window, and the displayed bijection witnesses into one named packet.*

The classifier has no coordinate for infinite products, completed power series, convergence, quotient partition equality, or a host-side all-n partition theorem outside the displayed finite data.

Theorem 9158.2 (Finite Euler distinct–odd count certificate)**.** *Let $D(n)$ be the finite list of partitions of n into distinct positive parts, represented as strict decreasing lists, and let $O(n)$ be the finite list of partitions of n into odd positive parts. For $1 \le n \le 12$ the checked count row is*

$$1, 1, 2, 2, 3, 4, 5, 6, 8, 10, 12, 15.$$

Thus $|D(n)| = |O(n)|$ throughout the displayed window. For example, at $n = 6$ the distinct side is

$$[6],\ [5, 1],\ [4, 2],\ [3, 2, 1],$$

and the odd side is

$$[5, 1],\ [3, 3],\ [3, 1, 1, 1],\ [1, 1, 1, 1, 1, 1].$$

Proof. The Lean certificate enumerates distinct partitions by bounded recursion over the largest permitted part. It enumerates odd partitions by bounded recursion over the largest odd head allowed at the current step. Each displayed equality is then checked by kernel reduction of the two list lengths. □

Theorem 9158.3 (Finite generating-function coefficient certificate)**.** *For the finite product*

$$P_{12}(q) = \prod_{n=1}^{12} (1 + q^n),$$

the coefficient row through degree 12 is

$$1, 1, 1, 2, 2, 3, 4, 5, 6, 8, 10, 12, 15.$$

For each $0 \le d \le 12$, this coefficient agrees with the finite distinct-partition count $|D(d)|$.

Proof. The Lean certificate computes $P_{12}(q)$ by finite polynomial multiplication over integer coefficient lists. The coefficient row is compared by Boolean list equality with the displayed table, and each coefficient in the window is separately identified with the corresponding distinct-partition count by reduction. □

Theorem 9158.4 (Finite Glaisher bijection witnesses)**.** *Glaisher's map from odd partitions to distinct partitions is encoded by carrying equal odd parts in base 2: if an odd part u has multiplicity $m = \sum_a \epsilon_a 2^a$, then every nonzero bit contributes the distinct part $2^a u$. The reverse map writes each distinct part as $2^a u$ with u odd and expands it into 2^a copies of u.*

In the checked finite carrier, the Lean rows include the round-trip witnesses

$$[5, 1] \mapsto [5, 1] \mapsto [5, 1],$$

$$[3, 3] \mapsto [6] \mapsto [3, 3],$$

$$[3, 1, 1, 1] \mapsto [3, 2, 1] \mapsto [3, 1, 1, 1],$$

and

$$[1, 1, 1, 1, 1, 1] \mapsto [4, 2] \mapsto [1, 1, 1, 1, 1, 1].$$

The same finite rows record preservation of the total sum for representative odd-to-distinct and distinct-to-odd expansions.

Proof. The Lean certificate implements the carry operation as an insertion into a finite distinct list, and implements the reverse operation by repeated halving until an odd kernel is reached. The displayed rows are concrete reductions of these functions. They are explicit finite Glaisher witnesses, not an all-n proof of bijectivity. □

Theorem 9158.5 (Euler–Glaisher finite NameCert reconstruction)**.** *The Euler–Glaisher packet is a finite NameCert reconstruction of the classical identity: the partition-count side verifies* $|D(n)| = |O(n)|$ *through* $n = 12$*, the generating-function side verifies the coefficients of* $\prod_{n=1}^{12}(1+q^n)$ *through degree* 12*, and the Glaisher side records concrete binary-carry round-trip witnesses.*

Lean4 ✓ `BEDC.Derived.EulerDistinctOddPartition.euler distinct odd partition certificate`

Proof. Combine the finite distinct-partition count row, the finite odd-partition count row, the coefficient-window row for $P_{12}(q)$, and the displayed Glaisher witnesses. The Lean target records these rows as a single conjunction. It is a finite certificate of the displayed reconstruction, not an analytic assertion about infinite products. □

Falsifiable prediction: Every accepted Euler–Glaisher finite carrier exposes the distinct-partition enumerator, odd-partition enumerator, count row through $n = 12$, coefficient row for $\prod_{n=1}^{12}(1+q^n)$ through degree 12, Glaisher binary-carry map, reverse odd-kernel expansion, and local NameCert row before exporting an Euler distinct–odd partition conclusion.

Independence witness: distinct partitions, odd partitions, q-series, Glaisher binary carry: this packet is not bijective to a generic polynomial row or a generic partition row because it jointly binds the finite distinct-count table, the finite odd-count table, the truncated Euler product coefficients, and the displayed Glaisher maps.

Closure status for NameCert$_{EulerDistinctOddPartitionUp}$.

Constructive story: The packet is generated from a distinct-partition enumerator, an odd-partition enumerator, a count-comparison row through $n = 12$, a coefficient window for $\prod_{n=1}^{12}(1+q^n)$ through degree 12, finite Glaisher binary-carry witnesses, reverse odd-kernel expansion witnesses, and a local NameCert row tying the Euler and Glaisher surfaces together.

Theory closure: TheoryGate(NameCert$_{EulerDistinctOddPartitionUp}$, scopedClosed)

Scope closed: distinct-part = odd-part partition counts through $n = 12$ + generating-function coefficients + Glaisher bijection witnesses

Formal verification: FormalStatus(NameCert$_{EulerDistinctOddPartitionUp}$, theoremChecked)

Lean target: `BEDC.Derived.EulerDistinctOddPartition.euler\_distinct\_odd\_partition\_certificate`

Bridge status: none

Not claimed: a finite reconstruction of Euler's distinct-equals-odd identity and Glaisher's bijection; counts verified through $n = 12$, not an all-n generating-function proof

Upgrade path: extend to the general Glaisher d-distinct=d-fold identity and to further q-series partition bijections

Chapter 9159

A Concrete Naming Certificate for Euler's Partition Pentagonal Recurrence

Following Euler, the partition pentagonal recurrence packet records a finite BEDC reconstruction of the classical partition function $p(n)$, where $p(n)$ counts unordered sums of positive integers with total n. The recurrence is

$$p(n) = \sum_{k\geq 1}(-1)^{k-1}\left(p\left(n - \frac{k(3k-1)}{2}\right) + p\left(n - \frac{k(3k+1)}{2}\right)\right),$$

with $p(0) = 1$ and every negative-index term omitted. This is the reciprocal consequence of Euler's pentagonal number theorem:

$$\left(\prod_{n\geq 1}(1-q^n)\right)\left(\sum_{n\geq 0} p(n)q^n\right) = 1.$$

The BEDC carrier below records an exact finite reconstruction of Euler's pentagonal recurrence for the partition function, verified through $n = 20$ together with the reciprocal identity against the pentagonal product; it is not an all-n generating-function proof.

Definition 9159.1 (Partition pentagonal recurrence finite carrier)**.** *A partition pentagonal recurrence finite carrier consists of the following displayed rows:*

1. *a generalized pentagonal row*

$$g_k = \frac{k(3k-1)}{2}, \qquad g'_k = \frac{k(3k+1)}{2}$$

   for positive k;

2. *a sign row $(-1)^{k-1}$ for the paired contribution at g_k and g'_k;*
3. *a prefix table row for $p(0), p(1), \ldots, p(20)$ generated by the pentagonal recurrence, not by enumerating partitions;*
4. *a recurrence-check row exposing the finite alternating sums at representative degrees $5, 10, 15, 20$;*
5. *a q-polynomial row for the truncated partition generating function $\sum_{n=0}^{20} p(n)q^n$;*

6. *a reciprocal row checking the coefficients of*

$$\left(\prod_{n=1}^{20}(1-q^n)\right)\left(\sum_{n=0}^{20}p(n)q^n\right)$$

through degree 20*;*

7. *a local NameCert row naming the finite recurrence table and the finite reciprocal coefficient window as the same Euler partition packet.*

The classifier has no coordinate for convergence of the infinite product, an infinite formal-power-series inverse, a Hardy–Ramanujan analytic estimate, or a host-side all-n partition theorem outside the displayed finite data.

Theorem 9159.2 (Finite partition value certificate)**.** *The checked partition row through* $n = 20$ *is*

$$1, 1, 2, 3, 5, 7, 11, 15, 22, 30, 42, 56, 77, 101, 135, 176, 231, 297, 385, 490, 627.$$

Equivalently,

$$p(0) = 1, \quad p(6) = 11, \quad p(10) = 42, \quad p(20) = 627.$$

Proof. The Lean certificate generates the table by the finite pentagonal recurrence itself. For each new n, it reads only the already generated prefix values at offsets $n - g_k$ and $n - g'_k$ whose indices are nonnegative, sums them with the sign $(-1)^{k-1}$, and appends the resulting integer value to the table. □

Theorem 9159.3 (Finite Euler recurrence certificate)**.** *The finite recurrence row includes the representative checks*

$$p(5) = p(4) + p(3) - p(0),$$
$$p(10) = p(9) + p(8) - p(5) - p(3),$$
$$p(15) = p(14) + p(13) - p(10) - p(8) + p(3) + p(0),$$

and

$$p(20) = p(19) + p(18) - p(15) - p(13) + p(8) + p(5).$$

These are the displayed finite instances of Euler's pentagonal recurrence.

Proof. Each row is a kernel reduction of the same prefix-table recurrence used to compute the values. The stopping condition is finite: once $k(3k-1)/2 > n$, all later positive generalized pentagonal offsets are outside the prefix window. □

Theorem 9159.4 (Finite reciprocal identity certificate)**.** *Let*

$$P_{20}(q) = \prod_{n=1}^{20}(1-q^n)$$

and

$$F_{20}(q) = \sum_{n=0}^{20}p(n)q^n.$$

The checked coefficient row of $P_{20}(q)F_{20}(q)$ *through degree* 20 *is*

$$1, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0.$$

Thus the finite carrier verifies the reciprocal identity

$$P_{20}(q)F_{20}(q) \equiv 1 \pmod{q^{21}}.$$

Proof. The Lean certificate reuses the finite q-polynomial multiplication and pentagonal product row from the Euler pentagonal-number certificate. It multiplies the product row by the partition prefix row and checks each coefficient from degree 0 through degree 20 by reduction. □

Theorem 9159.5 (Partition pentagonal recurrence finite NameCert reconstruction)**.** *The partition pentagonal recurrence packet is an exact finite reconstruction of Euler's pentagonal recurrence for $p(n)$: the recurrence-generated values are checked through $n = 20$, the representative pentagonal recurrence rows are checked at $n = 5, 10, 15, 20$, and the reciprocal identity against $\prod(1 - q^n)$ is checked through degree 20.*

Lean4 ✓ `BEDC.Derived.PartitionPentagonalRecurrence.partition pentagonal recurrence certificate`

Proof. Combine the finite prefix table, the representative recurrence rows, and the reciprocal coefficient window. The Lean target records these rows as one conjunction. It is a finite NameCert reconstruction of Euler's partition recurrence, not an all-n generating-function proof. □

Falsifiable prediction: Every accepted partition pentagonal recurrence carrier exposes the generalized pentagonal offsets, alternating sign row, recurrence-generated prefix table through $n = 20$, representative recurrence checks, reciprocal polynomial product row, coefficient window through degree 20, and local NameCert row before exporting an Euler partition-recurrence conclusion.

Independence witness: partition values, pentagonal recurrence, reciprocal q-series: this packet is not bijective to a generic partition table or a generic polynomial row because it jointly binds the recurrence-generated prefix values, the generalized pentagonal offsets, and the finite inverse relation against $\prod(1 - q^n)$.

Closure status for NameCert$_{PartitionPentagonalRecurrenceUp}$**.**

Constructive story: The packet is generated from generalized pentagonal offsets, alternating signs, a recurrence-generated partition prefix row through $n = 20$, representative recurrence checks, a finite pentagonal product, a partition generating-function prefix, a reciprocal coefficient window through degree 20, and a local NameCert row tying the recurrence and product surfaces together.

Theory closure: TheoryGate(NameCert$_{PartitionPentagonalRecurrenceUp}$, scopedClosed)

Scope closed: partition values $p(0)$ through $p(20)$, the pentagonal recurrence, and the reciprocal identity against $\prod(1 - q^n)$ through degree 20

Formal verification: FormalStatus(NameCert$_{PartitionPentagonalRecurrenceUp}$, theoremChecked)

Lean target: `BEDC.Derived.PartitionPentagonalRecurrence.partition\_pentagonal\_recurrence\_certificate`

Bridge status: none

Not claimed: a finite reconstruction of Euler's pentagonal recurrence for $p(n)$; verified through $n = 20$, not an all-n generating-function proof

Upgrade path: extend the reciprocal identity to arbitrary truncation degree and connect to the Hardy–Ramanujan asymptotics as an external analytic layer

Chapter 9160

A Concrete Naming Certificate for $\mathsf{IshiharaBoundednessFiniteTest}^{\uparrow}$

Following Bishop and Bridges' constructive real analysis, the $\mathsf{IshiharaBoundednessFiniteTest}^{\uparrow}$ packet records the finite inspection route by which an Ishihara-style argument may expose boundedness information for a real-name sequence without importing an omniscience principle. It sits beside the inspection boundary of chapter 1665, the finite-test boundary of chapter 8578, the stream window surface $\mathsf{StreamName}^{\uparrow}$ in chapter 126, the regular rational readback $\mathsf{RegSeqRat}^{\uparrow}$ in chapter 301, the dyadic tolerance ledger $\mathsf{DyadicRatCore}^{\uparrow}$ in chapter 291, the located real route $\mathsf{LocatedReal}^{\uparrow}$ in **??**, and the terminal real-name seal $\mathsf{Real}^{\uparrow}$ in chapter 38. The packet supplies a finite boundedness test for L10 Real and Completion consumers; it does not supply WLPO, LLPO, LPO, trichotomy, a selected supremum, quotient real equality, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 9160.1 (Ishihara boundedness finite-test carrier)**.** *An* $\mathsf{IshiharaBoundednessFiniteTest}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$F = (S, W, L, U, K, R, Q, D, E, H, C, P, N)$$

with the following displayed rows:

1. *S is the source sequence row whose boundedness-facing read is being inspected.*
2. *W is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row opened for the current boundedness request.*
3. *L is the lower finite-test row, naming the inspected evidence that the displayed window stays within the lower side of the bound.*
4. *U is the upper finite-test row, naming the inspected evidence that the displayed window stays within the upper side of the bound.*
5. *K is the* $\mathsf{LocatedReal}^{\uparrow}$ *split row through which the boundedness request is read as a located comparison rather than as a global order decision.*
6. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row attached to the same window.*
7. *Q is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance budget used by the lower and upper tests.*
8. *D is the finite boundedness ledger saying which inspected coordinates, tolerances, and comparison margins have been exposed.*
9. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row, available only after W, L, U, K, R, Q, D have been displayed.*

10. *H records componentwise* hsame *transport for the source, window, tests, located split, readback, tolerance, boundedness ledger, and seal rows.*
11. *C records displayed* Cont *replay of the same finite boundedness inspection route.*
12. *P records* Pkg *provenance over* $\mathsf{IshiharaBoundednessFiniteTest}^{\uparrow}$, $\mathsf{IshiharaTrick}^{\uparrow}$, $\mathsf{IshiharaFiniteTestBoundary}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{LocatedReal}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
13. *N is the local* $\mathsf{NameCert}_{\mathsf{IshiharaBoundednessFiniteTest}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $S, W, L, U, K, R, Q, D, E, H, C, P, N$. It has no coordinate for WLPO, LLPO, LPO, trichotomy of real names, an externally selected bound, quotient stream equality, countable choice, or ambient completeness of $\mathsf{Real}^{\uparrow}$.

Lean4 (statement) `BEDC.Derived.IshiharaBoundednessFiniteTestUp`

Theorem 9160.2 (Ishihara boundedness NameCert obligations)**.** *For every accepted* IshiharaBoundednessFiniteTest *carrier $F = (S, W, L, U, K, R, Q, D, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{IshiharaBoundednessFiniteTest}^{\uparrow}}$ *surface consists exactly of source-sequence admission, finite-window admission, lower-test admission, upper-test admission, located comparison split, regular rational readback, dyadic tolerance budgeting, boundedness-ledger exposure, terminal Real-seal exposure, componentwise transport, displayed replay, provenance, and local naming.*

Proof. Project the carrier of Definition 9160.1. The visible boundedness data are $S, W, L, U, K, R, Q, D, E, H, C, P,$

The boundedness read begins with the finite window W over the source row S. The lower and upper test rows L, U are then interpreted through the located split K, the regular readback R, and the dyadic budget Q before the finite boundedness ledger D is exposed.

The terminal Real seal E is downstream of those rows. Transport, replay, provenance, and local naming preserve the same finite route, so no WLPO, LLPO, LPO, trichotomy, selected bound, quotient equality, choice schedule, or ambient Real-completeness coordinate can enter the local NameCert surface. □

Theorem 9160.3 (Ishihara boundedness located case split)**.** *Every boundedness-facing read of an accepted* $\mathsf{IshiharaBoundednessFiniteTest}^{\uparrow}$ *packet passes through the displayed located split row K before it may consume the lower or upper finite-test rows. The split exposes only the finite comparison route W, K, R, Q, D and does not decide a global order on real names.*

Proof. Project the rows W, L, U, K, R, Q, D from the carrier. The two test rows are meaningful only against the displayed window W and the located comparison row K.

The regular readback R and dyadic budget Q attach the split to a finite rational request. The ledger D then records the boundedness-facing comparison margins that were actually inspected.

Since the carrier has no global order row, no trichotomy row, and no quotient-real equality row, a consumer can read the case split only as located finite evidence. It cannot turn the lower and upper test rows into an omniscience principle. □

Theorem 9160.4 (Ishihara boundedness L10 route)**.** *Any L10 Real or Completion consumer using an accepted* $\mathsf{IshiharaBoundednessFiniteTest}^{\uparrow}$ *packet must read the* $\mathsf{StreamName}^{\uparrow}$ *window W,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback R,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance budget Q,* $\mathsf{LocatedReal}^{\uparrow}$ *split K, finite boundedness ledger D, terminal* $\mathsf{Real}^{\uparrow}$ *seal E, and structural rows H, C, P, N before naming a boundedness conclusion.*

Proof. Apply Definition 9160.2. It exposes the finite source, window, test, located split, readback, tolerance, ledger, Real seal, transport, replay, provenance, and local naming rows.

Apply Definition 9160.3. The boundedness conclusion reaches the two test rows only through the located comparison route W, K, R, Q, D.

The terminal $\mathsf{Real}^{\uparrow}$ seal E is therefore a handoff boundary for L10 Real and Completion consumers, not an ambient completeness theorem. The structural rows H, C, P, N replay and name the same route, excluding WLPO, LLPO, LPO, trichotomy, selected suprema, quotient stream equality, and countable choice from the exported boundedness surface. □

Closure status for $\mathsf{NameCert}_{\mathsf{IshiharaBoundednessFiniteTest}^{\uparrow}}$.

Constructive story: An $\mathsf{IshiharaBoundednessFiniteTest}^{\uparrow}$ packet is generated from a source sequence, a finite StreamName window, lower and upper finite-test rows, a LocatedReal split, RegSeqRat readback, DyadicRatCore tolerance budget, boundedness ledger, Real seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{IshiharaBoundednessFiniteTest}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 9160.1, Definition 9160.2, Definition 9160.3, and Definition 9160.4 seed the finite boundedness test route for L10 Real and Completion consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{IshiharaBoundednessFiniteTest}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close WLPO, LLPO, LPO, trichotomy, selected suprema, quotient stream equality, countable choice, ambient Real completeness, Lean-checked obligations, or a standard bridge.

Upgrade path: Obligation closure requires checked carrier admission, lower and upper test exactness, located split stability, StreamName and RegSeqRat readback compatibility, DyadicRatCore tolerance preservation, Real-seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.IshiharaBoundednessFiniteTestUp.

Chapter 9161

A Concrete Naming Certificate for $\mathsf{FiniteMetricChainBound}^{\uparrow}$

Following Bishop and Bridges on constructive metric estimates, the $\mathsf{FiniteMetricChainBound}^{\uparrow}$ packet records the finite triangle-chain ledger by which metric distances, dyadic rational tolerances, and regular Cauchy readbacks are compared before compact finite-net or complete-metric consumers may use the estimate. It sits over the metric source of chapter 57, the rational and dyadic ledgers of chapter 37 and chapter 291, the finite-net source of chapter 2048, the compact metric source of chapter 129, the observation windows of chapter 126, and the regular rational readback of chapter 301. The packet names a finite ledger for chained triangle estimates only; it does not choose a path, assert a host geodesic, prove completeness, or import countable choice.

Definition 9161.1 (Finite metric chain-bound carrier)**.** *A* $\mathsf{FiniteMetricChainBound}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$F = (M, R, D, T, C, W, Q, E, H, P, N)$$

with the following displayed rows:

1. *M is the* $\mathsf{Met}^{\uparrow}$ *source row, exposing the metric distance observations used by the chain.*
2. *R is the* $\mathsf{Rat}^{\uparrow}$ *rational comparison row for the displayed intermediate bounds.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, recording dyadic endpoint and error budgets for the chain.*
4. *T is the finite* $\mathsf{TotallyBounded}^{\uparrow}$ *or totally-bounded-metric net row consumed by compact finite-net readers.*
5. *C is the* $\mathsf{CompactMetric}^{\uparrow}$ *source row, present only when the chain is read as a compact finite-net estimate.*
6. *W is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row through which endpoints and intermediate observations are inspected.*
7. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *regular rational readback obtained from W and D.*
8. *E is the terminal estimate row, making the accumulated bound public only after M, R, D, T, C, W, Q have been displayed.*
9. *H records componentwise* hsame *transport for the metric, rational, dyadic, finite-net, compact, window, readback, estimate, provenance, and local naming rows.*

10. *P records* Pkg *provenance over* $\mathsf{FiniteMetricChainBound}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{Rat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{TotallyBounded}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{FiniteMetricChainBound}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $M, R, D, T, C, W, Q, E, H, P, N$. It has no coordinate for a selected shortest path, a host geodesic, quotient equality of metric names, countable choice, or ambient completeness.

Theorem 9161.2 (Finite metric chain-bound triangle obligation)**.** *For every accepted* $\mathsf{FiniteMetricChainBound}^{\uparrow}$ *carrier*

$$F = (M, R, D, T, C, W, Q, E, H, P, N),$$

the public triangle-chain estimate is read only after the metric source M, rational comparison row R, dyadic tolerance ledger D, finite-net row T, compact metric row C, finite window row W, and regular rational readback row Q are visible. The terminal estimate row E may therefore be consumed by compact finite-net and complete-metric Cauchy readers only as the displayed finite ledger

$$M, R, D, T, C, W, Q, E, H, P, N.$$

It exports no selected path, geodesic representative, quotient metric equality, countable-choice schedule, host completion, or ambient compactness theorem.

Proof. Project the carrier of Definition 9161.1. The metric row M, rational row R, and dyadic row D provide the only distance and tolerance data available to the chain.

Read the finite-net and compact rows next. The rows T and C make the estimate available to totally bounded and compact metric consumers without turning it into an open-cover compactness or selected-subsequence theorem.

Finally read the finite observation window W and regular rational readback Q before the estimate row E is public. Transport, provenance, and local naming preserve exactly this row sequence, so no excluded host object can be exported by the triangle-chain obligation. □

Theorem 9161.3 (Finite metric chain-bound NameCert surface)**.** *The local* $\mathsf{NameCert}_{\mathsf{FiniteMetricChainBound}^{\uparrow}}$ *surface consists exactly of carrier admission for $M, R, D, T, C, W, Q, E, H, P, N$; metric-distance admission through M; rational comparison through R; dyadic tolerance exactness through D; compact finite-net exposure through T and C; finite-window inspection through W; regular rational readback through Q; terminal estimate nonescape through E; componentwise transport through H; provenance through P; and local naming through N.*

Proof. Start from the carrier rows. The analytic part of the NameCert surface is exactly the metric source, rational comparison, dyadic tolerance ledger, finite-net row, compact source, window row, regular readback, and terminal estimate.

The structural rows then preserve that analytic surface. Componentwise hsame transport keeps the same fields visible, package provenance records the sibling sources, and the local NameCert row names the packet.

Since the carrier contains no row for selected paths, geodesics, quotient metric names, choice schedules, host completions, or ambient compactness, the local certificate cannot export any of those readings. □

Falsifiable prediction: Every accepted $\mathsf{FiniteMetricChainBound}^{\uparrow}$ consumer that reads a compact finite-net or complete-metric Cauchy estimate must display Metric, Rat, DyadicRatCore, finite-net,

compact metric, StreamName, RegSeqRat, estimate, transport, provenance, and local NameCert rows before the bound is public.

Independence witness: metric, rat, dyadicratcore, totally-bounded-metric, compactmetric, streamname, regseqrat: $\mathsf{FiniteMetricChainBound}^{\uparrow}$ is not bijective to any listed sibling because it jointly binds metric distances, rational comparisons, dyadic tolerances, finite-net routing, compact source rows, finite windows, regular rational readback, terminal estimate, transport, provenance, and local naming as one chain-bound ledger.

Closure status for $\mathsf{NameCert}_{\mathsf{FiniteMetricChainBound}^{\uparrow}}$.

Constructive story: A $\mathsf{FiniteMetricChainBound}^{\uparrow}$ packet is generated from Metric distance observations, Rat comparison rows, DyadicRatCore tolerance ledgers, totally bounded finite-net rows, CompactMetric sources, StreamName windows, RegSeqRat readbacks, a terminal estimate row, componentwise hsame transport, Pkg provenance, and local NameCert evidence.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{FiniteMetricChainBound}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 9161.1, Definition 9161.2, and Definition 9161.3 seed the finite triangle-chain ledger over metric, rational, dyadic, finite-net, compact, window, readback, estimate, transport, provenance, and naming rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{FiniteMetricChainBound}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close selected paths, host geodesics, quotient metric equality, countable choice, host completion, ambient compactness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, triangle-chain row ordering, dyadic tolerance exactness, compact finite-net routing, StreamName window coverage, RegSeqRat readback, terminal estimate nonescape, provenance, and local naming for BEDC.Derived.FiniteMetricChainBoundUp.

Chapter 9162

A Concrete Naming Certificate for $\mathsf{HorosphereBusemannFlowBudget}^{\uparrow}$

The $\mathsf{HorosphereBusemannFlowBudget}^{\uparrow}$ packet realizes the boundary-fixed flow-window branch of chapter 9463 as finite BEDC NameCert data. It sits after the hyperbolic metric source of chapter 3474, the Busemann boundary packet of chapter 3732, the horosphere packet of chapter 8521, the visual metric readback of chapter 3866, and the terminal Real seal of chapter 38. The packet names boundary-fixed flow windows, Busemann levels, horosphere rows, visual-metric readback, Real-seal provenance, and local naming; it does not assert a host hyperbolic flow, quotient boundary equality, selected geodesic rays, physical observer dynamics, or ambient compactification.

Definition 9162.1 (Horosphere Busemann flow-budget carrier)**.** *A* $\mathsf{HorosphereBusemannFlowBudget}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$F = (M, B, L, S, V, E, R, H, C, P, N)$$

with the following displayed rows:

1. *M is the* $\mathsf{HyperbolicMetric}^{\uparrow}$ *metric-read row for the finite disk or hyperbolic source window.*
2. *B is the* $\mathsf{HyperbolicBusemannBoundary}^{\uparrow}$ *boundary-fixed Busemann row.*
3. *L is the Busemann-level budget row, recording the finite level interval in which the flow window is read.*
4. *S is the* $\mathsf{HyperbolicHorosphere}^{\uparrow}$ *horosphere row determined by the same boundary row B and level budget L.*
5. *V is the* $\mathsf{HyperbolicVisualMetric}^{\uparrow}$ *visual-metric readback row for the boundary-facing flow window.*
6. *E is the* $\mathsf{Real}^{\uparrow}$ *seal and provenance row, available only after M, B, L, S, V have been displayed.*
7. *R is the refusal row excluding quotient ideal-boundary equality, selected geodesic representatives, host hyperbolic flows, physical observer dynamics, and ambient compactification.*
8. *H records componentwise* hsame *transport for $M, B, L, S, V, E, R, C, P, N$.*
9. *C records displayed* Cont *replay from metric and boundary rows through the Busemann level, horosphere row, visual metric, Real seal, refusal, provenance, and local naming.*

10. *P is the* Pkg *provenance over* $\mathsf{HorosphereBusemannFlowBudget}^{\uparrow}$, $\mathsf{HyperbolicMetric}^{\uparrow}$, $\mathsf{HyperbolicBusemannBoundar}$ $\mathsf{HyperbolicHorosphere}^{\uparrow}$, $\mathsf{HyperbolicVisualMetric}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{HorosphereBusemannFlowBudget}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $M, B, L, S, V, E, R, H, C, P, N$. It has no coordinate for a host flow parameter space, quotient boundary equality, selected rays, physical observer trajectories, global horosphere foliations, or ambient compactification.

Theorem 9162.2 (Horosphere Busemann flow-budget NameCert surface)**.** *For every accepted* $\mathsf{HorosphereBusemannFlowBudget}^{\uparrow}$ *carrier*

$$F = (M, B, L, S, V, E, R, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{HorosphereBusemannFlowBudget}^{\uparrow}}$ *surface consists exactly of metric-read admission through M, Busemann-boundary admission through B, level-budget exposure through L, horosphere-row exposure through S, visual-metric readback through V, Real-seal provenance through E, refusal through R, componentwise transport through H, displayed replay through C, provenance through P, and local naming through N.*

Proof. Project the carrier of Definition 9162.1. The metric row M and Busemann boundary row B provide the only geometric source data available to the flow-budget packet.

Read the level, horosphere, and visual-metric rows next. The row L fixes the finite Busemann-level budget, S records the horosphere row over that same boundary and level data, and V supplies the boundary-facing visual-metric readback.

The Real seal E is downstream of those rows, while R, H, C, P, N refuse, transport, replay, source, and name the same finite packet. Since no row names a host flow parameter space, quotient boundary equality, selected ray, physical observer trajectory, global horosphere foliation, or compactification, the NameCert surface cannot export any such object. □

Theorem 9162.3 (Horosphere Busemann flow-budget TasteGate requirements)**.** *The Lean TasteGate for* $\mathsf{HorosphereBusemannFlowBudget}^{\uparrow}$ *must include* Nontrivial $\mathsf{HorosphereBusemannFlowBudget}^{\uparrow}$ *and* FieldFaithful $\mathsf{HorosphereBusemannFlowBudget}^{\uparrow}$ *instances for the same displayed carrier*

$$F = (M, B, L, S, V, E, R, H, C, P, N).$$

Nontriviality must distinguish a packet with all metric, boundary, level, horosphere, visual-metric, Real-seal, refusal, transport, replay, provenance, and local naming rows from any packet with a missing row. Field faithfulness must preserve the row order $M, B, L, S, V, E, R, H, C, P, N$ without replacing the finite flow budget by a host hyperbolic flow or quotient boundary object.

Proof. Read the requirement from the carrier. The packet is nontrivial only when all eleven rows are displayed together, because omitting any of $M, B, L, S, V, E, R, H, C, P, N$ removes a named face of the flow-budget surface.

Field faithfulness is the row-preservation demand. A classifier that changes the boundary row, level row, horosphere row, visual-metric readback, or Real-seal provenance while preserving the name would no longer classify the same finite packet.

The excluded host objects are absent from the carrier and from the NameCert surface of Definition 9162.2. The Lean TasteGate therefore certifies the finite budget rows, not a host flow theorem. □

Falsifiable prediction: Every accepted $\mathsf{HorosphereBusemannFlowBudget}^{\uparrow}$ flow-window read displays a HyperbolicMetric row, HyperbolicBusemannBoundary row, Busemann-level budget, HyperbolicHorosphere row, HyperbolicVisualMetric readback, RealUp seal, refusal, transport, replay, provenance, and local NameCert row before any boundary-fixed flow budget is public.

Independence witness: hyperbolic-metric, hyperbolic-busemann-boundary, hyperbolic-horosphere, hyperbolic-visual-metric, real: $\mathsf{HorosphereBusemannFlowBudget}^{\uparrow}$ is not bijective to any listed sibling because it jointly binds boundary-fixed flow windows, Busemann levels, horosphere rows, visual-metric readback, Real-seal provenance, refusal, transport, replay, provenance, and local naming as one finite packet.

Closure status for $\mathsf{NameCert}_{\mathsf{HorosphereBusemannFlowBudget}^{\uparrow}}$.

Constructive story: A $\mathsf{HorosphereBusemannFlowBudget}^{\uparrow}$ packet is generated from HyperbolicMetric source rows, HyperbolicBusemannBoundary rows, Busemann-level budgets, HyperbolicHorosphere rows, HyperbolicVisualMetric readback, RealUp seal provenance, refusal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert evidence.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{HorosphereBusemannFlowBudget}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 9162.1, Definition 9162.2, and Definition 9162.3 seed the finite boundary-fixed flow-budget packet over metric, Busemann boundary, level, horosphere, visual metric, Real seal, refusal, transport, replay, provenance, and naming rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{HorosphereBusemannFlowBudget}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close Lean verification, bridge checking, host hyperbolic flows, quotient ideal-boundary equality, selected geodesic rays, physical observer dynamics, global horosphere foliations, or ambient compactification.

Upgrade path: Obligation closure requires checked carrier admission, metric readback, Busemann-boundary admission, level-budget exactness, horosphere-row exposure, visual-metric readback, Real-seal provenance, refusal, and TasteGate Nontrivial and FieldFaithful instances for BEDC.Derived.HorosphereBusemannFlowBudgetUp.

Chapter 9163

A Concrete Naming Certificate for $\mathsf{RealConvergenceRateExtractor}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{RealConvergenceRateExtractor}^{\uparrow}$ packet records the finite route by which a displayed real-name convergence request is answered from explicit modulus data before any completed real is consumed. It sits over the dyadic tolerance core of chapter 291, the finite observation windows of chapter 126, the regular rational readback of chapter 301, the terminal Real seal of chapter 38, and the diagonal Cauchy telescope of chapter 5923. The packet names a constructive convergence-rate extractor for Real and Completion consumers; it is not a selected limit, quotient representative, countable-choice modulus, host real equality, or ambient completeness theorem.

Definition 9163.1 (Real convergence-rate extractor carrier)**.** *A* $\mathsf{RealConvergenceRateExtractor}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$E = (Q, D, W, R, G, S, H, C, P, N)$$

with the following displayed rows:

1. *Q is the tolerance-request row, recording the requested output precision and the consumer that asks for a Real-facing convergence read.*
2. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *budget row, translating Q into the dyadic radius and comparison slack used by the extractor.*
3. *W is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row, exposing the bounded prefix and tail windows inspected for that dyadic request.*
4. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row, recording the regular rational observations obtained from W under the budget D.*
5. *G is the convergence-rate row, returning a displayed index after which all accepted readbacks meet the requested tolerance.*
6. *S is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row, reached only after Q, D, W, R, G have been displayed.*
7. *H records componentwise* hsame *transport for tolerance requests, dyadic budgets, finite windows, regular rational readbacks, convergence-rate rows, Real seals, replay, provenance, and local naming.*
8. *C records displayed* Cont *replay from the request row through D, W, R, G to the Real seal row S.*

9. *P is the* Pkg *provenance over* $\mathsf{RealConvergenceRateExtractor}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{RealConvergenceRate}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{BishopDiagonalCauchyTelescope}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{RealConvergenceRateExtractor}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $Q, D, W, R, G, S, H, C, P, N$. It has no coordinate for a hidden limit selector, quotient representative, unbounded stream scan, countable choice, host equality of real names, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 9163.2 (Real convergence-rate extractor NameCert obligations)**.** *For every accepted* $\mathsf{RealConvergenceRateExtractor}^{\uparrow}$ *carrier $E = (Q, D, W, R, G, S, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{RealConvergenceRateExtract}}$ *surface consists exactly of tolerance-request admission, dyadic budget exposure, finite* $\mathsf{StreamName}^{\uparrow}$ *window readback,* $\mathsf{RegSeqRat}^{\uparrow}$ *rational observation, convergence-rate row extraction, terminal* $\mathsf{Real}^{\uparrow}$ *seal handoff, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. Every Real or Completion consumer that uses the extracted rate must therefore read the finite route*

$$Q,\ D,\ W,\ R,\ G \longmapsto S$$

before treating the requested convergence as Real-facing evidence.

Proof. Project the carrier of Definition 9163.1. The rows Q, D, W, R, G are the only pre-seal data available to the extractor.

The tolerance request Q is first translated into the dyadic budget D. The finite window row W then displays exactly which stream observations are inspected, and the regular rational readback row R records the observations seen on those windows.

The convergence-rate row G is downstream of those displayed rows. It returns an index for the request already budgeted by D and read through W and R; it cannot be replaced by a selected limit or an unbounded scan.

Finally the Real seal row S and structural rows H, C, P, N transport, replay, source, and name the same route. Since the carrier contains no further coordinate, the listed obligation groups exhaust the local $\mathsf{NameCert}_{\mathsf{RealConvergenceRateExtractor}^{\uparrow}}$ surface. □

Theorem 9163.3 (Real convergence-rate extractor Cauchy handoff)**.** *Every accepted* RealConvergenceRateExtracto *consumer read that reaches a* $\mathsf{Real}^{\uparrow}$ *seal or Completion-facing handoff factors through the same dyadic-window-readback route used by the* $\mathsf{BishopDiagonalCauchyTelescope}^{\uparrow}$ *packet: a tolerance request Q, a* $\mathsf{DyadicRatCore}^{\uparrow}$ *budget D, a* $\mathsf{StreamName}^{\uparrow}$ *finite window W, a* $\mathsf{RegSeqRat}^{\uparrow}$ *readback R, and a convergence-rate row G precede the terminal Real seal S. Thus convergence evidence for Real and Completion consumers depends on displayed finite modulus data, not on selected limits or quotient representatives.*

Proof. Start with an accepted carrier $E = (Q, D, W, R, G, S, H, C, P, N)$. The terminal seal S is not public until the request row, dyadic budget, finite windows, regular rational readback, and convergence-rate row have all been displayed.

Compare this route with chapter 5923. Both packets force a Real-facing consumer through dyadic tolerance data, finite stream windows, and regular rational readback before any Real seal is available.

The extractor's row G is the finite modulus output attached to that route. Componentwise transport H, replay C, provenance P, and local naming N preserve the same displayed dependency, so a downstream Real or Completion consumer has no coordinate from which to import

a selected limit, quotient representative, countable-choice modulus, host real equality, or ambient completeness. □

Falsifiable prediction: An accepted $\mathsf{RealConvergenceRateExtractor}^{\uparrow}$ consumer that reaches a $\mathsf{Real}^{\uparrow}$ seal or Completion-facing handoff without displaying a tolerance request, DyadicRatCore budget, StreamName finite window, RegSeqRat readback, and convergence-rate row refutes the carrier surface.

Independence witness: dyadicratcore, streamname, regseqrat, real, bishopdiagonalcauchytelescope: $\mathsf{RealConvergenceRateExtractor}^{\uparrow}$ is not bijective to any listed sibling because it binds a tolerance request to a finite extracted convergence-rate row before the Real seal, while the siblings separately supply budgets, windows, readbacks, seals, and diagonal-tail routes.

Closure status for $\mathsf{NameCert}_{\mathsf{RealConvergenceRateExtractor}^{\uparrow}}$.

Constructive story: A $\mathsf{RealConvergenceRateExtractor}^{\uparrow}$ packet is generated from a tolerance request, DyadicRatCore budget, StreamName finite windows, RegSeqRat readback, convergence-rate row, Real seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RealConvergenceRateExtractor}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 9163.1, Definition 9163.2, and Definition 9163.3 seed the finite convergence-rate route through dyadic budgets, stream windows, regular rational readback, and Real sealing.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RealConvergenceRateExtractor}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim selected limits, quotient real equality, countable-choice moduli, host real equality, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, dyadic budget exposure, finite-window readback, regular rational handoff, convergence-rate exactness, Real seal handoff, structural transport, and ledger non-escape for BEDC.Derived.RealConvergenceRateExtractorUp.

Chapter 9164

A Concrete Naming Certificate for $\mathsf{PrimaryDecomposition}^{\uparrow}$

Following Atiyah and Macdonald, Introduction to Commutative Algebra, the $\mathsf{PrimaryDecomposition}^{\uparrow}$ packet records the finite row data by which a noetherian algebra source displays an ideal or submodule as an intersection of primary components. It sits after the chain-stabilization surfaces of $\mathsf{NoetherianModule}^{\uparrow}$ and $\mathsf{NoetherianRing}^{\uparrow}$ in chapter 3648 and chapter 3637, the ideal membership surface of $\mathsf{Ideal}^{\uparrow}$ in chapter 81, the finite reduction witness $\mathsf{GroebnerBasis}^{\uparrow}$ of chapter 2197, the finite basis route $\mathsf{HilbertBasis}^{\uparrow}$ of chapter 3472, and the residue recombination sibling $\mathsf{ChineseRemainder}^{\uparrow}$ of chapter 8224. The packet exports only the displayed decomposition route; it is not a host quotient-ideal type, a uniqueness theorem, an ambient radical oracle, or a selected associated-prime principle.

Definition 9164.1 (Primary decomposition carrier)**.** *A* $\mathsf{PrimaryDecomposition}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$\mathsf{PrimDec}(R, M, I, B, G, L, E, H, C, Q, N)$$

with the following rows.

- *R is the* $\mathsf{NoetherianRing}^{\uparrow}$ *source row for the ambient commutative ring operations and ascending-chain control.*
- *M is the optional* $\mathsf{NoetherianModule}^{\uparrow}$ *row used when the decomposed object is a submodule rather than an ideal.*
- *I is the* $\mathsf{Ideal}^{\uparrow}$ *or submodule-membership row naming the object whose decomposition is being read.*
- *B is the* $\mathsf{HilbertBasis}^{\uparrow}$ *finite generator row for the displayed ideal or submodule presentation.*
- *G is the* $\mathsf{GroebnerBasis}^{\uparrow}$ *finite reduction row used only to replay membership in the listed components.*
- *L is the finite component list. Each entry records a component carrier, a primaryness witness row, and the radical-name row used by the classifier below.*
- *E is the exactness ledger: it stores the two finite membership directions between the original object I and the intersection of the component rows in L.*
- *H, C, Q, N are the componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance over the listed sibling packets, and local* $\mathsf{NameCert}_{\mathsf{PrimaryDecomposition}^{\uparrow}}$ *row.*

The classifier compares two carriers only when their ambient $\mathsf{NoetherianRing}^{\uparrow}$ *and optional* $\mathsf{NoetherianModule}^{\uparrow}$ *rows classify together, their original object rows classify together, their component lists match by displayed component rows, and their exactness ledgers replay the same two membership directions. It has no coordinate for uniqueness of minimal decompositions, equality of radicals except the radical-name rows stored in* L*, host quotient ideals, associated-prime selection, or a decomposition theorem outside the finite packet.*

Lean4 (definition) `BEDC.Derived.PrimaryDecompositionUp.PrimaryDecompositionUp`

Theorem 9164.2 (Primary decomposition NameCert obligations)**.** *For every accepted* $\mathsf{PrimaryDecomposition}^{\uparrow}$ *carrier* $\mathsf{PrimDec}(R, M, I, B, G, L, E, H, C, Q, N)$*, the local* $\mathsf{NameCert}_{\mathsf{PrimaryDecomposition}^{\uparrow}}$ *surface consists exactly of carrier admission for the eleven displayed rows, noetherian ring compatibility through* R*, optional noetherian module compatibility through* M*, ideal or submodule source exposure through* I*, finite generator access through* B*, finite reduction replay through* G*, primary component-list exposure through* L*, intersection exactness through* E*, componentwise* hsame *transport through* H*, displayed* Cont *replay through* C*, provenance non-escape through* Q*, and local naming through* N*.*

Proof. Project the carrier of Definition 9164.1. The source rows R and M determine the algebraic classifier before any component can be read.

The object row I is then inspected through the finite generator and reduction surfaces B and G. These rows expose the same membership problem to every component of L, but they do not introduce quotient ideals or a host decomposition primitive.

The component list L stores only displayed primaryness and radical-name rows, while E stores the two finite membership directions between I and the displayed intersection. Transport, continuation, provenance, and local naming repack those rows. Since no other coordinate appears in the carrier, the local certificate cannot claim uniqueness, associated-prime selection, or radical equality beyond the listed classifier rows. □

Theorem 9164.3 (Primary decomposition localization route)**.** *Let* $\mathsf{PrimDec}(R, M, I, B, G, L, E, H, C, Q, N)$ *be an accepted* $\mathsf{PrimaryDecomposition}^{\uparrow}$ *carrier. Any downstream local computation that reads a component of the decomposition must first expose the ambient* $\mathsf{NoetherianRing}^{\uparrow}$ *row* R*, the optional* $\mathsf{NoetherianModule}^{\uparrow}$ *row* M *when present, the original* $\mathsf{Ideal}^{\uparrow}$ *or submodule row* I*, and the finite component-list row* L*. The localized read may use only the selected component row, its stored primaryness witness, its radical-name row, the membership replay supplied by* G*, and the exactness ledger* E*.*

Proof. Start from R and M. They bind the algebraic source and chain-control surface for every later component read.

Next expose I, B, and G. The finite generator and reduction rows are the only route by which membership in the original object or in a listed component is replayed.

Finally choose a displayed component position in L and use the corresponding rows together with E. This yields a local component computation inside the same finite decomposition packet. The route does not pass through host quotient ideals, a selected localization theorem, or a hidden associated-prime construction. □

Theorem 9164.4 (Primary decomposition NameCert route)**.** *Every public consumer of an accepted* $\mathsf{PrimaryDecomposition}^{\uparrow}$ *packet that claims a primary decomposition must read the route*

$$\mathsf{NoetherianRing}^{\uparrow},\ \mathsf{NoetherianModule}^{\uparrow},\ \mathsf{Ideal}^{\uparrow},\ \mathsf{HilbertBasis}^{\uparrow},\ \mathsf{GroebnerBasis}^{\uparrow} \longrightarrow \mathsf{NameCert}_{\mathsf{PrimaryDecomposition}^{\uparrow}}.$$

The exported object is exactly the finite component list L, the exactness ledger E, and the structural rows H, C, Q, N. The route may be compared with ChineseRemainder$^{\uparrow}$ *only as a finite recombination sibling:* PrimaryDecomposition$^{\uparrow}$ *stores intersection components and primaryness witnesses, while* ChineseRemainder$^{\uparrow}$ *stores residue rows and coprime recombination data.*

Proof. Read the noetherian source row R, and read M when the carrier decomposes a submodule. These rows provide chain-control context but do not by themselves export a decomposition.

Open the object row I, the finite basis row B, and the reduction row G. They supply the membership and generator surface over which component membership can be checked.

The public decomposition is then exactly L together with E. The remaining rows H, C, Q, N transport, replay, record provenance, and name that same finite packet. The comparison with ChineseRemainder$^{\uparrow}$ is therefore only a sibling boundary: recombination data and component-intersection data remain different carrier coordinates. □

Falsifiable prediction: Every PrimaryDecomposition$^{\uparrow}$ consumer that claims a primary decomposition must exhibit the noetherian ring row, optional noetherian module row, ideal or submodule source row, Hilbert-basis row, Groebner reduction row, finite component list, exactness ledger, transport, continuation, provenance, and local naming row.

Independence witness: noetherian-module, noetherian-ring, ideal, groebner-basis, hilbert-basis, chinese-remainder: PrimaryDecomposition$^{\uparrow}$ is not bijective to any listed sibling because it jointly carries a noetherian source, a decomposed object row, finite generator and reduction witnesses, primary component rows, radical-name classifier rows, and a two-sided intersection exactness ledger.

Closure status for NameCert$_{\text{PrimaryDecomposition}^{\uparrow}}$.

Constructive story: A PrimaryDecomposition$^{\uparrow}$ packet is generated from NoetherianRingUp and optional NoetherianModuleUp source rows, an IdealUp or submodule source row, HilbertBasisUp finite generator data, GroebnerBasisUp finite reduction traces, a finite primary component list with radical-name rows, a two-sided intersection exactness ledger, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\text{PrimaryDecomposition}^{\uparrow}}$, seed)

Scope closed: Definition 9164.1, Definition 9164.2, Definition 9164.3, and Definition 9164.4 seed the finite primary-decomposition route over NoetherianRingUp, NoetherianModuleUp, IdealUp, HilbertBasisUp, GroebnerBasisUp, ChineseRemainderUp-adjacent recombination boundaries, and local NameCert rows.

Formal verification: FormalStatus(NameCert$_{\text{PrimaryDecomposition}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close uniqueness of primary decompositions, radical equality beyond the displayed classifier rows, Lean verification, bridge checking, host quotient ideals, associated-prime selection, or an ambient decomposition theorem.

Upgrade path: Obligation closure requires checked carrier admission, noetherian source compatibility, component-list primaryness, radical-name classifier stability, exactness-ledger coverage, localized read non-escape, componentwise transport, provenance non-escape, and local NameCert exactness for BEDC.Derived.PrimaryDecompositionUp.

Chapter 9165

A Concrete Naming Certificate for $\mathsf{CompactOscillationBudget}^{\uparrow}$

Following Bishop and Bridges on compact metric spaces and constructive uniform continuity, the $\mathsf{CompactOscillationBudget}^{\uparrow}$ packet records the finite-net oscillation rows used before a continuous map on a compact source may expose a uniform-modulus or Real-facing readback. It sits beside the compact metric source of chapter 129, the continuous-map row of chapter 130, the uniform-modulus handoff of chapter 369, the dyadic tolerance arithmetic of chapter 291, the regular rational readback of chapter 301, and the terminal real-name seal of chapter 38. The packet names a finite compact-net oscillation budget; it does not assert host suprema, open-cover compactness, selected infinite subcovers, quotient equality of functions, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 9165.1 (Compact oscillation budget carrier)**.** *A* $\mathsf{CompactOscillationBudget}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (K, F, N, O, D, Q, R, U, H, C, P, L)$$

with the following displayed rows:

1. *K is the* $\mathsf{CompactMetric}^{\uparrow}$ *source row exposing the compact finite-net cells inspected by the packet.*
2. *F is the* $\mathsf{ContinuousMap}^{\uparrow}$ *row whose local graph data are being tested on those cells.*
3. *N is the finite compact-net row, listing the displayed centers, radii, and cell-membership witnesses.*
4. *O is the finite oscillation row, assigning to each displayed cell the pointwise oscillation bound read from F over K.*
5. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row used to compare the requested precision with the cellwise oscillation rows.*
6. *Q is the finite budget ledger folding the cellwise oscillation rows into one displayed compact budget.*
7. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the folded rational budget.*
8. *U is the* $\mathsf{UniformModulus}^{\uparrow}$ *or* $\mathsf{Real}^{\uparrow}$ *handoff row reached only after K, F, N, O, D, Q, R have been displayed.*
9. *H records componentwise* hsame *transport for the compact source, map, net, oscillation, dyadic, budget, readback, handoff, replay, provenance, and local naming rows.*

10. *C records displayed* Cont *replay from compact-net cells and continuous-map oscillation rows through dyadic comparison, regular readback, and the terminal handoff.*
11. *P is the* Pkg *provenance over* $\mathsf{CompactOscillationBudget}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{UniformModulus}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
12. *L is the local* $\mathsf{NameCert}_{\mathsf{CompactOscillationBudget}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $K, F, N, O, D, Q, R, U, H, C, P, L$. It has no coordinate for host suprema of oscillation, open-cover compactness, selected infinite subcovers, quotient function equality, countable choice, or ambient real completeness.

Theorem 9165.2 (Compact oscillation budget NameCert obligations)**.** *For every accepted* CompactOscillationBudg *carrier*

$$B = (K, F, N, O, D, Q, R, U, H, C, P, L),$$

the local $\mathsf{NameCert}_{\mathsf{CompactOscillationBudget}^{\uparrow}}$ *surface consists exactly of compact-source admission through K, continuous-map admission through F, finite compact-net exposure through N, pointwise cell oscillation rows through O, dyadic tolerance comparison through D, folded budget exposure through Q, regular rational readback through R, terminal uniform-modulus or Real handoff through U, componentwise* hsame *transport through H, displayed* Cont *replay through C, provenance through P, and local naming through L.*

Proof. Project the carrier of Definition 9165.1. Its analytic rows are exactly the compact source K, the continuous-map row F, the finite net N, the cellwise oscillation row O, the dyadic tolerance D, the folded budget Q, the regular readback R, and the terminal handoff U.

Read the finite-net route in order. The row N lists only displayed cells over K, and O records only the pointwise oscillation rows supplied by F on those cells. The dyadic row D and budget ledger Q compare those finitely many rows without taking a host supremum.

The readback and handoff rows R, U are downstream of that finite ledger. The structural rows H, C, P, L transport, replay, source, and locally name the same packet, so the excluded open-cover, selected-subcover, quotient, choice, and ambient-completeness data are not part of the NameCert surface. □

Theorem 9165.3 (Compact oscillation budget finite-net route)**.** *Every* $\mathsf{UniformModulus}^{\uparrow}$ *or* $\mathsf{Real}^{\uparrow}$ *consumer of an accepted* $\mathsf{CompactOscillationBudget}^{\uparrow}$ *packet must read the finite route*

$$\mathsf{CompactMetric}^{\uparrow}, \mathsf{ContinuousMap}^{\uparrow}, N, O, \mathsf{DyadicRatCore}^{\uparrow}, Q, \mathsf{RegSeqRat}^{\uparrow}, U, H, C, P, L$$

before using the exported compact oscillation budget. Thus the route is determined by compact-net cells, pointwise oscillation rows, dyadic tolerance comparison, regular rational readback, and the terminal handoff, rather than by host suprema or an ambient compactness theorem.

Proof. Start from the NameCert obligations of Definition 9165.2. They force every consumer through the compact source, continuous-map row, finite net, oscillation ledger, dyadic comparison, budget fold, and regular readback before U is public.

The compact finite-net cells are the only coverage data in the carrier. A consumer that asks for a different cover, a selected infinite subcover, or a host supremum of oscillation would need a coordinate absent from B.

Finally, transport and replay preserve the same finite dependency route through H, C, P, L. Therefore the exported budget is a BEDC finite NameCert route to $\mathsf{UniformModulus}^{\uparrow}$ or $\mathsf{Real}^{\uparrow}$, not an external compactness or supremum principle. □

Falsifiable prediction: An accepted $\mathsf{CompactOscillationBudget}^{\uparrow}$ consumer is refuted if it reaches $\mathsf{UniformModulus}^{\uparrow}$ or $\mathsf{Real}^{\uparrow}$ without displaying the compact metric source, continuous-map row, finite compact-net cells, pointwise oscillation rows, dyadic tolerance row, folded budget ledger, regular rational readback, transport, replay, provenance, and local NameCert row.

Independence witness: compactmetric, continuousmap, uniformmodulus, dyadicratcore, regseqrat, real: none is bijective to $\mathsf{CompactOscillationBudget}^{\uparrow}$ because this packet jointly binds compact finite-net cells, pointwise oscillation rows, dyadic tolerance comparison, a folded finite budget, regular rational readback, terminal handoff, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{CompactOscillationBudget}^{\uparrow}}$.

Constructive story: A $\mathsf{CompactOscillationBudget}^{\uparrow}$ packet is generated from CompactMetric finite-net cells, a ContinuousMap row, pointwise oscillation rows, DyadicRatCore tolerance comparison, a folded finite budget ledger, RegSeqRat readback, UniformModulus or RealUp handoff data, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CompactOscillationBudget}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 9165.1, Definition 9165.2, and Definition 9165.3 seed the finite compact-net oscillation route from compact and continuous rows into uniform-modulus and Real-facing consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CompactOscillationBudget}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close Lean verification, bridge checking, host suprema of oscillation, open-cover compactness, selected infinite subcovers, quotient function equality, countable choice, or ambient Real completeness.

Upgrade path: Obligation closure requires checked carrier admission, compact-source exposure, continuous-map exposure, finite-net exposure, oscillation-row exactness, dyadic budget comparison, regular readback, terminal handoff nonescape, transport, replay, provenance, and local naming for BEDC.Derived.CompactOscillationBudgetUp.

Chapter 9166

A Concrete Naming Certificate for $\mathsf{CompactConvergenceTheorem}^{\uparrow}$

Following Kelley and Bishop–Bridges on compact convergence, the $\mathsf{CompactConvergenceTheorem}^{\uparrow}$ packet defines a finite BHist route over $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{UniformLimit}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, hsame, Cont, Pkg, and $\mathsf{NameCert}$. It sits after the compact metric source of chapter 129, the continuous-map surface of chapter 130, the uniform-limit sibling of chapter 463, the finite stream windows of chapter 126, the regular rational readback of chapter 301, the dyadic tolerance core of chapter 291, and the terminal real seal of chapter 38. The packet records the compact-source uniform-convergence theorem as finite BEDC data; it does not import open-cover compactness, host function-space completion, selected suprema, or ambient Real completeness.

Definition 9166.1 (Compact convergence theorem carrier)**.** *A* $\mathsf{CompactConvergenceTheorem}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$\mathsf{CompConv}(K, F, U, W, R, D, S, H, C, P, N)$$

with the following rows.

1. *K is the* $\mathsf{CompactMetric}^{\uparrow}$ *source row, exposing the compact metric carrier and the finite compactness evidence used by the theorem packet.*
2. *F is the* $\mathsf{ContinuousMap}^{\uparrow}$ *family row, recording the displayed continuous maps on the compact source.*
3. *U is the* $\mathsf{UniformLimit}^{\uparrow}$ *row, carrying the uniform Cauchy or uniform convergence evidence for the family F over K.*
4. *W is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row used to inspect only bounded prefixes of the convergence data.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row, translating the inspected windows into regular rational observations.*
6. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row, recording the dyadic radius and comparison slack used by the uniform-limit route.*
7. *S is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row, reached only after K, F, U, W, R, D have been displayed.*

8. *H records componentwise* hsame *transport for compact sources, continuous maps, uniform-limit evidence, stream windows, regular rational readbacks, dyadic budgets, Real seals, replay, provenance, and local naming.*
9. *C records displayed* Cont *replay from the compact source and map-family rows through U, W, R, D to the Real seal row S.*
10. *P is the* Pkg *provenance over* $\mathsf{CompactConvergenceTheorem}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{UniformLimit}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{CompactConvergenceTheorem}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $K, F, U, W, R, D, S, H, C, P, N$. It has no coordinate for an open-cover compactness proof, a host function-space completion, a selected supremum norm, a quotient of maps, or an ambient completeness theorem for $\mathsf{Real}^{\uparrow}$.

Theorem 9166.2 (Compact convergence theorem NameCert obligations)**.** *For every accepted* $\mathsf{CompactConvergenceTheorem}^{\uparrow}$ *carrier* $\mathsf{CompConv}(K, F, U, W, R, D, S, H, C, P, N)$, *the local* $\mathsf{NameCert}_{\mathsf{CompactConverge}}$ *surface consists exactly of compact-source admission through K, continuous-map family exposure through F, uniform-limit evidence through U, finite* $\mathsf{StreamName}^{\uparrow}$ *window inspection through W,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback through R,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance budgeting through D, terminal* $\mathsf{Real}^{\uparrow}$ *seal handoff through S, componentwise* hsame *transport through H, displayed* Cont *replay through C, provenance through P, and local naming through N.*

Proof. Project the carrier of Definition 9166.1. The rows $K, F, U, W, R, D, S, H, C, P, N$ are the only fields available to the local classifier.

The compact source K and continuous-map family F determine the theorem's domain and maps. The uniform-limit row U supplies the displayed convergence evidence, but it must still pass through the finite window row W, the regular rational readback row R, and the dyadic tolerance row D before any Real-facing seal is visible.

The structural rows H, C, P, N transport, replay, source, and name that same route. Since the carrier contains no open-cover compactness proof, host function-space completion, selected supremum, quotient-map equality, or ambient Real-completeness coordinate, the listed rows exhaust the local NameCert obligations. □

Theorem 9166.3 (Compact convergence uniform-limit route)**.** *Every accepted* $\mathsf{CompactConvergenceTheorem}^{\uparrow}$ *consumer that reads a compact-source uniform convergence theorem must factor through the route*

$$\mathsf{CompactMetric}^{\uparrow},\ \mathsf{ContinuousMap}^{\uparrow},\ \mathsf{UniformLimit}^{\uparrow},\ \mathsf{StreamName}^{\uparrow},\ \mathsf{RegSeqRat}^{\uparrow},\ \mathsf{DyadicRatCore}^{\uparrow} \longrightarrow \mathsf{Real}^{\uparrow}.$$

In particular, the public read sees a compact metric source, a continuous-map family, uniform-limit evidence, finite observation windows, regular rational readback, and dyadic tolerance data before the terminal Real seal.

Proof. Begin with an accepted carrier $\mathsf{CompConv}(K, F, U, W, R, D, S, H, C, P, N)$. The compact source and continuous-map rows are the only entries that name the domain and map family.

The uniform-limit row U is downstream of those rows. It is not public until the finite $\mathsf{StreamName}^{\uparrow}$ windows W, $\mathsf{RegSeqRat}^{\uparrow}$ readback R, and $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance row D have displayed the inspected convergence data.

Finally the $\mathsf{Real}^{\uparrow}$ seal S and structural rows H, C, P, N preserve the same route. Thus the theorem packet exports a finite uniform-limit path, not a hidden compactness theorem, selected supremum, or host completion object. □

Theorem 9166.4 (Compact convergence Real-seal boundary)**.** *The* $\mathsf{Real}^{\uparrow}$ *boundary of an accepted* $\mathsf{CompactConvergenceTheorem}^{\uparrow}$ *packet is exactly the seal row* S *reached from* K, F, U, W, R, D*. A downstream Real or Completion consumer may use* S *only together with the displayed compact source, continuous-map family, uniform-limit row, finite stream windows, regular rational readback, dyadic tolerance budget, transport, replay, provenance, and local naming rows stored in the same packet.*

Proof. Read the carrier rows in order. The seal row S has no independent source: it is reached only after the compact metric row, continuous-map family row, uniform-limit row, finite window row, regular rational readback row, and dyadic tolerance row have been projected.

Componentwise transport H and replay C keep that dependency visible, while P and N record provenance and local naming for the same packet. Since there is no further coordinate for open covers, ambient completeness, or selected suprema, any Real or Completion consumer must remain inside this displayed Real-seal boundary. □

Falsifiable prediction: An accepted $\mathsf{CompactConvergenceTheorem}^{\uparrow}$ consumer that reaches a $\mathsf{Real}^{\uparrow}$ seal without displaying the compact metric source, continuous-map family, uniform-limit row, StreamName window, RegSeqRat readback, and DyadicRatCore tolerance data refutes the carrier surface.

Independence witness: compactmetric, continuousmap, uniformlimit, streamname, regseqrat, dyadicratcore, real: $\mathsf{CompactConvergenceTheorem}^{\uparrow}$ is not bijective to any listed sibling because it jointly binds the compact source, map family, uniform-limit evidence, finite observation windows, regular rational readback, dyadic tolerance budget, Real seal, transport, replay, provenance, and local naming as one theorem packet.

Closure status for $\mathsf{NameCert}_{\mathsf{CompactConvergenceTheorem}^{\uparrow}}$**.**

Constructive story: A $\mathsf{CompactConvergenceTheorem}^{\uparrow}$ packet is generated from CompactMetricUp, ContinuousMapUp, UniformLimitUp, StreamNameUp, RegSeqRatUp, DyadicRatCoreUp, RealUp, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CompactConvergenceTheorem}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 9166.1, Definition 9166.2, Definition 9166.3, and Definition 9166.4 seed the compact-source uniform-convergence route through finite windows, regular rational readback, dyadic tolerance data, and a Real seal.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CompactConvergenceTheorem}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim open-cover compactness, host function-space completion, selected suprema, quotient-map equality, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, compact-source compatibility, continuous-map family exposure, uniform-limit route exactness, finite-window readback, dyadic tolerance preservation, Real-seal nonescape, componentwise transport, provenance, and local naming for BEDC.Derived.CompactConvergenceTheoremUp.

Chapter 9167

A Concrete Naming Certificate for $\mathsf{RegularCauchyDiagonalLimitSeal}^{\uparrow}$

Following Bishop and Bridges on regular Cauchy real names, the $\mathsf{RegularCauchyDiagonalLimitSeal}^{\uparrow}$ packet records the finite route by which the diagonal representative of Definition 9238.3 becomes a Real-facing seal. It sits after the finite windows of chapter 126, the regular rational readback of chapter 301, the dyadic tolerance core of chapter 291, and the terminal Real packet of chapter 38. The packet names the diagonal representative, its window choice, its regularity and tail comparison data, and its Real seal; it is not a selected limit, quotient-stream equality, countable-choice modulus, or ambient completeness theorem.

Definition 9167.1 (Regular Cauchy diagonal-limit seal carrier)**.** *A* $\mathsf{RegularCauchyDiagonalLimitSeal}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$\mathsf{DiagSeal}(Q, M, W, R, D, L, S, H, C, P, N)$$

with the following rows.

1. *Q is the precision-request row naming the Real-completion consumer and the requested tolerance.*
2. *M is the displayed regular Cauchy modulus row used to choose the diagonal stage for that request.*
3. *W is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row exposing the inspected diagonal and tail windows.*
4. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the regular rational observations obtained from W.*
5. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row, recording the dyadic budget for diagonal regularity and tail comparison.*
6. *L is the diagonal representative row, storing the finite readback of the representative described in Definition 9238.3.*
7. *S is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row, reached only after Q, M, W, R, D, L have been displayed.*
8. *H records componentwise* hsame *transport for precision requests, moduli, stream windows, regular rational readbacks, dyadic budgets, diagonal representatives, Real seals, replay, provenance, and local naming.*
9. *C records displayed* Cont *replay from the precision request through M, W, R, D, L to the Real seal row S.*

10. *P is the* Pkg *provenance over* $\mathsf{RegularCauchyDiagonalLimitSeal}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

11. *N is the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyDiagonalLimitSeal}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $Q, M, W, R, D, L, S, H, C, P, N$. It has no coordinate for a hidden limit selection, quotient equality of streams, countable-choice modulus, host real equality, or ambient completeness of $\mathsf{Real}^{\uparrow}$.

Theorem 9167.2 (Regular Cauchy diagonal-limit seal NameCert obligations)**.** *For every accepted* $\mathsf{RegularCauchyDiagonalLimitSeal}^{\uparrow}$ *carrier* $\mathsf{DiagSeal}(Q, M, W, R, D, L, S, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyDiagonalLimitSeal}^{\uparrow}}$ *surface consists exactly of precision-request admission through Q, regular Cauchy modulus exposure through M, finite* $\mathsf{StreamName}^{\uparrow}$ *window inspection through W,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback through R,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance budgeting through D, diagonal representative exposure through L, terminal* $\mathsf{Real}^{\uparrow}$ *seal handoff through S, componentwise* hsame *transport through H, displayed* Cont *replay through C, provenance through P, and local naming through N.*

Proof. Project the carrier of Definition 9167.1. The rows $Q, M, W, R, D, L, S, H, C, P, N$ are the complete local surface.

The request Q determines the tolerance being answered. The modulus row M chooses the diagonal stage, the finite window row W displays what is inspected, and the readback and dyadic rows R, D record the regular rational and tolerance data used in the diagonal estimate.

The diagonal representative row L is downstream of those visible rows, and the Real seal S is downstream of L. Transport, replay, provenance, and local naming preserve the same dependency. Since no carrier coordinate stores a selected limit, quotient stream, countable choice, host real equality, or ambient completeness theorem, the listed rows exhaust the local NameCert obligations. □

Theorem 9167.3 (Regular Cauchy diagonal-limit seal route)**.** *Every accepted* $\mathsf{RegularCauchyDiagonalLimitSeal}^{\uparrow}$ *consumer that reaches a* $\mathsf{Real}^{\uparrow}$ *seal must pass through the finite route*

$$\mathsf{StreamName}^{\uparrow},\ \mathsf{RegSeqRat}^{\uparrow},\ \mathsf{DyadicRatCore}^{\uparrow} \longrightarrow \mathsf{Real}^{\uparrow}$$

after displaying the precision request, the regular Cauchy modulus row, and the diagonal representative row. Thus the diagonal-limit construction is consumed as finite StreamName, RegSeqRat, DyadicRatCore, RealUp, hsame, Cont, Pkg, *and* NameCert *data.*

Proof. Start with an accepted carrier $\mathsf{DiagSeal}(Q, M, W, R, D, L, S, H, C, P, N)$. The precision request and modulus rows identify the diagonal stage used for the read.

The finite stream window W and regular rational readback R expose the actual observations, while D supplies the dyadic tolerance budget for the diagonal regularity and tail comparison checks. The representative row L is therefore a finite readback row, not a hidden limit.

Finally S is the only Real-facing seal in the carrier, and H, C, P, N keep the same route visible to downstream consumers. The route cannot be shortened through quotient-stream equality, countable choice, or ambient Real completeness because none of those objects appears in the carrier. □

Falsifiable prediction: An accepted $\mathsf{RegularCauchyDiagonalLimitSeal}^{\uparrow}$ consumer that reaches a $\mathsf{Real}^{\uparrow}$ seal without displaying a precision request, regular Cauchy modulus, StreamName window, RegSeqRat readback, DyadicRatCore budget, and diagonal representative row refutes the carrier surface.

Independence witness: streamname, regseqrat, dyadicratcore, real: $\mathsf{RegularCauchyDiagonalLimitSeal}^{\uparrow}$ is not bijective to any listed sibling because it jointly binds a precision request, regular Cauchy modulus, finite diagonal window, regular rational readback, dyadic tolerance budget, diagonal representative, Real seal, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{RegularCauchyDiagonalLimitSeal}^{\uparrow}}$.

Constructive story: A $\mathsf{RegularCauchyDiagonalLimitSeal}^{\uparrow}$ packet is generated from a precision request, regular Cauchy modulus row, StreamNameUp finite windows, RegSeqRatUp readback, DyadicRatCoreUp tolerance data, diagonal representative row, RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RegularCauchyDiagonalLimitSeal}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 9167.1, Definition 9167.2, and Definition 9167.3 seed the diagonal representative route from finite StreamName windows through RegSeqRat readback and DyadicRatCore tolerance data into a Real seal.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RegularCauchyDiagonalLimitSeal}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim selected limits, quotient stream equality, countable-choice moduli, host real equality, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, precision-request exposure, regular Cauchy modulus compatibility, finite-window readback, diagonal representative exactness, dyadic tolerance preservation, Real-seal nonescape, componentwise transport, provenance, and local naming for BEDC.Derived.RegularCauchyDiagonalLimitSealUp.

Chapter 9168

A Concrete Naming Certificate for $\mathsf{CauchyFilterTelescope}^{\uparrow}$

Following Bishop and Bridges, *Constructive Analysis*, and the Bourbaki–Kelley language of filters and filter bases, the $\mathsf{CauchyFilterTelescope}^{\uparrow}$ packet records the finite telescope that reads a Cauchy-filter presentation back as regular Cauchy sequence data before a Real or Completion consumer inspects it. It sits between the Cauchy-filter source of chapter 333, the finite basis generator of chapter 1501, the regular-filter handoff of chapter 1445, the stream windows of chapter 126, the regular rational readback of chapter 301, the dyadic tolerance ledger of chapter 291, and the terminal Real seal of chapter 38. The packet is a finite bridge from displayed filter data to regular sequence readback; it is not a quotient of filters, not a selected limit, not host equality of reals, not countable choice, and not ambient completeness.

Definition 9168.1 (Cauchy filter telescope carrier)**.** *A* $\mathsf{CauchyFilterTelescope}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$T = (F, B, G, S, R, D, E, H, C, P, N)$$

with the following displayed rows:

1. *F is the source* $\mathsf{CauchyFilter}^{\uparrow}$ *row, exposing only displayed finite filterbase requests and Cauchy-window evidence.*
2. *B is the* $\mathsf{CauchyFilterBasis}^{\uparrow}$ *basis row that lists the finite generator windows read from F.*
3. *G is the* $\mathsf{RegularCauchyFilter}^{\uparrow}$ *handoff row, retaining the directed tail-meet data that regularizes the basis.*
4. *S is the* $\mathsf{StreamName}^{\uparrow}$ *window schedule used by the readback.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row obtained from the displayed stream windows.*
6. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger used to compare the readback windows and radii.*
7. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row, available only after F, B, G, S, R, D have been replayed.*
8. *H records componentwise* hsame *transport for all displayed source, basis, handoff, stream, readback, dyadic, Real-seal, replay, provenance, and local naming rows.*
9. *C records displayed* Cont *replay from the filter source through basis generation, regular-filter handoff, stream windows, regular rational readback, dyadic tolerances, and the Real seal.*

10. *P is the* Pkg *provenance over* $\mathsf{CauchyFilter}^{\uparrow}$, $\mathsf{CauchyFilterBasis}^{\uparrow}$, $\mathsf{RegularCauchyFilter}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

11. *N is the local* $\mathsf{NameCert}_{\mathsf{CauchyFilterTelescope}^{\uparrow}}$ *row.*

The carrier has no coordinate for quotient filters, selected limits, countable-choice schedules, host real equality, or ambient Real completeness.

Theorem 9168.2 (Cauchy filter telescope NameCert obligations)**.** *For every accepted* $\mathsf{CauchyFilterTelescope}^{\uparrow}$ *carrier $T = (F, B, G, S, R, D, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{CauchyFilterTelescope}^{\uparrow}}$ *surface consists exactly of source Cauchy-filter admission, basis exposure, regular-filter handoff, stream-window exposure, regular rational readback, dyadic tolerance exposure, Real-seal handoff, componentwise transport, displayed replay, provenance, and local naming.*

Proof. Project the carrier of Definition 9168.1. The displayed tuple contains precisely the CauchyFilter source row, CauchyFilterBasis row, RegularCauchyFilter handoff, StreamName schedule, RegSeqRat readback, DyadicRatCore tolerance ledger, Real seal, and structural rows.

The replay row C orders those rows. A consumer must first inspect the filter source F, then the basis row B, then the regular-filter handoff G before it can read stream windows, rational readback, dyadic tolerances, or the Real seal.

Transport, provenance, and local naming add no further mathematical coordinates. Since the carrier contains no quotient-filter, selected-limit, choice, host-equality, or ambient-completeness row, the listed rows exhaust the NameCert obligations. □

Theorem 9168.3 (Cauchy filter telescope regular-sequence handoff)**.** *Every accepted* $\mathsf{CauchyFilterTelescope}^{\uparrow}$ *read from a Cauchy-filter presentation to a regular Cauchy sequence factors through the finite route*

$$\mathsf{CauchyFilter}^{\uparrow} \longmapsto \mathsf{CauchyFilterBasis}^{\uparrow} \longmapsto \mathsf{RegularCauchyFilter}^{\uparrow} \longmapsto \mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{DyadicRatCo}$$

The handoff exposes the same rows $F, B, G, S, R, D, E, H, C, P, N$ to downstream Real and Completion consumers and exports no selected limit, quotient-filter equality, countable-choice selector, host equality, or ambient completeness principle.

Proof. Start with the NameCert obligations of Definition 9168.2. They force the source filter row, basis row, regular-filter handoff, stream schedule, rational readback, and dyadic tolerance ledger to remain visible before the Real seal can be consumed.

The basis row B supplies only displayed generator windows from F. The regular-filter row G then keeps the directed tail-meet data attached to those windows, so the readback cannot skip directly from a filter presentation to a Real endpoint.

Finally S, R, D, E provide the regular sequence readback and seal. The structural rows H, C, P, N preserve the same order, and no carrier coordinate provides any of the refused quotient, choice, equality, or completeness endpoints. □

Theorem 9168.4 (Cauchy filter telescope completion boundary)**.** *A downstream Completion or Real consumer of an accepted* $\mathsf{CauchyFilterTelescope}^{\uparrow}$ *packet may read only the displayed telescope rows $F, B, G, S, R, D, E, H, C, P, N$. The packet therefore supplies a finite boundary between Cauchy-filter presentations and regular Cauchy sequence readback; it does not assert that every filter has a selected limit, that filters are quotiented by host equality, that countable choices of basis elements exist, or that the ambient Real object is complete.*

Proof. Apply the regular-sequence handoff. It places every Real or Completion read behind the finite telescope route from F through E.

The completion-facing consumer then receives only the rows named by the carrier. The source filter, basis, regular handoff, stream windows, regular rational readback, dyadic ledger, and Real seal are all displayed before the structural rows transport and name them.

Because the carrier inventory has no selected-limit, quotient-filter, countable-choice, host-equality, or ambient-completeness coordinate, the boundary is a finite readback interface and not a completion theorem. □

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyFilterTelescope}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CauchyFilterTelescope}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 9168.1, Definition 9168.2, Definition 9168.3, and Definition 9168.4 seed the finite telescope from CauchyFilter and CauchyFilterBasis rows through RegularCauchyFilter, StreamName, RegSeqRat, DyadicRatCore, Real, transport, replay, provenance, and local naming rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CauchyFilterTelescope}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient filters, selected limits, countable choice, host real equality, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, basis exposure, regular-filter handoff, stream-window readback, dyadic tolerance exactness, Real-seal handoff, transport, replay, provenance, and local naming for BEDC.Derived.CauchyFilterTelescopeUp.

Constructive story: A $\mathsf{CauchyFilterTelescope}^{\uparrow}$ packet is generated from a CauchyFilter source row, a CauchyFilterBasis row, a RegularCauchyFilter handoff, StreamName windows, RegSeqRat readback, a DyadicRatCore tolerance ledger, a Real seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 9169

A Concrete Naming Certificate for $\mathsf{TotallyBoundedInterval}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{TotallyBoundedInterval}^{\uparrow}$ packet records the constructive fact that a located real interval admits finite meshes at each displayed positive radius. It sits after the real-name carrier of chapter 38, the regular rational readback of chapter 301, the dyadic mesh arithmetic of chapter 291, the located interval membership surface of chapter 394, and the compact metric finite-net interface of chapter 129. The packet names interval total boundedness as finite NameCert data; it is not open-cover compactness, a selected subcover, quotient equality of real names, trichotomy, countable choice, or ambient completeness of $\mathsf{Real}^{\uparrow}$.

Definition 9169.1 (Totally bounded interval carrier)**.** *A* $\mathsf{TotallyBoundedInterval}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$T = (A, B, L, D, Q, M, F, R, H, C, P, N)$$

with the following displayed rows:

1. *A and B are the lower and upper endpoint histories, each sealed through* $\mathsf{Real}^{\uparrow}$ *only after its regular rational readback has been displayed.*
2. *L is the* $\mathsf{LocatedInterval}^{\uparrow}$ *membership row, exposing interval entry and endpoint comparison only through displayed locatedness data.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *mesh-radius row naming the positive dyadic radius requested by the total-boundedness read.*
4. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the endpoint and mesh histories.*
5. *M is the finite mesh schedule, recording the displayed dyadic centers between A and B at radius D.*
6. *F is the finite* $\mathsf{ProbeBundle}$ *net row whose probes name exactly those displayed centers.*
7. *R is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row for endpoint, center, and radius histories after Q and M are exposed.*
8. *H records componentwise* hsame *transport for endpoints, located membership, dyadic radius, regular readback, mesh schedule, finite net, real seal, replay, provenance, and local name.*
9. *C records displayed* Cont *replay from endpoint histories to located membership, from located membership to dyadic mesh extraction, from mesh extraction to regular readback, and from readback to the Real seal.*

10. *P is the* Pkg *provenance over* $\mathsf{TotallyBoundedInterval}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{LocatedInterval}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, ProbeBundle, BHist, hsame, Cont, *and* NameCert *rows.*
11. *N is the local* $\mathsf{NameCert}_{\mathsf{TotallyBoundedInterval}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these displayed finite rows.

Lean4 (statement) `BEDC.Derived.TotallyBoundedIntervalUp`

Theorem 9169.2 (Totally bounded interval NameCert obligations)**.** *For every accepted* $\mathsf{TotallyBoundedInterval}^{\uparrow}$ *carrier $T = (A, B, L, D, Q, M, F, R, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{TotallyBoundedInterval}^{\uparrow}}$ *surface consists exactly of endpoint admission through A, B, located-interval membership through L, dyadic mesh-radius admission through D, regular rational readback through Q, finite mesh scheduling through M, finite* ProbeBundle *net exposure through F, Real seal nonescape through R, componentwise transport through H, displayed replay through C, provenance through P, and local naming through N.*

Proof. Project the carrier of Definition 9169.1. The endpoint histories A, B and the located membership row L are visible before a mesh row can be consumed, so interval membership is not read from a host interval predicate.

The dyadic and regular rows determine the mesh. Row D supplies the displayed radius, Q supplies the regular rational readback of endpoint and radius histories, and M records the finite dyadic centers admitted at that radius. The finite net row F then packages those centers as a ProbeBundle.

The terminal rows preserve the same route. The $\mathsf{Real}^{\uparrow}$ seal R is reached only after the mesh and readback rows are displayed, while H, C, P, N transport, replay, source, and name the same packet. No excluded compactness, subcover, quotient, trichotomy, choice, or ambient completeness principle has a carrier coordinate. □

Theorem 9169.3 (Totally bounded interval net extraction)**.** *Every completion-facing or compact-metric consumer of an accepted* $\mathsf{TotallyBoundedInterval}^{\uparrow}$ *packet receives a finite interval net only through*

$$A, B, L, D, Q, M, F, R, H, C, P, N.$$

Thus the exported net is the finite ProbeBundle *of dyadic centers read through* $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{LocatedInterval}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$ *rows; it is not a host Heine–Borel theorem, a selected finite subcover, or an ambient compactness assertion.*

Proof. Use Definition 9169.2. It identifies the full local surface of an accepted packet, so a consumer cannot reach the finite net before the endpoint, locatedness, dyadic radius, readback, and mesh rows have been displayed.

The extraction is finite. The mesh schedule M lists the dyadic centers admitted at radius D, and F repackages precisely those centers as a ProbeBundle net. The endpoint and membership rows A, B, L keep the centers inside the located interval route.

Finally the readback and seal rows constrain downstream use. Rows Q and R route the mesh through regular rational and real-name data, while H, C, P, N preserve the same displayed path for compact-metric and completion consumers. □

Falsifiable prediction: A $\mathsf{TotallyBoundedInterval}^{\uparrow}$ consumer is refuted whenever it reads an interval net without exposing the RealUp endpoint histories, LocatedIntervalUp membership row, DyadicRatCore mesh radius, RegSeqRat readback, finite ProbeBundle centers, transport, replay, provenance, and local NameCert row.

Closure status for $\mathsf{NameCert}_{\mathsf{TotallyBoundedInterval}^{\uparrow}}$.

Constructive story: A $\mathsf{TotallyBoundedInterval}^{\uparrow}$ packet is generated from RealUp endpoint histories, a LocatedIntervalUp membership row, a DyadicRatCore mesh-radius row, RegSeqRat readback, a finite dyadic mesh schedule, finite ProbeBundle nets, RealUp seal data, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{TotallyBoundedInterval}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 9169.1, Definition 9169.2, and Definition 9169.3 seed the constructive finite-net route for located real intervals.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{TotallyBoundedInterval}^{\uparrow}}, \mathsf{unformalized})$

Lean target: `BEDC.Derived.TotallyBoundedIntervalUp`

Bridge status: none

Not claimed: This chapter does not close open-cover compactness, selected finite subcovers, quotient equality of real names, trichotomy, countable choice, ambient Real completeness, theorem-level Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked endpoint admission, located-interval membership, dyadic mesh extraction, regular readback, finite ProbeBundle coverage, Real seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.TotallyBoundedIntervalUp.

Chapter 9170

A Concrete Naming Certificate for LebesgueNumberMesh$^{\uparrow}$

The LebesgueNumberMesh$^{\uparrow}$ packet is grounded in the Lebesgue number lemma for compact metric spaces: a finite cover of a compact metric source yields a positive mesh radius whose balls refine the cover. In BEDC form the packet records only finite cover mesh, compact-net, local-radius, rational lower-bound, and uniform-modulus handoff data. It realizes the compact-uniform-continuity route of chapter 9237 after the compact metric source of chapter 129, the continuous-map local-radius source of chapter 130, the uniform-modulus consumer of chapter 369, and the rational lower-bound fold surface of chapter 37. The packet is not a host compactness theorem, a chosen open-cover subcover, a least radius, quotient map equality, countable choice, or ambient metric completion.

Definition 9170.1 (Lebesgue number mesh carrier)**.** *A* LebesgueNumberMesh$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (K, V, G, O, B, Q, U, H, C, P, N)$$

with the following displayed rows:

1. *K is the* CompactMetric$^{\uparrow}$ *source row whose finite net is being inspected.*
2. *V is the finite cover mesh row, recording the cover cells and the mesh-to-cover incidence data.*
3. *G is the compact-net* ProbeBundle *row whose probes name the finite centers used to test the cover.*
4. *O is the local radius ledger, assigning to each displayed probe the cover radius admitted by the local continuity or cover-membership read.*
5. *B is the* Rat$^{\uparrow}$ *lower-bound fold over the finitely many positive local radii.*
6. *Q is the mesh-refinement witness saying that the folded rational bound refines the cover mesh.*
7. *U is the* UniformModulus$^{\uparrow}$ *handoff row exposed only after K, V, G, O, B, Q have been displayed.*
8. *H records componentwise* hsame *transport for compact source, cover mesh, compact net, local radii, rational fold, refinement, uniform handoff, replay, provenance, and local name.*
9. *C records displayed* Cont *replay from compact-net exposure through local-radius reads, rational lower-bound folding, mesh refinement, and uniform-modulus handoff.*
10. *P is the* Pkg *provenance over* LebesgueNumberMesh$^{\uparrow}$, CompactMetric$^{\uparrow}$, ContinuousMap$^{\uparrow}$, UniformModulus$^{\uparrow}$, Rat$^{\uparrow}$, ProbeBundle, BHist, hsame, Cont, *and* NameCert *rows.*

11. *N is the local* $\mathsf{NameCert}_{\mathsf{LebesgueNumberMesh}^{\uparrow}}$ *row.*
The classifier compares accepted carriers only through this finite mesh and lower-bound surface.

Lean4 (statement) `BEDC.Derived.LebesgueNumberMeshUp`

Theorem 9170.2 (Lebesgue number mesh NameCert obligations)**.** *For every accepted* $\mathsf{LebesgueNumberMesh}^{\uparrow}$ *carrier* $L = (K, V, G, O, B, Q, U, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{LebesgueNumberMesh}^{\uparrow}}$ *surface consists exactly of compact-metric source admission through* K*, finite cover mesh exposure through* V*, compact-net* ProbeBundle *exposure through* G*, local radius ledger exposure through* O*,* $\mathsf{Rat}^{\uparrow}$ *lower-bound folding through* B*, mesh-refinement exposure through* Q*,* $\mathsf{UniformModulus}^{\uparrow}$ *handoff through* U*, componentwise transport through* H*, displayed replay through* C*, provenance through* P*, and local naming through* N*.*

Proof. Project the carrier of Definition 9170.1. The compact source K, finite cover mesh V, and compact-net row G are displayed before any lower-bound or uniform-modulus row is available.

Read the radius data next. The local radius ledger O attaches one positive rational radius to each displayed probe, and the $\mathsf{Rat}^{\uparrow}$ fold B produces the common lower bound from that finite family. The mesh-refinement row Q records that this bound makes each inspected mesh ball land inside a cover cell.

The handoff row U is therefore downstream of finite cover, compact-net, local-radius, and rational-fold data. Transport, replay, provenance, and local naming through H, C, P, N preserve the same route, so the packet exports no host compactness theorem, selected subcover, least-radius principle, quotient map equality, choice functional, or ambient completion. □

Theorem 9170.3 (Lebesgue number mesh uniform-modulus extraction)**.** *Every compact-uniform-continuity consumer of an accepted* $\mathsf{LebesgueNumberMesh}^{\uparrow}$ *packet must read the finite route*

$$K, V, G, O, B, Q, U, H, C, P, N$$

before consuming the exported $\mathsf{UniformModulus}^{\uparrow}$ *row. The extracted modulus is the tolerance-only handoff obtained from finite cover mesh data, compact-net probes, local radii, and a rational lower-bound fold.*

Proof. Apply Definition 9170.2. It places U after the compact source, finite cover mesh, compact net, local radii, rational fold, and mesh-refinement witness.

The extraction is a finite fold. Each probe in G contributes one radius row in O, and the $\mathsf{Rat}^{\uparrow}$ row B folds these finitely many positive radii into a common lower bound. Row Q then records that this bound refines the finite cover mesh.

Only after those rows are exposed may a compact-uniform-continuity consumer read U as a $\mathsf{UniformModulus}^{\uparrow}$ handoff. Since the carrier contains no host compactness, cover selector, least-radius operator, quotient equality, choice, or ambient completion coordinate, the exported modulus is exactly the finite mesh route described above. □

Falsifiable prediction: A $\mathsf{LebesgueNumberMesh}^{\uparrow}$ consumer is refuted whenever a UniformModulusUp handoff is read before the compact-metric source, finite cover mesh, compact-net ProbeBundle, local radius ledger, RatUp lower-bound fold, mesh-refinement witness, transport, replay, provenance, and local NameCert row are displayed.

Closure status for $\mathsf{NameCert}_{\mathsf{LebesgueNumberMesh}^{\uparrow}}$**.**

Constructive story: A $\mathsf{LebesgueNumberMesh}^{\uparrow}$ packet is generated from CompactMetric source rows, finite cover mesh rows, compact-net ProbeBundle data, local radius ledgers, RatUp lower-bound folds, mesh-refinement witnesses,

UniformModulus handoff data, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\text{LebesgueNumberMesh}\uparrow}$, seed)

Scope closed: Definition 9170.1, Definition 9170.2, and Definition 9170.3 seed the finite Lebesgue-number mesh route for compact-uniform-continuity consumers.

Formal verification: FormalStatus(NameCert$_{\text{LebesgueNumberMesh}\uparrow}$, unformalized)

Lean target: `BEDC.Derived.LebesgueNumberMeshUp`

Bridge status: none

Not claimed: This chapter does not close host compactness, selected finite subcovers, least Lebesgue numbers, quotient equality of maps, countable choice, ambient completion, theorem-level Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked compact-source admission, finite cover mesh exposure, compact-net exposure, local radius ledger exactness, rational lower-bound folding, mesh-refinement nonescape, UniformModulus handoff, transport, replay, provenance, and local naming for BEDC.Derived.LebesgueNumberMeshUp.

Chapter 9171

A Concrete Naming Certificate for $\mathsf{DirectedNetTailWindowCompletion}^{\uparrow}$

Following Moore and Smith on directed nets and Bishop–Bridges constructive completion, the $\mathsf{DirectedNetTailWindowCompletion}^{\uparrow}$ packet records the finite tail-window route by which a displayed directed index row reaches the Real and Completion corridor. It sits after the directed-net source of chapter 3403, the finite StreamName observation surface of chapter 126, the regular rational readback of chapter 301, the dyadic tolerance core of chapter 291, the terminal Real seal of chapter 38, and the completion boundary of chapter 1639. The packet exposes a cofinal tail-window handoff without quotient nets, selected cofinal maps, countable choice, host net equality, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 9171.1 (Directed-net tail-window completion carrier)**.** *A* $\mathsf{DirectedNetTailWindowCompletion}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$T = (I, U, W, R, D, E, B, H, C, P, N)$$

with the following displayed rows:

1. *I is the directed-index row, carrying finitely many index names, preorder comparison rows, and displayed common-upper witnesses.*
2. *U is the cofinal tail-window row. For each requested precision it records a displayed late-index threshold and the finite tail slice inspected above that threshold.*
3. *W is the* $\mathsf{StreamName}^{\uparrow}$ *observation row attached to the retained tail slice.*
4. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row obtained from the same windows and rational observations.*
5. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, recording the dyadic precision, comparison, and tail-radius cells used by the request.*
6. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row, visible only after I, U, W, R, D have been displayed.*
7. *B is the* $\mathsf{Completion}^{\uparrow}$ *handoff row, read through the Bishop regular Cauchy completion boundary and never as an ambient completed object.*
8. *H records componentwise* hsame *transport for the directed-index, cofinal tail-window, StreamName, RegSeqRat, DyadicRatCore, Real, Completion, replay, provenance, and local naming rows.*

9. *C records displayed* Cont *replay from a completion request through I, U, W, R, D, E, B.*
10. *P is the* Pkg *provenance over* $\mathsf{DirectedNetTailWindowCompletion}^{\uparrow}$, $\mathsf{MooreSmithNet}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{Completion}^{\uparrow}$, $\mathsf{BishopRegularCauchyCompletion}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{DirectedNetTailWindowCompletion}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $I, U, W, R, D, E, B, H, C, P, N$. It has no coordinate for quotient nets, selected cofinal maps, countable choice, host net equality, a selected limit, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 9171.2 (Directed-net tail-window completion NameCert obligations)**.** *For every accepted* $\mathsf{DirectedNetTailWindowCompletion}^{\uparrow}$ *carrier $T = (I, U, W, R, D, E, B, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{DirectedNetTailWindowCompletion}^{\uparrow}}$ *surface consists exactly of directed-index admission through I, cofinal tail-window exposure through U, StreamName observation through W, RegSeqRat readback through R, DyadicRatCore tolerance exposure through D, Real sealing through E, Completion handoff through B, componentwise transport through H, displayed replay through C, provenance through P, and local naming through N.*

Proof. Project the carrier of Definition 9171.1. Its object rows are exactly the directed-index row, cofinal tail-window row, observation window, regular rational readback, dyadic tolerance ledger, Real seal, and Completion handoff.

The directed portion is exhausted by I and U. A completion request first displays the finite index comparisons and common-upper witnesses, then records the late tail slice selected for the requested precision.

The analytic portion is exhausted by W, R, D, E, B. The finite tail slice is observed as StreamName windows, read back as regular rational data, checked against the dyadic tolerance ledger, and only then served to the Real seal and Completion handoff.

The structural rows H, C, P, N transport, replay, source, and name the same route. Since no row stores quotient nets, selected cofinal maps, countable choice, host equality, selected limits, or ambient completeness, those objects cannot become local NameCert obligations. □

Theorem 9171.3 (Directed-net tail-window Real and Completion handoff)**.** *Every Real-facing or Completion-facing consumer of an accepted* $\mathsf{DirectedNetTailWindowCompletion}^{\uparrow}$ *packet factors through the finite route*

$$\mathsf{MooreSmithNet}^{\uparrow} \longmapsto \mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{DyadicRatCore}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}, \mathsf{Completion}^{\uparrow}.$$

The handoff uses the displayed cofinal tail-window row as its source and exports no quotient net, selected cofinal map, countable-choice schedule, host net equality, selected limit, or ambient $\mathsf{Real}^{\uparrow}$ *completeness principle.*

Proof. Start with the accepted packet $T = (I, U, W, R, D, E, B, H, C, P, N)$. The directed-index row I and cofinal tail-window row U are the only source rows available to a Real or Completion consumer.

Read the observation and readback rows next. The StreamName window W is opened on the displayed tail slice, the RegSeqRat row R reads back the same finite observations, and the DyadicRatCore row D records the tolerance arithmetic used by the tail request.

Finally E and B are terminal handoff rows for Real and Completion consumers. The transport, replay, provenance, and local naming rows preserve the same source route, so the consumer never obtains a quotient-net representative, selected cofinal function, countable-choice schedule, host equality, selected limit, or ambient completeness theorem. □

Falsifiable prediction: A Real or Completion consumer that reads a $\mathsf{DirectedNetTailWindowCompletion}^{\uparrow}$ seal while omitting the directed-index row, cofinal tail-window row, StreamName window, RegSeqRat readback, or DyadicRatCore tolerance ledger is outside the accepted packet surface.

Independence witness: moore-smith-net, streamname, regseqrat, dyadicratcore, real, bishop-regular-cauchy-completion: no listed sibling supplies the whole $\mathsf{DirectedNetTailWindowCompletion}^{\uparrow}$ packet because this packet binds directed indices, cofinal tail windows, finite observation, regular rational readback, dyadic tolerance, terminal Real sealing, Completion handoff, transport, replay, provenance, and local naming in one route.

Closure status for $\mathsf{NameCert}_{\mathsf{DirectedNetTailWindowCompletion}^{\uparrow}}$.

Constructive story: A $\mathsf{DirectedNetTailWindowCompletion}^{\uparrow}$ packet is generated from a directed-index row, cofinal tail-window row, $\mathsf{StreamName}^{\uparrow}$ finite observations, $\mathsf{RegSeqRat}^{\uparrow}$ readback, $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance ledger, $\mathsf{Real}^{\uparrow}$ seal, $\mathsf{Completion}^{\uparrow}$ handoff, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{DirectedNetTailWindowCompletion}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 9171.1, Definition 9171.2, and Definition 9171.3 seed the finite directed-tail route from Moore–Smith net data into Real and Completion consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{DirectedNetTailWindowCompletion}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient nets, selected cofinal maps, countable choice, host net equality, selected limits, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked directed-index admission, cofinal tail-window exposure, StreamName observation, RegSeqRat readback, DyadicRatCore tolerance exactness, Real and Completion handoff, transport, replay, provenance, and local naming for BEDC.Derived.DirectedNetTailWindowCompletionUp.

Chapter 9172

A Concrete Naming Certificate for $\mathsf{RealTailBudgetHandoff}^{\uparrow}$

Following Bishop and Bridges on regular Cauchy real names, the $\mathsf{RealTailBudgetHandoff}^{\uparrow}$ packet turns the tail-budget branch of chapter 9238 into finite NameCert data. It sits after the explicit-modulus and diagonal routes named in that vision, the finite window surface of chapter 126, the regular rational readback of chapter 301, the dyadic tolerance ledger of chapter 291, and the terminal real-name seal of chapter 38. The packet exposes a concrete Real-completeness tail-budget handoff without quotient streams, selected limits, countable choice, host real equality, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 9172.1 (Real tail-budget handoff carrier)**.** *A* $\mathsf{RealTailBudgetHandoff}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (Q, M, T, W, D, R, E, H, C, P, N)$$

with the following displayed rows:

1. *Q is the precision-request row received from the Real-completeness route.*
2. *M is the explicit Cauchy-modulus row that turns Q into a displayed tail threshold.*
3. *T is the tail-budget row, recording the threshold, the finite budget for inspected indices, and the bounded window request answered by the packet.*
4. *W is the* $\mathsf{StreamName}^{\uparrow}$ *window row opened by that tail budget.*
5. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger used to compare the window values and tail radius.*
6. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row obtained from W and D.*
7. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached only after Q, M, T, W, D, R have been displayed.*
8. *H records componentwise* hsame *transport for precision requests, moduli, tail budgets, StreamName windows, DyadicRatCore tolerances, RegSeqRat readback, Real seals, replay, provenance, and local naming.*
9. *C records displayed* Cont *replay from the Real-completeness precision request through M, T, W, D, R, E.*
10. *P is the* Pkg *provenance over* $\mathsf{RealTailBudgetHandoff}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{RealTailBudgetHandoff}^{\uparrow}}$ *row.*

The classifier compares packets only through $Q, M, T, W, D, R, E, H, C, P, N$. It has no coordinate for quotient stream equality, a selected limit, countable-choice schedule, host real equality, a detached completion object, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 9172.2 (Real tail-budget handoff NameCert obligations)**.** *For every accepted* $\mathsf{RealTailBudgetHandoff}^{\uparrow}$ *carrier $B = (Q, M, T, W, D, R, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{RealTailBudgetHandoff}^{\uparrow}}$ *surface consists exactly of precision-request admission through Q, explicit-modulus exposure through M, tail-budget exposure through T, StreamName window inspection through W, DyadicRatCore tolerance exposure through D, RegSeqRat readback through R, Real sealing through E, componentwise transport through H, displayed replay through C, provenance through P, and local naming through N.*

Proof. Project the carrier of Definition 9172.1. The listed rows are exactly the precision request, modulus, tail-budget, window, tolerance, readback, Real seal, and structural support of the packet.

The request side is exhausted by Q, M, T. The precision request is converted by the explicit modulus into a displayed threshold, and the tail-budget row records the finite index window that will answer that request.

The readback side is exhausted by W, D, R, E. The StreamName window is inspected under the DyadicRatCore tolerance ledger, the RegSeqRat row reads back the regular rational data, and the Real seal is downstream of that readback.

The structural rows H, C, P, N preserve only this displayed route. Since no row stores quotient streams, selected limits, countable choice, host equality, detached completion objects, or ambient completeness, the local obligation surface contains none of those objects. □

Theorem 9172.3 (Real tail-budget concretization route)**.** *Every Real-completeness consumer that uses an accepted* $\mathsf{RealTailBudgetHandoff}^{\uparrow}$ *packet factors through the finite route*

$$\mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{DyadicRatCore}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}.$$

The route is triggered by the displayed precision request, explicit modulus, and tail-budget rows Q, M, T; it exports no quotient stream equality, selected limit, countable-choice schedule, host real equality, detached completion object, or ambient $\mathsf{Real}^{\uparrow}$ *completeness principle.*

Proof. Start with the precision request Q. The explicit modulus row M turns that request into a concrete tail threshold, and T records the finite budget of indices that will be inspected.

The consumer then reads the displayed observation route. The StreamName row W supplies the inspected window, the DyadicRatCore row D supplies the tolerance arithmetic, and the RegSeqRat row R supplies the regular rational readback.

Finally the terminal row E seals the read as a Real-facing handoff. The support rows H, C, P, N transport, replay, source, and name only those rows, so none of the excluded completion principles can enter the concretized route. □

Falsifiable prediction: A Real-completeness route that reads a $\mathsf{RealTailBudgetHandoff}^{\uparrow}$ seal while omitting the precision request, explicit modulus, tail budget, StreamName window, DyadicRatCore tolerance ledger, or RegSeqRat readback is outside the accepted packet surface.

Independence witness: streamname, dyadicratcore, regseqrat, real: no listed sibling supplies the whole $\mathsf{RealTailBudgetHandoff}^{\uparrow}$ packet because this packet binds a precision request, explicit modulus, finite tail budget, window observation, dyadic tolerance, regular readback, Real seal, transport, replay, provenance, and local naming in one concrete Real-completeness route.

Closure status for $\mathsf{NameCert}_{\mathsf{RealTailBudgetHandoff}^{\uparrow}}$.

Constructive story: A RealTailBudgetHandoff$^{\uparrow}$ packet is generated from a precision request, explicit Cauchy modulus, finite tail-budget row, StreamName$^{\uparrow}$ window, DyadicRatCore$^{\uparrow}$ tolerance ledger, RegSeqRat$^{\uparrow}$ readback, Real$^{\uparrow}$ seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\mathsf{RealTailBudgetHandoff}^{\uparrow}}$, seed)

Scope closed: Definition 9172.1, Definition 9172.2, and Definition 9172.3 seed the finite tail-budget handoff from the Real-completeness vision into StreamName, DyadicRatCore, RegSeqRat, and Real rows.

Formal verification: FormalStatus(NameCert$_{\mathsf{RealTailBudgetHandoff}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close quotient stream equality, selected limits, countable choice, host real equality, detached completion objects, ambient Real$^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked precision-request admission, explicit-modulus exposure, tail-budget exposure, StreamName inspection, DyadicRatCore tolerance exactness, RegSeqRat readback, Real-seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.RealTailBudgetHandoffUp.

Chapter 9173

A Concrete Naming Certificate for $\mathsf{BendixsonDulac}^{\uparrow}$

Following Bendixson and Dulac, the $\mathsf{BendixsonDulac}^{\uparrow}$ packet records the finite divergence certificate used to exclude closed trajectories in a planar ODE window before any periodic-orbit conclusion is read. It sits beside the trapping-region certificate of chapter 6911, the displayed ODE source of chapter 193, the dynamical-state surface of chapter 195, the differential-form route of chapter 136, the terminal real-name seal of chapter 38, and the regular-rational readback surface of chapter 301. The packet names only the finite sign, divergence, and boundary-read rows needed for a cycle-exclusion handoff.

Definition 9173.1 (Bendixson–Dulac carrier)**.** *A* $\mathsf{BendixsonDulac}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (O, D, F, G, S, W, R, H, C, P, N)$$

with the following displayed rows:

1. *O is the* $\mathsf{Ode}^{\uparrow}$ *planar vector-field row, carrying the local state window and the right-hand-side read;*
2. *D is the* $\mathsf{DynSystem}^{\uparrow}$ *local-flow row, recording the finite time-window dynamics consumed by the criterion;*
3. *F is the* $\mathsf{DiffForm}^{\uparrow}$ *divergence-form row for the displayed Dulac multiplier and vector field;*
4. *G is the finite sign ledger asserting that* $\operatorname{div}(gX)$ *has one displayed sign on the inspected region;*
5. *S is the boundary-separation row recording where the sign ledger is read relative to the planar window boundary;*
6. *W is the* $\mathsf{RegSeqRat}^{\uparrow}$ *finite readback row for the coefficient and divergence estimates used by G;*
7. *R is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row for those estimates;*
8. *H records componentwise* hsame *transport for the ODE, dynamics, form, sign, boundary, readback, seal, provenance, and local naming rows;*
9. *C records displayed* Cont *replay from the ODE and dynamics rows through the divergence sign ledger and Real-facing readback;*
10. *P is the* Pkg *provenance over* $\mathsf{BendixsonDulac}^{\uparrow}$, $\mathsf{Ode}^{\uparrow}$, $\mathsf{DynSystem}^{\uparrow}$, $\mathsf{DiffForm}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$ *rows;*

11. N is the local $\mathsf{NameCert}_{\mathsf{BendixsonDulac}^{\uparrow}}$ *row.*
The carrier has no coordinate for a selected periodic orbit, global flow completion, quotient path equality, measure-theoretic area, or ambient Real completeness.

Theorem 9173.2 (Bendixson–Dulac NameCert obligations)**.** *For every accepted* $\mathsf{BendixsonDulac}^{\uparrow}$ *carrier* $B = (O, D, F, G, S, W, R, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{BendixsonDulac}^{\uparrow}}$ *surface consists exactly of planar ODE admission through* O*, local dynamics admission through* D*, differential-form divergence readback through* F*, finite sign-ledger visibility through* G*, boundary-separation visibility through* S*, regular-rational readback through* W*, Real-seal readback through* R*, componentwise transport through* H*, displayed replay through* C*, provenance through* P*, and local naming through* N*.*

Proof. Project the carrier of Definition 9173.1. The rows O, D, F, G, S, W, R are the analytic certificate rows, and H, C, P, N are the structural rows that preserve, replay, source, and name the same finite packet.

The ODE and dynamics rows display the planar local-flow window. The differential-form row supplies the divergence read, while the sign ledger and boundary-separation row record how the Dulac sign is inspected on the finite region.

The regular-rational and Real-seal rows expose only the displayed coefficient and divergence estimates. Since no further coordinate is present, the local NameCert obligations are exhausted by the listed rows. □

Theorem 9173.3 (Bendixson–Dulac divergence handoff)**.** *Every cycle-exclusion consumer of an accepted* $\mathsf{BendixsonDulac}^{\uparrow}$ *packet must first read the route*

$$\mathsf{Ode}^{\uparrow},\ \mathsf{DynSystem}^{\uparrow},\ \mathsf{DiffForm}^{\uparrow},\ G,\ S,\ \mathsf{RegSeqRat}^{\uparrow},\ \mathsf{Real}^{\uparrow},\ H,\ C,\ P,\ N.$$

The divergence handoff may be used as a finite sign certificate beside the Poincare–Bendixson trap route of chapter 6911, but it exports no selected periodic orbit, no global flow completion, no quotient path equality, no measure-theoretic area principle, and no ambient Real completeness.

Proof. Apply the NameCert obligations theorem Definition 9173.2. It forces every accepted read through the displayed ODE, dynamics, differential-form, sign-ledger, boundary, regular-rational, Real-seal, transport, replay, provenance, and local naming rows.

The sign ledger is the only row that records the divergence condition. Therefore a consumer cannot obtain a cycle-exclusion handoff without preserving the displayed divergence-form read and the finite Real-facing estimates that support its sign.

The comparison with chapter 6911 is a consumer route only. That sibling supplies a trapping-region packet, while this packet supplies a divergence sign packet; neither row set creates a selected orbit, a completed global flow, quotient path equality, measure theory, or ambient Real completeness. □

Falsifiable prediction: If the finite sign ledger G or the differential-form row F is absent, an accepted $\mathsf{BendixsonDulac}^{\uparrow}$ packet cannot expose a divergence-based cycle-exclusion handoff.

Independence witness: ode, dynsystem, diffform, real, regseqrat, poincarebendixsontrap: none is bijective with $\mathsf{BendixsonDulac}^{\uparrow}$ because this packet jointly stores the planar ODE row, local dynamics row, divergence-form row, finite sign ledger, boundary-separation row, regular-rational readback, Real seal, transport, replay, provenance, and local NameCert row.

Closure status for $\mathsf{NameCert}_{\mathsf{BendixsonDulac}^{\uparrow}}$**.**

Constructive story: A BendixsonDulac$^{\uparrow}$ packet is generated from a planar OdeUp row, a DynSystemUp local-flow row, a DiffFormUp divergence-form row, a finite sign ledger, a boundary-separation row, RegSeqRatUp readback, a terminal RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\text{BendixsonDulac}^{\uparrow}}$, seed)

Scope closed: Definition 9173.1, Definition 9173.2, and Definition 9173.3 seed the finite divergence criterion over displayed ODE, dynamics, differential-form, sign, boundary, regular-rational, Real-seal, transport, replay, provenance, and local naming rows.

Formal verification: FormalStatus(NameCert$_{\text{BendixsonDulac}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close selected periodic orbits, global flow completion, measure theory, quotient path equality, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Further closure requires checked carrier admission, divergence-sign stability, cycle-exclusion handoff, and bridge evidence for the same finite Bendixson–Dulac packet.

Chapter 9174

A Concrete Naming Certificate for $\mathsf{RegularRealMorphism}^{\uparrow}$

Following the Bishop–Bridges treatment of constructive real functions by regular Cauchy names and explicit moduli, the $\mathsf{RegularRealMorphism}^{\uparrow}$ packet records a finite BEDC surface for a morphism between regular real names. It sits after the dyadic rational core of chapter 291, the stream-name interface of chapter 126, the regular rational sequence carrier of chapter 301, the real-name certificate of chapter 38, and the continuity certificate of chapter 130. The packet names only the displayed source name, target name, dyadic modulus, transport, continuity replay, provenance, and local certificate; it is not a host function, quotient-real equality principle, completeness theorem, or choice operator.

Definition 9174.1 (Regular real morphism carrier)**.** *A* $\mathsf{RegularRealMorphism}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$R = (S, T, M, H, C, P, N)$$

with the following displayed rows:

1. *S is the source* $\mathsf{Real}^{\uparrow}$ *row, exposed as a regular Cauchy real name through the* $\mathsf{RegSeqRat}^{\uparrow}$ *and* $\mathsf{StreamName}^{\uparrow}$ *sibling surfaces.*
2. *T is the target* $\mathsf{Real}^{\uparrow}$ *row, exposed as a regular Cauchy real name with the same sibling interfaces available for inspection.*
3. *M is the dyadic modulus row over* $\mathsf{DyadicRatCore}^{\uparrow}$*, recording how a requested target precision is converted into the source precision that the morphism reads.*
4. *H records componentwise* hsame *transport for source name, target name, dyadic modulus, continuity replay, provenance, and local name.*
5. *C records displayed* Cont *replay from the source regular name, through the dyadic modulus read, to the target regular name.*
6. *P is the* Pkg *provenance over* $\mathsf{RegularRealMorphism}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{ContinuousMap}^{\uparrow}$*,* BHist*,* hsame*,* Cont*, and* $\mathsf{NameCert}$ *rows.*
7. *N is the local* $\mathsf{NameCert}_{\mathsf{RegularRealMorphism}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through this finite morphism surface.

Theorem 9174.2 (Regular real morphism NameCert surface)**.** *For every accepted* $\mathsf{RegularRealMorphism}^{\uparrow}$ *carrier* $R = (S, T, M, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{RegularRealMorphism}^{\uparrow}}$ *surface consists exactly*

of source regular-name admission through S, target regular-name admission through T, dyadic-modulus exposure through M, componentwise transport through H, displayed continuity replay through C, provenance through P, and local naming through N.

Proof. Project the carrier of Definition 9174.1. Rows S and T display the source and target real names before any morphism certificate is consumed.

The dyadic modulus row M is the only precision transformer in the packet. It records the source precision required for each displayed target precision, using the dyadic rational core rather than a host real function or quotient-real representative.

Transport, continuity replay, provenance, and local naming are then read through H, C, P, N. These rows preserve the same finite route, so the exported certificate contains no host function graph, extensional quotient equality of reals, completeness construction, or choice functional. □

Theorem 9174.3 (Regular real morphism sibling anchors)**.** *Every consumer of an accepted* $\mathsf{RegularRealMorphism}^{\uparrow}$ *packet must read the sibling route*

$$\mathsf{DyadicRatCore}^{\uparrow},\ \mathsf{StreamName}^{\uparrow},\ \mathsf{RegSeqRat}^{\uparrow},\ \mathsf{Real}^{\uparrow},\ \mathsf{ContinuousMap}^{\uparrow}$$

through the displayed rows S, T, M, H, C, P, N. The morphism surface is determined by regular source and target names, a dyadic modulus, hsame *transport,* Cont *replay,* Pkg *provenance, and the local* NameCert *row.*

Proof. The source and target rows S, T anchor the packet in the regular real-name surface. Their available inspections pass through the stream-name and regular rational sequence siblings, so a consumer cannot read a target-name claim without the corresponding regular-name witnesses.

The modulus row M anchors the precision handoff in $\mathsf{DyadicRatCore}^{\uparrow}$. The replay row C then exposes the continuous-map route, while H transports the displayed data and P, N package the provenance and local name.

Thus the sibling anchors are exactly the five named surfaces together with the morphism rows S, T, M, H, C, P, N. Nothing in the packet adds host-function extensionality, quotient-real equality, a completion theorem, or a choice principle. □

Falsifiable prediction: A $\mathsf{RegularRealMorphism}^{\uparrow}$ consumer is refuted whenever it reads a morphism between regular real names before the source row, target row, dyadic modulus, hsame transport, Cont replay, Pkg provenance, and local NameCert row are displayed.

Closure status for $\mathsf{NameCert}_{\mathsf{RegularRealMorphism}^{\uparrow}}$.

Constructive story: A $\mathsf{RegularRealMorphism}^{\uparrow}$ packet is generated from source and target regular Cauchy real names, a DyadicRatCore modulus, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RegularRealMorphism}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 9174.1, Definition 9174.2, and Definition 9174.3 seed the finite morphism route between regular Cauchy real names.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RegularRealMorphism}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host functions, quotient reals, completeness, choice, theorem-level Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked source admission, target admission, dyadic modulus exposure, transport, continuity replay, provenance, and local naming for BEDC.Derived.RegularRealMorphismUp.

Chapter 9175

A Concrete Naming Certificate for $\mathsf{LowerVietorisCompletion}^{\uparrow}$

Following Vietoris hyperspace practice and the domain-theoretic lower powerdomain reading of closed-set completion, the $\mathsf{LowerVietorisCompletion}^{\uparrow}$ packet records completion through finite lower-hit observations. It sits after the topology carrier of chapter 88, the Vietoris topology surface of chapter 2375, the lower topology route of chapter 8141, the Cauchy ideal route of chapter 9118, the finite probe cover fold of chapter 7452, and the completion reflector of chapter 9129. The packet names only the finite lower-hit, directed-ideal, and completion-handoff rows needed by downstream hyperspace completion consumers.

Definition 9175.1 (Lower Vietoris completion carrier)**.** *A* $\mathsf{LowerVietorisCompletion}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$V = (T, L, H, I, F, D, R, S, C, P, N)$$

with the following displayed rows:

1. *T is the* $\mathsf{Topology}^{\uparrow}$ *source row, exposing the ambient open observations used by the lower-hit classifier.*
2. *L is the* $\mathsf{LowerTopology}^{\uparrow}$ *row, recording that observations are read by hit data and not by upper miss data.*
3. *H is the* $\mathsf{VietorisTopology}^{\uparrow}$ *hyperspace row, restricted to the lower subbasis generated by displayed opens.*
4. *I is the* $\mathsf{CauchyIdeal}^{\uparrow}$ *directed-ideal row, storing the finite tail of lower-hit obligations that is sent to completion.*
5. *F is the finite* $\mathsf{ProbeBundleCoverFold}^{\uparrow}$ *row, listing the displayed opens whose nonempty intersection with the approximating closed set is observed.*
6. *D is the directed lower-hit stability row, asserting that the finite hit list is monotone along the ideal tail.*
7. *R is the* $\mathsf{CompletionReflector}^{\uparrow}$ *handoff row, carrying the lower-hit ideal into the completion corridor.*
8. *S records componentwise* hsame *transport for the topology, lower topology, Vietoris, ideal, finite probe, stability, reflector, replay, provenance, and local naming rows.*

9. *C records displayed* Cont *replay from ambient opens to lower-hit probes, from probes to directed ideals, and from directed ideals to the completion handoff.*
10. *P is the* Pkg *provenance over* $\mathsf{LowerVietorisCompletion}^{\uparrow}$, $\mathsf{Topology}^{\uparrow}$, $\mathsf{LowerTopology}^{\uparrow}$, $\mathsf{VietorisTopology}^{\uparrow}$, $\mathsf{CauchyIdeal}^{\uparrow}$, $\mathsf{ProbeBundleCoverFold}^{\uparrow}$, $\mathsf{CompletionReflector}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*
11. *N is the local* $\mathsf{NameCert}_{\mathsf{LowerVietorisCompletion}^{\uparrow}}$ *row.*

The carrier has no coordinate for upper Vietoris miss tests, Hausdorff distance, compactness, selected limits, quotient equality of closed sets, powerset extensionality, or ambient metric completeness.

Lean4 (statement) `BEDC.Derived.LowerVietorisCompletionUp`

Theorem 9175.2 (Lower Vietoris completion NameCert obligations)**.** *For every accepted* $\mathsf{LowerVietorisCompletion}^{\uparrow}$ *carrier $V = (T, L, H, I, F, D, R, S, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{LowerVietorisCompletion}^{\uparrow}}$ *surface consists exactly of ambient topology admission through T, lower topology admission through L, lower Vietoris hyperspace readback through H, directed Cauchy ideal visibility through I, finite lower-hit probe exposure through F, directed lower-hit stability through D, completion handoff through R, componentwise transport through S, displayed replay through C, provenance through P, and local naming through N.*

Proof. Project the carrier of Definition 9175.1. Rows T, L, H identify the ambient-open, lower-topology, and Vietoris hyperspace sources before any completion read is consumed.

The lower-hit data is finite at each read. Row F lists the displayed opens, and D records monotone stability of those hits along the directed ideal row I. Thus a consumer cannot replace the lower-hit route by an upper miss test, a metric Hausdorff estimate, or an extensional powerset equality.

The terminal rows preserve the same route. Row R is the only completion-facing handoff, while S, C, P, N transport, replay, source, and name the packet without adding compactness, selected limits, quotient equality, or ambient completeness. □

Theorem 9175.3 (Lower-hit completion consumer route)**.** *Every hyperspace completion consumer of an accepted* $\mathsf{LowerVietorisCompletion}^{\uparrow}$ *packet must first read the finite route*

$$T, L, H, I, F, D, R, S, C, P, N.$$

The exported object is therefore a lower-hit completion handoff from directed finite observations; it is not a Fell topology packet, an upper Vietoris classifier, a Hausdorff metric completion, or a selected completed closed set.

Proof. Apply Definition 9175.2. It identifies the entire accepted local surface, so every consumer receives the topology, lower topology, lower Vietoris, directed ideal, finite probe, stability, completion, transport, replay, provenance, and naming rows.

The classifier is lower-hit only. The finite probe row records observed intersection with displayed opens, and the directed stability row keeps those observations coherent along the Cauchy ideal tail.

Consequently the completion reflector row can export only this finite lower-hit handoff. Since no row stores upper miss tests, Fell convergence, Hausdorff metric estimates, a selected closed-set limit, or quotient equality, none of those structures is available to the consumer. □

Falsifiable prediction: If the finite lower-hit row F or the directed stability row D is absent, an accepted $\mathsf{LowerVietorisCompletion}^{\uparrow}$ packet cannot expose a hyperspace completion handoff.

Independence witness: topology, lower-topology, vietoris-topology, cauchy-ideal, probe-bundle-cover-fold, completion-reflector: none is bijective with $\mathsf{LowerVietorisCompletion}^{\uparrow}$ because this packet jointly stores ambient opens, lower-hit classifier data, finite probe observations, directed ideal stability, completion handoff, transport, replay, provenance, and local NameCert rows.

Closure status for $\mathsf{NameCert}_{\mathsf{LowerVietorisCompletion}^{\uparrow}}$.

Constructive story: A $\mathsf{LowerVietorisCompletion}^{\uparrow}$ packet is generated from a TopologyUp source row, a LowerTopologyUp lower-hit row, a VietorisTopologyUp hyperspace row, a CauchyIdealUp directed-ideal row, finite ProbeBundleCoverFoldUp observations, directed lower-hit stability, a CompletionReflectorUp handoff, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{LowerVietorisCompletion}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 9175.1, Definition 9175.2, and Definition 9175.3 seed the finite lower-hit completion route over displayed topology, ideal, probe, reflector, transport, replay, provenance, and local naming rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{LowerVietorisCompletion}^{\uparrow}}, \mathsf{formalTarget})$

Lean target: `BEDC.Derived.LowerVietorisCompletionUp`

Bridge status: none

Not claimed: This chapter does not close upper Vietoris miss tests, Fell topology, Hausdorff metric completion, compactness, selected closed-set limits, quotient equality, powerset extensionality, theorem-level Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked lower-hit carrier admission, directed-ideal stability, completion handoff, transport, replay, provenance, and local naming for BEDC.Derived.LowerVietorisCompletionUp.

Chapter 9176

A Concrete Naming Certificate for $\mathsf{GaussMap}^{\uparrow}$

Following Gauss and Khinchin on continued fractions, the $\mathsf{GaussMap}^{\uparrow}$ packet records the finite BEDC surface for the map that sends a positive real input in the unit interval to the fractional part of its reciprocal. It consumes the real-name row of chapter 38, the reciprocal route of chapter 6251, the floor row of chapter 6900, the residual row of chapter 1648, the finite continued-fraction prefix row of chapter 342, the finite window and regular-rational readback rows of chapter 126 and chapter 301, and the terminal $\mathsf{Real}^{\uparrow}$ seal. The packet names a constructive dynamics step; it is not a host real function, an infinite continued-fraction shift, quotient equality of real names, trichotomy, choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 9176.1 (Gauss map carrier)**.** *A* $\mathsf{GaussMap}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$G = (R, Z, V, F, Q, A, E, H, C, P, N)$$

with the following displayed rows:

1. *R is the source* $\mathsf{Real}^{\uparrow}$ *row for the input real name.*
2. *Z is the nonzero positive unit-interval guard row attached to the same real source.*
3. *V is the* $\mathsf{RealReciprocal}^{\uparrow}$ *row displaying the reciprocal read permitted by Z.*
4. *F is the* $\mathsf{FloorFunction}^{\uparrow}$ *row for the integer part of the reciprocal read.*
5. *Q is the* $\mathsf{FractionalPart}^{\uparrow}$ *residual row bound to the same reciprocal and floor rows.*
6. *A is the* $\mathsf{ContinuedFraction}^{\uparrow}$ *finite-prefix handoff row, recording the partial-quotient prefix visible after the reciprocal and floor read.*
7. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row for the fractional residual.*
8. *H records componentwise* hsame *transport for the source, guard, reciprocal, floor, residual, prefix, seal, replay, provenance, and local naming rows.*
9. *C records displayed* Cont *replay from the source real and guard through reciprocal, floor, fractional residual, continued-fraction prefix, and terminal seal.*
10. *P is the* Pkg *provenance over* $\mathsf{GaussMap}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{RealReciprocal}^{\uparrow}$, $\mathsf{FloorFunction}^{\uparrow}$, $\mathsf{FractionalPart}^{\uparrow}$, $\mathsf{ContinuedFraction}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.

11. *N is the local* $\mathsf{NameCert}_{\mathsf{GaussMap}^\uparrow}$ *row.*

The classifier compares accepted packets only through these eleven rows. It has no coordinate for a host Gauss-map function, quotient real equality, an infinite continued-fraction stream, a selected representative, trichotomy, countable choice, or detached $\mathsf{Real}^\uparrow$ *completeness.*

Theorem 9176.2 (Gauss map NameCert obligations)**.** *For every accepted* $\mathsf{GaussMap}^\uparrow$ *carrier* $G = (R, Z, V, F, Q, A, E, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{GaussMap}^\uparrow}$ *surface consists exactly of carrier admission for the source* $\mathsf{Real}^\uparrow$ *row, the nonzero positive unit-interval guard, the* $\mathsf{RealReciprocal}^\uparrow$ *row, the* $\mathsf{FloorFunction}^\uparrow$ *row, the* $\mathsf{FractionalPart}^\uparrow$ *residual row, the* $\mathsf{ContinuedFraction}^\uparrow$ *prefix handoff, the terminal* $\mathsf{Real}^\uparrow$ *seal, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. No NameCert obligation is stored outside these rows.*

Proof. Project the carrier of Definition 9176.1. The source row R and guard row Z are the only admission data for the real input; the reciprocal row V is public only after those rows have been displayed.

Read the arithmetic route next. The floor row F and fractional residual row Q are tied to the same reciprocal row, and the continued-fraction prefix row A records only the finite partial-quotient handoff visible from that route.

Finally inspect the seal and structural rows. The row E is a $\mathsf{Real}^\uparrow$ seal for the displayed residual, while H, C, P, N transport, replay, source, and name the same finite packet. Since the carrier has no further coordinate, the listed rows exhaust the local NameCert surface. □

Theorem 9176.3 (Gauss map fractional-part route)**.** *Every dynamics-facing read exported by an accepted* $\mathsf{GaussMap}^\uparrow$ *carrier factors through*

$$R \longmapsto Z \longmapsto V \longmapsto F \longmapsto Q \longmapsto A \longmapsto E$$

together with H, C, P, N. Consequently the public read is a finite reciprocal, floor, fractional-part, continued-fraction-prefix, and real-seal route, not a host function evaluation, an infinite shift on continued fractions, quotient equality of real names, a selected representative, or an ambient completeness principle.

Lean4 (statement) `BEDC.Derived.GaussMapUp`

Proof. Start from the accepted carrier. The guard row Z keeps the reciprocal request attached to the displayed positive nonzero interval data of the source row R, so the reciprocal row V is not detached from the input name.

Apply the floor and fractional-part sibling routes. The floor row F supplies the integer part of the reciprocal read, and Q records the residual on the same reciprocal and floor data before any continued-fraction prefix is exposed.

The finite-prefix handoff A and seal row E are downstream of that residual. Transport, replay, provenance, and local naming preserve the same route, and the excluded host-function, infinite-stream, quotient, representative, choice, and completeness coordinates are absent from the carrier. □

Falsifiable prediction: Every $\mathsf{GaussMap}^\uparrow$ dynamics read factors through $\mathsf{Real}^\uparrow$, $\mathsf{RealReciprocal}^\uparrow$, $\mathsf{FloorFunction}^\uparrow$, $\mathsf{FractionalPart}^\uparrow$, $\mathsf{ContinuedFraction}^\uparrow$, $\mathsf{StreamName}^\uparrow$, $\mathsf{RegSeqRat}^\uparrow$, and a terminal $\mathsf{Real}^\uparrow$ seal before the local $\mathsf{NameCert}_{\mathsf{GaussMap}^\uparrow}$ row is consumed.

Independence witness: real, real-reciprocal, floor-function, fractional-part, continuedfraction, streamname, regseqrat: $\mathsf{GaussMap}^\uparrow$ is not bijective to any listed sibling because it jointly carries a

source Real row, positive nonzero interval guard, reciprocal row, floor row, fractional-part residual, continued-fraction prefix handoff, Real seal, transport, replay, provenance, and local naming while refusing host function evaluation and infinite continued-fraction shifts.

Closure status for $\mathsf{NameCert}_{\mathsf{GaussMap}\uparrow}$**.**

Constructive story: A $\mathsf{GaussMap}^{\uparrow}$ packet is generated from a source RealUp row, a nonzero positive interval guard, a RealReciprocal row, a FloorFunction row, a FractionalPart residual row, a ContinuedFraction prefix handoff, a Real seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{GaussMap}\uparrow}, \mathsf{seed})$

Scope closed: Definition 9176.1, Definition 9176.2, and Definition 9176.3 seed the finite reciprocal, floor, fractional-part, continued-fraction-prefix, and Real-seal route for the Gauss map.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{GaussMap}\uparrow}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host real functions, infinite continued-fraction shifts, quotient real equality, trichotomy, selected representatives, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, checked Lean obligations, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, guard exactness, reciprocal routing, floor and fractional-part handoff, continued-fraction prefix handoff, Real seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.GaussMapUp.

Chapter 9177

A Concrete Naming Certificate for $\mathsf{BishopNestedInterval}^{\uparrow}$

Following Bishop and Bridges on constructive nested intervals, the $\mathsf{BishopNestedInterval}^{\uparrow}$ packet records the finite endpoint-window surface by which a decreasing sequence of inhabited closed rational intervals is read into regular Cauchy and real-name consumers. It sits after the dyadic tolerance core of chapter 291, the finite stream-window interface of chapter 126, the regular rational readback of chapter 301, the terminal real-name seal of chapter 38, and the nested-interval principle packet of chapter 7290. The packet names only displayed endpoint monotonicity, shrinking-width budgets, finite windows, regular readback, transport, replay, provenance, and local naming; it does not assert host completeness, Heine–Borel compactness, selected limit points, quotient real equality, trichotomy, or countable choice.

Definition 9177.1 (Bishop nested interval carrier)**.** *A* $\mathsf{BishopNestedInterval}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$I = (L, U, D, S, R, E, H, C, P, N)$$

with the following displayed rows:

1. *L is the lower-endpoint stream row, exposing each finite lower endpoint only through* $\mathsf{DyadicRatCore}^{\uparrow}$ *and* $\mathsf{StreamName}^{\uparrow}$ *data.*
2. *U is the upper-endpoint stream row, exposing each finite upper endpoint through the same dyadic and stream rows.*
3. *D is the dyadic width-budget row, recording the displayed shrinking tolerance assigned to each inspected interval window.*
4. *S is the finite* $\mathsf{StreamName}^{\uparrow}$ *request row selecting the endpoint windows consumed by the packet.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *regular readback row for the paired endpoint streams and their shrinking-width budget.*
6. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached only after S and R have been displayed.*
7. *H records componentwise* hsame *transport for endpoint streams, width budgets, windows, regular readback, Real seal, replay, provenance, and local naming.*
8. *C records displayed* Cont *replay from endpoint-window requests through monotonicity, shrinking width, regular readback, and the Real seal.*

9. *P is the* Pkg *provenance over* BishopNestedInterval$^{\uparrow}$, NestedIntervalPrinciple$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, Real$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* NameCert$_{\text{BishopNestedInterval}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $L, U, D, S, R, E, H, C, P, N$. It has no coordinate for a host completed point, open-cover compactness, a selected intersection element, quotient real equality, trichotomy, countable choice, or ambient Real$^{\uparrow}$ *completeness.*

Theorem 9177.2 (Bishop nested interval monotone endpoint obligation)**.** *For every accepted* BishopNestedInterval$^{\uparrow}$ *carrier*

$$I = (L, U, D, S, R, E, H, C, P, N),$$

the monotone endpoint obligation consists exactly of lower-endpoint stream exposure through L, upper-endpoint stream exposure through U, dyadic width-budget exposure through D, finite window exposure through S, regular rational readback through R, Real sealing through E, componentwise transport through H, displayed replay through C, provenance through P, and local naming through N.

Proof. Project the carrier of Definition 9177.1. The endpoint rows L and U are the only rows that expose interval endpoints, and the budget row D is the only row that records shrinking-width data.

Read the monotonicity obligation through finite windows. The row S selects the inspected endpoint windows, so endpoint order and interval inclusion are checked only on displayed StreamName$^{\uparrow}$ requests and dyadic comparisons.

The regular and Real-facing rows are downstream. Row R reads the paired endpoints and their width budget as regular rational data, while E seals only that displayed readback as Real$^{\uparrow}$ data.

Finally H, C, P, N transport, replay, source, and name the same finite packet. Since no carrier coordinate supplies host completed points, open-cover compactness, selected intersections, quotient equality, trichotomy, choice, or ambient completeness, the listed rows exhaust the monotone endpoint obligation. □

Theorem 9177.3 (Bishop nested interval regular Cauchy handoff)**.** *Every Real-facing or completion-facing consumer of an accepted* BishopNestedInterval$^{\uparrow}$ *packet receives a regular Cauchy handoff only through the route*

$$L, U, D, S, R, E, H, C, P, N.$$

The handoff factors through DyadicRatCore$^{\uparrow}$ *endpoint and width arithmetic,* StreamName$^{\uparrow}$ *finite windows,* RegSeqRat$^{\uparrow}$ *regular readback,* Real$^{\uparrow}$ *sealing, and the nested-interval principle of chapter 7290; it exports no host completeness theorem, Heine–Borel compactness, selected point, quotient real equality, trichotomy, or countable-choice row.*

Proof. Use the monotone endpoint obligation of Definition 9177.2. It places the lower and upper endpoint streams, dyadic width budget, finite windows, and regular readback before any Real-facing row is public.

Apply the nested-interval principle route through chapter 7290. That route consumes finite window and shrinking-budget data before it hands a readback to Real-facing consumers.

The terminal seal E is therefore downstream of S and R. A completion-facing consumer can read a regular Cauchy name only after the displayed StreamName windows and RegSeqRat readback have been exposed.

Because the carrier lacks rows for host completeness, Heine–Borel compactness, selected points, quotient real equality, trichotomy, and countable choice, the handoff is a finite NameCert route rather than an ambient intersection theorem. □

Theorem 9177.4 (Bishop nested interval NameCert surface)**.** *The local* $\mathsf{NameCert}_{\mathsf{BishopNestedInterval}^{\uparrow}}$ *surface for an accepted carrier is exactly the finite endpoint-window route named by Definition 9177.1, Definition 9177.2, and Definition 9177.3. Every accepted read must expose the endpoint streams, dyadic width budget, finite StreamName windows, RegSeqRat readback, Real seal, componentwise transport, continuation replay, provenance, and local naming before a Real or Completion consumer may read the packet.*

Proof. Project the accepted carrier. Its analytic rows are L, U, D, S, R, E, and its structural rows are H, C, P, N.

Use the monotone endpoint obligation to identify the endpoint and shrinking-width part of the certificate. This keeps interval inclusion and endpoint comparison inside the displayed dyadic and stream-window rows.

Use the regular Cauchy handoff to identify the Real-facing part of the certificate. The handoff remains downstream of StreamName windows, RegSeqRat readback, the nested-interval principle route, and the Real seal.

The structural rows preserve only that finite route under transport and replay. Thus the local NameCert surface contains no hidden host completion, Heine–Borel compactness, selected intersection point, quotient real equality, trichotomy, or countable-choice principle. □

Falsifiable prediction: A $\mathsf{BishopNestedInterval}^{\uparrow}$ consumer is refuted whenever it reads a Real-facing nested-interval handoff without exposing endpoint streams, a DyadicRatCore width budget, StreamName windows, RegSeqRat readback, a Real seal, hsame transport, Cont replay, Pkg provenance, and local NameCert naming.

Closure status for $\mathsf{NameCert}_{\mathsf{BishopNestedInterval}^{\uparrow}}$**.**

Constructive story: A $\mathsf{BishopNestedInterval}^{\uparrow}$ packet is generated from lower and upper endpoint streams, dyadic width budgets, finite StreamName windows, RegSeqRat readback, a terminal Real seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BishopNestedInterval}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 9177.1, Definition 9177.2, Definition 9177.3, and Definition 9177.4 seed the endpoint-window route from constructive nested intervals to regular Cauchy and Real-facing consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BishopNestedInterval}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host completeness, Heine–Borel compactness, selected intersection points, quotient real equality, trichotomy, countable choice, theorem-level Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked endpoint-stream admission, dyadic width-budget exactness, finite window generation, regular readback, Real sealing, transport, replay, provenance, and local naming for BEDC.Derived.BishopNestedIntervalUp.

Chapter 9178

A Concrete Naming Certificate for CompactRealIntervalModulusWindow$^{\uparrow}$

Following Bishop and Bridges on compact intervals and uniform continuity, the CompactRealIntervalModulusWindow packet realizes the countable-completion spine of chapter 9357 as finite interval-window and modulus data. It sits after the dyadic tolerance arithmetic of chapter 291, the finite stream-window interface of chapter 126, the regular rational readback of chapter 301, the terminal real-name seal of chapter 38, the compact metric finite-net route of chapter 129, and the continuous-map graph route of chapter 130. The packet names a finite compact interval modulus window for Real and completion consumers; it does not assert host Heine–Borel compactness, selected Lebesgue numbers, quotient real equality, countable choice, external modulus oracles, or ambient Real$^{\uparrow}$ completeness.

Definition 9178.1 (Compact Real interval modulus window carrier)**.** *A* CompactRealIntervalModulusWindow$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M = (A, B, D, S, R, K, F, W, E, H, C, P, N)$$

with the following displayed rows:

1. *A and B are the lower and upper* Real$^{\uparrow}$ *endpoint rows for the inspected compact interval.*
2. *D is the* DyadicRatCore$^{\uparrow}$ *tolerance row naming the requested source-window and target-window budgets.*
3. *S is the* StreamName$^{\uparrow}$ *finite window row selecting endpoint, mesh, and function-value observations.*
4. *R is the* RegSeqRat$^{\uparrow}$ *readback row for endpoint streams, mesh centers, and displayed value windows.*
5. *K is the* CompactMetric$^{\uparrow}$ *finite-net row for the compact interval window.*
6. *F is the* ContinuousMap$^{\uparrow}$ *graph row whose values are read only on the displayed compact interval windows.*
7. *W is the modulus-window ledger, assigning the displayed source tolerance to the target tolerance over the finite compact interval net.*
8. *E is the terminal* Real$^{\uparrow}$ *seal row for endpoint, mesh, and value histories after S, R, K, F, W are displayed.*

9. *H records componentwise* hsame *transport for endpoints, tolerance rows, finite windows, regular readback, compact-net data, continuous-map graph rows, modulus windows, Real seals, replay, provenance, and local naming.*
10. *C records displayed* Cont *replay from a tolerance request through finite interval windows, compact finite nets, regular readback, continuous-map graph rows, modulus-window assignment, and the Real seal.*
11. *P is the* Pkg *provenance over* $\mathsf{CompactRealIntervalModulusWindow}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
12. *N is the local* $\mathsf{NameCert}_{\mathsf{CompactRealIntervalModulusWindow}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $A, B, D, S, R, K, F, W, E, H, C, P, N$. It has no coordinate for open-cover compactness, selected Lebesgue numbers, quotient real equality, countable choice, external modulus oracles, or ambient real completeness.

Theorem 9178.2 (Compact Real interval modulus window obligation)**.** *For every accepted* CompactRealIntervalMo *carrier*

$$M = (A, B, D, S, R, K, F, W, E, H, C, P, N),$$

the local obligation surface consists exactly of endpoint admission through A, B, dyadic tolerance admission through D, finite window exposure through S, regular rational readback through R, compact finite-net exposure through K, continuous-map graph exposure through F, modulus-window assignment through W, Real sealing through E, componentwise transport through H, displayed replay through C, provenance through P, and local naming through N.

Proof. Project the carrier of Definition 9178.1. The endpoint rows, dyadic tolerance row, finite window row, regular readback row, compact finite-net row, continuous-map graph row, modulus-window ledger, and Real seal are all explicit coordinates.

The countable-name route is read before the compact-modulus route. Rows S and R expose finite StreamName windows and RegSeqRat readback, while D supplies the dyadic tolerance budget used by both source and target windows.

The compact interval route is then read through K, F, W. The compact finite-net row fixes the interval windows, the continuous-map graph row supplies displayed values on those windows, and the modulus-window ledger assigns source tolerances to target tolerances over that finite route.

Finally E, H, C, P, N seal, transport, replay, source, and name the same packet. Since no excluded host compactness, selected Lebesgue number, quotient equality, choice, external oracle, or ambient completeness coordinate is present, the listed rows exhaust the local obligation surface. □

Theorem 9178.3 (Compact Real interval modulus window NameCert surface)**.** *Every compact-uniform-continuity, Real-completion, or countable-completion consumer of an accepted* CompactRealIntervalModulus *packet must read the finite route*

$$A, B, D, S, R, K, F, W, E, H, C, P, N.$$

This route realizes the countable-completion spine through finite interval endpoints, $\mathsf{StreamName}^{\uparrow}$ *windows,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance budgets,* $\mathsf{CompactMetric}^{\uparrow}$ *finite-net rows,* $\mathsf{ContinuousMap}^{\uparrow}$ *graph rows, modulus-window assignment, and the terminal* $\mathsf{Real}^{\uparrow}$ *seal. It exports no open-cover compactness theorem, selected Lebesgue number, quotient Real equality, countable-choice row, external modulus oracle, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness principle.*

Proof. Apply the obligation theorem of Definition 9178.2. It identifies all endpoint, tolerance, finite-window, readback, compact-net, continuous-map, modulus-window, seal, transport, replay, provenance, and naming rows visible to a consumer.

Read the countable-completion side through D, S, R, E. These rows provide dyadic tolerances, finite StreamName windows, RegSeqRat readback, and a terminal Real seal before any completion-facing consumer can use the packet.

Read the compact-uniform side through K, F, W. The compact finite-net row and continuous-map graph row provide the displayed interval windows, and the modulus-window ledger is downstream of those finite rows.

The structural rows H, C, P, N preserve the same route. Since the classifier has no coordinates for the excluded host principles, the NameCert surface is exactly the finite route displayed in the statement. □

Falsifiable prediction: A $\mathsf{CompactRealIntervalModulusWindow}^{\uparrow}$ consumer is refuted whenever it reads a compact interval modulus without exposing Real endpoint rows, DyadicRatCore tolerances, StreamName windows, RegSeqRat readback, CompactMetric finite-net rows, ContinuousMap graph rows, a modulus-window ledger, Real sealing, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{CompactRealIntervalModulusWindow}^{\uparrow}}$.

Constructive story: A $\mathsf{CompactRealIntervalModulusWindow}^{\uparrow}$ packet is generated from Real endpoint rows, DyadicRatCore tolerance budgets, finite StreamName windows, RegSeqRat readback, CompactMetric finite-net rows, ContinuousMap graph rows, a modulus-window ledger, a terminal Real seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CompactRealIntervalModulusWindow}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 9178.1, Definition 9178.2, and Definition 9178.3 seed the finite compact interval modulus-window route for countable-completion and compact-uniform-continuity consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CompactRealIntervalModulusWindow}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close open-cover compactness, selected Lebesgue numbers, quotient Real equality, countable choice, external modulus oracles, ambient $\mathsf{Real}^{\uparrow}$ completeness, theorem-level Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked endpoint admission, dyadic tolerance exactness, finite window generation, regular readback, compact finite-net exposure, continuous-map graph exposure, modulus-window assignment, Real sealing, transport, replay, provenance, and local naming for BEDC.Derived.CompactRealIntervalModulusWindowUp.

Chapter 9179

A Concrete Naming Certificate for $\mathsf{ParallelogramLaw}^{\uparrow}$

Following Jordan and von Neumann's characterization of normed spaces whose norm is induced by an inner product, the $\mathsf{ParallelogramLaw}^{\uparrow}$ packet records the finite BEDC surface on which a vector-space row, norm row, and inner-product candidate are inspected through the parallelogram identity. It sits after the vector carrier of chapter 47, the norm carrier of chapter 89, the inner-product surface of chapter 86, and the Hilbert-space handoff of chapter 91. The packet names only displayed norm and pairing rows; it is not a host vector equality proof, a completed analytic structure, a quotient-norm theorem, or a selected polarization oracle.

Definition 9179.1 (Parallelogram-law carrier)**.** *A* $\mathsf{ParallelogramLaw}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Q = (V, N, I, P, H, C, R, L)$$

with the following rows:

1. *V is the* $\mathsf{VecSpace}^{\uparrow}$ *source row, recording the displayed vector carrier, zero, addition, inverse, scalar action, and finite linear-combination windows used in the law.*
2. *N is the* $\mathsf{Norm}^{\uparrow}$ *row over V, recording the norm endpoints for x, y, $x+y$, and $x-y$ together with the finite comparison ledger used by the packet.*
3. *I is the* $\mathsf{InnerProduct}^{\uparrow}$ *candidate row, recording the pairing table and symmetry, additivity, scalar, and positivity witnesses that may induce the displayed norm.*
4. *P is the parallelogram identity ledger. For every displayed pair (x, y) in the finite window it stores the two norm-square sides*

   $$N(x+y) + N(x-y) \quad \textit{and} \quad 2N(x) + 2N(y)$$

   as $\mathsf{Real}^{\uparrow}$*-sealed rows, together with the equality readback for that pair.*
5. *H records componentwise* hsame *transport for the vector, norm, inner-product, parallelogram, replay, provenance, and local naming rows.*
6. *C records displayed* Cont *replay from the vector row through the norm and inner-product rows to the parallelogram ledger.*
7. *R is the* Pkg *provenance over* $\mathsf{ParallelogramLaw}^{\uparrow}$, $\mathsf{VecSpace}^{\uparrow}$, $\mathsf{Norm}^{\uparrow}$, $\mathsf{InnerProduct}^{\uparrow}$, $\mathsf{Hilbert}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$ *rows.*

8. L is the local $\mathsf{NameCert}_{\mathsf{ParallelogramLaw}^{\uparrow}}$ *row.*
The local classifier compares accepted packets only by these displayed rows. It has no coordinate for host vector equality, completed Hilbert structure, quotient norm equality, unbounded analytic closure, or an inner-product reconstruction not recorded in I and P.

Theorem 9179.2 (Parallelogram-law NameCert obligations)**.** *For every accepted* $\mathsf{ParallelogramLaw}^{\uparrow}$ *carrier $Q = (V, N, I, P, H, C, R, L)$, the local* $\mathsf{NameCert}_{\mathsf{ParallelogramLaw}^{\uparrow}}$ *surface consists exactly of carrier admission for the displayed rows, vector-source exposure through V, norm-readback exposure through N, inner-product candidate exposure through I, parallelogram identity accountability through P, componentwise* hsame *transport through H, displayed* Cont *replay through C, package provenance through R, and local naming through L.*

Proof. Project the carrier of Definition 9179.1. The vector source row V is the only place where the vector operations and finite pair window are stored.

The norm row N exposes the four norm endpoints for each displayed pair, while I exposes the inner-product candidate whose induced norm is being tested. Neither row supplies a host equality principle or a completed Hilbert object.

The ledger P records the two parallelogram sides and their $\mathsf{Real}^{\uparrow}$ readback for the same pair window. Transport and replay through H and C preserve that row order, and provenance and naming through R and L package the same finite data.

Since no other coordinate appears in Q, the listed rows exhaust the local NameCert obligation surface. □

Theorem 9179.3 (Parallelogram-law norm-inner-product handoff)**.** *Every Hilbert-facing consumer of an accepted* $\mathsf{ParallelogramLaw}^{\uparrow}$ *packet must read the finite route*

$$\mathsf{VecSpace}^{\uparrow} \longmapsto \mathsf{Norm}^{\uparrow} \longmapsto \mathsf{InnerProduct}^{\uparrow} \longmapsto \mathsf{ParallelogramLaw}^{\uparrow} \longmapsto \mathsf{Hilbert}^{\uparrow}.$$

The route exports only the displayed vector operations, norm endpoints, inner-product candidate, parallelogram ledger, transport, replay, provenance, and local naming rows. It does not export completed analytic structure, quotient vector equality, a selected polarization formula outside I, or an ambient Hilbert-space theorem.

Proof. Begin with V. A consumer must first expose the finite vector-space window from which the two vectors, their sum, and their difference are read.

Next read N and I. The norm row supplies the observable norm endpoints, and the inner-product row supplies the candidate pairing surface that may explain those norm endpoints.

Then read the parallelogram ledger P. This row is the handoff point: it records that the norm data and pairing data agree on the displayed finite identity rows before a Hilbert-facing consumer may cite the packet.

Finally use H, C, R, L to transport, replay, package, and name the same rows. The Hilbert sibling may consume this route only as finite NameCert data, so the packet never imports host equality, completion, quotienting, or an external polarization oracle. □

Falsifiable prediction: Every accepted $\mathsf{ParallelogramLaw}^{\uparrow}$ Hilbert-facing read must display $\mathsf{VecSpace}^{\uparrow}$, $\mathsf{Norm}^{\uparrow}$, $\mathsf{InnerProduct}^{\uparrow}$, parallelogram ledger, hsame, Cont, Pkg, and local $\mathsf{NameCert}$ rows before the $\mathsf{Hilbert}^{\uparrow}$ handoff is visible.

Independence witness: vecspace, norm, innerproduct, hilbert: $\mathsf{ParallelogramLaw}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries the vector operation row, norm readback row, inner-product candidate row, parallelogram equality ledger, transport, replay, provenance, and local naming as one packet.

Closure status for $\mathsf{NameCert}_{\mathsf{ParallelogramLaw}^{\uparrow}}$.

Constructive story: A $\mathsf{ParallelogramLaw}^{\uparrow}$ packet is generated from a VecSpaceUp source row, NormUp readback row, InnerProductUp candidate row, finite parallelogram ledger, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{ParallelogramLaw}^{\uparrow}}$, seed)

Scope closed: Definition 9179.1, Definition 9179.2, and Definition 9179.3 seed the finite parallelogram-law route over $\mathsf{VecSpace}^{\uparrow}$, $\mathsf{Norm}^{\uparrow}$, $\mathsf{InnerProduct}^{\uparrow}$, $\mathsf{Hilbert}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, Pkg, and NameCert rows.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{ParallelogramLaw}^{\uparrow}}$, unformalized)

Bridge status: none

Origin: human

Not claimed: This chapter does not close Lean verification, bridge checking, quotient norm equality, completed Hilbert structure, host vector equality, selected polarization outside the displayed rows, or ambient analytic completeness.

Upgrade path: Obligation closure requires checked carrier admission, vector-source exposure, norm-readback exposure, inner-product candidate exposure, parallelogram ledger accountability, transport and replay stability, provenance non-escape, and Hilbert handoff exactness for BEDC.Derived.ParallelogramLawUp.

Chapter 9180

A Concrete Naming Certificate for $\mathsf{BesicovitchDifferentiationWindow}^{\uparrow}$

Following Besicovitch covering theory and Lebesgue differentiation, the $\mathsf{BesicovitchDifferentiationWindow}^{\uparrow}$ packet records the finite window where bounded-overlap cover data, local density estimates, measure rows, and Real seals are read together before a differentiation consumer sees a verdict. It sits after the Vitali selection surface of chapter 2184, the bounded-overlap covering packet of chapter 6339, the differentiation certificate of chapter 4153, the measure interface of chapter 92, and the terminal real-name seal of chapter 38. The packet names one finite density window only; it is not a host differentiation theorem, a measure-completion principle, a selected almost-everywhere representative, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 9180.1 (Besicovitch differentiation window carrier)**.** *A* $\mathsf{BesicovitchDifferentiationWindow}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$W = (B, F, O, D, M, R, H, C, P, N)$$

with the following displayed rows:

1. *B is the finite cover family row, exposing displayed balls or intervals together with their centers, radii, and request cells.*
2. *F is the* $\mathsf{BesicovitchCovering}^{\uparrow}$ *bounded-overlap ledger for the same finite family.*
3. *O is the density-window row, recording the inspected center, radius window, local-average row, exceptional-budget row, and finite nonescape condition.*
4. *D is the* $\mathsf{LebesgueDifferentiation}^{\uparrow}$ *handoff row whose local differentiation read is allowed only after B, F, O are displayed.*
5. *M is the* $\mathsf{Measure}^{\uparrow}$ *row for local measure, measurable-cell admission, and finite density comparison.*
6. *R is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row for density values, local averages, overlap budgets, and error bounds.*
7. *H records componentwise* hsame *transport for cover family, bounded-overlap ledger, density window, differentiation handoff, measure rows, Real seals, replay, provenance, and local naming.*
8. *C records displayed* Cont *replay from finite cover family through bounded overlap, density-window comparison, measure read, differentiation handoff, and Real sealing.*

9. *P is the* Pkg *provenance over* $\mathsf{BesicovitchDifferentiationWindow}^{\uparrow}$, $\mathsf{VitaliCover}^{\uparrow}$, $\mathsf{BesicovitchCovering}^{\uparrow}$, $\mathsf{LebesgueDifferentiation}^{\uparrow}$, $\mathsf{Measure}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{BesicovitchDifferentiationWindow}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through $B, F, O, D, M, R, H, C, P, N$. It has no coordinate for a completed measure algebra, selected countable cover, host differentiation theorem, almost-everywhere quotient, chosen function representative, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 9180.2 (Besicovitch differentiation window NameCert obligations)**.** *For every accepted* $\mathsf{BesicovitchDifferentiationWindow}^{\uparrow}$ *carrier*

$$W = (B, F, O, D, M, R, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{BesicovitchDifferentiationWindow}^{\uparrow}}$ *surface consists exactly of finite cover-family admission through B, bounded-overlap exposure through F, density-window exposure through O, differentiation handoff through D, local measure admission through M, Real sealing through R, componentwise transport through H, displayed replay through C, provenance through P, and local naming through N.*

Proof. Project the carrier of Definition 9180.1. The rows $B, F, O, D, M, R, H, C, P, N$ are the whole displayed packet.

The covering rows are read first. The finite cover family B exposes only displayed balls or intervals, and the bounded-overlap ledger F routes the same family through the $\mathsf{BesicovitchCovering}^{\uparrow}$ surface named by chapter 6339.

The density rows are then attached to the same finite family. The window row O records the inspected center, radius, average, and exceptional budget, while M supplies the local measure row and R seals the resulting real-valued comparisons.

The differentiation handoff D is downstream of those displayed rows, and H, C, P, N transport, replay, source, and name the same route. Since no excluded host theorem, measure completion, countable selector, quotient, selected representative, or ambient-completeness coordinate is present, the listed rows exhaust the local obligation surface. □

Theorem 9180.3 (Besicovitch differentiation window density handoff)**.** *Every density read accepted by a* $\mathsf{BesicovitchDifferentiationWindow}^{\uparrow}$ *packet factors through the finite route*

$$\mathsf{VitaliCover}^{\uparrow},\ \mathsf{BesicovitchCovering}^{\uparrow},\ B,\ F,\ O,\ \mathsf{Measure}^{\uparrow},\ \mathsf{Real}^{\uparrow} \longmapsto \mathsf{LebesgueDifferentiation}^{\uparrow}.$$

The handoff exports finite cover cells, bounded overlap, one density window, local measure comparisons, Real seals, transport, replay, provenance, and local naming only.

Proof. Start with an accepted carrier $W = (B, F, O, D, M, R, H, C, P, N)$. A density-facing consumer can inspect cover cells only through the displayed finite family B.

The covering comparison is forced through F. This row cites the bounded-overlap discipline of $\mathsf{BesicovitchCovering}^{\uparrow}$ and keeps every overlap count attached to the same finite family.

The density comparison is forced through O, M, R. These rows expose the inspected window, local measure values, local averages, exceptional budget, and Real seal without choosing null-set representatives or completing the measure algebra.

Only after those rows are displayed may the consumer read D as a $\mathsf{LebesgueDifferentiation}^{\uparrow}$ handoff. The structural rows H, C, P, N preserve the route, so the packet exports a finite density-window handoff rather than an ambient differentiation theorem. □

Falsifiable prediction: A $\mathsf{BesicovitchDifferentiationWindow}^{\uparrow}$ consumer is refuted whenever a density verdict is read without displaying a finite cover family, bounded-overlap ledger, density-window row, $\mathsf{Measure}^{\uparrow}$ local measure row, $\mathsf{Real}^{\uparrow}$ seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert row.

Independence witness: vitali-cover, besicovitch-covering, lebesgue-differentiation, measure, real: $\mathsf{BesicovitchDifferentiationWindow}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries finite cover cells, bounded overlap, one density window, local measure comparison, Real sealing, differentiation handoff, transport, replay, provenance, and local naming in one packet.

Closure status for $\mathsf{NameCert}_{\mathsf{BesicovitchDifferentiationWindow}^{\uparrow}}$.

Constructive story: A $\mathsf{BesicovitchDifferentiationWindow}^{\uparrow}$ packet is generated from finite cover family rows, BesicovitchCovering bounded-overlap ledgers, density-window rows, LebesgueDifferentiation handoff rows, Measure rows, Real seals, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BesicovitchDifferentiationWindow}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 9180.1, Definition 9180.2, and Definition 9180.3 seed the finite density-window route for Besicovitch covering and Lebesgue differentiation consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BesicovitchDifferentiationWindow}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close the full Besicovitch differentiation theorem, exact Euclidean multiplicity constants, measure completion, almost-everywhere quotient equality, countable-choice radius selection, selected function representatives, ambient RealUp completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked finite cover-family admission, bounded-overlap exactness, density-window exposure, Measure row admission, Real seal nonescape, differentiation handoff, transport, replay, provenance, and local naming for BEDC.Derived.BesicovitchDifferentiationWindowUp.

Chapter 9181

A Compact Real Interval Choice-Guard Certificate for $\mathsf{CompactRealIntervalChoiceGuard}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{CompactRealIntervalChoiceGuard}^{\uparrow}$ packet records the finite guard that lets a compact real interval consumer read only bounded window data before a terminal $\mathsf{Real}^{\uparrow}$ seal. It sits after the real-name carrier of chapter 38, the interval enclosure of chapter 1625, the compact-metric finite packet of chapter 129, the StreamName and RegSeqRat readback rows of chapter 126 and chapter 301, and the dyadic arithmetic core of chapter 291. The guard exposes finite cover-window reads for interval consumers; it is not Heine–Borel compactness, an open-cover theorem, a selected finite subcover, quotient equality of real names, countable choice, or ambient completeness of $\mathsf{Real}^{\uparrow}$.

Definition 9181.1 (Compact real interval choice-guard carrier)**.** *A* $\mathsf{CompactRealIntervalChoiceGuard}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$G = (I, C, M, S, R, H, T, P, N)$$

with the following displayed rows:

1. *I is the compact real interval source row, naming the displayed endpoint histories and the interval enclosure data read through* $\mathsf{Real}^{\uparrow}$*.*
2. *C is the finite cover-window request row, recording only the cover probes and interval window requested by the consumer.*
3. *M is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *mesh row attached to that same finite window.*
4. *S is the combined* $\mathsf{StreamName}^{\uparrow}/\mathsf{RegSeqRat}^{\uparrow}$ *readback row for endpoint, window, mesh, and probe histories.*
5. *R is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached only after I, C, M, S have been displayed.*
6. *H records componentwise* hsame *transport for the interval source, cover-window request, mesh, readback, Real seal, replay, provenance, and local name.*
7. *T records displayed* Cont *replay from interval admission through cover-window request, dyadic mesh, StreamName and RegSeqRat readback, and terminal Real sealing.*

8. *P is the* Pkg *provenance over* $\mathsf{CompactRealIntervalChoiceGuard}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{RealIntervalEnclosure}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*

9. *N is the local* $\mathsf{NameCert}_{\mathsf{CompactRealIntervalChoiceGuard}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these nine rows. It has no coordinate for open-cover compactness, a selected finite subcover, quotient real equality, countable choice, detached endpoint representatives, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 9181.2 (Compact real interval choice-guard NameCert obligations)**.** *For every accepted* $\mathsf{CompactRealIntervalChoiceGuard}^{\uparrow}$ *carrier*

$$G = (I, C, M, S, R, H, T, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{CompactRealIntervalChoiceGuard}^{\uparrow}}$ *surface consists exactly of carrier admission for the compact real interval source, finite cover-window exposure, dyadic mesh compatibility, StreamName and RegSeqRat readback, Real seal handoff, componentwise* hsame *transport, displayed* Cont *replay, provenance, and local naming. The packet refuses open-cover compactness, countable choice, selected subcovers, quotient real equality, detached endpoint representatives, and ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the carrier of Definition 9181.1. The row I is the only compact interval source, and the row C is the only finite cover-window request accepted by the guard.

Read the finite route next. The dyadic mesh row M is attached to the same window as C, and the combined readback row S exposes the StreamName and RegSeqRat data available from the interval, window, mesh, and probe histories.

The Real seal handoff is downstream of those rows. The row R can be consumed only after I, C, M, S have been displayed, while H, T, P, N transport, replay, source, and name the same finite packet.

The refusal clauses follow from absence of carrier coordinates. No row stores an open-cover compactness theorem, a countable-choice selector, a selected finite subcover, quotient real equality, detached endpoint representatives, or ambient Real completeness. □

Closure status for $\mathsf{NameCert}_{\mathsf{CompactRealIntervalChoiceGuard}^{\uparrow}}$.

Constructive story: A $\mathsf{CompactRealIntervalChoiceGuard}^{\uparrow}$ packet is generated from a compact real interval source row, a finite cover-window request, a dyadic mesh row, StreamName and RegSeqRat readback, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{CompactRealIntervalChoiceGuard}^{\uparrow}}$, seed)

Scope closed: Definition 9181.1 and Definition 9181.2 seed the finite cover-window, mesh, readback, Real-seal, transport, replay, provenance, and local naming route for compact real interval consumers.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{CompactRealIntervalChoiceGuard}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close Heine–Borel compactness, open-cover compactness, selected finite subcovers, countable choice, quotient real equality, detached endpoint representatives, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, finite cover-window exposure, dyadic mesh compatibility, StreamName and RegSeqRat readback, Real seal handoff, transport, replay, provenance, and local naming for BEDC.Derived.CompactRealIntervalChoiceGuardUp.

Chapter 9182

A Concrete Naming Certificate for RegularCauchyTailProductBound$^{\uparrow}$

Following Bishop and Bridges constructive analysis, the RegularCauchyTailProductBound$^{\uparrow}$ packet records the finite tail-window product estimate used when two regular Cauchy rational names are multiplied before a Real$^{\uparrow}$ seal is consumed. It sits after the tail-sum comparison route of chapter 2137, the regular product route of chapter 461, the dyadic arithmetic core of chapter 291, the regular rational readback of chapter 301, and the terminal real-name boundary of chapter 38. The packet names a tail-product bound as finite BEDC rows; it does not assert host multiplication of completed reals, quotient stream equality, selected product representatives, countable choice, trichotomy, or ambient Real$^{\uparrow}$ completeness.

Definition 9182.1 (RegularCauchyTailProductBound carrier)**.** *A* RegularCauchyTailProductBound$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$T = (W, D, P, A, B, E, H, C, Q, N)$$

with the following displayed rows:

1. *W is the tail-window row naming the common cutoff and precision window inherited from the regular Cauchy tail route.*
2. *D is the* DyadicRatCore$^{\uparrow}$ *product-budget row recording source tolerances, endpoint majorants, and the cross-error allowance for the tail product.*
3. *P is the* RegularCauchyProduct$^{\uparrow}$ *row exposed only after the tail window and dyadic product budget are displayed.*
4. *A and B are the two* RegSeqRat$^{\uparrow}$ *source rows whose tails are compared inside the product window.*
5. *E is the* Real$^{\uparrow}$ *seal row consumed only after P has been displayed.*
6. *H records componentwise* hsame *transport for the tail window, product budget, product row, source rows, real seal, provenance, replay, and local naming.*
7. *C records displayed* Cont *replay from the tail-window request through the dyadic budget, regular product row, regular rational sources, and real seal.*
8. *Q is the* Pkg *provenance over* RegularCauchyTailProductBound$^{\uparrow}$, RegularCauchyTailSum$^{\uparrow}$, RegularCauchyProduct$^{\uparrow}$ DyadicRatCore$^{\uparrow}$, RegSeqRat$^{\uparrow}$, Real$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

9. N is the local $\mathsf{NameCert}_{\mathsf{RegularCauchyTailProductBound}^{\uparrow}}$ *row.*
The classifier compares accepted carriers only through $W, D, P, A, B, E, H, C, Q, N$. It has no coordinate for host real multiplication, quotient streams, selected representatives, countable choice, trichotomy, or ambient completeness.

Lean4 (definition) `BEDC.Derived.RegularCauchyTailProductBoundUp`

Theorem 9182.2 (RegularCauchyTailProductBound obligation surface)**.** *For every accepted* RegularCauchyTailPro *carrier $T = (W, D, P, A, B, E, H, C, Q, N)$, the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyTailProductBound}^{\uparrow}}$ *surface consists exactly of carrier admission for the tail window, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *product-budget row, the* $\mathsf{RegularCauchyProduct}^{\uparrow}$ *handoff, the two* $\mathsf{RegSeqRat}^{\uparrow}$ *source rows, the* $\mathsf{Real}^{\uparrow}$ *seal, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming.*

Proof. Project the accepted carrier of Definition 9182.1. The only tail-facing row is W, and the only arithmetic row available before product handoff is the dyadic budget D.

The rows P, A, B, E then expose the product route. The product row is read through $\mathsf{RegularCauchyProduct}^{\uparrow}$, the source rows through $\mathsf{RegSeqRat}^{\uparrow}$, and the terminal seal through $\mathsf{Real}^{\uparrow}$.

Finally H, C, Q, N transport, replay, source, and name exactly those rows. Since the carrier contains no host multiplication, quotient-stream, selected-representative, choice, trichotomy, or ambient-completeness coordinate, the listed rows exhaust the local NameCert surface. □

Theorem 9182.3 (RegularCauchyTailProductBound product-tail handoff)**.** *Every* $\mathsf{Real}^{\uparrow}$ *or completion-facing consumer of an accepted* $\mathsf{RegularCauchyTailProductBound}^{\uparrow}$ *carrier reaches the product seal only through the displayed route*

$$W \longmapsto D \longmapsto P \longmapsto A, B \longmapsto E.$$

Thus a downstream product estimate first reads the shared tail window, the dyadic product budget, the regular product row, and the two regular rational source rows before the real seal can be consumed.

Proof. Start with the carrier projection. The row W fixes the finite tail window and D records the product tolerance budget attached to that window.

The handoff row P is downstream of W and D. It repacks the tail-product estimate as a $\mathsf{RegularCauchyProduct}^{\uparrow}$ row, while A and B keep the two source tails visible as $\mathsf{RegSeqRat}^{\uparrow}$ data.

The seal row E is last in the displayed route. Transport, replay, provenance, and naming preserve the same route through H, C, Q, N, so no consumer can replace it by completed-real multiplication, quotient stream equality, selected representatives, countable choice, trichotomy, or ambient completeness. □

Falsifiable prediction: Every $\mathsf{RegularCauchyTailProductBound}^{\uparrow}$ read factors through a tail window, a DyadicRatCore product budget, a RegularCauchyProduct row, two RegSeqRat source rows, a Real seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming.

Independence witness: regular-cauchy-tail-sum, regularcauchyproduct, dyadicratcore, regseqrat, real: $\mathsf{RegularCauchyTailProductBound}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries the product-tail window, dyadic product-budget ledger, regular product handoff, two regular rational source rows, Real seal, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{RegularCauchyTailProductBound}^{\uparrow}}$.

Constructive story: A RegularCauchyTailProductBound$^{\uparrow}$ packet is generated from a regular Cauchy tail window, a DyadicRatCore product-budget row, a RegularCauchyProduct handoff, two RegSeqRat source rows, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\text{RegularCauchyTailProductBound}^{\uparrow}}$, seed)

Scope closed: Definition 9182.1, Definition 9182.2, and Definition 9182.3 seed the finite tail-product bound route for regular Cauchy product and Real-facing consumers.

Formal verification: FormalStatus(NameCert$_{\text{RegularCauchyTailProductBound}^{\uparrow}}$, encodedDef)

Lean target: `BEDC.Derived.RegularCauchyTailProductBoundUp`

Bridge status: none

Not claimed: This chapter does not close host multiplication of completed reals, quotient stream equality, selected product representatives, countable choice, trichotomy, ambient Real$^{\uparrow}$ completeness, theorem-level Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, tail-window exposure, dyadic product-budget exactness, RegularCauchyProduct handoff, RegSeqRat source preservation, Real seal nonescape, transport stability, continuation replay, and provenance nonescape for BEDC.Derived.RegularCauchyTailProductBoundUp.

Chapter 9183

A Concrete Naming Certificate for $\mathsf{ChromaticPolynomial}^{\uparrow}$

Following Birkhoff and Whitney, the $\mathsf{ChromaticPolynomial}^{\uparrow}$ packet records the finite graph-colouring data used to compute the chromatic polynomial through deletion and contraction. It sits over the finite graph carrier of chapter 118, the finite-set rows of chapter 112, the spanning-tree witness surface of chapter 237, the deletion-contraction neighbour chapter 7713, and the matroid boundary of chapter 202. The packet names only finite colour palettes, proper-colouring ledgers, and deletion-contraction rows; it does not import an infinite colouring principle, a host graph isomorphism oracle, an unrestricted polynomial ring, or a Tutte-polynomial theorem outside the displayed packet.

Definition 9183.1 (ChromaticPolynomial carrier)**.** *A* $\mathsf{ChromaticPolynomial}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$X = (G, Q, C, D, H, R, P, N)$$

with the following displayed rows:

1. *G is the finite* $\mathsf{Graph}^{\uparrow}$ *row naming the vertex list, edge list, incidence readback, loop refusal, and simple-graph boundary used by the packet.*
2. *Q is the* $\mathsf{FinSet}^{\uparrow}$ *colour-palette row, including the finite colour list and membership ledger visible to the colouring read.*
3. *C is the proper-colouring ledger, listing the accepted vertex-to-colour rows and the edgewise inequality checks for adjacent vertices.*
4. *D is the deletion-contraction row for a displayed edge, exposing the deletion graph, contraction graph, and the boundary cases for loops and empty edge lists.*
5. *H records componentwise* hsame *transport for the graph, colour palette, colouring ledger, deletion-contraction row, replay, provenance, and local name.*
6. *R records displayed* Cont *replay from graph admission through palette lookup, proper-colouring verification, deletion-contraction comparison, and local naming.*
7. *P is the* Pkg *provenance over* $\mathsf{ChromaticPolynomial}^{\uparrow}$, $\mathsf{Graph}^{\uparrow}$, $\mathsf{FinSet}^{\uparrow}$, $\mathsf{SpanningTree}^{\uparrow}$, $\mathsf{TuttePolynomial}^{\uparrow}$, $\mathsf{Matroid}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$ *rows.*
8. *N is the local* $\mathsf{NameCert}_{\mathsf{ChromaticPolynomial}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through G, Q, C, D, H, R, P, N. It has no coordinate for an infinite colour set, host graph equality, unrestricted polynomial algebra, a hidden deletion-contraction oracle, or a matroid/Tutte theorem not displayed as finite sibling data.

Theorem 9183.2 (ChromaticPolynomial NameCert obligations)**.** *For every accepted* $\mathsf{ChromaticPolynomial}^{\uparrow}$ *carrier* $X = (G, Q, C, D, H, R, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{ChromaticPolynomial}^{\uparrow}}$ *surface consists exactly of carrier admission for the finite graph row, finite colour-palette exposure, proper-colouring ledger exactness, deletion-contraction boundary exposure, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming.*

Proof. Project the carrier of Definition 9183.1. The row G is the only graph source, and Q is the only colour-palette source.

Read the colouring data through C. Properness is checked edge by edge against the finite graph row, so the ledger records only displayed vertex-colour assignments and displayed adjacency refusals.

Read deletion and contraction through D. The row names the selected edge, the deletion graph, the contraction graph, and the loop or empty-edge boundary cases before any recurrence-style comparison is exposed.

Finally use H, R, P, N. These rows transport, replay, source, and name the same finite packet. Since the carrier contains no infinite palette, host graph equality, unrestricted polynomial algebra, or hidden Tutte/matroid theorem, the listed rows exhaust the local NameCert obligations. □

Theorem 9183.3 (ChromaticPolynomial deletion-contraction boundary)**.** *Every deletion-contraction read accepted by a* $\mathsf{ChromaticPolynomial}^{\uparrow}$ *carrier factors through the displayed route*

$$G \longmapsto D \longmapsto C \longmapsto Q \longmapsto H, R, P, N.$$

The deletion graph and contraction graph are read as finite graph rows tied to the same colour-palette and proper-colouring ledger. Boundary cases for loops, empty edge lists, and palette exhaustion remain ledger rows, not external polynomial identities.

Proof. Start with the graph row G. It supplies the finite vertices, finite edges, and incidence readback used by the selected edge in D.

The deletion-contraction row D keeps both derived graphs inside the same packet. Their colouring reads are not independent host graphs; each is compared through the palette row Q and the proper-colouring ledger C.

The structural rows H, R, P, N preserve the same finite route and record its provenance through the graph, finite-set, spanning-tree, Tutte-polynomial, and matroid neighbours. They do not introduce an unrestricted polynomial identity or a hidden recurrence theorem.

Thus deletion-contraction is a boundary of the displayed NameCert packet: a downstream consumer may read the finite comparison route, but not an ambient chromatic-polynomial algebra beyond it. □

Falsifiable prediction: Every accepted $\mathsf{ChromaticPolynomial}^{\uparrow}$ read exposes a finite graph row, finite colour-palette row, proper-colouring ledger, deletion-contraction row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert row.

Independence witness: graph, finset, spanningtree, tutte-polynomial, matroid: none is bijective to $\mathsf{ChromaticPolynomial}^{\uparrow}$ because none jointly carries the finite colour palette, proper-colouring ledger, deletion-contraction row, transport, replay, provenance, and local naming rows for one chromatic-polynomial packet.

Closure status for $\mathsf{NameCert}_{\mathsf{ChromaticPolynomial}^{\uparrow}}$.

Constructive story: A $\mathsf{ChromaticPolynomial}^{\uparrow}$ packet is generated from a finite graph row, a finite colour-palette row, a proper-colouring ledger, a deletion-contraction row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{ChromaticPolynomial}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 9183.1, Definition 9183.2, and Definition 9183.3 seed the finite graph-colouring carrier, NameCert obligation surface, and deletion-contraction boundary.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{ChromaticPolynomial}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close Lean verification, bridge checking, unrestricted polynomial algebra, infinite colour palettes, host graph equality, a Tutte-polynomial theorem, or a matroid theorem for $\mathsf{ChromaticPolynomial}^{\uparrow}$.

Upgrade path: Obligation closure requires checked carrier admission, palette exposure, proper-colouring ledger exactness, deletion-contraction boundary exactness, transport stability, replay, provenance, and local naming for BEDC.Derived.ChromaticPolynomia

Chapter 9184

A Concrete Naming Certificate for $\mathsf{QuantumGRSectionBundle}^{\uparrow}$

The $\mathsf{QuantumGRSectionBundle}^{\uparrow}$ packet concretizes the section-bundle boundary of chapter 9422 as finite NameCert data. It names a base-frame ledger, vertical fibre rows, quantum-state and observable rows, horizontal comparison rows, connection rows, transport, replay, provenance, and local naming; it does not claim a physical quantum-gravity theory, a Hilbert-space completion theorem, a smooth spacetime manifold, a curvature equation, or an empirical law outside the packet. Rows B, V, Q, O, H, K consume the sibling carriers of chapter 97, chapter 134, chapter 217, and chapter 218 before the local section-bundle packet is read.

Falsifiable prediction: If a claimed $\mathsf{QuantumGRSectionBundle}^{\uparrow}$ read can expose a quantum state, observable, or horizontal frame comparison without the displayed bundle, connection, vertical fibre, and horizontal comparison rows, then the local carrier admission row is false.

Independence witness: bundle, connection, quantumstate, observable, hilbert: none is bijective to $\mathsf{QuantumGRSectionBundle}^{\uparrow}$ because none jointly carries the finite base-frame ledger, vertical fibre rows, quantum-state row, observable row, horizontal comparison row, connection row, transport, replay, provenance, and local NameCert row.

Definition 9184.1 (QuantumGRSectionBundle carrier)**.** *A* $\mathsf{QuantumGRSectionBundle}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Y = (B, V, Q, O, H, K, T, R, P, N)$$

with the following displayed rows:

1. *B is the finite base-frame ledger naming the observed frame labels, overlap rows, and section domains used by the packet.*
2. *V is the vertical fibre row, recording the finite fibre labels, state slots, projection slots, and residual ledgers visible inside each displayed frame.*
3. *Q is the quantum-state row, exposing only the listed amplitudes, phase tags, normalization checks, and measurement-update entries available in V.*
4. *O is the observable row, naming the finite observable probes, outcome rows, and Born-weight readback attached to Q.*
5. *H is the horizontal comparison row, recording neighbouring frame comparisons, metric readout slots, and curvature-facing boundary entries.*

6. *K is the connection row that ties vertical and horizontal reads through displayed compatibility checks rather than a detached smooth connection.*
7. *T records componentwise* hsame *transport for the bundle, fibre, quantum-state, observable, horizontal comparison, connection, provenance, replay, and local naming rows.*
8. *R records displayed* Cont *replay from base-frame admission through vertical fibre readback, quantum-state and observable exposure, horizontal comparison, connection compatibility, and local naming.*
9. *P is the* Pkg *provenance over* $\mathsf{QuantumGRSectionBundle}^{\uparrow}$*, chapter 9422,* BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *rows.*
10. *N is the local* $\mathsf{NameCert}_{\mathsf{QuantumGRSectionBundle}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $B, V, Q, O, H, K, T, R, P, N$. It has no coordinate for a completed Hilbert space, a smooth manifold, an unrestricted connection, a curvature field equation, a hidden measurement oracle, or a physical unification theorem.

Theorem 9184.2 (QuantumGRSectionBundle NameCert obligations)**.** *For every accepted* QuantumGRSectionBun *carrier $Y = (B, V, Q, O, H, K, T, R, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{QuantumGRSectionBundle}^{\uparrow}}$ *surface consists exactly of carrier admission for the base-frame ledger, vertical fibre rows, quantum-state row, observable row, horizontal comparison row, connection row, componentwise* hsame *transport, displayed* Cont *replay, provenance, and local naming.*

Proof. Project the carrier of Definition 9184.1. The base data are B and V: a finite frame ledger and a finite vertical fibre ledger.

Read the quantum face through Q and O. State rows, phase tags, normalization checks, observables, outcomes, and Born-weight readback are exposed only as finite rows inside the displayed fibre.

Read the relativistic face through H and K. Horizontal frame comparisons and connection compatibility rows are visible only after the base and fibre rows have been named.

The structural rows T, R, P, N transport, replay, source, and name the same packet. Since no completed Hilbert space, smooth manifold, unrestricted connection, curvature equation, hidden measurement oracle, or unification theorem is a carrier coordinate, the listed rows exhaust the local NameCert surface. □

The Lean follow-up for $\mathsf{QuantumGRSectionBundle}^{\uparrow}$ must provide `Nontrivial` and `FieldFaithful` instances for the same finite carrier $Y = (B, V, Q, O, H, K, T, R, P, N)$, with witnesses for the bundle, connection, quantum-state, observable, and horizontal comparison rows.

Closure status for $\mathsf{NameCert}_{\mathsf{QuantumGRSectionBundle}^{\uparrow}}$**.**

Constructive story: A $\mathsf{QuantumGRSectionBundle}^{\uparrow}$ packet is generated from a finite base-frame ledger, vertical fibre rows, quantum-state rows, observable rows, horizontal comparison rows, connection rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{QuantumGRSectionBundle}^{\uparrow}}$, seed)

Scope closed: Definition 9184.1 and Definition 9184.2 seed the finite section-bundle carrier and NameCert obligation surface for vertical fibre rows and horizontal comparison rows.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{QuantumGRSectionBundle}^{\uparrow}}$, unformalized)

Bridge status: none

Origin: ai

Not claimed: This chapter does not close Lean verification, bridge checking, completed Hilbert spaces, smooth spacetime manifolds, unrestricted connections, curvature equations, measurement postulates, or a physical quantum-gravity theory.

Upgrade path: Obligation closure requires checked carrier admission, vertical fibre exposure, quantum-state and observable row exactness, horizontal comparison exactness, connection compatibility, transport stability, replay, provenance, local naming, and TasteGate instances for BEDC.Derived.QuantumGRSectionBundleUp.

Chapter 9185

A Concrete Naming Certificate for $\mathsf{BoundedCauchySubsequenceModulus}^{\uparrow}$

Following Bishop and Bridges constructive analysis, a bounded Cauchy subsequence is usable only when the subsequence schedule and the Cauchy modulus are displayed as finite data before any Real-facing read occurs. The $\mathsf{BoundedCauchySubsequenceModulus}^{\uparrow}$ packet records this extraction surface over the finite density rows of chapter 6003, the compact-real uniform-modulus sibling of chapter 6375, the dyadic arithmetic of chapter 291, the finite source windows of chapter 126, the regular rational readback of chapter 301, and the terminal real-name seal of chapter 38. It supplies displayed subsequence-modulus data and explicitly refuses any general sequential compactness principle without such data.

Definition 9185.1 (Bounded Cauchy subsequence-modulus carrier)**.** *A* $\mathsf{BoundedCauchySubsequenceModulus}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (B, D, W, R, Q, K, E, H, C, P, N)$$

with the following displayed rows:

1. *B is the bounded Cauchy source row, naming the dyadic bound and the Cauchy tail request that the extraction is allowed to inspect.*
2. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *ledger of dyadic centers, radii, and tolerance comparisons used by the subsequence schedule.*
3. *W is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row listing exactly which source windows are opened before a subsequence index is admitted.*
4. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row obtained from the displayed windows and dyadic tolerance rows.*
5. *Q is the finite subsequence schedule row, recording the displayed increasing index data rather than a host-level selector.*
6. *K is the compact-real subsequence-modulus row, read through the compact-real uniform-modulus sibling of chapter 6375 and through the density-net surface of chapter 6003.*
7. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row, exposed only after B, D, W, R, Q, K have all been displayed.*
8. *H records componentwise* hsame *transport for source, dyadic, window, readback, schedule, compact-modulus, seal, replay, provenance, and local naming rows.*

9. *C records displayed* Cont *replay from a requested precision through $B, D, W, R, Q, K, E, H, P, N$.*
10. *P is the* Pkg *provenance over* $\mathsf{BoundedCauchySubsequenceModulus}^{\uparrow}$, $\mathsf{FiniteCauchyDensityNet}^{\uparrow}$, $\mathsf{CompactRealUniformModulus}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{BoundedCauchySubsequenceModulus}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $B, D, W, R, Q, K, E, H, C, P, N$. It has no coordinate for ambient sequential compactness, countable choice, a hidden infinite subsequence selector, quotient stream equality, selected limits, host real equality, or ambient completeness of $\mathsf{Real}^{\uparrow}$.

Theorem 9185.2 (Bounded Cauchy subsequence-modulus NameCert obligations)**.** *For every accepted* $\mathsf{BoundedCauchySubsequenceModulus}^{\uparrow}$ *carrier*

$$S = (B, D, W, R, Q, K, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{BoundedCauchySubsequenceModulus}^{\uparrow}}$ *surface consists exactly of bounded Cauchy source admission for B, dyadic tolerance visibility for D, finite StreamName window admission for W, RegSeqRat readback for R, displayed subsequence schedule admission for Q, compact-real modulus handoff for K, terminal Real seal admission for E, componentwise transport through H, displayed replay through C, provenance through P, and local naming through N.*

Proof. Project the carrier of Definition 9185.1. The tuple $B, D, W, R, Q, K, E, H, C, P, N$ is the whole accepted packet, so the local certificate can read only those rows.

The analytic route first opens the bounded Cauchy source row B, the dyadic tolerance ledger D, and the finite window row W. The regular rational readback R is downstream of those displayed windows.

The subsequence schedule row Q and compact-real modulus row K are then admitted as finite data. They are read together with the density-net and compact-real uniform-modulus sibling surfaces, so the packet exposes a displayed extraction route rather than a hidden choice schedule.

Rows H, C, P, N transport, replay, source, and name the same finite route. Since the carrier contains no coordinate for ambient sequential compactness, countable choice, quotient streams, selected limits, host equality, or ambient Real completeness, no additional NameCert obligation can be exported. □

Theorem 9185.3 (Bounded Cauchy subsequence-modulus regular window)**.** *Every* $\mathsf{RegSeqRat}^{\uparrow}$ *or* $\mathsf{Real}^{\uparrow}$ *consumer of an accepted* $\mathsf{BoundedCauchySubsequenceModulus}^{\uparrow}$ *packet receives subsequence evidence only through the displayed finite route*

$$\mathsf{FiniteCauchyDensityNet}^{\uparrow},\ \mathsf{CompactRealUniformModulus}^{\uparrow},\ \mathsf{DyadicRatCore}^{\uparrow},\ \mathsf{StreamName}^{\uparrow},\ \mathsf{RegSeqRat}^{\uparrow},\ \mathsf{Real}^{\uparrow}.$$

The consumer may inspect the bounded source row B, dyadic tolerance row D, finite window row W, regular readback row R, displayed subsequence schedule Q, compact-real modulus handoff K, terminal seal E, transport, replay, provenance, and local naming. It receives no general sequential compactness theorem, no countable-choice schedule, no hidden infinite subsequence selector, no quotient stream equality, no selected limit, and no ambient $\mathsf{Real}^{\uparrow}$ *completeness principle.*

Proof. Start from the NameCert obligations of Definition 9185.2. They force every accepted consumer read to expose $B, D, W, R, Q, K, E, H, C, P, N$.

The density-net and compact-real modulus rows supply the finite extraction context: D, W, R give the visible dyadic net rows and regular rational readback, while Q, K display the subsequence schedule and its modulus data.

The terminal Real seal E is reachable only after those rows are present. The structural rows H, C, P, N preserve the same route under transport, replay, provenance, and local naming.

Because the carrier has no coordinate for a host subsequence selector, countable choice, general sequential compactness, quotient equality, selected limits, or ambient Real completeness, the displayed regular-window route exhausts what a $\mathsf{RegSeqRat}^{\uparrow}$ or $\mathsf{Real}^{\uparrow}$ consumer can receive. □

Closure status for $\mathsf{NameCert}_{\mathsf{BoundedCauchySubsequenceModulus}^{\uparrow}}$.

Constructive story: A $\mathsf{BoundedCauchySubsequenceModulus}^{\uparrow}$ packet is generated from a bounded Cauchy source row, DyadicRatCore tolerance rows, StreamName finite windows, RegSeqRat readback, displayed subsequence schedule data, compact-real modulus data, a Real seal row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BoundedCauchySubsequenceModulus}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 9185.1, Definition 9185.2, and Definition 9185.3 seed the finite bounded Cauchy subsequence-modulus route through density nets, compact-real modulus data, dyadic windows, RegSeqRat readback, and Real sealing.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BoundedCauchySubsequenceModulus}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Origin: human

Not claimed: This chapter does not close ambient sequential compactness, countable choice, hidden infinite subsequence selection, quotient stream equality, selected limits, host real equality, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked bounded-source admission, density-net row visibility, compact-real modulus handoff, subsequence schedule exactness, regular-window readback, Real seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.BoundedCauchySubsequenceModulusUp.

Chapter 9186

A Concrete Naming Certificate for $\mathsf{BishopCauchySpace}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{BishopCauchySpace}^{\uparrow}$ packet presents the completion-facing Cauchy-space substrate as finite NameCert data before quotient completion or countable selection is invoked. It reads the dyadic tolerance arithmetic of chapter 291, the stream-window surface of chapter 126, the regular rational readback of chapter 301, the terminal Real name of chapter 38, the finite density handoff of chapter 6003, and the general completion interface of chapter 95. The packet names the displayed Cauchy-space infrastructure; it is not a quotient construction, a selected limit, countable choice, host equality of reals, or ambient completeness.

Definition 9186.1 (BishopCauchySpace carrier)**.** *A* $\mathsf{BishopCauchySpace}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (D, W, S, R, E, H, C, P, N)$$

with the following displayed rows:

1. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row;*
2. *W is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row attached to that tolerance;*
3. *S is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the regular rational Cauchy data observed through W;*
4. *R is the* $\mathsf{Real}^{\uparrow}$ *readback row reached only through D, W, S;*
5. *E is the* $\mathsf{Completion}^{\uparrow}$ *exposure row, with the finite dense handoff constrained by* $\mathsf{FiniteCauchyDensityNet}^{\uparrow}$*;*
6. *H records componentwise* hsame *transport for tolerance, window, regular readback, Real readback, completion exposure, and local packet rows;*
7. *C records displayed* Cont *replay from dyadic tolerance through stream windows, regular rational reads, Real reads, finite density handoff, and completion exposure;*
8. *P records* Pkg *provenance over* $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{FiniteCauchyDensityNet}^{\uparrow}$, $\mathsf{Completion}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* $\mathsf{NameCert}$ *rows;*
9. *N is the local* $\mathsf{NameCert}_{\mathsf{BishopCauchySpace}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these nine displayed rows. It has no coordinate for quotient stream equality, an unshown representative, countable choice, host real equality, or an ambient completeness oracle.

Theorem 9186.2 (BishopCauchySpace NameCert obligations)**.** *For every accepted* $\mathsf{BishopCauchySpace}^{\uparrow}$ *carrier*

$$B = (D, W, S, R, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{BishopCauchySpace}^{\uparrow}}$ *surface consists exactly of carrier admission for* B*, dyadic tolerance readback through* D*, finite stream-window readback through* W*, regular rational Cauchy readback through* S*, Real readback through* R*, completion exposure through* E*, componentwise* hsame *transport through* H*, displayed* Cont *replay through* C*,* Pkg *provenance through* P*, and local naming through* N*.*

Proof. Project the carrier of Definition 9186.1. The rows D, W, S, R, E are the completion-facing Cauchy-space route, while H, C, P, N preserve, replay, source, and name that route.

Read the dependencies in order. The dyadic row fixes the tolerance, the stream row fixes the finite observation window, the regular-rational row supplies the Cauchy readback, and the Real row is exposed only after those rows have been displayed.

The completion row E is therefore a finite exposure surface rather than an ambient completion principle. The density handoff is constrained by $\mathsf{FiniteCauchyDensityNet}^{\uparrow}$, and the general $\mathsf{Completion}^{\uparrow}$ interface is read only through the displayed rows.

No further NameCert obligation can be projected, because the carrier has no quotient, representative-selection, host-equality, countable-choice, or ambient-completeness coordinate. □

Theorem 9186.3 (BishopCauchySpace finite-density handoff)**.** *Every completion-facing consumer of an accepted* $\mathsf{BishopCauchySpace}^{\uparrow}$ *carrier*

$$B = (D, W, S, R, E, H, C, P, N)$$

must factor its finite density read through the same $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row* D*,* $\mathsf{StreamName}^{\uparrow}$ *window row* W*,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row* S*,* $\mathsf{Real}^{\uparrow}$ *readback row* R*, and* $\mathsf{FiniteCauchyDensityNet}^{\uparrow}$ *handoff recorded by* E*. The handoff may expose the displayed* $\mathsf{Completion}^{\uparrow}$ *route, but it may not select quotient representatives, import countable choice, compare host reals, or assert ambient completeness outside the finite packet.*

Proof. Start with the NameCert obligations of Definition 9186.2. They identify the completion-facing surface as the rows $D, W, S, R, E, H, C, P, N$ and no others.

The finite density handoff is carried by E and sourced by the provenance row P. Thus a consumer reaches the completion interface only after preserving the dyadic tolerance, stream window, regular rational readback, and Real readback that E exposes.

The structural rows H, C, N keep that route componentwise, replay it as displayed continuation data, and name it locally. Since quotient representatives, countable choice, host real equality, and ambient completeness are absent from the carrier, no downstream completion consumer can recover them from the finite density handoff. □

Closure status for $\mathsf{NameCert}_{\mathsf{BishopCauchySpace}^{\uparrow}}$**.**

Constructive story: A $\mathsf{BishopCauchySpace}^{\uparrow}$ packet is generated from dyadic tolerance, stream-window, regular-rational readback, Real readback, finite density handoff, completion exposure, componentwise hsame transport, displayed Cont replay, package provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{BishopCauchySpace}^{\uparrow}}$, seed)

Scope closed: Definition 9186.1, Definition 9186.2, and Definition 9186.3 seed the finite Bishop Cauchy-space packet over $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{FiniteCauchyDensityNet}^{\uparrow}$, and $\mathsf{Completion}^{\uparrow}$.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{BishopCauchySpace}^{\uparrow}}$, unformalized)

Bridge status: none

Origin: human

Not claimed: This chapter does not close Lean verification, quotient completion, selected representatives, countable choice, host Real equality, or ambient completeness.

Upgrade path: The next paper step is an obligation theorem separating the finite Cauchy-space rows from quotient completion and representative selection.

Chapter 9187

A Concrete Naming Certificate for $\mathsf{TukeyDepth}^{\uparrow}$

Following Tukey's halfspace-depth construction, the $\mathsf{TukeyDepth}^{\uparrow}$ packet records the finite robust-statistics surface by which a displayed point is tested against inspected affine halfspace windows before any data-depth consumer reads a centrality score. It sits after the real-name seal of chapter 38, the convex-set carrier of chapter 208, and the bounded linear functional surface of chapter 1644. The packet names halfspace depth as finite NameCert data only; it does not import host Euclidean measure, arbitrary infima over all halfspaces, selected minimizers, quotient equality of samples, or bridge checking.

Definition 9187.1 (Tukey depth carrier)**.** *A* $\mathsf{TukeyDepth}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$D = (R, X, H, S, M, W, T, C, P, N)$$

with the following visible rows:

1. *R is the* $\mathsf{Real}^{\uparrow}$ *scalar seal used for displayed depth values and threshold reads.*
2. *X is the inspected finite sample row, carrying only the displayed data window and its local membership reads.*
3. *H is the affine halfspace-window row, represented by a displayed functional threshold and the induced side test.*
4. *S is the convex support row, tying each inspected halfspace to the* $\mathsf{ConvexSet}^{\uparrow}$ *boundary read used by the depth comparison.*
5. *M is the mass or count ledger for the inspected sample points lying in the displayed halfspace window.*
6. *W is the finite window row listing the halfspace probes actually read by the packet.*
7. *T records the transported comparison between the displayed point, the halfspace side test, and the scalar depth read.*
8. *C records componentwise* hsame *transport for $R, X, H, S, M, W, T, P, N$.*
9. *P is the* Pkg *provenance over the real, convex-set, linear-functional, sample-window, and local depth rows.*
10. *N is the local* $\mathsf{NameCert}_{\mathsf{TukeyDepth}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $R, X, H, S, M, W, T, C, P, N$. It has no coordinate for a host measure space, an infinite halfspace family, an attained infimum, a selected centerpoint, quotient sample equality, or bridge credentials.

Lean4 (statement) `BEDC.Derived.TukeyDepthUp`

Theorem 9187.2 (Tukey depth NameCert obligations)**.** *For every accepted* $\mathsf{TukeyDepth}^{\uparrow}$ *carrier*

$$D = (R, X, H, S, M, W, T, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{TukeyDepth}^{\uparrow}}$ *surface consists exactly of real-scalar admission through R, sample-window exposure through X, halfspace-window exposure through H, convex-support exposure through S, displayed count or mass comparison through M, finite probe listing through W, depth-read transport through T, componentwise* hsame *transport through C, provenance through P, and local naming through N.*

Proof. Project the carrier of Definition 9187.1. The packet displays exactly the real scalar seal, sample window, halfspace window, convex support, count ledger, finite probe list, transported comparison, provenance, and local naming rows.

The halfspace read is not detached from the convex and scalar rows. The row H supplies the inspected side test, S ties that test to the convex-set boundary, and R, M, T expose the scalar comparison read used as a depth value.

Finally C, P, N transport, source, and name the same finite route. Since no coordinate ranges over all host halfspaces or all subsets of the sample, the listed rows exhaust the local NameCert obligations. □

Theorem 9187.3 (Tukey depth halfspace-window route)**.** *Every Tukey-depth read exported by an accepted* $\mathsf{TukeyDepth}^{\uparrow}$ *packet must expose the displayed* $\mathsf{Real}^{\uparrow}$ *scalar seal of chapter 38, the* $\mathsf{ConvexSet}^{\uparrow}$ *halfspace boundary of chapter 208, and the linear-functional comparison route of chapter 1644 before a depth consumer reads the scalar centrality value. The exported route is the finite sequence $R, X, H, S, M, W, T, C, P, N$, not an ambient infimum over all halfspaces, a host probability measure, or a selected deepest point.*

Proof. Start with the displayed halfspace window. The row H gives only the inspected functional-threshold side test, and W lists the finite probes available to the packet.

Read the geometric and scalar support next. The convex-set row S keeps the halfspace boundary visible, while the real row R and count ledger M expose the scalar comparison used by the depth read.

The transport row T and structural rows C, P, N replay that same finite window to downstream consumers. Because the carrier lacks coordinates for host measure, arbitrary halfspace families, selected minimizers, or quotient sample equality, the depth read remains a finite BEDC window route. □

Falsifiable prediction: Every accepted $\mathsf{TukeyDepth}^{\uparrow}$ read exposes a $\mathsf{Real}^{\uparrow}$ scalar seal, finite sample row, displayed halfspace-window row, $\mathsf{ConvexSet}^{\uparrow}$ support row, count or mass ledger, finite probe list, transport, provenance, and local naming before any data-depth consumer reads centrality.

Independence witness: real, convexset, bounded-linear-operator: $\mathsf{TukeyDepth}^{\uparrow}$ is not bijective to any listed sibling because it binds sample-window counts and halfspace probe windows into one robust-statistics NameCert carrier rather than merely naming scalars, convex sets, or functionals.

Closure status for $\mathsf{NameCert}_{\mathsf{TukeyDepth}^{\uparrow}}$.

Constructive story: A $\mathsf{TukeyDepth}^{\uparrow}$ packet is generated from a Real scalar seal, a finite sample row, an affine halfspace-window row, a ConvexSet support row, a count or mass ledger, finite probe listing, scalar-depth transport, componentwise hsame transport, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{TukeyDepth}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 9187.1, Definition 9187.2, and Definition 9187.3 seed the finite halfspace-depth carrier over real scalar, sample-window, convex halfspace, count-ledger, transport, provenance, and local naming rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{TukeyDepth}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host probability measure, arbitrary infima over all halfspaces, selected deepest points, quotient sample equality, Euclidean compactness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, halfspace-window exactness, count-ledger exactness, scalar-depth transport, provenance, local naming, and non-escape for BEDC.Derived.TukeyDepthUp.

Chapter 9188

A Concrete Naming Certificate for $\mathsf{HyperbolicPhaseLens}^{\uparrow}$

The $\mathsf{HyperbolicPhaseLens}^{\uparrow}$ packet realizes the observer-expansion window of chapter 9463 as finite boundary-shadow, Busemann-displacement, Real-seal, transport, replay, provenance, and local naming rows. It sits beside the boundary-shadow packet of chapter 3813, the Busemann boundary surface of chapter 3732, the visual-boundary readout of chapter 4181, the observer-expansion packet of chapter 4167, and the observer-shadow metric route of chapter 4154. The packet names a finite observer-window lens; it does not construct a global hyperbolic model, quotient an ideal boundary, choose geodesic rays, identify physical spacetime, or bridge-check the route.

Definition 9188.1 (Hyperbolic phase lens carrier)**.** *A* $\mathsf{HyperbolicPhaseLens}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (B, U, V, D, R, W, H, C, P, N)$$

with the following visible rows:

1. *B is the boundary-shadow source row, exposing the displayed shadow window read from a finite observer boundary packet.*
2. *U is the Busemann-displacement row, recording the signed displacement comparison used by the lens.*
3. *V is the visual-boundary row, keeping the boundary endpoint readback visible before any phase interpretation.*
4. *D is the observer-distance row, tying the phase lens to the observer-shadow metric route.*
5. *R is the* $\mathsf{Real}^{\uparrow}$ *seal for the displayed scalar comparison attached to U and D.*
6. *W is the finite observer-window row listing the shadows, displacements, and scalar reads inspected by the packet.*
7. *H records componentwise* hsame *transport for $B, U, V, D, R, W, C, P, N$.*
8. *C records displayed* Cont *replay from boundary shadow through Busemann displacement, visual-boundary readback, observer-distance comparison, Real sealing, and local naming.*
9. *P is the* Pkg *provenance over the hyperbolic shadow, Busemann, visual-boundary, observer-expansion, Real-seal, transport, and replay rows.*
10. *N is the local* $\mathsf{NameCert}_{\mathsf{HyperbolicPhaseLens}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $B, U, V, D, R, W, H, C, P, N$. It has no coordinate for a global hyperbolic space, quotient ideal boundary, chosen geodesic ray family, physical observer law, ambient compactification, or bridge credential.

Lean4 (statement) `BEDC.Derived.HyperbolicPhaseLensUp`

Theorem 9188.2 (Hyperbolic phase lens NameCert obligations)**.** *For every accepted* $\mathsf{HyperbolicPhaseLens}^{\uparrow}$ *carrier*

$$L = (B, U, V, D, R, W, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{HyperbolicPhaseLens}^{\uparrow}}$ *surface consists exactly of boundary-shadow exposure through B, Busemann-displacement exposure through U, visual-boundary readback through V, observer-distance comparison through D, Real sealing through R, finite observer-window listing through W, componentwise* hsame *transport through H, displayed* Cont *replay through C, provenance through P, and local naming through N.*

Proof. Project the carrier of Definition 9188.1. The packet displays the shadow, displacement, boundary, observer-distance, Real-seal, window, transport, replay, provenance, and naming rows as its whole public surface.

The observer-window read is chained rather than detached. Boundary-shadow data enters through B, Busemann displacement through U, visual-boundary readback through V, and observer-distance comparison through D before the Real-sealed scalar row R can be consumed.

Finally W, H, C, P, N list, transport, replay, source, and name the same finite route. Since no coordinate supplies a global boundary quotient or selected geodesic family, the listed rows exhaust the NameCert obligations. □

Theorem 9188.3 (Hyperbolic phase lens observer-window route)**.** *Every observer-expansion read exported by an accepted* $\mathsf{HyperbolicPhaseLens}^{\uparrow}$ *packet must first pass through chapter 3813, chapter 3732, chapter 4181, and chapter 4154. The exported lens is the finite route $B, U, V, D, R, W, H, C, P, N$, not a global hyperbolic compactification, a quotient ideal-boundary object, a physical observer law, or a selected geodesic-ray representative.*

Proof. Read the hyperbolic siblings in dependency order. The boundary-shadow row B supplies the finite shadow window, while U and V keep the Busemann and visual-boundary rows visible before a phase-lens read is public.

The observer-distance and Real rows then bind the scalar comparison. Rows D and R make the observer-shadow metric and Real seal explicit, and W records the finite observer windows actually inspected by the packet.

The structural rows H, C, P, N transport, replay, source, and name that same route. Because the packet has no coordinates for global compactification, quotient endpoints, geodesic-ray choice, or physical spacetime semantics, the exported lens remains a finite observer-window route. □

Falsifiable prediction: Every accepted $\mathsf{HyperbolicPhaseLens}^{\uparrow}$ read exposes boundary-shadow, Busemann-displacement, visual-boundary, observer-distance, Real-seal, finite observer-window, transport, replay, provenance, and local naming rows before any observer-expansion consumer reads the lens.

Independence witness: hyperbolic-boundary-shadow, hyperbolic-busemann-boundary, hyperbolic-visual-boundary, hyperbolic-observer-expansion, hyperbolic-observer-shadow-metric: $\mathsf{HyperbolicPhaseLens}^{\uparrow}$ is not bijective to any listed sibling because it binds shadow, displacement, visual-boundary, observer-distance, and Real-seal rows into one finite lens packet.

Closure status for $\mathsf{NameCert}_{\mathsf{HyperbolicPhaseLens}^{\uparrow}}$.

Constructive story: A $\mathsf{HyperbolicPhaseLens}^{\uparrow}$ packet is generated from a boundary-shadow source row, a Busemann-displacement row, a visual-boundary row, an observer-distance row, a Real seal, a finite observer-window listing, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{HyperbolicPhaseLens}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 9188.1, Definition 9188.2, and Definition 9188.3 seed the finite hyperbolic observer-window lens over boundary-shadow, Busemann-displacement, visual-boundary, observer-distance, Real-seal, transport, replay, provenance, and local naming rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{HyperbolicPhaseLens}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close global hyperbolic compactification, quotient ideal-boundary equality, selected geodesic rays, physical observer laws, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, boundary-shadow exactness, Busemann-displacement exactness, observer-window listing, Real-seal handoff, transport, replay, provenance, local naming, and non-escape for BEDC.Derived.HyperbolicPhaseLensUp.

Chapter 9189

A Concrete Naming Certificate for $\mathsf{RegularCauchyInverseGuard}^{\uparrow}$

Following Bishop and Bridges constructive real analysis, the $\mathsf{RegularCauchyInverseGuard}^{\uparrow}$ packet records the finite guard that must be displayed before a regular Cauchy reciprocal or inverse read is admitted. It sits after the regular rational source of chapter 301, the dyadic lower-bound ledger of chapter 291, the reciprocal budget route of chapter 703, the terminal real-name seal of chapter 38, the located apartness route of chapter 6730, and the guarded reciprocal surface of chapter 6251. The packet is a denominator-guard certificate for inspected finite windows; it is not trichotomy, quotient real equality, total inversion on all $\mathsf{Real}^{\uparrow}$ names, countable choice, or ambient completion.

Definition 9189.1 (Regular Cauchy inverse guard carrier)**.** *A* $\mathsf{RegularCauchyInverseGuard}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$G = (Q, A, D, L, B, R, E, H, C, P, N)$$

with the following displayed rows:

1. *Q is the accepted* $\mathsf{RegSeqRat}^{\uparrow}$ *source row whose denominator-facing tail is being inspected.*
2. *A is the located apartness row, exposing a positive separation from zero for the inspected tail.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *ledger recording the finite dyadic lower-bound, tolerance, and reciprocal-radius data read from the same inspected window.*
4. *L is the* $\mathsf{RegularCauchyLocatedApartness}^{\uparrow}$ *handoff row tying Q, A, D to the located-apartness surface.*
5. *B is the* $\mathsf{CauchyInverseBudget}^{\uparrow}$ *row consumed by the guarded reciprocal or inverse read.*
6. *R is the* $\mathsf{RealReciprocal}^{\uparrow}$ *row, available only after Q, A, D, L, B have been displayed.*
7. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal for the guarded reciprocal candidate.*
8. *H records componentwise* hsame *transport for the source, apartness, dyadic ledger, located-apartness handoff, reciprocal budget, reciprocal row, Real seal, replay, provenance, and local naming rows.*
9. *C records displayed* Cont *replay from source inspection through located apartness, dyadic lower-bound reading, reciprocal-budget selection, reciprocal handoff, and Real sealing.*
10. *P is the* Pkg *provenance over* $\mathsf{RegularCauchyInverseGuard}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{CauchyInverseBudget}^{\uparrow}$, $\mathsf{RegularCauchyLocatedApartness}^{\uparrow}$, $\mathsf{RealReciprocal}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.

11. N is the local $\mathsf{NameCert}_{\mathsf{RegularCauchyInverseGuard}^{\uparrow}}$ *row.*
The classifier compares accepted packets only through $Q, A, D, L, B, R, E, H, C, P, N$. It has no coordinate for a total reciprocal operation, quotient equality of regular names, trichotomy, selected denominators, countable choice, or detached $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 9189.2 (Regular Cauchy inverse guard NameCert obligations)**.** *For every accepted* $\mathsf{RegularCauchyInverseGuard}^{\uparrow}$ *carrier $G = (Q, A, D, L, B, R, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyInverseGuard}^{\uparrow}}$ *surface consists exactly of carrier admission for the* $\mathsf{RegSeqRat}^{\uparrow}$ *source, located apartness row,* $\mathsf{DyadicRatCore}^{\uparrow}$ *lower-bound ledger,* $\mathsf{RegularCauchyLocatedApartness}^{\uparrow}$ *handoff,* $\mathsf{CauchyInverseBudget}^{\uparrow}$ *row,* $\mathsf{RealReciprocal}^{\uparrow}$ *guarded reciprocal row, terminal* $\mathsf{Real}^{\uparrow}$ *seal, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming.*

Proof. Project the carrier of Definition 9189.1. The analytic rows are Q, A, D, L, B, R, E, and the structural rows are H, C, P, N.

Read the guard rows first. The regular rational source Q is inspected only through the displayed apartness row A and dyadic ledger D, and the located-apartness handoff L records that this lower-bound data is visible before any reciprocal budget is consumed.

Next read the reciprocal side. The budget row B can feed the guarded reciprocal row R only after Q, A, D, L are already present, and the terminal seal E receives only that guarded read.

Finally the transport, replay, provenance, and naming rows preserve the same finite route. Since the carrier has no further coordinate, the listed rows exhaust the local NameCert obligations. □

Theorem 9189.3 (Regular Cauchy inverse guard finite denominator bound)**.** *Every accepted* $\mathsf{RegularCauchyInverseGuard}^{\uparrow}$ *carrier $G = (Q, A, D, L, B, R, E, H, C, P, N)$ exposes the finite denominator guard*

$$Q, A, D, L \longmapsto B \longmapsto R \longmapsto E$$

before any reciprocal or inverse read is public. Thus a consumer that reaches R or E without the $\mathsf{RegSeqRat}^{\uparrow}$ *source row, located apartness row,* $\mathsf{DyadicRatCore}^{\uparrow}$ *lower-bound ledger, and located-apartness handoff remains outside the local classifier.*

Proof. Start from Definition 9189.2. It places Q, A, D, L before the reciprocal budget row B in the displayed packet.

The dyadic row D is the finite denominator-bound ledger. It records the lower-bound and tolerance data read from the inspected regular Cauchy window, while L ties that ledger to the located-apartness surface.

The reciprocal rows are downstream. A consumer must pass from Q, A, D, L to B, then to the guarded reciprocal row R, and only then to the terminal Real seal E. The structural rows H, C, P, N transport, replay, source, and name this route without adding total inversion, quotient equality, trichotomy, countable choice, or ambient completion data. □

Theorem 9189.4 (Regular Cauchy inverse guard reciprocal-read boundary)**.** *Every reciprocal-facing or inverse-facing consumer of an accepted* $\mathsf{RegularCauchyInverseGuard}^{\uparrow}$ *packet must read the sibling surfaces of chapter 301, chapter 291, chapter 703, chapter 6730, chapter 6251, and chapter 38 through the displayed rows $Q, A, D, L, B, R, E, H, C, P, N$. The handoff exports a finite denominator guard and no total reciprocal, no quotient real equality, no selected inverse, no trichotomy, and no ambient* $\mathsf{Real}^{\uparrow}$ *completeness principle.*

Proof. Use the finite denominator-bound theorem to fix the route $Q, A, D, L \longmapsto B \longmapsto R \longmapsto E$.

The sibling chapters supply the meanings of those rows. The regular rational source is read through $\mathsf{RegSeqRat}^{\uparrow}$, the lower-bound ledger through $\mathsf{DyadicRatCore}^{\uparrow}$, the budget through $\mathsf{CauchyInverseBudget}^{\uparrow}$, the apartness handoff through $\mathsf{RegularCauchyLocatedApartness}^{\uparrow}$, the guarded reciprocal row through $\mathsf{RealReciprocal}^{\uparrow}$, and the terminal seal through $\mathsf{Real}^{\uparrow}$.

Since every consumer route is carried by the displayed rows and their H, C, P, N structure, no hidden reciprocal operator or completion principle can be exported by the packet. □

Falsifiable prediction: Every accepted $\mathsf{RegularCauchyInverseGuard}^{\uparrow}$ reciprocal read exposes a $\mathsf{RegSeqRat}^{\uparrow}$ source, located apartness row, $\mathsf{DyadicRatCore}^{\uparrow}$ lower-bound ledger, $\mathsf{CauchyInverseBudget}^{\uparrow}$ row, $\mathsf{RealReciprocal}^{\uparrow}$ handoff, and terminal $\mathsf{Real}^{\uparrow}$ seal before the local $\mathsf{NameCert}_{\mathsf{RegularCauchyInverseGuard}^{\uparrow}}$ row is consumed.

Independence witness: regseqrat, dyadicratcore, cauchyinversebudget, regular-cauchy-located-apartness, real-reciprocal, real: $\mathsf{RegularCauchyInverseGuard}^{\uparrow}$ is not bijective to any listed sibling because it binds a regular Cauchy source, located apartness row, dyadic lower-bound ledger, reciprocal budget, guarded reciprocal row, terminal Real seal, transport, replay, provenance, and local naming as one finite inverse-guard packet.

Closure status for $\mathsf{NameCert}_{\mathsf{RegularCauchyInverseGuard}^{\uparrow}}$.

Constructive story: A $\mathsf{RegularCauchyInverseGuard}^{\uparrow}$ packet is generated from a $\mathsf{RegSeqRat}^{\uparrow}$ source, located apartness evidence, a $\mathsf{DyadicRatCore}^{\uparrow}$ lower-bound ledger, a located-apartness handoff, a $\mathsf{CauchyInverseBudget}^{\uparrow}$ row, a $\mathsf{RealReciprocal}^{\uparrow}$ guarded reciprocal row, a terminal $\mathsf{Real}^{\uparrow}$ seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RegularCauchyInverseGuard}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 9189.1, Definition 9189.2, Definition 9189.3, and Definition 9189.4 seed the finite denominator-guard surface for regular Cauchy reciprocal reads over $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{CauchyInverseBudget}^{\uparrow}$, $\mathsf{RegularCauchyLocatedApartness}^{\uparrow}$, $\mathsf{RealReciprocal}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RegularCauchyInverseGuard}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close total reciprocal construction, quotient real equality, selected inverses, trichotomy, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, located apartness exposure, finite denominator-bound exactness, reciprocal-budget routing, guarded reciprocal handoff, Real seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.RegularCauchyInverseGuardUp.

Chapter 9190

A Concrete Naming Certificate for $\mathsf{LocaleFrame}^{\uparrow}$

Following Johnstone and constructive locale theory, the $\mathsf{LocaleFrame}^{\uparrow}$ packet records the point-free topology interface as finite frame operations and finite cover-refinement data. It sits after the open-index topology of chapter 88, the meet–join order surface of chapter 55, the implication boundary of chapter 8536, and the locale-space handoff of chapter 5153; it also supplies a point-free input surface for compact-open consumers such as chapter 4138. The packet names finite generators, finite meets and joins, cover refinement, topology handoff, Heyting/frame boundary, transport, replay, provenance, and local naming without importing host powersets, selected points, quotient spaces, choice-indexed covers, or spatiality.

Definition 9190.1 (Locale frame carrier)**.** *A* $\mathsf{LocaleFrame}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$F = (G, M, J, C, T, B, H, R, P, N)$$

with the following displayed rows:

1. *G is the finite open-generator row, naming the basic point-free observations available to the frame.*
2. *M is the finite-meet row, recording displayed finite intersections of generators and generated opens.*
3. *J is the finite-join row, recording displayed finite unions of generators and generated opens.*
4. *C is the cover-refinement row, recording finite cover requests and finite refinement witnesses between generated-open families.*
5. *T is the topology handoff row, exposing generated-open reads to* $\mathsf{Topology}^{\uparrow}$ *without replacing the frame by a host open-set powerset.*
6. *B is the Heyting/frame boundary row, exposing implication-shaped or complemented finite fragments through* $\mathsf{HeytingAlgebra}^{\uparrow}$ *only when those fragments are displayed.*
7. *H records componentwise* hsame *transport for generator, meet, join, cover-refinement, topology handoff, Heyting/frame boundary, replay, provenance, and local naming rows.*
8. *R records displayed* Cont *replay from a frame request through generators, finite meets, finite joins, cover refinement, topology handoff, Heyting/frame boundary, transport, provenance, and local naming.*

9. *P is the* Pkg *provenance over* $\mathsf{LocaleFrame}^{\uparrow}$, $\mathsf{LocaleSpace}^{\uparrow}$, $\mathsf{Topology}^{\uparrow}$, $\mathsf{Lattice}^{\uparrow}$, $\mathsf{HeytingAlgebra}^{\uparrow}$, $\mathsf{CompactOpenTopology}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*
10. *N is the local* $\mathsf{NameCert}_{\mathsf{LocaleFrame}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $G, M, J, C, T, B, H, R, P, N$. It has no coordinate for host powersets of opens, selected points, quotient spatial presentations, arbitrary joins, choice-indexed covers, ambient completeness, or a global Boolean algebra of all opens.

Theorem 9190.2 (Locale frame NameCert obligations)**.** *For every accepted* $\mathsf{LocaleFrame}^{\uparrow}$ *carrier*

$$F = (G, M, J, C, T, B, H, R, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{LocaleFrame}^{\uparrow}}$ *surface consists exactly of finite open-generator admission through G, finite-meet exposure through M, finite-join exposure through J, cover-refinement exactness through C, topology handoff through T, Heyting/frame boundary exposure through B, componentwise* hsame *transport through H, displayed* Cont *replay through R,* Pkg *provenance through P, and local naming through N.*

Proof. Project the carrier of Definition 9190.1. The rows G, M, J, C display the point-free frame data before any topology-facing or implication-facing consumer is allowed to read the packet.

The topology handoff is exactly the row T. It sends generated-open reads to $\mathsf{Topology}^{\uparrow}$ but does not create a host powerset of all opens, a selected point carrier, or a quotient spatial presentation.

The Heyting/frame boundary is exactly the row B. It may expose implication-shaped or complemented finite fragments through $\mathsf{HeytingAlgebra}^{\uparrow}$, but only for fragments already displayed by the generator, meet, join, and cover-refinement rows.

Finally H, R, P, N transport, replay, source, and name the same finite packet. Since the carrier has no coordinate for arbitrary joins, choice-indexed covers, ambient completeness, or global Boolean openness, the listed rows exhaust the local NameCert surface. □

Theorem 9190.3 (Locale frame finite-meet cover route)**.** *Every accepted* $\mathsf{LocaleFrame}^{\uparrow}$ *read that compares a finite meet against a cover-refinement request factors through the finite route*

$$G \longmapsto M \longmapsto J \longmapsto C \longmapsto T \longmapsto B \longmapsto H \longmapsto R \longmapsto P \longmapsto N.$$

A $\mathsf{LocaleSpace}^{\uparrow}$, $\mathsf{Topology}^{\uparrow}$, $\mathsf{Lattice}^{\uparrow}$, $\mathsf{HeytingAlgebra}^{\uparrow}$, *or* $\mathsf{CompactOpenTopology}^{\uparrow}$ *consumer may inherit only the displayed generator, finite-meet, finite-join, cover-refinement, topology handoff, Heyting/frame boundary, transport, replay, provenance, and local naming rows. The route exports no host powerset, selected point, quotient spatial carrier, arbitrary cover choice, ambient compactness theorem, or global Boolean algebra of opens.*

Proof. Start with the generator row G. A finite-meet comparison has no accepted source until the basic open observations are displayed and the finite-meet row M records the intersection being inspected.

Add the finite-join and cover-refinement rows. The row J keeps generated finite unions in the same point-free ledger, and C records the finite cover family and its refinement witness before any topology-facing consumer may use the comparison.

Only after those rows are fixed may the handoff rows be read. The topology handoff T exposes generated-open data to $\mathsf{Topology}^{\uparrow}$, while the Heyting/frame boundary B exposes implication-shaped or complemented finite fragments without turning the whole packet into a Boolean algebra of opens.

The structural rows H, R, P, N preserve the same route by transport, replay, provenance, and local naming. Thus every finite-meet cover read is point-free and finite before any sibling consumer receives it. □

Falsifiable prediction: Every accepted $\mathsf{LocaleFrame}^{\uparrow}$ read exposes finite open generators, finite meets, finite joins, cover-refinement, topology handoff, Heyting/frame boundary, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert rows before a topology, lattice, Heyting, locale-space, or compact-open consumer may use the frame.

Independence witness: topology, lattice, heytingalgebra, localespace, compactopentopology: $\mathsf{LocaleFrame}^{\uparrow}$ is not bijective to any listed sibling because it binds generators, finite frame operations, cover-refinement, topology handoff, Heyting/frame boundary, transport, replay, provenance, and local NameCert rows in one point-free packet.

Closure status for $\mathsf{NameCert}_{\mathsf{LocaleFrame}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{LocaleFrame}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 9190.1, Definition 9190.2, and Definition 9190.3 seed the point-free finite-frame packet over generator, meet, join, cover-refinement, topology handoff, Heyting/frame boundary, transport, replay, provenance, and local naming rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{LocaleFrame}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim host powersets of opens, selected points, quotient spatial presentations, arbitrary joins, choice-indexed covers, spatiality, ambient compactness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, finite meet and join exactness, cover-refinement stability, topology handoff, Heyting/frame boundary restriction, transport, replay, provenance, and local naming for BEDC.Derived.LocaleFrameUp.

Constructive story: A $\mathsf{LocaleFrame}^{\uparrow}$ packet is generated from finite open generators, finite meet rows, finite join rows, cover-refinement rows, topology handoff rows, Heyting/frame boundary rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 9191

A Concrete Naming Certificate for the Fibonacci-Window Weil Positivity Matrix

Following Weil and Bombieri, this packet records a finite positive-semidefiniteness shadow of the Weil explicit-formula criterion. The carrier is the displayed degree-3 Fibonacci-hat test window together with a concrete rational approximant of the Weil quadratic form on that window. It is a finite rational matrix certificate, not a global positivity theorem for all test functions.

The matrix is the scaled integer form

$$W = \begin{pmatrix} 303318 & -12152 & -193136 \\ -12152 & 303318 & -12152 \\ -193136 & -12152 & 303318 \end{pmatrix}.$$

For $x = (x_0, x_1, x_2)$ the represented quadratic form is

$$x^{\mathsf{T}} W x = 303318(x_0^2 + x_1^2 + x_2^2) - 24304(x_0x_1 + x_1x_2) - 386272x_0x_2.$$

The corner entry is genuinely negative, so positivity is not termwise positivity.

Definition 9191.1 (Fibonacci-window Weil matrix packet)**.** *The finite packet consists of the rational matrix W, the coordinate row x_0, x_1, x_2, the symmetric coordinates*

$$u = x_0 + x_2, \qquad v = x_0 - x_2, \qquad w = x_1,$$

and the two positive-semidefiniteness subcertificates

$$B = \begin{pmatrix} 110182 & -24304 \\ -24304 & 606636 \end{pmatrix}, \qquad d = 496454.$$

The displayed determinant comparison is

$$(-24304)^2 = 590684416 \le 66840367752 = 110182 \cdot 606636.$$

The minimum-eigenvalue subcertificate uses the shifted integer matrix $W - 100000I$:

$$B_{\mathrm{sh}} = \begin{pmatrix} 10182 & -24304 \\ -24304 & 406636 \end{pmatrix}, \qquad d_{\mathrm{sh}} = 396454,$$

with

$$(-24304)^2 = 590684416 \le 4140367752 = 10182 \cdot 406636.$$

Theorem 9191.2 (Fibonacci-window Weil matrix positive definiteness)**.** *For all rational x_0, x_1, x_2,*

$$x^{\mathsf{T}} W x \geq 0.$$

More precisely, the exact rational identity

$$\begin{aligned} 2(x^{\mathsf{T}} W x) = (110182)u^2 + 2(-24304)uw + (606636)w^2 \\ + (496454)v^2 \end{aligned}$$

holds for $u = x_0 + x_2$, $v = x_0 - x_2$, and $w = x_1$. The first line is nonnegative by the 2×2 positive-semidefiniteness criterion for B, and the second line is nonnegative by the 1×1 criterion for d.

The same coordinates certify the minimum-eigenvalue lower bound for the scaled integer form:

$$x^{\mathsf{T}} W x \geq 100000(x_0^2 + x_1^2 + x_2^2).$$

Equivalently, the inspected rational Weil matrix $10^{-9}W$ satisfies

$$10^{-9} W \succeq 10^{-4} I.$$

Indeed,

$$\begin{aligned} 2x^{\mathsf{T}}(W - 100000I)x = (10182)u^2 + 2(-24304)uw + (406636)w^2 \\ + (396454)v^2, \end{aligned}$$

and the shifted 2×2 block and shifted scalar block are nonnegative by the displayed determinant and scalar comparisons.

Proof. The displayed change of variables separates the symmetric and antisymmetric coordinates for the endpoints x_0 and x_2. Expanding u^2, v^2, and uw gives

$$\begin{aligned} &(110182)(x_0 + x_2)^2 + 2(-24304)(x_0 + x_2)x_1 + (606636)x_1^2 \\ &\quad + (496454)(x_0 - x_2)^2 \\ &= 606636(x_0^2 + x_1^2 + x_2^2) - 48608(x_0x_1 + x_1x_2) - 772544x_0x_2 \\ &= 2(x^{\mathsf{T}} W x). \end{aligned}$$

The diagonal entries 110182 and 606636 are nonnegative, and the determinant comparison in Definition 9191.1 verifies the 2×2 block. The scalar coefficient 496454 is nonnegative. Therefore the right-hand side is a sum of a nonnegative 2×2 quadratic block and a nonnegative 1×1 block. Since $2 > 0$, the original quadratic form is nonnegative.

For the lower bound, replace the diagonal coefficient 303318 by $203318 = 303318 - 100000$ and keep the off-diagonal coefficients unchanged. The same expansion gives

$$\begin{aligned} &(10182)(x_0 + x_2)^2 + 2(-24304)(x_0 + x_2)x_1 + (406636)x_1^2 \\ &\quad + (396454)(x_0 - x_2)^2 \\ &= 406636(x_0^2 + x_1^2 + x_2^2) - 48608(x_0x_1 + x_1x_2) - 772544x_0x_2 \\ &= 2x^{\mathsf{T}}(W - 100000I)x. \end{aligned}$$

The shifted diagonal entries 10182 and 406636 are nonnegative, the determinant comparison for B_{sh} verifies the shifted 2×2 block, and 396454 verifies the shifted 1×1 block. Hence $x^{\mathsf{T}}(W - 100000I)x \geq 0$, which is the displayed lower bound. □

Lean4 ✓ `BEDC.Derived.RHRoute.FibonacciWindowWeilMatrixPositivity.fibonacci window weil matrix positivity certificate`

Theorem 9191.3 (Finite Weil-positivity shadow boundary)**.** *The packet is a finite Weil-positivity shadow: a concrete rational approximant of the degree-3 Fibonacci-windowed Weil quadratic form is positive semidefinite despite genuine negative off-diagonal entries, so positivity is a nontrivial cancellation certified by symmetric diagonalization onto the* 2×2 *and* 1×1 *positive-semidefiniteness criteria.*

Proof. The rational matrix $W/10^9$ is the inspected approximant to the Weil functional $T(\psi_r * \psi_s^\sharp)$ on the three-dimensional Fibonacci-hat test space. Its entries are computed from the von Mangoldt prime contribution for $n \le F_5^2 = 25$ together with the archimedean Γ-factor logarithmic-derivative density. This construction is non-circular: it does not input zeta zero locations.

The Lean theorem is exact only after the rational entries are fixed. It proves the rational positive-semidefiniteness statement, the eigenvalue lower bound $W \succeq 10^{-4}I$ for the normalized matrix, and the displayed change of variables. The eigenvalue lower bound $W \succeq 10^{-4}I$, together with the external entry-certification error of order $10^{-9} \ll 10^{-4}$, shows the exact degree-3 Fibonacci-windowed Weil matrix is positive definite, not merely that the rational approximant is positive semidefinite. □

Falsifiable prediction: Recomputing the displayed rational matrix, the determinant comparisons $590684416 \le 66840367752$ and $590684416 \le 4140367752$, the diagonalization identities for $u = x_0 + x_2$, $v = x_0 - x_2$, $w = x_1$, the shifted lower-bound identity, or the exact Lean certificate refutes this packet if any listed equality or inequality fails.

Independence witness: fibonacci-window-weil-matrix-positivity: this finite packet is not a global Weil-positivity theorem, not a zeta-zero computation, and not a proof of RH; it is the exact rational PSD and minimum-eigenvalue certificate for one degree-3 Fibonacci-hat approximant.

Closure status for $\mathsf{NameCert}_{FibonacciWindowWeilMatrixPositivity}$.

Theory closure: TheoryGate($\mathsf{NameCert}_{FibonacciWindowWeilMatrixPositivity}$, scopedClosed)

Scope closed: positive semidefiniteness and the lower bound $10^{-9}W \succeq 10^{-4}I$ for a concrete 3×3 rational approximant of the degree-3 Fibonacci-windowed Weil quadratic form, via symmetric diagonalization onto the 2×2 and 1×1 criteria

Formal verification: FormalStatus($\mathsf{NameCert}_{FibonacciWindowWeilMatrixPositivity}$, theoremChecked)

Lean target: `BEDC.Derived.RHRoute.FibonacciWindowWeilMatrixPositivity.fibonacci\_window\_weil\_matrix\_positivity`

Bridge status: none

Not claimed: a finite Weil-positivity shadow on a 3-dimensional Fibonacci-hat test subspace; not a proof of RH; entry values are external interval numerics, the Lean theorem is exact rational positive semidefiniteness and a minimum-eigenvalue lower bound

Upgrade path: raise the window degree m (minimum eigenvalue shrinks $\sim F_m^{-2}$, needing higher-precision certified rational enclosures) and discharge the WeilPositivityRoute reduction obligations

Part VI

Concrete Hardening

Chapter 9192

Internal Domain Judgments and Signature Token Reflection

This chapter replaces two external-looking concrete notations by internal judgments:

$$h \in D, \qquad \mathsf{Tok}_{\Pi}(s).$$

They are readable, but both carry too much external mathematical flavor. This chapter replaces them with internal judgments.

Definition 9192.1 (Internal domain judgment)**.** *A concrete source domain is not treated as a set. It is a source name D equipped with a judgment*

$$\mathsf{InDom}(D, h),$$

read as: the history h is admitted by the source domain name D.

Lean4 ✓ `BEDC.FKernel.Gap.InDom iff setup field`

Remark 9192.2 (Layer discipline)**.** *The notation $\mathsf{InDom}(D, h)$ is still written in the metalanguage, but it is the public BEDC judgment to be used in all concrete gap statements. The notation $h \in D$ is not used in the active concrete presentation.*

Definition 9192.3 (Signature token introduction)**.** *For a probe bundle Π and an answer history s, a visible package token is introduced by a judgment*

$$\mathsf{TokIntro}(\Pi, s, p).$$

It means that p is a package token introduced from the signature history s under bundle Π.

Lean4 ✓ `BEDC.FKernel.Package.TokIntro iff setup field`
Lean4 (definition) `BEDC.FKernel.Package.SignatureTokenIntro`
↪ variant `BEDC.FKernel.Package.SignatureTokenIntro iff TokIntro`

Definition 9192.4 (Concrete signature package)**.** *The concrete signature package relation is defined by token introduction:*

$$\mathsf{Pkg}^{\mathrm{sig}}(\Pi, s, p) \quad \Longleftrightarrow \quad \mathsf{TokIntro}(\Pi, s, p).$$

Lean4 (definition) `BEDC.FKernel.Package.PkgSig`

Lean4 ✓ `BEDC.FKernel.Package.PkgSig iff TokIntro`

↪ variant `BEDC.FKernel.Package.TokIntro iff PkgSig`

↪ variant `BEDC.FKernel.Package.PkgSig intro from token`

↪ variant `BEDC.FKernel.Package.TokIntro nonempty pkg`

Definition 9192.5 (Concrete package-sameness policy)**.** *For the signature-token instance, package-sameness is generated only from history-sameness of source signatures:*

$$\mathsf{TokIntro}(\Pi, s, p), \quad \mathsf{TokIntro}(\Pi, t, q), \quad \mathsf{hsame}(s, t) \quad \Rightarrow \quad \mathsf{psame}(p, q).$$

No additional package-sameness constructors are admitted for the concrete signature-token instance.

Theorem 9192.6 (Package reflection for signature tokens)**.** *Assume* $\mathsf{PackageTokenPolicy}(\Pi)$ *for the concrete signature-token package policy. If*

$$\mathsf{TokIntro}(\Pi, s, p), \qquad \mathsf{TokIntro}(\Pi, t, q), \qquad \mathsf{psame}(p, q),$$

then

$$\mathsf{hsame}(s, t).$$

Lean4 ✓ `BEDC.FKernel.Package.package reflection`

↪ variant `BEDC.FKernel.Package.package reflection forward`

↪ variant `BEDC.FKernel.Package.package reflection roundtrip pair`

↪ variant `BEDC.FKernel.Package.package reflection iff hsame`

↪ variant `BEDC.FKernel.Package.psame reflection witness chain under tok unique`

Proof. Apply the reflection field of $\mathsf{PackageTokenPolicy}(\Pi)$ to the displayed token-introduction judgments and the package-sameness judgment. In the base-relation presentation, inversion on the constructor exposes introducing signatures for p and q; the policy reflection field, or a token-uniqueness theorem supplying that field, transports those constructor witnesses to the displayed introductions and yields $\mathsf{hsame}(s, t)$. □

Corollary 9192.7 (Concrete package equivalence is signature-grounded)**.** *Assume* $\mathsf{PackageTokenPolicy}(\Pi)$ *for the concrete signature-token package policy. If*

$$\mathsf{TokIntro}(\Pi, s, p) \qquad \textit{and} \qquad \mathsf{TokIntro}(\Pi, t, q),$$

then

$$\mathsf{psame}(p, q) \quad \Longleftrightarrow \quad \mathsf{hsame}(s, t).$$

Lean4 ✓ `BEDC.FKernel.Package.package reflection iff hsame`

Proof. Apply the two fields of $\mathsf{PackageTokenPolicy}(\Pi)$ to the displayed token-introduction judgments. The reflection field sends $\mathsf{psame}(p, q)$ to $\mathsf{hsame}(s, t)$, and the soundness field sends $\mathsf{hsame}(s, t)$ back to $\mathsf{psame}(p, q)$. □

Chapter 9193

Internalized Concrete Gaps and Globalize Soundness

This chapter restates the concrete gap policy using InDom and $\mathsf{TokIntro}$. This removes the remaining set-membership notation from the concrete instance.

Definition 9193.1 (Internalized signature gap)**.** *Given a source domain name D, a bundle Π, and a package token p, define*

$$\mathsf{InGap}^{\mathrm{sig}}(\Pi, D, p, h)$$

to mean that there exist an answer history s and an evidence ledger Δ such that

$$\mathsf{InDom}(D, h), \qquad \mathsf{Sig}(\Pi, h, s, \Delta), \qquad \mathsf{TokIntro}(\Pi, s, p).$$

Lean4 ✓ `BEDC.FKernel.Gap.internalized signature gap iff`
↪ variant `BEDC.FKernel.Gap.policySupportedSignatureGap token witness`

Definition 9193.2 (Internalized concrete Globalize instance)**.** *The internalized concrete signature globalization is the triple*

$$\mathsf{Glob}^{\mathrm{sig}}(\Pi, D) := (\mathsf{Pkg}^{\mathrm{sig}}, \mathsf{psame}, \mathsf{InGap}^{\mathrm{sig}}).$$

It is the active concrete finite-kernel Globalize instance.

Lean4 (definition) `BEDC.FKernel.Gap.InternalizedConcreteGlobalizeInstance`
Lean4 ✓ `BEDC.FKernel.Gap.internalized concrete globalize instance`

Theorem 9193.3 (Internalized gap coverage)**.** *Assume $\mathsf{AskPolicy}(\Pi, D)$ and the dependent generated-signature token condition: whenever $\mathsf{InDom}(D, h)$ and $\mathsf{Sig}(\Pi, h, s, \Delta)$, there exists a token p with $\mathsf{TokIntro}(\Pi, s, p)$. If $\mathsf{InDom}(D, h)$, then there exists a token p such that*

$$\mathsf{InGap}^{\mathrm{sig}}(\Pi, D, p, h).$$

Lean4 ✓ `BEDC.FKernel.Gap.internalized gap coverage`

Proof. From $\mathsf{AskPolicy}(\Pi, D)$ and $\mathsf{InDom}(D, h)$, obtain a generated signature event

$$\mathsf{Sig}(\Pi, h, s, \Delta).$$

By the dependent token condition, obtain p with $\mathsf{TokIntro}(\Pi, s, p)$. These data witness $\mathsf{InGap}^{\mathrm{sig}}(\Pi, D, p, h)$. □

Theorem 9193.4 (Internalized gap separation)**.** *Assume* $\mathsf{AskPolicy}(\Pi, D)$*. If*

$$\mathsf{InGap}^{\mathrm{sig}}(\Pi, D, p, h) \quad \textit{and} \quad \mathsf{InGap}^{\mathrm{sig}}(\Pi, D, q, h),$$

then

$$\mathsf{psame}(p, q).$$

Lean4 ✓ `BEDC.FKernel.Gap.internalized gap separation`
↪ variant `BEDC.FKernel.Gap.concrete gap separation witnesses`
↪ variant `BEDC.FKernel.Gap.internalized gap separation witnesses`
↪ variant `BEDC.FKernel.Gap.internalized gap separation packed`
↪ variant `BEDC.FKernel.Gap.gap separation concrete`

Proof. Unpack the two gap memberships. We obtain signatures s, t and evidence ledgers Δ, Θ such that

$$\mathsf{Sig}(\Pi, h, s, \Delta), \qquad \mathsf{TokIntro}(\Pi, s, p),$$
$$\mathsf{Sig}(\Pi, h, t, \Theta), \qquad \mathsf{TokIntro}(\Pi, t, q).$$

By signature determinacy under $\mathsf{AskPolicy}(\Pi, D)$, $\mathsf{hsame}(s, t)$. The concrete package-sameness introduction rule then yields $\mathsf{psame}(p, q)$. □

Theorem 9193.5 (Same-source gap memberships share signatures)**.** *Assume* $\mathsf{AskPolicy}(\Pi, D)$*. If*

$$\mathsf{InGap}^{\mathrm{sig}}(\Pi, D, p, h) \quad \textit{and} \quad \mathsf{InGap}^{\mathrm{sig}}(\Pi, D, q, h),$$

then there exist generated signatures s, t *introducing* p, q *such that* $\mathsf{hsame}(s, t)$*.*

Lean4 ✓ `BEDC.FKernel.Gap.inGapSig same source package witnesses`
↪ variant `BEDC.FKernel.Gap.inGapSig same source full witnesses`
↪ variant `BEDC.FKernel.Gap.inGapSig same source signature events same`
↪ variant `BEDC.FKernel.Gap.inGapSig same source sigRel witnesses`
↪ variant `BEDC.FKernel.Gap.gap memberships share signature`

Proof. Unpack the two gap memberships. Signature determinacy for their shared source history gives $\mathsf{hsame}(s, t)$, while the unpacked memberships provide the two token-introduction witnesses. □

Theorem 9193.6 (Concrete Globalize soundness)**.** *If* $\mathsf{Sig}(\Pi, h, s, \Delta)$*,* $\mathsf{Sig}(\Pi, k, t, \Theta)$*,* $\mathsf{TokIntro}(\Pi, s, p)$*,* $\mathsf{TokIntro}(\Pi, t, q)$*, and* $\mathsf{hsame}(s, t)$*, then* $\mathsf{psame}(p, q)$*.*

Lean4 ✓ `BEDC.FKernel.Gap.concrete globalize soundness intro`

Proof. Apply the concrete package-sameness constructor to the two token-introduction premises and the internal signature-sameness premise. □

Theorem 9193.7 (Concrete Globalize completeness)**.** *Assume* $\mathsf{PackageTokenPolicy}(\Pi)$*. If*

$$\mathsf{InGap}^{\mathrm{sig}}(\Pi, D, p, h), \qquad \mathsf{InGap}^{\mathrm{sig}}(\Pi, D, q, k), \qquad \mathsf{psame}(p, q),$$

then there exist answer histories s, t *and evidence ledgers* Δ, Θ *such that*

$$\mathsf{Sig}(\Pi, h, s, \Delta), \qquad \mathsf{Sig}(\Pi, k, t, \Theta), \qquad \mathsf{hsame}(s, t).$$

Proof. The two gap premises provide generated signatures and token-introduction witnesses for p and q. The package-token policy reflects $\mathsf{psame}(p, q)$ back to internal sameness of those generated signatures, giving the displayed witnesses. □

Lean4 ✓ `BEDC.FKernel.Gap.concrete globalize completeness`

↪ variant `BEDC.FKernel.Gap.globalize completeness`

Corollary 9193.8 (Concrete Globalize classifies exactly by signatures)**.** *Assume* $\mathsf{AskPolicy}(\Pi, D)$, $\mathsf{PackageTokenPolicy}(\Pi)$,

$$\mathsf{InGap}^{\mathrm{sig}}(\Pi, D, p, h), \qquad \mathsf{InGap}^{\mathrm{sig}}(\Pi, D, q, k).$$

Then visible package sameness and internal sameness of generated answer histories agree in both orientations:

$$\mathsf{psame}(p, q) \iff \exists s, t, \Delta, \Theta.\ \mathsf{Sig}(\Pi, h, s, \Delta) \wedge \mathsf{Sig}(\Pi, k, t, \Theta) \wedge \mathsf{hsame}(s, t).$$

Symmetrically,

$$\mathsf{psame}(q, p) \iff \exists t, s, \Theta, \Delta.\ \mathsf{Sig}(\Pi, k, t, \Theta) \wedge \mathsf{Sig}(\Pi, h, s, \Delta) \wedge \mathsf{hsame}(t, s).$$

Proof. The forward directions are Theorem 9193.7 applied to the two ordered pairs of gap memberships. The reverse direction for $\mathsf{psame}(p, q)$ is Theorem 9199.5 applied to the ordered memberships for p and q. The reverse direction for $\mathsf{psame}(q, p)$ applies the same local classification theorem to the ordered memberships for q and p. In both cases, the local theorem performs the transport from the displayed existential signatures to the token-introducing signatures carried by the two gap witnesses. □

Theorem 9193.9 (Bundle-local internalized gap separation)**.** *Assume* $\mathsf{BundleAskPolicy}(\Pi, D)$*. If*

$$\mathsf{InGap}^{\mathrm{sig}}(\Pi, D, p, h) \quad \textit{and} \quad \mathsf{InGap}^{\mathrm{sig}}(\Pi, D, q, h),$$

then

$$\mathsf{psame}(p, q).$$

Proof. Unpack the first gap membership using Definition 9193.1. It supplies the admitted-source judgment $\mathsf{InDom}(D, h)$, an answer history s, and an evidence ledger Δ such that

$$\mathsf{Sig}(\Pi, h, s, \Delta), \qquad \mathsf{TokIntro}(\Pi, s, p).$$

Unpack the second gap membership in the same way, obtaining an answer history t and an evidence ledger Θ such that

$$\mathsf{Sig}(\Pi, h, t, \Theta), \qquad \mathsf{TokIntro}(\Pi, t, q).$$

The shared admitted-source judgment and the two generated signatures are exactly the hypotheses of Definition 6.63 under $\mathsf{BundleAskPolicy}(\Pi, D)$, so $\mathsf{hsame}(s, t)$. The concrete package-sameness introduction rule, equivalently Definition 9193.6 applied to the two generated signatures, the two token-introduction witnesses, and $\mathsf{hsame}(s, t)$, yields $\mathsf{psame}(p, q)$. □

Theorem 9193.10 (Bundle-local internalized gap coverage)**.** *Assume* $\mathsf{BundleAskPolicy}(\Pi, D)$ *and the dependent generated-signature token condition: whenever* $\mathsf{InDom}(D, u)$ *and* $\mathsf{Sig}(\Pi, u, s, \Delta)$*, there exists a token* p *with* $\mathsf{TokIntro}(\Pi, s, p)$*. If* $\mathsf{InDom}(D, h)$*, then there exists a token* p *such that*

$$\mathsf{InGap}^{\mathrm{sig}}(\Pi, D, p, h).$$

Proof. By bundle-local signature existence, Definition 6.62, the bundle-local asking policy and the admitted-source premise give an answer history s and an evidence ledger Δ such that

$$\mathsf{Sig}(\Pi, h, s, \Delta).$$

Apply the dependent token condition to $\mathsf{InDom}(D, h)$ and this generated signature. It supplies a token p with

$$\mathsf{TokIntro}(\Pi, s, p).$$

The admitted-source premise, the generated signature, and this token-introduction judgment are exactly the witnesses required by Definition 9193.1. Therefore

$$\mathsf{InGap}^{\mathrm{sig}}(\Pi, D, p, h),$$

and the displayed token p gives the required coverage. □

Theorem 9193.11 (Bundle-local same-source gap memberships share signatures)**.** *Assume* $\mathsf{BundleAskPolicy}(\Pi, D)$ *If*

$$\mathsf{InGap}^{\mathrm{sig}}(\Pi, D, p, h) \quad \textit{and} \quad \mathsf{InGap}^{\mathrm{sig}}(\Pi, D, q, h),$$

then there exist answer histories s, t *and evidence ledgers* Δ, Θ *such that*

$$\mathsf{Sig}(\Pi, h, s, \Delta), \qquad \mathsf{TokIntro}(\Pi, s, p),$$

$$\mathsf{Sig}(\Pi, h, t, \Theta), \qquad \mathsf{TokIntro}(\Pi, t, q), \qquad \mathsf{hsame}(s, t).$$

Proof. Unpack the first gap membership by Definition 9193.1. It supplies the admitted-source judgment $\mathsf{InDom}(D, h)$, an answer history s, and an evidence ledger Δ such that

$$\mathsf{Sig}(\Pi, h, s, \Delta), \qquad \mathsf{TokIntro}(\Pi, s, p).$$

Unpack the second gap membership in the same way. It supplies an answer history t and an evidence ledger Θ such that

$$\mathsf{Sig}(\Pi, h, t, \Theta), \qquad \mathsf{TokIntro}(\Pi, t, q).$$

The two generated signatures have the same bundle and the same admitted source history. Applying Definition 6.63 under $\mathsf{BundleAskPolicy}(\Pi, D)$ gives $\mathsf{hsame}(s, t)$. The displayed signatures, token-introduction witnesses, and this history-sameness witness are the required data. □

Chapter 9194

Unary Continuation Commutativity and the Additive Name

The $\mathsf{Add}^{\uparrow}$ certificate establishes a unary continuation interface with unit, associativity, determinacy, and closure. To justify the additive name rather than merely a monoid-like continuation name, one more paper-level obligation is needed: unary continuation commutativity.

Definition 9194.1 (Unary histories)**.** *The unary judgment* $\mathsf{Unary}(h)$ *is generated by*

$$\mathsf{Unary}(\mathsf{e}) \qquad \textit{and} \qquad \mathsf{Unary}(h) \Rightarrow \mathsf{Unary}(\mathsf{E1}(h)).$$

No rule generates $\mathsf{Unary}(\mathsf{E0}(h))$*.*

Lean4 ✓ `BEDC.FKernel.Unary.unary histories iff empty or eone tail`

Definition 9194.2 (Unary continuation result)**.** $\mathsf{UnaryCont}(h, k, r)$ *means*

$$\mathsf{Unary}(h), \qquad \mathsf{Unary}(k), \qquad \mathsf{Cont}(h, k, r).$$

Lean4 (definition) `BEDC.FKernel.Unary.UnaryCont`

↪ variant BEDC.FKernel.Unary.unary append factors iff result
↪ variant BEDC.FKernel.Unary.unary continuation closed and factors
↪ variant BEDC.FKernel.Unary.unary repetition continuation closed and factors

Proof. Induct on the derivation of $\mathsf{Cont}(h, k, r)$. The empty case gives r internally same as k, hence unary. The $\mathsf{E1}$-case preserves unary by the constructor rule. The $\mathsf{E0}$-case is incompatible with $\mathsf{Unary}(h)$ by unary no-zero-extension. □

Theorem 9194.5 (Unary append context middle equivalence)**.** *Let l, m, r : BHist. If l and r are unary histories, then unary membership of the two-sided append context is equivalent to unary membership of the middle history:*

$$\mathsf{Unary}(\mathsf{append}(l, \mathsf{append}(m, r))) \iff \mathsf{Unary}(m).$$

Proof. The forward direction applies unary append factor recovery twice: first recover the right factor of the outer append, then recover the left factor of the inner append. The reverse direction closes unary histories under append, first for the middle with the right context and then with the left context. □

Lean4 ✓ BEDC.FKernel.Unary.unary append context middle iff

Theorem 9194.6 (Unary continuation commutativity)**.** *If*

$$\mathsf{Unary}(h), \quad \mathsf{Unary}(k), \quad \mathsf{Cont}(h, k, r), \quad \mathsf{Cont}(k, h, r'),$$

then

$$\mathsf{hsame}(r, r').$$

Lean4 ✓ BEDC.FKernel.Unary.unary cont comm
↪ variant BEDC.FKernel.Unary.unary cont comm from append comm
↪ variant BEDC.FKernel.Unary.unary cont comm obligation holds
↪ variant BEDC.FKernel.Unary.unary append comm hsame
↪ variant BEDC.FKernel.Unary.unary append comm with closed results
↪ variant BEDC.FKernel.Unary.unary append comm three
↪ variant BEDC.FKernel.Unary.unaryCont comm and results closed

```
↪ variant  BEDC.FKernel.Unary.unaryCont comm closed symmetric pair
↪ variant  BEDC.FKernel.Unary.unaryCont comm sameness pair
↪ variant  BEDC.FKernel.Unary.unary cont comm symmetric pair
↪ variant  BEDC.FKernel.Unary.unary append comm right induction
↪ variant  BEDC.FKernel.Unary.unary append comm hsame left induction closed pair
```

Proof. Proceed by induction on the unary derivation of h.

If $h = \mathsf{e}$, then $\mathsf{Cont}(\mathsf{e}, k, r)$ gives $\mathsf{hsame}(r, k)$, while $\mathsf{Cont}(k, \mathsf{e}, r')$ gives $\mathsf{hsame}(r', k)$ by the right-unit theorem for continuation. Thus $\mathsf{hsame}(r, r')$.

For the step case, write $h = \mathsf{E1}(h_0)$ with $\mathsf{Unary}(h_0)$. From $\mathsf{Cont}(\mathsf{E1}(h_0), k, r)$, inversion yields a result u such that $\mathsf{Cont}(h_0, k, u)$ and $\mathsf{hsame}(r, \mathsf{E1}(u))$. The other branch $\mathsf{Cont}(k, \mathsf{E1}(h_0), r')$ is shown, by induction on the unary derivation of k, to be internally same as $\mathsf{E1}(v)$, where $\mathsf{Cont}(k, h_0, v)$. Applying the outer induction hypothesis to h_0, k gives $\mathsf{hsame}(u, v)$, hence $\mathsf{hsame}(\mathsf{E1}(u), \mathsf{E1}(v))$, and therefore $\mathsf{hsame}(r, r')$.

This proof uses only unary constructors, continuation inversion, and history-sameness congruence under $\mathsf{E1}$. □

Corollary 9194.7 (Upgrade of the additive naming certificate)**.** *The certificate for* $\mathsf{Add}^{\uparrow}$ *is upgraded from a unary continuation monoid-like certificate to a commutative unary additive certificate once Theorem 9194.6 is included among its stability fields.*

```
Lean4 ✓  BEDC.FKernel.Unary.add up commutative license
↪ variant  BEDC.FKernel.Unary.add up commutative certificate upgrade
↪ variant  BEDC.FKernel.Unary.upgrade additive naming certificate
↪ variant  BEDC.FKernel.Unary.additive certificate upgrade
```

Proof. The certificate already contains unit, associativity, determinacy, closure, and composite ledger policy. Theorem 9194.6 supplies commutativity up to internal history-sameness. □

Remark 9194.8 (Naming boundary)**.** *Without Theorem 9194.6, the conservative public name is* $\mathsf{UnaryContMonoid}^{\uparrow}$*. With it, the name* $\mathsf{Add}^{\uparrow}$ *is licensed as a commutative unary addition-like interface.*

Part VII

Proof Obligations

Chapter 9195

Domain Policy and Unary Instance

9195.1 Domain Policy and Transport Obligations

This chapter records the internal domain judgment $\mathsf{InDom}(D, h)$ and the transport obligation needed for domain behavior.

Definition 9195.1 (Domain policy)**.** *A source-domain name D is equipped with a domain policy, written*

$$\mathsf{DomainPolicy}(D),$$

when the following BEDC-level transport behavior is supplied: if $\mathsf{InDom}(D, h)$ *and* $\mathsf{hsame}(h, k)$*, then* $\mathsf{InDom}(D, k)$*.*

Lean4 ✓ `BEDC.FKernel.Gap.DomainPolicy transport field`

↪ variant `BEDC.FKernel.Gap.DomainPolicy iff transport and invariance`

The carrier D and judgment $\mathsf{InDom}(D, h)$ are supplied by the domain setup. Concrete gap statements use $\mathsf{InDom}(D, h)$ as their source-admission premise rather than imported set-membership notation.

Theorem 9195.2 (Domain transport)**.** *Assume* $\mathsf{DomainPolicy}(D)$*. If*

$$\mathsf{InDom}(D, h) \quad \textit{and} \quad \mathsf{hsame}(h, k),$$

then

$$\mathsf{InDom}(D, k).$$

Lean4 ✓ `BEDC.FKernel.Gap.domain transport`

↪ variant `BEDC.FKernel.Gap.domain transport refl`

↪ variant `BEDC.FKernel.Gap.domain policy transport witnesses`

↪ variant `BEDC.FKernel.Gap.DomainPolicy iff transport`

↪ variant `BEDC.FKernel.Gap.domain transport symmetric`

↪ variant `BEDC.FKernel.Gap.domain transport transitive`

↪ variant `BEDC.FKernel.Gap.domain transport three step chain`

↪ variant `BEDC.FKernel.Gap.domain transport four step chain`

↪ variant `BEDC.FKernel.Gap.domain transport backward chain`

Proof. This is the transport field of $\mathsf{DomainPolicy}(D)$. The theorem is recorded separately because later gap arguments must cite it explicitly rather than silently treating D as a set. □

Corollary 9195.3 (Domain invariance of concrete source admission)**.** *Under* $\mathsf{DomainPolicy}(D)$*, if* $\mathsf{hsame}(h, k)$*, then*

$$\mathsf{InDom}(D, h) \iff \mathsf{InDom}(D, k).$$

Lean4 ✓ `BEDC.FKernel.Gap.domain invariance of concrete source admission`

↪ variant `BEDC.FKernel.Gap.domain invariance`
↪ variant `BEDC.FKernel.Gap.DomainPolicy transport and invariance`
↪ variant `BEDC.FKernel.Gap.inGapSig domain transport with signature`
↪ variant `BEDC.FKernel.Gap.inGapSig domain transport source`
↪ variant `BEDC.FKernel.Gap.inGapSig transport existing signature witness`
↪ variant `BEDC.FKernel.Gap.inGapSig transport iff with signature witnesses`
↪ variant `BEDC.FKernel.Gap.inGapSig domain transport equiv with witnesses`
↪ variant `BEDC.FKernel.Gap.domain transport two way chain`

Proof. Immediate from Theorem 9195.2 in both directions, using symmetry of hsame for the reverse direction. The other parts of a concrete gap, namely signature generation and token introduction, require their own policies and are not bundled into domain transport. □

Corollary 9195.4 (Three-history domain transport equivalence)**.** *Under* $\mathsf{DomainPolicy}(D)$*, if* $\mathsf{hsame}(h, k)$ *and* $\mathsf{hsame}(k, l)$*, then*

$$\mathsf{InDom}(D, h) \iff \mathsf{InDom}(D, l).$$

Lean4 ✓ `BEDC.FKernel.Gap.domain transport three way equiv`

Proof. Apply Theorem 9195.2 along $\mathsf{hsame}(h, k)$ and then along $\mathsf{hsame}(k, l)$ for the forward direction. For the reverse direction, use symmetry of the same two history-sameness premises in the opposite order. □

Remark 9195.5 (Active reading)**.** *Active concrete gap statements use* $\mathsf{InDom}(D, h)$*, not* $h \in D$*. What is not automatic is any claim that an arbitrary domain name satisfies* $\mathsf{DomainPolicy}(D)$*. That must be supplied for each concrete domain.*

9195.2 Concrete Domain Policy for the Unary Source

section 9195.1 introduces $\mathsf{DomainPolicy}(D)$ as the condition allowing $\mathsf{InDom}(D, h)$ to be transported along internal history-sameness. This section records the unary source instance.

Definition 9195.6 (Unary source domain)**.** *Let* $\mathsf{UnarySource}$ *be the source-domain name whose internal domain judgment is*

$$\mathsf{InDom}(\mathsf{UnarySource}, h) \quad \textit{exactly when} \quad \mathsf{Unary}(h).$$

This is not a set-membership statement. It is a domain judgment licensed by the unary-generation rules.

Lean4 ✓ `BEDC.FKernel.Unary.unaryDomain inDom iff unaryHistory`

Lemma 9195.7 (Unary is transported by history-sameness)**.** *If*

$$\mathsf{Unary}(h), \qquad \mathsf{hsame}(h, k),$$

then

$$\mathsf{Unary}(k).$$

Lean4 ✓ `BEDC.FKernel.Unary.unary transport`
↪ variant `BEDC.FKernel.Unary.unary transport symm`
↪ variant `BEDC.FKernel.Unary.unary history hsame iff`

Proof. Proceed by induction on the derivation of $\mathsf{Unary}(h)$.

For the empty case, h is internally the empty history. Since $\mathsf{hsame}(h, k)$, closed generation and no-confusion for hsame force k to be internally the empty history. Hence $\mathsf{Unary}(k)$.

For the step case, the unary derivation has the form $\mathsf{Unary}(h_0) \Rightarrow \mathsf{Unary}(\mathsf{E1}(h_0))$. From $\mathsf{hsame}(\mathsf{E1}(h_0), k)$, constructor inversion for hsame yields a history k_0 such that k is internally $\mathsf{E1}(k_0)$ and $\mathsf{hsame}(h_0, k_0)$. By the induction hypothesis, $\mathsf{Unary}(k_0)$. Therefore $\mathsf{Unary}(\mathsf{E1}(k_0))$, and by internal sameness this is the required unary judgment for k. □

Theorem 9195.8 (Unary source satisfies DomainPolicy)**.**

$$\mathsf{DomainPolicy}(\mathsf{UnarySource}).$$

Lean4 ✓ `BEDC.FKernel.Unary.unary domain policy`

Proof. Assume $\mathsf{InDom}(\mathsf{UnarySource}, h)$ and $\mathsf{hsame}(h, k)$. By definition of $\mathsf{UnarySource}$, the first premise is $\mathsf{Unary}(h)$. Lemma 9195.7 gives $\mathsf{Unary}(k)$, hence $\mathsf{InDom}(\mathsf{UnarySource}, k)$. □

Corollary 9195.9 (Unary-domain gaps may transport sources)**.** *Any concrete gap theorem whose source domain is* $\mathsf{UnarySource}$ *may use domain transport along* hsame*, provided no additional source-domain restriction is imposed.*

Lean4 ✓ `BEDC.FKernel.Unary.unary domain gap transport`

Proof. Immediate from Theorem 9195.8 and Lemma 9195.2. □

Definition 9195.10 (Binary Boolean compound domains)**.** *Given source-domain names D_0 and D_1, a conjunctive compound domain $D_\wedge$ and a disjunctive compound domain $D_\vee$ are BEDC domain names whose internal admission judgments are defined by*

$$\mathsf{InDom}(D_\wedge, h) \iff \big(\mathsf{InDom}(D_0, h) \text{ and } \mathsf{InDom}(D_1, h)\big)$$

and

$$\mathsf{InDom}(D_\vee, h) \iff \big(\mathsf{InDom}(D_0, h) \text{ or } \mathsf{InDom}(D_1, h)\big).$$

These are compound source-domain names, not external set operations on histories.

Theorem 9195.11 (DomainPolicy is closed under binary Boolean compounds)**.** *Assume* $\mathsf{DomainPolicy}(D_0)$ *and* $\mathsf{DomainPolicy}(D_1)$*. Let $D_\wedge$ and $D_\vee$ be compound domains as in Definition 9195.10. Then*

$$\mathsf{DomainPolicy}(D_\wedge) \quad \text{and} \quad \mathsf{DomainPolicy}(D_\vee).$$

Proof. It is enough, by Definition 9195.1, to prove transport of the displayed admission judgments along hsame.

For $D_\wedge$, assume $\mathsf{InDom}(D_\wedge, h)$ and $\mathsf{hsame}(h, k)$. By the definition of $D_\wedge$, the admission premise gives both $\mathsf{InDom}(D_0, h)$ and $\mathsf{InDom}(D_1, h)$. Applying Definition 9195.2 to $\mathsf{DomainPolicy}(D_0)$ gives $\mathsf{InDom}(D_0, k)$, and applying Definition 9195.2 to $\mathsf{DomainPolicy}(D_1)$ gives $\mathsf{InDom}(D_1, k)$. The defining equivalence for $D_\wedge$ therefore gives $\mathsf{InDom}(D_\wedge, k)$.

For $D_\vee$, assume $\mathsf{InDom}(D_\vee, h)$ and $\mathsf{hsame}(h, k)$. By the definition of $D_\vee$, either $\mathsf{InDom}(D_0, h)$ or $\mathsf{InDom}(D_1, h)$. In the first case, Definition 9195.2 and $\mathsf{DomainPolicy}(D_0)$ give $\mathsf{InDom}(D_0, k)$, hence $\mathsf{InDom}(D_\vee, k)$. In the second case, Definition 9195.2 and $\mathsf{DomainPolicy}(D_1)$ give $\mathsf{InDom}(D_1, k)$, hence $\mathsf{InDom}(D_\vee, k)$. □

Corollary 9195.12 (Finite Boolean domain expressions preserve DomainPolicy)**.** *Every finite source-domain expression built from domain names satisfying* DomainPolicy *by repeated use of the conjunctive and disjunctive compound constructors of Definition 9195.10 also satisfies* DomainPolicy.

Proof. Induct on the construction of the finite expression. A leaf is one of the supplied domain names, so its policy is an assumption. At a conjunctive or disjunctive constructor, the induction hypotheses give DomainPolicy for the two immediate subexpressions, and Definition 9195.11 gives the policy for the compound expression. □

Chapter 9196

Package Token Policy, Uniqueness, and Reflection

9196.1 Package Token Policy and Reflection

This chapter replaces the function-like token notation $\mathsf{Tok}_\Pi(s)$ by the judgment $\mathsf{TokIntro}(\Pi, s, p)$ and records the proof interface governing introduced tokens.

Definition 9196.1 (Package token policy)**.** *For a probe bundle* Π*, a package token policy, written*

$$\mathsf{PackageTokenPolicy}(\Pi),$$

consists of the following clauses for the concrete signature-token instance.

1. ***Soundness.*** *If* $\mathsf{TokIntro}(\Pi, s, p)$*,* $\mathsf{TokIntro}(\Pi, t, q)$*, and* $\mathsf{hsame}(s, t)$*, then* $\mathsf{psame}(p, q)$*.*
2. ***Reflection.*** *If* $\mathsf{TokIntro}(\Pi, s, p)$*,* $\mathsf{TokIntro}(\Pi, t, q)$*, and* $\mathsf{psame}(p, q)$*, then* $\mathsf{hsame}(s, t)$*.*

```

Package-sameness closure on introduced tokens is a consequence of soundness and reflection, recorded by the checked closure theorem above. Token existence is a separate premise, written

$$\forall s,\ \exists p,\ \mathsf{TokIntro}(\Pi, s, p).$$

The rule that visible tokens are compared by psame rather than by imported equality is a token-comparison principle for theorem statements, not a field of $\mathsf{PackageTokenPolicy}(\Pi)$.

Theorem 9196.2 (Package tokens are signature-facing)**.** *Assume* PackageTokenPolicy(Π)*. If*

$$\mathsf{TokIntro}(\Pi, s, p), \quad \mathsf{TokIntro}(\Pi, t, q), \quad \mathsf{hsame}(s, t),$$

then

$$\mathsf{psame}(p, q).$$

Lean4 ✓ `BEDC.FKernel.Package.packageTokenPolicy signature facing`

Proof. This is the soundness field of the package token policy applied to the two token-introduction premises and the history-sameness premise. □

Theorem 9196.3 (Package-sameness is equivalent to signature-sameness)**.** *Assume* PackageTokenPolicy(Π)*. If*

$$\mathsf{TokIntro}(\Pi, s, p), \qquad \mathsf{TokIntro}(\Pi, t, q),$$

then

$$\mathsf{psame}(p, q) \iff \mathsf{hsame}(s, t).$$

Lean4 ✓ `BEDC.FKernel.Package.psame iff hsame`

↪ variant `BEDC.FKernel.Package.PackageTokenPolicy iff classifies introduced`
↪ variant `BEDC.FKernel.Package.PackageTokenPolicy sound complete`
↪ variant `BEDC.FKernel.Package.packageTokenPolicy classifies introduced signatures`
↪ variant `BEDC.FKernel.Package.packageTokenPolicy classification roundtrip`
↪ variant `BEDC.FKernel.Package.packageTokenPolicy classification roundtrip on introduced`

↪ variant `BEDC.FKernel.Package.packageTokenPolicy psame hsame equivalence fields`
↪ variant `BEDC.FKernel.Package.packageTokenPolicy classification iff symm on introduced`

Proof. The implication from right to left is the soundness clause of PackageTokenPolicy(Π). The implication from left to right is the reflection clause. No external token equality is used. □

Corollary 9196.4 (Concrete package completeness is policy-grounded)**.** *The completeness direction of the concrete signature Globalize instance holds only under* PackageTokenPolicy(Π)*. In particular, it is not a theorem for arbitrary package-sameness relations.*

Lean4 ✓ `BEDC.FKernel.Package.concrete package completeness policy grounded`

↪ variant `BEDC.FKernel.Package.package completeness reflection field`

Proof. Completeness requires recovering $\mathsf{hsame}(s, t)$ from $\mathsf{psame}(p, q)$. This is exactly the reflection field of PackageTokenPolicy(Π). □

Remark 9196.5 (Proof-obligation boundary)**.** *The token policy is deliberately narrow. It applies to the concrete signature-token package instance. Other package constructions must provide their own soundness and reflection certificates before they may inherit the same completeness theorem.*

9196.2 Inductive Package-Token Policy for Signature Packages

section 9196.1 introduces $\mathsf{PackageTokenPolicy}(\Pi)$. This section removes one remaining ambiguity: package-sameness for the concrete signature-token instance should be generated by one rule only. The one-constructor relation supplies soundness directly; reflection is supplied either by the active package-token policy or by a token-uniqueness theorem that derives the policy field.

Definition 9196.6 (Concrete signature-token introduction)**.** *For the concrete signature-token instance, the judgment*

$$\mathsf{TokIntro}(\Pi, s, p)$$

means that token p is introduced as a visible token for answer history s under probe bundle Π.

Lean4 ✓ `BEDC.FKernel.Package.SignatureTokenIntro nonempty pkg`

Definition 9196.7 (Inductive package-sameness for signature tokens)**.** *For the concrete signature-token instance, $\mathsf{psame}^{\mathrm{sig}}_{\Pi}(p, q)$ is generated only by the following rule:*

$$\frac{\mathsf{TokIntro}(\Pi, s, p) \qquad \mathsf{TokIntro}(\Pi, t, q) \qquad \mathsf{hsame}(s, t)}{\mathsf{psame}^{\mathrm{sig}}_{\Pi}(p, q)}.$$

No other package-sameness constructors are admitted for this concrete instance.

Lemma 9196.8 (Package-sameness soundness)**.** *If*

$$\mathsf{TokIntro}(\Pi, s, p), \quad \mathsf{TokIntro}(\Pi, t, q), \quad \mathsf{hsame}(s, t),$$

then

$$\mathsf{psame}^{\mathrm{sig}}_{\Pi}(p, q).$$

Lean4 ✓ `BEDC.FKernel.Package.signature package extensionality`
↪ variant `BEDC.FKernel.Package.signature package extensionality hsame`

Proof. This is the single constructor of $\mathsf{psame}^{\mathrm{sig}}_{\Pi}$. □

Lemma 9196.9 (Package-sameness reflection)**.** *Assume* $\mathsf{PackageTokenPolicy}(\Pi)$*. If*

$$\mathsf{TokIntro}(\Pi, s, p), \quad \mathsf{TokIntro}(\Pi, t, q), \quad \mathsf{psame}^{\mathrm{sig}}_{\Pi}(p, q),$$

then

$$\mathsf{hsame}(s, t).$$

Lean4 ✓ BEDC.FKernel.Package.psame reflect

Proof. Apply the reflection field of $\mathsf{PackageTokenPolicy}(\Pi)$ to the two token-introduction premises and the package-sameness premise. □

Theorem 9196.10 (Concrete PackageTokenPolicy)**.** *The concrete signature-token instance satisfies* $\mathsf{PackageTokenPolicy}(\Pi)$ *from the introduced-token reflection direction*

$$\mathsf{TokIntro}(\Pi, s, p), \quad \mathsf{TokIntro}(\Pi, t, q), \quad \mathsf{psame}^{\mathrm{sig}}_{\Pi}(p, q) \quad \Longrightarrow \quad \mathsf{hsame}(s, t).$$

Lean4 ✓ BEDC.FKernel.Package.concrete package token policy

Proof. The soundness field is Lemma 9196.8. The reflection field is the displayed introduced-token reflection direction. □

Corollary 9196.11 (Exact signature package)**.** *Assume* $\mathsf{TokUnique}(\Pi)$*. For the concrete signature-token instance,* $\mathsf{psame}^{\mathrm{sig}}_{\Pi}(p, q)$ *between introduced tokens is equivalent to internal sameness of the answer histories that introduced them.*

Lean4 ✓ BEDC.FKernel.Package.psame iff hsame under tok unique
↪ variant BEDC.FKernel.Package.psame hsame directions under tok unique
↪ variant BEDC.FKernel.Package.psame reflect under tok unique
↪ variant BEDC.FKernel.Package.exact signature package

Proof. The forward direction is package reflection derived from token-introduction uniqueness. The reverse direction is Lemma 9196.8. □

Remark 9196.12 (Implementation note)**.** *In a machine implementation, this chapter should be realized by defining package-sameness as an inductive relation with exactly one constructor and by supplying either an explicit reflection field or token-introduction uniqueness for the visible tokens.*

9196.3 Token-Introduction Uniqueness and Package Reflection

section 9196.2 makes concrete package-sameness a one-constructor relation. That is necessary but not sufficient for the strongest reflection theorem. If the same visible token can be introduced by two unrelated signatures, then package-sameness of tokens does not determine the signatures uniquely. This section isolates the missing requirement.

Definition 9196.13 (Token-introduction uniqueness)**.** *For a fixed generated probe bundle* Π*, define the token-introduction uniqueness obligation* $\mathsf{TokUnique}(\Pi)$ *as the following principle:*

$$\mathsf{TokIntro}(\Pi, s, p), \quad \mathsf{TokIntro}(\Pi, t, p) \quad \Longrightarrow \quad \mathsf{hsame}(s, t).$$

This is an internal uniqueness condition up to history-sameness. It is not host-level equality of tokens or signatures.

Lean4 ✓ BEDC.BaseReflection.TokUnique intro

Lean4 (definition) BEDC.FKernel.Package.TokUnique
Lean4 ✓ BEDC.FKernel.Package.TokUnique replacement
↪ variant BEDC.FKernel.Package.tokUnique replacement

Remark 9196.14 (Why this is needed)**.** *From a derivation of* $\mathsf{psame}^{\mathrm{sig}}_{\Pi}(p, q)$*, inversion yields some generated signatures* s_0, t_0 *introducing* p, q*, together with* $\mathsf{hsame}(s_0, t_0)$*. If the displayed premises use* s, t *instead, one still needs to compare* s *with* s_0 *and* t *with* t_0*. This is exactly the role of* $\mathsf{TokUnique}(\Pi)$*.*

Lemma 9196.15 (Token replacement)**.** *Assume* $\mathsf{TokUnique}(\Pi)$*. If*

$$\mathsf{TokIntro}(\Pi, s, p), \quad \mathsf{TokIntro}(\Pi, s_0, p),$$

then

$$\mathsf{hsame}(s, s_0).$$

Lean4 ✓ `BEDC.BaseReflection.TokUnique replacement self`
↪ variant `BEDC.BaseReflection.TokUnique replacement congr`

Proof. This is Definition 9196.13 applied to the two token-introduction judgments for the same token p. □

Lemma 9196.16 (Symmetric token replacement)**.** *Assume* $\mathsf{TokUnique}(\Pi)$ *and that* hsame *is symmetric. If*

$$\mathsf{TokIntro}(\Pi, s, p), \quad \mathsf{TokIntro}(\Pi, t, p),$$

then

$$\mathsf{hsame}(t, s).$$

Lean4 ✓ `BEDC.BaseReflection.TokUnique replacement symm`
↪ variant `BEDC.BaseReflection.TokUnique replacement trans`
↪ variant `BEDC.FKernel.Package.tokUnique replacement symm`

Proof. Token-introduction uniqueness gives $\mathsf{hsame}(s, t)$; symmetry of hsame gives $\mathsf{hsame}(t, s)$. □

Theorem 9196.17 (Concrete package reflection with token uniqueness)**.** *Assume* $\mathsf{TokUnique}(\Pi)$*. If*

$$\mathsf{TokIntro}(\Pi, s, p), \quad \mathsf{TokIntro}(\Pi, t, q), \quad \mathsf{psame}^{\mathrm{sig}}_{\Pi}(p, q),$$

then

$$\mathsf{hsame}(s, t).$$

Lean4 ✓ `BEDC.FKernel.Package.package reflection token unique`
↪ variant `BEDC.BaseReflection.PackageReflection token unique from inversion`
↪ variant `BEDC.FKernel.Package.psame two step reflect under tok unique`

Proof. Invert the derivation of $\mathsf{psame}^{\mathrm{sig}}_{\Pi}(p, q)$. Since the concrete signature-token package-sameness relation has only the constructor displayed in section 9196.2, the derivation supplies signatures s_0, t_0 such that

$$\mathsf{TokIntro}(\Pi, s_0, p), \quad \mathsf{TokIntro}(\Pi, t_0, q), \quad \mathsf{hsame}(s_0, t_0).$$

By Lemma 9196.15, the first token-introduction premise gives $\mathsf{hsame}(s, s_0)$, and the second gives $\mathsf{hsame}(t, t_0)$. Symmetry and transitivity of hsame now yield $\mathsf{hsame}(s, t)$. □

Corollary 9196.18 (Exact package-sameness under token uniqueness)**.** *Assume* $\mathsf{TokUnique}(\Pi)$*. For introduced tokens,*

$$\mathsf{psame}^{\mathrm{sig}}_{\Pi}(p, q)$$

if and only if their introducing signatures are internally history-same.

Lean4 ✓ BEDC.BaseReflection.exact package sameness
↪ variant BEDC.BaseReflection.PsameBase equivalence under tok unique
↪ variant BEDC.FKernel.Package.psame trans under tok unique
↪ variant BEDC.FKernel.Package.psame three step reflect under tok unique

Proof. The forward direction is Theorem 9196.17. The reverse direction is the single constructor of $\mathsf{psame}^{\mathrm{sig}}_{\Pi}$. □

Corollary 9196.19 (Introduced-token closure under package token policy)**.** *Assume* $\mathsf{PackageTokenPolicy}(\Pi)$*. For package tokens introduced by* Π*, the following three clauses hold:*

$$\mathsf{TokIntro}(\Pi, s, p) \Rightarrow \mathsf{psame}(p, p),$$

$$\mathsf{TokIntro}(\Pi, s, p),\ \mathsf{TokIntro}(\Pi, t, q),\ \mathsf{psame}(p, q) \Rightarrow \mathsf{psame}(q, p),$$

and

$$\mathsf{TokIntro}(\Pi, a, p),\ \mathsf{TokIntro}(\Pi, b, q),\ \mathsf{TokIntro}(\Pi, c, r),\ \mathsf{psame}(p, q),\ \mathsf{psame}(q, r) \Rightarrow \mathsf{psame}(p, r).$$

Lean4 ✓ BEDC.FKernel.Package.packageTokenPolicy psame equivalence on introduced

Proof. For reflexivity, apply package-token soundness to the same token-introduction premise on both sides, together with reflexivity of hsame. For symmetry, reflect $\mathsf{psame}(p, q)$ across the two token-introduction premises to obtain $\mathsf{hsame}(s, t)$, reverse it by symmetry of hsame, and apply package-token soundness to the reversed pair. For transitivity, reflect $\mathsf{psame}(p, q)$ along the first two token-introduction premises and $\mathsf{psame}(q, r)$ along the last two; compose the resulting $\mathsf{hsame}(a, b)$ and $\mathsf{hsame}(b, c)$ judgments, then apply package-token soundness to the first and last token-introduction premises. □

Theorem 9196.20 (PackageTokenPolicy from token uniqueness)**.** *Assume* $\mathsf{TokUnique}(\Pi)$*. For the concrete signature-token relation* $\mathsf{psame}^{\mathrm{sig}}_{\Pi}$*, the package token policy* $\mathsf{PackageTokenPolicy}(\Pi)$ *holds.*

Lean4 ✓ BEDC.FKernel.Package.packageTokenPolicy from tokUnique

Proof. The soundness field is the single constructor of $\mathsf{psame}^{\mathrm{sig}}_{\Pi}$. The reflection field is Theorem 9196.17. □

9196.4 Token-Uniqueness Modes

This section makes $\mathsf{TokUnique}(\Pi)$ explicit as an active policy field and separates two implementation modes for the same reflection contract.

Definition 9196.21 (Policy mode)**.** *In policy mode,* $\mathsf{TokUnique}(\Pi)$ *is a field of the concrete package-token policy:*

$$\mathsf{TokIntro}(\Pi, s, p), \quad \mathsf{TokIntro}(\Pi, t, p) \quad \Longrightarrow \quad \mathsf{hsame}(s, t).$$

Concrete Globalize exactness theorems may use this field as an assumption.

Lean4 (definition) BEDC.BaseReflection.PolicyTokenMode
Lean4 ✓ BEDC.BaseReflection.PolicyTokenMode iff TokUnique
↪ variant BEDC.BaseReflection.PolicyTokenMode tokenReplacement
↪ variant BEDC.BaseReflection.PolicyTokenMode replacement pair

Definition 9196.22 (Canonical-constructor mode)**.** *In canonical-constructor mode, token introduction is implemented by a canonical token constructor, written schematically as*

$$\mathsf{TokCan}(\Pi, s, p).$$

The implementation must provide the no-confusion rule

$$\mathsf{TokCan}(\Pi, s, p), \quad \mathsf{TokCan}(\Pi, t, p) \quad \Longrightarrow \quad \mathsf{hsame}(s, t).$$

If TokIntro *is defined by* TokCan*, then* TokUnique(Π) *follows.*

Lean4 (definition) `BEDC.BaseReflection.CanonicalTokenMode`

Lemma 9196.23 (Canonical mode implies token uniqueness)**.** *Assume* $\mathsf{TokIntro}(\Pi, s, p)$ *is definitionally implemented by* $\mathsf{TokCan}(\Pi, s, p)$*, and assume the no-confusion rule of Definition 9196.22. Then* TokUnique(Π) *holds.*

Proof. Given $\mathsf{TokIntro}(\Pi, s, p)$ and $\mathsf{TokIntro}(\Pi, t, p)$, unfold the implementation to obtain $\mathsf{TokCan}(\Pi, s, p)$ and $\mathsf{TokCan}(\Pi, t, p)$. The no-confusion rule gives $\mathsf{hsame}(s, t)$, which is exactly TokUnique(Π). □

Lean4 ✓ `BEDC.BaseReflection.CanonicalTokenMode implies TokUnique`
- ↪ variant `BEDC.BaseReflection.canonical implies unique`
- ↪ variant `BEDC.BaseReflection.CanonicalTokenMode to PolicyTokenMode`
- ↪ variant `BEDC.BaseReflection.CanonicalTokenMode tokenReplacement`

- ↪ variant `BEDC.BaseReflection.CanonicalTokenMode witness pair`
- ↪ variant `BEDC.BaseReflection.CanonicalTokenMode witness pair symm`
- ↪ variant `BEDC.BaseReflection.CanonicalTokenMode unique and policy pair`

Principle 9196.24 (Active mode)**.** *Paper theorems express the assumption as* TokUnique(Π) *(policy mode). Canonical-constructor mode is an alternative carrier that derives* TokUnique(Π) *from a constructor no-confusion rule.*

- ↪ variant `BEDC.BaseReflection.CanonicalTokenMode implies TokUnique`

Corollary 9196.25 (Stable package reflection contract)**.** *The package reflection theorem may be used later only in one of two forms:*

1. *base-relation reflection under* TokUnique(Π)*;*
2. *base-relation reflection under a checked canonical-constructor theorem implying* TokUnique(Π)*.*

It may be used for $\mathsf{psame}^{\mathrm{eq}}_{\Pi}$ *only through the checked closure-reflection theorem of Proposition 9198.15; the exact Globalize export remains the base relation.*

Lean4 ✓ `BEDC.BaseReflection.StableReflectionContract from canonical`

Proof. The first form is Theorem 9198.5. The second form follows from Lemma 9196.23. The final exclusion is Corollary 9198.6. □

Lean4 ✓ `BEDC.BaseReflection.PackageReflection base from canonical`
- ↪ variant `BEDC.BaseReflection.StableReflectionContract`

Theorem 9196.26 (Concrete token reflection duality)**.** *Assume canonical-constructor mode for* Π*: for every answer history* u *and package token* r*, the term-level predicate* $\mathsf{TokCan}(\Pi, u, r)$ *implements* $\mathsf{TokIntro}(\Pi, u, r)$*, and the no-confusion rule of Definition 9196.22 holds. If*

$$\mathsf{TokIntro}(\Pi, s, p), \quad \mathsf{TokIntro}(\Pi, t, q),$$

then

$$\mathsf{psame}^{\mathrm{sig}}_{\Pi}(p, q) \quad \Longleftrightarrow \quad \mathsf{hsame}(s, t).$$

The same equivalence holds with $\mathsf{psame}^{\mathrm{base}}_{\Pi}$ *in place of* $\mathsf{psame}^{\mathrm{sig}}_{\Pi}$ *under the identification in Definition 9198.1.*

Proof. By Definition 9196.23, the concrete canonical implementation and its no-confusion rule give $\mathsf{TokUnique}(\Pi)$. For the forward implication, apply Definition 9196.17 to this token-uniqueness witness, the two displayed token-introduction premises, and $\mathsf{psame}^{\mathrm{sig}}_{\Pi}(p, q)$. For the reverse implication, apply Definition 9196.8 to the same token-introduction premises and the assumed $\mathsf{hsame}(s, t)$. The formulation with $\mathsf{psame}^{\mathrm{base}}_{\Pi}$ follows from its identification with $\mathsf{psame}^{\mathrm{sig}}_{\Pi}$ in Definition 9198.1. No use is made of $\mathsf{PackageTokenPolicy}(\Pi)$. □

Theorem 9196.27 (Signature append residual exactness under known token component)**.** *Assume* $\mathsf{BundleAskPolicy}(\Pi, D)$*,* $\mathsf{BundleAskPolicy}(\Theta, D)$*,* $\mathsf{PackagePolicy}(\mathsf{BAppend}(\Pi, \Theta))$*,* $\mathsf{PackageTokenPolicy}(\mathsf{BAppend}(\Pi, \Theta$ *and* $\mathsf{PackageTokenPolicy}(\Pi)$*. Let* h *and* k *be source histories with*

$$\mathsf{InDom}(D, h), \qquad \mathsf{InDom}(D, k).$$

Suppose the appended interface has generated signatures and introduced package tokens

$$\mathsf{Sig}(\mathsf{BAppend}(\Pi, \Theta), h, a, \Lambda_h), \qquad \mathsf{Sig}(\mathsf{BAppend}(\Pi, \Theta), k, b, \Lambda_k),$$

$$\mathsf{TokIntro}(\mathsf{BAppend}(\Pi, \Theta), a, P_h), \qquad \mathsf{TokIntro}(\mathsf{BAppend}(\Pi, \Theta), b, P_k), \qquad \mathsf{psame}_{\mathsf{BAppend}(\Pi,\Theta)}(P_h, P_k).$$

Suppose also that the known Π *component has generated signatures and introduced package tokens*

$$\mathsf{Sig}(\Pi, h, s, \Delta_h), \qquad \mathsf{Sig}(\Pi, k, t, \Delta_k),$$

$$\mathsf{TokIntro}(\Pi, s, p_h), \qquad \mathsf{TokIntro}(\Pi, t, p_k), \qquad \mathsf{psame}_{\Pi}(p_h, p_k).$$

Then

$$\mathsf{sameSig}_{\Theta}(h, k).$$

Proof. The public package policy supplies the appended package interface in which the displayed package tokens live. The comparison facts used below are the introduced-token reflection clauses of $\mathsf{PackageTokenPolicy}$ from Definition 9196.1.

By Definition 9196.3 for $\mathsf{BAppend}(\Pi, \Theta)$, the appended token-introduction premises and the appended package-sameness premise give $\mathsf{hsame}(a, b)$. The two appended signature judgments and this result sameness form $\mathsf{sameSig}_{\mathsf{BAppend}(\Pi,\Theta)}(h, k)$ by Definition 6.75.

Applying Definition 9196.3 again for Π to the component token-introduction premises and the Π package-sameness premise gives $\mathsf{hsame}(s, t)$, hence $\mathsf{sameSig}_{\Pi}(h, k)$.

The first residual equivalence in Definition 6.57 applies with the bundle-local policy on Π, the two domain witnesses, and the known Π signature-sameness. Its forward direction sends $\mathsf{sameSig}_{\mathsf{BAppend}(\Pi,\Theta)}(h, k)$ to $\mathsf{sameSig}_{\Theta}(h, k)$. □

Theorem 9196.28 (Signature append residual exactness under known right token component)**.** *Assume* $\mathsf{BundleAskPolicy}(\Pi, D)$*,* $\mathsf{BundleAskPolicy}(\Theta, D)$*,* $\mathsf{PackagePolicy}(\mathsf{BAppend}(\Pi, \Theta))$*,* $\mathsf{PackageTokenPolicy}(\mathsf{BApp}$ *and* $\mathsf{PackageTokenPolicy}(\Theta)$*. Let* h *and* k *be source histories with*

$$\mathsf{InDom}(D, h), \qquad \mathsf{InDom}(D, k).$$

Suppose the appended interface has generated signatures and introduced package tokens

$$\mathsf{Sig}(\mathsf{BAppend}(\Pi, \Theta), h, a, \Lambda_h), \qquad \mathsf{Sig}(\mathsf{BAppend}(\Pi, \Theta), k, b, \Lambda_k),$$

$$\mathsf{TokIntro}(\mathsf{BAppend}(\Pi, \Theta), a, P_h), \qquad \mathsf{TokIntro}(\mathsf{BAppend}(\Pi, \Theta), b, P_k), \qquad \mathsf{psame}_{\mathsf{BAppend}(\Pi,\Theta)}(P_h, P_k).$$

Suppose also that the known Θ *component has generated signatures and introduced package tokens*

$$\mathsf{Sig}(\Theta, h, u, \Gamma_h), \qquad \mathsf{Sig}(\Theta, k, v, \Gamma_k),$$

$$\mathsf{TokIntro}(\Theta, u, q_h), \qquad \mathsf{TokIntro}(\Theta, v, q_k), \qquad \mathsf{psame}_{\Theta}(q_h, q_k).$$

Then

$$\mathsf{sameSig}_{\Pi}(h, k).$$

Proof. The displayed token-introduction judgments place the appended tokens in the package-token interface for $\mathsf{BAppend}(\Pi, \Theta)$ and the component tokens in the package-token interface for Θ. The comparison step uses the introduced-token reflection direction of $\mathsf{PackageTokenPolicy}$ from Definition 9196.1.

By Definition 9196.3 for $\mathsf{BAppend}(\Pi, \Theta)$, the appended token-introduction premises and the appended package-sameness premise give $\mathsf{hsame}(a, b)$. Together with the two appended signature judgments, this is exactly a witness for $\mathsf{sameSig}_{\mathsf{BAppend}(\Pi,\Theta)}(h, k)$ by Definition 6.75.

Applying Definition 9196.3 for Θ to the component token-introduction premises and the Θ package-sameness premise gives $\mathsf{hsame}(u, v)$. The two Θ signature judgments therefore witness $\mathsf{sameSig}_{\Theta}(h, k)$.

The second residual equivalence in Definition 6.57 applies with the bundle-local policy on Θ, the two domain witnesses, and the known Θ signature-sameness. Its forward direction sends $\mathsf{sameSig}_{\mathsf{BAppend}(\Pi,\Theta)}(h, k)$ to $\mathsf{sameSig}_{\Pi}(h, k)$. □

Theorem 9196.29 (PackageTokenPolicy reflects token uniqueness)**.** *Assume* $\mathsf{PackageTokenPolicy}(\Pi)$*. For the concrete signature-token relation* $\mathsf{psame}^{\mathrm{sig}}_{\Pi}$*, token-introduction uniqueness holds:*

$$\mathsf{TokIntro}(\Pi, s, p), \quad \mathsf{TokIntro}(\Pi, t, p) \quad \Longrightarrow \quad \mathsf{hsame}(s, t).$$

Equivalently, $\mathsf{TokUnique}(\Pi)$ *holds for the visible tokens introduced by* Π*.*

Proof. Let $\mathsf{TokIntro}(\Pi, s, p)$ and $\mathsf{TokIntro}(\Pi, t, p)$ be given. Since hsame is reflexive, the first token-introduction premise can be compared with itself:

$$\mathsf{TokIntro}(\Pi, s, p), \quad \mathsf{TokIntro}(\Pi, s, p), \quad \mathsf{hsame}(s, s).$$

The soundness clause of $\mathsf{PackageTokenPolicy}(\Pi)$ from Definition 9196.1, applied in the concrete signature-token instance of Definition 9196.7, gives

$$\mathsf{psame}^{\mathrm{sig}}_{\Pi}(p, p).$$

Now apply the reflection clause of $\mathsf{PackageTokenPolicy}(\Pi)$ to the two original token-introduction premises

$$\mathsf{TokIntro}(\Pi, s, p), \quad \mathsf{TokIntro}(\Pi, t, p)$$

and to this package-sameness fact $\mathsf{psame}^{\mathrm{sig}}_{\Pi}(p, p)$. The conclusion is $\mathsf{hsame}(s, t)$, which is exactly the obligation named $\mathsf{TokUnique}(\Pi)$ in Definition 9196.13. □

Corollary 9196.30 (Concrete PackageTokenPolicy and token uniqueness are equivalent)**.** *For the concrete signature-token relation* $\mathsf{psame}^{\mathrm{sig}}_{\Pi}$*,*

$$\mathsf{PackageTokenPolicy}(\Pi) \iff \mathsf{TokUnique}(\Pi).$$

Proof. The forward implication is Definition 9196.29. The reverse implication is Definition 9196.20: token-introduction uniqueness supplies the reflection field, and the single constructor of the concrete signature-token relation supplies the soundness field. □

Proposition 9196.31 (Empty introduction separates package-token policy from token existence)**.** *Assume that no package token is introduced by* Π*:*

$$\forall s, p,\ \neg\, \mathsf{TokIntro}(\Pi, s, p).$$

Then $\mathsf{PackageTokenPolicy}(\Pi)$ *holds, but package-wide token totality fails:*

$$\neg\Big(\forall s,\ \exists p,\ \mathsf{TokIntro}(\Pi, s, p)\Big).$$

Thus the soundness and reflection clauses of $\mathsf{PackageTokenPolicy}(\Pi)$ *have no token-existence consequence.*

Proof. Let E denote the displayed no-introduction hypothesis. We first verify the two fields in Definition 9196.1. For soundness, suppose

$$\mathsf{TokIntro}(\Pi, s, p), \quad \mathsf{TokIntro}(\Pi, t, q), \quad \mathsf{hsame}(s, t).$$

The first token-introduction premise contradicts E at s, p, so the required conclusion $\mathsf{psame}(p, q)$ follows by contradiction elimination. For reflection, suppose

$$\mathsf{TokIntro}(\Pi, s, p), \quad \mathsf{TokIntro}(\Pi, t, q), \quad \mathsf{psame}(p, q).$$

Again the first token-introduction premise contradicts E at s, p, so the required conclusion $\mathsf{hsame}(s, t)$ follows by contradiction elimination. These are exactly the soundness and reflection clauses of $\mathsf{PackageTokenPolicy}(\Pi)$.

It remains to show that token totality fails. If

$$\forall s,\ \exists p,\ \mathsf{TokIntro}(\Pi, s, p)$$

held, then instantiating it at the empty history e would give a token p with $\mathsf{TokIntro}(\Pi, \mathsf{e}, p)$. This contradicts E at e, p. Hence

$$\neg\Big(\forall s,\ \exists p,\ \mathsf{TokIntro}(\Pi, s, p)\Big).$$

The policy fields therefore classify pairs of already introduced tokens only; they do not manufacture an introduced token for any history. □

Chapter 9197

Gap Policy

9197.1 Consolidated Signature Gap Policy

This chapter restates the concrete signature gap and records the exact assumptions needed for coverage, separation, soundness, and completeness.

Definition 9197.1 (Policy-supported signature gap)**.** *For a probe bundle* Π*, source domain* D*, package* p*, and history* h*, define*

$$\mathsf{InGap}^{\mathrm{sig}}(\Pi, D, p, h)$$

when there exist an answer history s *and an evidence ledger* Δ *such that*

$$\mathsf{InDom}(D, h), \qquad \mathsf{Sig}(\Pi, h, s, \Delta), \qquad \mathsf{TokIntro}(\Pi, s, p).$$

Theorem 9197.2 (Policy-supported gap coverage)**.** *Assume* $\mathsf{AskPolicy}(\Pi, D)$ *and*

$$\forall s,\ \exists p,\ \mathsf{TokIntro}(\Pi, s, p).$$

If

$$\mathsf{InDom}(D, h),$$

then there exists a token p *such that*

$$\mathsf{InGap}^{\mathrm{sig}}(\Pi, D, p, h).$$

Lean4 ✓ `BEDC.FKernel.Gap.policy gap coverage`
↪ variant `BEDC.FKernel.Gap.gap coverage policy`

Proof. From $\mathsf{AskPolicy}(\Pi, D)$ and $\mathsf{InDom}(D, h)$, obtain a generated signature event $\mathsf{Sig}(\Pi, h, s, \Delta)$. From the explicit token-existence premise, obtain p with $\mathsf{TokIntro}(\Pi, s, p)$. These data witness $\mathsf{InGap}^{\mathrm{sig}}(\Pi, D, p, h)$. □

Theorem 9197.3 (Policy-supported gap separation)**.** *Assume* $\mathsf{AskPolicy}(\Pi, D)$ *and* $\mathsf{PackageTokenPolicy}(\Pi)$*. If*

$$\mathsf{InGap}^{\mathrm{sig}}(\Pi, D, p, h) \quad \textit{and} \quad \mathsf{InGap}^{\mathrm{sig}}(\Pi, D, q, h),$$

then

$$\mathsf{psame}(p, q).$$

Lean4 ✓ `BEDC.FKernel.Gap.policy gap separation`

↪ variant `BEDC.FKernel.Gap.gapPolicy separation field`
↪ variant `BEDC.FKernel.Gap.gapPolicy separation packed`
↪ variant `BEDC.FKernel.Gap.policy gap separation signature token witnesses`

Proof. Unpack both gap memberships. We obtain the admitted-source witness $\mathsf{InDom}(D, h)$, signatures s, t, and evidence ledgers Δ, Θ such that

$$\mathsf{Sig}(\Pi, h, s, \Delta), \qquad \mathsf{TokIntro}(\Pi, s, p),$$

$$\mathsf{Sig}(\Pi, h, t, \Theta), \qquad \mathsf{TokIntro}(\Pi, t, q).$$

Theorem 6.67, applied to $\mathsf{AskPolicy}(\Pi, D)$, the admitted-source witness, and the two generated signatures, gives $\mathsf{hsame}(s, t)$. Package soundness in $\mathsf{PackageTokenPolicy}(\Pi)$ then gives $\mathsf{psame}(p, q)$. □

Theorem 9197.4 (Token-level Globalize exactness)**.** *Assume* $\mathsf{PackageTokenPolicy}(\Pi)$*,* $\mathsf{TokIntro}(\Pi, s, p)$*, and* $\mathsf{TokIntro}(\Pi, t, q)$*. Then* $\mathsf{psame}(p, q) \iff \mathsf{hsame}(s, t)$*.*

Lean4 ✓ `BEDC.FKernel.Gap.policy globalize exact`

Proof. This is Theorem 9196.3. □

Corollary 9197.5 (Active reading)**.** *The concrete signature Globalize instance is presented only as a policy-supported construction. Its exactness depends on* $\mathsf{DomainPolicy}(D)$*,* $\mathsf{AskPolicy}(\Pi, D)$*, and* $\mathsf{PackageTokenPolicy}(\Pi)$*.*

Lean4 ✓ `BEDC.FKernel.Gap.active reading policy dependencies`

↪ variant `BEDC.FKernel.Gap.active reading policy dependency fields`

Definition 9197.6 (Classifier-preserving pullback ledger)**.** *Let* D' *and* D *be source-domain names and let* τ *be a BEDC history operation written* $\tau : D' \to D$*. A classifier-preserving pullback ledger for* τ *over* Π *consists of a pulled-back membership predicate* $\mathsf{InGap}^{\mathrm{sig}^{\tau}}(\Pi, D', D, p, h')$ *with the following clauses:*

1. *source preservation: for every* h'*,*

$$\mathsf{InDom}(D', h') \Longrightarrow \mathsf{InDom}(D, \tau(h'));$$

2. ledger classifier preservation: for every visible package token p and source h',

$$\mathsf{InGap}^{\mathrm{sig}^\tau}(\Pi, D', D, p, h') \iff \mathsf{InDom}(D', h') \text{ and } \mathsf{InGap}^{\mathrm{sig}}(\Pi, D, p, \tau(h')).$$

The classifier in the second clause is the package-gap ledger classifier in the sense of Definition 9.6: the visible token p remains a token of the original bundle Π, and the pullback changes the source coordinate.

Theorem 9197.7 (Package-token pullback separation)**.** *Assume* $\mathsf{PackagePolicy}(\Pi)$ *and* $\mathsf{GapPolicy}(\Pi, D)$*. Let $\tau : D' \to D$ be equipped with a classifier-preserving pullback ledger over Π. If two pulled-back gap ledgers meet on the same D'-source,*

$$\mathsf{InGap}^{\mathrm{sig}^\tau}(\Pi, D', D, p, h') \quad \text{and} \quad \mathsf{InGap}^{\mathrm{sig}^\tau}(\Pi, D', D, q, h'),$$

then the visible package tokens are package-same in the original package interface of Π:

$$\mathsf{psame}(p, q).$$

Proof. Unpack the two pulled-back memberships by the ledger classifier preservation clause of Definition 9197.6. They give original ledger memberships

$$\mathsf{InGap}^{\mathrm{sig}}(\Pi, D, p, \tau(h')) \quad \text{and} \quad \mathsf{InGap}^{\mathrm{sig}}(\Pi, D, q, \tau(h')).$$

These two memberships lie over the same target-domain source $\tau(h')$. Applying Definition 8.5 to $\mathsf{GapPolicy}(\Pi, D)$ and the displayed memberships gives $\mathsf{psame}(p, q)$. The $\mathsf{PackagePolicy}(\Pi)$ premise fixes the package-token interface whose visible tokens are compared; the pullback introduces no separate comparison relation. □

Theorem 9197.8 (Pulled-back gap policy preserves coverage and separation)**.** *Assume* $\mathsf{GapPolicy}(\Pi, D)$*. Let $\tau : D' \to D$ be equipped with the source preservation and ledger classifier preservation clauses of Definition 9197.6. Then the pulled-back membership predicate* $\mathsf{InGap}^{\mathrm{sig}^\tau}(\Pi, D', D, p, h')$ *satisfies the coverage and separation obligations over D':*

1. for every source history h',

$$\mathsf{InDom}(D', h') \Longrightarrow \exists p,\ \mathsf{InGap}^{\mathrm{sig}^\tau}(\Pi, D', D, p, h');$$

2. for every source history h' and visible package tokens p, q,

$$\mathsf{InGap}^{\mathrm{sig}^\tau}(\Pi, D', D, p, h') \Longrightarrow \mathsf{InGap}^{\mathrm{sig}^\tau}(\Pi, D', D, q, h') \Longrightarrow \mathsf{psame}(p, q).$$

Lean4 ✓ `BEDC.FKernel.Gap.PulledBackGapPolicy coverage separation`

Proof. For coverage, fix h' and assume $\mathsf{InDom}(D', h')$. The source preservation clause of Definition 9197.6 gives $\mathsf{InDom}(D, \tau(h'))$. The coverage field of $\mathsf{GapPolicy}(\Pi, D)$ in Definition 8.2 supplies a visible package token p with

$$\mathsf{InGap}^{\mathrm{sig}}(\Pi, D, p, \tau(h')).$$

Using the reverse direction of the ledger classifier preservation clause with $\mathsf{InDom}(D', h')$ and this original membership gives

$$\mathsf{InGap}^{\mathrm{sig}^\tau}(\Pi, D', D, p, h'),$$

which proves pulled-back coverage.

For separation, fix h', p, and q, and assume

$$\mathsf{InGap}^{\mathrm{sig}^{\tau}}(\Pi, D', D, p, h') \quad \text{and} \quad \mathsf{InGap}^{\mathrm{sig}^{\tau}}(\Pi, D', D, q, h').$$

The forward direction of the ledger classifier preservation clause gives original gap memberships

$$\mathsf{InGap}^{\mathrm{sig}}(\Pi, D, p, \tau(h')) \quad \text{and} \quad \mathsf{InGap}^{\mathrm{sig}}(\Pi, D, q, \tau(h')).$$

Applying Definition 8.5 to $\mathsf{GapPolicy}(\Pi, D)$ and these two memberships gives $\mathsf{psame}(p, q)$. □

Theorem 9197.9 (Composite pullback gap policy)**.** *Assume* $\mathsf{GapPolicy}(\Pi, D)$*. Let* $\tau_1 : D' \to D$ *and* $\tau_2 : D'' \to D'$ *be BEDC history operations, each equipped with a classifier-preserving pullback ledger over* Π *in the sense of Definition 9197.6. Let the composite pulled-back membership predicate be the pullback of the* τ_1*-ledger along* τ_2*:*

$$\mathsf{InGap}^{\mathrm{sig}^{\tau_1 \circ \tau_2}}(\Pi, D'', D, p, h'') \iff \mathsf{InDom}(D'', h'') \text{ and } \mathsf{InGap}^{\mathrm{sig}^{\tau_1}}(\Pi, D', D, p, \tau_2(h'')).$$

Then the operation $\tau_1 \circ \tau_2 : D'' \to D$ *carries a classifier-preserving pullback ledger over* Π*. Its composite membership predicate satisfies the coverage and separation obligations over* D''*:*

1. for every source history h''*,*

$$\mathsf{InDom}(D'', h'') \Longrightarrow \exists p,\ \mathsf{InGap}^{\mathrm{sig}^{\tau_1 \circ \tau_2}}(\Pi, D'', D, p, h'');$$

2. for every source history h'' *and visible package tokens* p, q*,*

$$\mathsf{InGap}^{\mathrm{sig}^{\tau_1 \circ \tau_2}}(\Pi, D'', D, p, h'') \Longrightarrow \mathsf{InGap}^{\mathrm{sig}^{\tau_1 \circ \tau_2}}(\Pi, D'', D, q, h'') \Longrightarrow \mathsf{psame}(p, q).$$

Proof. First verify the two clauses of Definition 9197.6 for the composite operation. If $\mathsf{InDom}(D'', h'')$, the source-preservation clause for the τ_2-ledger gives $\mathsf{InDom}(D', \tau_2(h''))$. Applying the source-preservation clause for the τ_1-ledger gives

$$\mathsf{InDom}(D, \tau_1(\tau_2(h''))).$$

Thus $\tau_1 \circ \tau_2$ preserves admitted sources from D'' to D.

For classifier preservation, fix p and h''. Suppose first that

$$\mathsf{InGap}^{\mathrm{sig}^{\tau_1 \circ \tau_2}}(\Pi, D'', D, p, h'')$$

holds. By the displayed definition, $\mathsf{InDom}(D'', h'')$ and

$$\mathsf{InGap}^{\mathrm{sig}^{\tau_1}}(\Pi, D', D, p, \tau_2(h''))$$

hold. The classifier-preservation clause for the τ_1-ledger gives

$$\mathsf{InGap}^{\mathrm{sig}}(\Pi, D, p, \tau_1(\tau_2(h''))).$$

Hence the forward direction of the composite classifier clause holds.

Conversely, assume $\mathsf{InDom}(D'', h'')$ and

$$\mathsf{InGap}^{\mathrm{sig}}(\Pi, D, p, \tau_1(\tau_2(h''))).$$

Source preservation for the τ_2-ledger gives $\mathsf{InDom}(D', \tau_2(h''))$. The reverse direction of the classifier-preservation clause for the τ_1-ledger then gives

$$\mathsf{InGap}^{\mathrm{sig}^{\tau_1}}(\Pi, D', D, p, \tau_2(h'')),$$

and the displayed definition gives

$$\mathsf{InGap}^{\mathrm{sig}^{\tau_1 \circ \tau_2}}(\Pi, D'', D, p, h'').$$

Therefore the composite predicate satisfies

$$\mathsf{InGap}^{\mathrm{sig}^{\tau_1 \circ \tau_2}}(\Pi, D'', D, p, h'') \iff \mathsf{InDom}(D'', h'') \text{ and } \mathsf{InGap}^{\mathrm{sig}}(\Pi, D, p, \tau_1(\tau_2(h''))),$$

which is the classifier-preservation clause for $\tau_1 \circ \tau_2$.

The composite operation is therefore equipped with the source-preservation and classifier-preservation clauses required by Definition 9197.6. Applying Definition 9197.8 to $\mathsf{GapPolicy}(\Pi, D)$ and this composite ledger gives the displayed coverage and separation obligations on D''. □

Theorem 9197.10 (Identity pullback gap policy unit law)**.** *Assume* $\mathsf{GapPolicy}(\Pi, D)$*. Let* $\mathrm{id}_D : D \to D$ *be the identity BEDC history operation,* $\mathrm{id}_D(h) = h$*, and define its pulled-back package-gap membership predicate by*

$$\mathsf{InGap}^{\mathrm{sig}^{\mathrm{id}_D}}(\Pi, D, D, p, h) \iff \mathsf{InDom}(D, h) \textit{ and } \mathsf{InGap}^{\mathrm{sig}}(\Pi, D, p, h).$$

Then id_D *carries a classifier-preserving pullback ledger over* Π *in the sense of Definition 9197.6. Moreover, on every admitted history* h*,*

$$\mathsf{InDom}(D, h) \implies \big(\mathsf{InGap}^{\mathrm{sig}^{\mathrm{id}_D}}(\Pi, D, D, p, h) \iff \mathsf{InGap}^{\mathrm{sig}}(\Pi, D, p, h)\big),$$

and the identity pulled-back membership predicate satisfies the coverage and separation obligations over D*:*

1. for every source history h*,*

$$\mathsf{InDom}(D, h) \implies \exists p,\ \mathsf{InGap}^{\mathrm{sig}^{\mathrm{id}_D}}(\Pi, D, D, p, h);$$

2. for every source history h *and visible package tokens* p, q*,*

$$\mathsf{InGap}^{\mathrm{sig}^{\mathrm{id}_D}}(\Pi, D, D, p, h) \implies \mathsf{InGap}^{\mathrm{sig}^{\mathrm{id}_D}}(\Pi, D, D, q, h) \implies \mathsf{psame}(p, q).$$

Proof. First verify the two clauses of Definition 9197.6. Source preservation is immediate: from $\mathsf{InDom}(D, h)$ and $\mathrm{id}_D(h) = h$ we obtain

$$\mathsf{InDom}(D, \mathrm{id}_D(h)).$$

For classifier preservation, fix p and h. The displayed definition gives

$$\mathsf{InGap}^{\mathrm{sig}^{\mathrm{id}_D}}(\Pi, D, D, p, h) \iff \mathsf{InDom}(D, h) \text{ and } \mathsf{InGap}^{\mathrm{sig}}(\Pi, D, p, h).$$

Since $\mathrm{id}_D(h) = h$, this is exactly

$$\mathsf{InGap}^{\mathrm{sig}^{\mathrm{id}_D}}(\Pi, D, D, p, h) \iff \mathsf{InDom}(D, h) \text{ and } \mathsf{InGap}^{\mathrm{sig}}(\Pi, D, p, \mathrm{id}_D(h)),$$

which is the classifier-preservation clause for the identity operation.

Now assume $\mathsf{InDom}(D, h)$. If $\mathsf{InGap}^{\mathrm{sig}^{\mathrm{id}_D}}(\Pi, D, D, p, h)$ holds, the defining equivalence gives $\mathsf{InGap}^{\mathrm{sig}}(\Pi, D, p, h)$. Conversely, if $\mathsf{InGap}^{\mathrm{sig}}(\Pi, D, p, h)$ holds, pairing it with the admitted-source witness $\mathsf{InDom}(D, h)$ and applying the reverse direction of the displayed definition gives $\mathsf{InGap}^{\mathrm{sig}^{\mathrm{id}_D}}(\Pi, D, D, p, h)$. This proves the exact admitted-history equivalence.

The identity operation has therefore been equipped with the source-preservation and classifier-preservation clauses required by Definition 9197.6. Applying Definition 9197.8 to $\mathsf{GapPolicy}(\Pi, D)$ and this identity ledger gives the displayed coverage and separation obligations over D. □

Theorem 9197.11 (Pullback gap-policy composition associativity)**.** *Assume* $\mathsf{GapPolicy}(\Pi, D)$*. Let* $\tau_1 : D' \to D$*,* $\tau_2 : D'' \to D'$*, and* $\tau_3 : D''' \to D''$ *be BEDC history operations, each equipped with a classifier-preserving pullback ledger over* Π *in the sense of Definition 9197.6. For a visible package token* p *and a source* h'''*, define the left-associated composite pulled-back predicate by*

$$L_{\tau_1,\tau_2,\tau_3}(p, h''') \iff \mathsf{InDom}(D''', h''') \text{ and } \big(\mathsf{InDom}(D'', \tau_3(h''')) \text{ and } \mathsf{InGap}^{\mathrm{sig}^{\tau_1}}(\Pi, D', D, p, \tau_2(\tau_3(h'''))))\big),$$

which is the pullback along τ_3 *of the* $\tau_1 \circ \tau_2$ *composite predicate from Definition 9197.9. Define the right-associated composite pulled-back predicate by*

$$R_{\tau_1,\tau_2,\tau_3}(p, h''') \iff \mathsf{InDom}(D''', h''') \text{ and } \mathsf{InGap}^{\mathrm{sig}^{\tau_1}}(\Pi, D', D, p, \tau_2(\tau_3(h'''))),$$

which is the pullback of the τ_1*-ledger along the composed source operation* $\tau_2 \circ \tau_3 : D''' \to D'$*. Then the two associated composite gap predicates are pointwise equivalent:*

$$L_{\tau_1,\tau_2,\tau_3}(p, h''') \iff R_{\tau_1,\tau_2,\tau_3}(p, h''').$$

Consequently the two composite presentations determine the same coverage and separation obligations over D'''*:*

$$\big(\mathsf{InDom}(D''', h''') \implies \exists p,\ L_{\tau_1,\tau_2,\tau_3}(p, h''')\big) \iff \big(\mathsf{InDom}(D''', h''') \implies \exists p,\ R_{\tau_1,\tau_2,\tau_3}(p, h''')\big),$$

and

$$\big(L_{\tau_1,\tau_2,\tau_3}(p, h''') \implies L_{\tau_1,\tau_2,\tau_3}(q, h''') \implies \mathsf{psame}(p, q)\big) \iff \big(R_{\tau_1,\tau_2,\tau_3}(p, h''') \implies R_{\tau_1,\tau_2,\tau_3}(q, h''') \implies \mathsf{psame}(p, q)\big).$$

Proof. Fix p and h'''. The defining equivalence for the left-associated predicate gives

$$L_{\tau_1,\tau_2,\tau_3}(p, h''') \iff \mathsf{InDom}(D''', h''') \text{ and } \big(\mathsf{InDom}(D'', \tau_3(h''')) \text{ and } \mathsf{InGap}^{\mathrm{sig}^{\tau_1}}(\Pi, D', D, p, \tau_2(\tau_3(h'''))))\big).$$

The source-preservation clause for the τ_3-ledger in Definition 9197.6 gives

$$\mathsf{InDom}(D''', h''') \implies \mathsf{InDom}(D'', \tau_3(h''')).$$

Hence the middle admitted-source conjunct is forced whenever the outer admitted-source conjunct holds, and the displayed formula is equivalent to

$$\mathsf{InDom}(D''', h''') \text{ and } \mathsf{InGap}^{\mathrm{sig}^{\tau_1}}(\Pi, D', D, p, \tau_2(\tau_3(h'''))).$$

By the defining equivalence for the right-associated predicate, this is exactly $R_{\tau_1,\tau_2,\tau_3}(p, h''')$. This proves the pointwise equivalence.

Equivalently, unfolding the τ_1-ledger classifier clause of Definition 9197.6 shows that both sides reduce to the same original target classifier. For the right-associated side one obtains

$$R_{\tau_1,\tau_2,\tau_3}(p, h''') \iff \mathsf{InDom}(D''', h''') \text{ and } \big(\mathsf{InDom}(D', \tau_2(\tau_3(h'''))) \text{ and } \mathsf{InGap}^{\mathrm{sig}}(\Pi, D, p, \tau_1(\tau_2(\tau_3(h'''))))\big).$$

For the left-associated side the same unfolding gives the same target classifier with the extra conjunct $\mathsf{InDom}(D'', \tau_3(h'''))$. The source-preservation clauses for τ_3 and τ_2 make the D'' and D' admitted-source conjuncts consequences of $\mathsf{InDom}(D''', h''')$. Thus both associated routes read the original gap ledger at the identical source coordinate $\tau_1(\tau_2(\tau_3(h'''))$.

For coverage, apply the pointwise equivalence inside the existential over p: a witness for the left-associated predicate is the same token read through the right-associated predicate, and conversely. Placing the common implication premise $\mathsf{InDom}(D''', h''')$ in front of both statements preserves the equivalence of the two coverage obligations.

For separation, assume the left-associated implication. Given $R_{\tau_1,\tau_2,\tau_3}(p, h''')$ and $R_{\tau_1,\tau_2,\tau_3}(q, h''')$, convert both hypotheses to the corresponding left-associated memberships by the pointwise equivalence and obtain $\mathsf{psame}(p, q)$. The converse implication is identical with left and right interchanged. Therefore the two composite predicates determine the same separation obligation over D'''. □

Theorem 9197.12 (Gap transport has a package-same representative)**.** *Assume* $\mathsf{DomainPolicy}(D)$*,* $\mathsf{BundleAskPolicy}(\Pi, D)$*,* $\mathsf{PackageTokenPolicy}(\Pi)$*, and token totality for the bundle:*

$$\forall u,\ \exists r,\ \mathsf{TokIntro}(\Pi, u, r).$$

If

$$\mathsf{InGap}^{\mathrm{sig}}(\Pi, D, p, h) \quad \textit{and} \quad \mathsf{hsame}(h, k),$$

then there exists a package token q such that

$$\mathsf{InGap}^{\mathrm{sig}}(\Pi, D, q, k) \quad \textit{and} \quad \mathsf{psame}(p, q).$$

Proof. Unpack the gap membership by Definition 9197.1. It supplies an admitted-source judgment, an answer history s, and an evidence ledger Δ such that

$$\mathsf{InDom}(D, h), \qquad \mathsf{Sig}(\Pi, h, s, \Delta), \qquad \mathsf{TokIntro}(\Pi, s, p).$$

By Definition 9195.2, the premises $\mathsf{DomainPolicy}(D)$, $\mathsf{InDom}(D, h)$, and $\mathsf{hsame}(h, k)$ give

$$\mathsf{InDom}(D, k).$$

Apply bundle-local signature existence from Definition 6.62 to $\mathsf{BundleAskPolicy}(\Pi, D)$ and this admitted source. This gives an answer history t and an evidence ledger Θ with

$$\mathsf{Sig}(\Pi, k, t, \Theta).$$

Token totality supplies a package token q such that

$$\mathsf{TokIntro}(\Pi, t, q).$$

The three judgments $\mathsf{InDom}(D, k)$, $\mathsf{Sig}(\Pi, k, t, \Theta)$, and $\mathsf{TokIntro}(\Pi, t, q)$ witness

$$\mathsf{InGap}^{\mathrm{sig}}(\Pi, D, q, k).$$

It remains to compare p and q. Bundle-local source respect, Definition 6.64, applied to $\mathsf{BundleAskPolicy}(\Pi, D)$, the premise $\mathsf{hsame}(h, k)$, and the two generated signatures gives

$$\mathsf{hsame}(s, t).$$

The package-token soundness direction in Definition 9196.2, applied to $\mathsf{PackageTokenPolicy}(\Pi)$, the two token-introduction judgments, and $\mathsf{hsame}(s, t)$, yields

$$\mathsf{psame}(p, q).$$

Thus the displayed q is both a gap representative over k and package-same to the original token p. □

Theorem 9197.13 (Second-layer separation obstruction for composite gaps)**.** *The second-layer separation premise in Definition 8.9 is not implied by first-layer coverage, first-layer separation, and second-layer coverage. More concretely, there is a finite composite-gap setup with a source x, an intermediate token y, and final tokens* $\mathsf{b0}, \mathsf{b1}$ *such that:*

1. *the first gap covers x and separates all first-layer witnesses over x;*
2. *the second gap covers y;*
3. *x lies in the composite gaps of both* $\mathsf{b0}$ *and* $\mathsf{b1}$*;*
4. *the final comparison is* $\mathsf{finalSame} = \mathsf{msame}$*, and* $\mathsf{finalSame}(\mathsf{b0}, \mathsf{b1})$ *fails.*

Thus second-layer coverage alone cannot yield composite separation.

Proof. Take the finite source carrier $\{x\}$, the finite intermediate carrier $\{y\}$, and the final carrier given by the two BEDC raw marks $\{\mathsf{b0}, \mathsf{b1}\}$. Let the admitted-source and intermediate-admissibility predicates hold on their unique elements:

$$\mathsf{SourceOk}(x), \qquad \mathsf{InterOk}(y).$$

Define the first-layer gap by the single membership

$$\mathsf{firstGap}(y, x),$$

and no other first-layer memberships. Define the intermediate sameness relation on the one-point intermediate carrier by

$$\mathsf{interSame}(y, y).$$

Then first-layer coverage holds because y covers x. First-layer separation also holds: if u and v are first-layer witnesses over x, the displayed definition of $\mathsf{firstGap}$ forces $u = y$ and $v = y$, and hence $\mathsf{interSame}(u, v)$ is exactly $\mathsf{interSame}(y, y)$.

Define the second-layer gap by

$$\mathsf{secondGap}(\mathsf{b0}, y) \qquad \text{and} \qquad \mathsf{secondGap}(\mathsf{b1}, y),$$

and no other second-layer memberships. Second-layer coverage holds for the only intermediate token y, for instance by the witness $\mathsf{b0}$.

Let the final comparison relation be raw mark-sameness:

$$\mathsf{finalSame}(z, w) \iff \mathsf{msame}(z, w).$$

By the composite ledger definition in Definition 8.7, the witness y gives

$$\mathsf{CompGap}(\mathsf{firstGap}, \mathsf{secondGap}, \mathsf{b0}, x)$$

from $\mathsf{firstGap}(y, x)$ and $\mathsf{secondGap}(\mathsf{b0}, y)$, and the same witness gives

$$\mathsf{CompGap}(\mathsf{firstGap}, \mathsf{secondGap}, \mathsf{b1}, x)$$

from $\mathsf{firstGap}(y, x)$ and $\mathsf{secondGap}(\mathsf{b1}, y)$.

However, raw mark no-confusion in Definition 2.9 gives

$$\neg\, \mathsf{msame}(\mathsf{b0}, \mathsf{b1}).$$

Since $\mathsf{finalSame}$ is msame, this is

$$\neg\, \mathsf{finalSame}(\mathsf{b0}, \mathsf{b1}).$$

Therefore the same source x belongs to composite gaps of two final tokens that are not final-same. The only failed hypothesis from the layered separation theorem is the second-layer separation condition, because that condition would have to turn

$$\mathsf{interSame}(y, y), \qquad \mathsf{secondGap}(\mathsf{b0}, y), \qquad \mathsf{secondGap}(\mathsf{b1}, y)$$

into $\mathsf{finalSame}(\mathsf{b0}, \mathsf{b1})$, contradicting raw mark no-confusion. Hence first-layer coverage, first-layer separation, and second-layer coverage do not suffice for composite separation. □

Chapter 9198

Package-Sameness Design and Base Reflection

9198.1 Concrete Package-Sameness Design Contract

The reflection theorem is correct for the one-constructor concrete package-sameness relation. It must not be silently transferred to an equivalence closure. This chapter fixes the active design.

Definition 9198.1 (Base concrete package-sameness)**.** *For a fixed generated probe bundle* Π*, the active concrete signature-token package-sameness relation is written*

$$\mathsf{psame}^{\mathrm{base}}_{\Pi}(p, q).$$

It is generated by exactly one constructor:

$$\mathsf{TokIntro}(\Pi, s, p), \quad \mathsf{TokIntro}(\Pi, t, q), \quad \mathsf{hsame}(s, t) \quad \Longrightarrow \quad \mathsf{psame}^{\mathrm{base}}_{\Pi}(p, q).$$

The active notation $\mathsf{psame}^{\mathrm{sig}}_{\Pi}$ *is identified with this base relation:*

$$\mathsf{psame}^{\mathrm{sig}}_{\Pi} := \mathsf{psame}^{\mathrm{base}}_{\Pi}.$$

Lean4 (definition) `BEDC.BaseReflection.PsameSig`

↪ variant `BEDC.BaseReflection.PsameEqClosure equivalence`
↪ variant `BEDC.BaseReflection.PsameEqClosure symm`
↪ variant `BEDC.BaseReflection.PsameEqClosure trans`

This relation is not the active relation for concrete Globalize exactness.

Lean4 ✓ `BEDC.BaseReflection.PsameEqClosure base intro`

Definition 9198.4 (Closure-reflection obligation)**.** *The optional equivalence-closure relation is reflection-safe only if the following additional theorem is proved:*

$$\mathsf{TokIntro}(\Pi,s,p),\quad \mathsf{TokIntro}(\Pi,t,q),\quad \mathsf{psame}^{\mathrm{eq}}_{\Pi}(p,q) \implies \mathsf{hsame}(s,t).$$

This obligation is named $\mathsf{ClosureReflect}(\Pi)$.
Lean4 (definition) `BEDC.BaseReflection.ClosureReflect`
Lean4 ✓ `BEDC.BaseReflection.ClosureReflect base edge`
↪ variant `BEDC.BaseReflection.ClosureReflect apply`

Theorem 9198.5 (Base reflection remains the active theorem)**.** *Assume* $\mathsf{TokUnique}(\Pi)$. *If*

$$\mathsf{TokIntro}(\Pi,s,p),\quad \mathsf{TokIntro}(\Pi,t,q),\quad \mathsf{psame}^{\mathrm{base}}_{\Pi}(p,q),$$

then

$$\mathsf{hsame}(s,t).$$

↪ variant `BEDC.BaseReflection.PackageReflection base`

Proof. This is Theorem 9196.17 with the notation of Definition 9198.1. The only constructor of $\mathsf{psame}^{\mathrm{base}}_{\Pi}$ exposes introducing signatures s_0, t_0 with $\mathsf{hsame}(s_0,t_0)$. Token-introduction uniqueness compares s with s_0 and t with t_0; symmetry and transitivity of hsame finish the proof. □

Corollary 9198.6 (Equivalence closure is not exported as exact)**.** *The exact concrete Globalize theorem exports* $\mathsf{psame}^{\mathrm{base}}_{\Pi}$*, not* $\mathsf{psame}^{\mathrm{eq}}_{\Pi}$*. Reflection through* $\mathsf{psame}^{\mathrm{eq}}_{\Pi}$ *requires the explicit hypothesis* $\mathsf{ClosureReflect}(\Pi)$.

Lean4 ✓ `BEDC.BaseReflection.eqClosure export requires closure reflect`
↪ variant `BEDC.BaseReflection.NotExported GeneratedSameSig to base`

Proof. By Principle 9198.2, equivalence closure is a separate construction. Definition 9198.4 records the extra theorem required for reflection through that closure. The checked export theorem applies that predicate directly to the two token introductions and the closure proof, so the base relation remains the exact Globalize export. □

9198.2 Base Reflection Schema

This chapter isolates the smallest constructor-inversion chain needed for base package reflection. It is the first proof-check target in the present base-reflection contract.

Definition 9198.7 (Base package witness data)**.** *For fixed* Π, p, q*, define the witness predicate*

$$\mathsf{PBaseData}(\Pi, p, q) :\Longleftrightarrow \exists s_0, t_0,\ \mathsf{TokIntro}(\Pi, s_0, p) \wedge \mathsf{TokIntro}(\Pi, t_0, q) \wedge \mathsf{hsame}(s_0, t_0).$$

Lean4 ✓ `BEDC.BaseReflection.PBaseData witnesses`

Base inversion	`PsameBase.inversion`
Token replacement	`TokUnique.tokenReplacement`
Base package reflection	`PackageReflection.base`

Lean4 ✓ `BEDC.BaseReflection.base reflection public name contract`

9198.3 Optional Closure Reflection Target

The equivalence closure of the base package relation is useful for package algebra, but it must not be confused with the active exact relation. This chapter records the closure relation and its conditional reflection theorem without exporting it as exactness.

Definition 9198.13 (Equivalence closure target)**.** *The optional relation remains*

$$\mathsf{psame}^{\mathrm{eq}}_{\Pi}(p, q) := \mathsf{EqCl}(\mathsf{psame}^{\mathrm{base}}_{\Pi})(p, q).$$

Lean4 (definition) `BEDC.BaseReflection.PsameEqClosure`

It is not part of $\mathsf{ExactGlobalizeBase}(\Pi, D)$.

Protocol 9198.14 (Closure-reflection proof route)**.** *The theorem* `PackageReflection.eqClosure` *proves* $\mathsf{ClosureReflect}(\Pi)$ *by induction over* $\mathsf{EqCl}(\mathsf{psame}^{\mathrm{base}}_{\Pi})$*. The proof cases are:*

1. *reflexive case: use two introductions of the same token and* $\mathsf{TokUnique}(\Pi)$*;*
2. *base-edge case: use Theorem 9198.11;*
3. *symmetric case: use symmetry of* hsame*;*
4. *transitive case: use transitivity of* hsame*.*

Lean4 ✓ `BEDC.BaseReflection.closure reflection route cases`

Proposition 9198.15 (Conditional closure-reflection schema)**.** *Assume* hsame *is an equivalence relation, assume* $\mathsf{TokUnique}(\Pi)$*, assume every package has an introducing signature witness, and assume* $\mathsf{psame}^{\mathrm{eq}}_{\Pi}$ *is implemented as the ordinary reflexive-symmetric-transitive closure of* $\mathsf{psame}^{\mathrm{base}}_{\Pi}$*. Then the proof route of Protocol 9198.14 proves*

$$\mathsf{TokIntro}(\Pi, s, p), \quad \mathsf{TokIntro}(\Pi, t, q), \quad \mathsf{psame}^{\mathrm{eq}}_{\Pi}(p, q) \Longrightarrow \mathsf{hsame}(s, t).$$

Lean4 ✓ `BEDC.BaseReflection.PackageReflection eqClosure`

↪ variant `BEDC.BaseReflection.PsameEqClosure iff hsame under tok unique`

↪ variant `BEDC.BaseReflection.ClosureReflect from eqClosure`

↪ variant `BEDC.BaseReflection.conditional closure reflection schema`

↪ variant `BEDC.BaseReflection.PsameEqClosure endpoint reflection pair`

↪ variant `BEDC.BaseReflection.PsameEqClosure two base reflection`

↪ variant `BEDC.BaseReflection.PsameEqClosure three base reflection`

↪ variant `BEDC.BaseReflection.ClosureReflect from canonical`

Proof. Induct on the derivation of $\mathsf{psame}^{\mathrm{eq}}_{\Pi}(p, q)$. The reflexive case compares two introductions of one token by token uniqueness. The base-edge case is Theorem 9198.11. The symmetric case reverses the induction result by symmetry of hsame. The transitive case chooses an introducing signature witness for the middle package and composes the two induction results by transitivity of hsame. □

Corollary 9198.16 (Four base-edge reflection)**.** *Assume* hsame *is an equivalence relation and* $\mathsf{TokUnique}(\Pi)$*. Let* p, q, r, u, w *be package tokens, with endpoint introductions* $\mathsf{TokIntro}(\Pi, x, p)$ *and* $\mathsf{TokIntro}(\Pi, v, w)$*, and with introducing signature witnesses for* q*,* r*, and* u*. If*

$$\mathsf{psame}^{\mathrm{base}}_{\Pi}(p, q), \quad \mathsf{psame}^{\mathrm{base}}_{\Pi}(q, r), \quad \mathsf{psame}^{\mathrm{base}}_{\Pi}(r, u), \quad \mathsf{psame}^{\mathrm{base}}_{\Pi}(u, w),$$

then $\mathsf{hsame}(x, v)$*.*

Lean4 ✓ `BEDC.BaseReflection.PsameEqClosure four base reflection`

Proof. Apply base-package reflection to each adjacent base edge, using the middle introducing witnesses for the internal package tokens. Transitivity of hsame composes the four reflected comparisons into the endpoint comparison. □

Corollary 9198.17 (Closure reflection yields generated signature sameness)**.** *When a package pair is related by* $\mathsf{psame}^{\mathrm{eq}}_{\Pi}$ *and both endpoints have token introductions, a closure-reflection witness produces the corresponding generated signature sameness comparison.*

Lean4 ✓ `BEDC.BaseReflection.ClosureReflect to GeneratedSameSig`

Proof. Unfold the generated signature sameness target for the introduced endpoints. The closure-reflection witness applies directly to the two introductions and the equivalence-closure premise, yielding the required hsame comparison. □

Corollary 9198.18 (Closure reflection preserves base export)**.** *Adding a closure-reflection witness does not change the exported package relation of* $\mathsf{ExactGlobalizeBase}(\Pi, D)$*: exactness continues to export* $\mathsf{psame}^{\mathrm{base}}_{\Pi}$*.*

Lean4 ✓ `BEDC.BaseReflection.ClosureReflect preserves base export`

Proof. The export discipline is Protocol 9199.9 together with Corollary 9199.18. Closure reflection is consumed only as a local theorem for introduced endpoints, while the exactness predicate continues to name $\mathsf{psame}^{\mathrm{base}}_{\Pi}$ as its package relation. □

Theorem 9198.19 (Finite equivalence-closure reflection obstruction)**.** *Let* Π *be a generated probe bundle. Suppose there are signatures* a, b, c, d *and package tokens* p, r, q *with token introductions*

$$\mathsf{TokIntro}(\Pi, a, p), \quad \mathsf{TokIntro}(\Pi, c, r), \quad \mathsf{TokIntro}(\Pi, d, r), \quad \mathsf{TokIntro}(\Pi, b, q),$$

and history-sameness data

$$\mathsf{hsame}(a, c), \quad \mathsf{hsame}(d, b), \quad \neg\mathsf{hsame}(c, d), \quad \neg\mathsf{hsame}(a, b).$$

Then the finite configuration satisfies

$$\mathsf{psame}^{\mathrm{eq}}_{\Pi}(p, q), \qquad \neg\,\mathsf{TokUnique}(\Pi), \qquad \neg\,\mathsf{ClosureReflect}(\Pi).$$

In particular, the endpoints a *and* b *introduce the closure-related tokens* p *and* q *but fail to reflect to* $\mathsf{hsame}(a, b)$*.*

Proof. The first and second token-introduction judgments, together with $\mathsf{hsame}(a, c)$, give

$$\mathsf{psame}^{\mathrm{base}}_{\Pi}(p, r)$$

by Definition 9198.8. The third and fourth token-introduction judgments, together with $\mathsf{hsame}(d, b)$, give

$$\mathsf{psame}^{\mathrm{base}}_{\Pi}(r, q)$$

by the same constructor. Since $\mathsf{psame}^{\mathrm{eq}}_{\Pi}$ is the equivalence closure of $\mathsf{psame}^{\mathrm{base}}_{\Pi}$ in Definition 9198.13, and Definition 9198.14 records the base-edge and transitive closure cases, the two displayed base edges compose to $\mathsf{psame}^{\mathrm{eq}}_{\Pi}(p, q)$.

If $\mathsf{TokUnique}(\Pi)$ held, Definition 9196.13 applied to $\mathsf{TokIntro}(\Pi, c, r)$ and $\mathsf{TokIntro}(\Pi, d, r)$ would give $\mathsf{hsame}(c, d)$, contradicting the displayed separation. Hence $\neg\,\mathsf{TokUnique}(\Pi)$.

If $\mathsf{ClosureReflect}(\Pi)$ held, unfolding Definition 9198.4 and applying it to $\mathsf{TokIntro}(\Pi, a, p)$, $\mathsf{TokIntro}(\Pi, b, q)$, and the closure proof $\mathsf{psame}^{\mathrm{eq}}_{\Pi}(p, q)$ would give $\mathsf{hsame}(a, b)$, contradicting the displayed endpoint separation. Hence $\neg\,\mathsf{ClosureReflect}(\Pi)$. □

Corollary 9198.20 (Equivalence-closure exactness needs reflection)**.** *The base exact Globalize contract of Definition 9199.11 cannot be converted into an exactness statement for* $\mathsf{psame}^{\mathrm{eq}}_{\Pi}$ *by replacing the exported relation name alone. Any such conversion must add* $\mathsf{ClosureReflect}(\Pi)$*, or hypotheses such as those in Definition 9198.15 that prove it.*

Proof. An exactness statement at $\mathsf{psame}^{\mathrm{eq}}_{\Pi}$ needs the endpoint reflection step

$$\mathsf{TokIntro}(\Pi, s, p), \quad \mathsf{TokIntro}(\Pi, t, q), \quad \mathsf{psame}^{\mathrm{eq}}_{\Pi}(p, q) \quad \Longrightarrow \quad \mathsf{hsame}(s, t).$$

The finite configuration in Definition 9198.19 supplies the antecedents for $s = a$ and $t = b$ and also supplies $\neg\mathsf{hsame}(a, b)$. Thus the reflection step is not derivable from the base constructor and equivalence closure alone. The export relation in Definition 9199.11 is $\mathsf{psame}^{\mathrm{base}}_{\Pi}$, and Definition 9199.18 records that the closure relation is not exported as exactness. □

Chapter 9199

Exact Globalize Base Contract

9199.1 Exact Concrete Signature Globalize Under Explicit Policies

The concrete signature Globalize instance becomes exact only when the checked concrete inputs are visible:

$$\mathsf{AskPolicy}(\Pi, D) + \mathsf{PackageTokenPolicy}(\Pi) + \forall h, s, \Delta,\ \mathsf{InDom}(D, h) \wedge \mathsf{Sig}(\Pi, h, s, \Delta) \Longrightarrow \exists p,\ \mathsf{TokIntro}(\Pi, s, p).$$

This chapter records the exactness theorem in its non-overclaiming form. Domain transport is the separate policy recorded in Theorem 9195.2.

The predicate $\mathsf{InGap}^{\mathrm{sig}}(\Pi, D, p, h)$ is Definition 9193.1.

Theorem 9199.1 (Concrete gap coverage)**.** *Assume* $\mathsf{AskPolicy}(\Pi, D)$ *and the dependent generated-signature token condition: whenever* $\mathsf{InDom}(D, h)$ *and* $\mathsf{Sig}(\Pi, h, s, \Delta)$*, there exists a token* p *with* $\mathsf{TokIntro}(\Pi, s, p)$*. If* $\mathsf{InDom}(D, h)$*, then there exists a token* p *such that*

$$\mathsf{InGap}^{\mathrm{sig}}(\Pi, D, p, h).$$

Lean4 ✓ `BEDC.FKernel.Gap.gap coverage globalize`

Proof. By the totality field of $\mathsf{AskPolicy}(\Pi, D)$, the admitted history h generates some signature s with evidence Δ. The dependent token condition applied to $\mathsf{InDom}(D, h)$ and $\mathsf{Sig}(\Pi, h, s, \Delta)$ supplies a token p with $\mathsf{TokIntro}(\Pi, s, p)$. The three displayed judgments witness $\mathsf{InGap}^{\mathrm{sig}}(\Pi, D, p, h)$. □

Theorem 9199.2 (Concrete gap separation)**.** *Let* $\mathsf{psame}^{\mathrm{sig}}_{\Pi}$ *be the concrete package-sameness relation generated by its signature-sameness constructor. Assume* $\mathsf{AskPolicy}(\Pi, D)$*. If*

$$\mathsf{InGap}^{\mathrm{sig}}(\Pi, D, p, h) \quad \textit{and} \quad \mathsf{InGap}^{\mathrm{sig}}(\Pi, D, q, h),$$

then

$$\mathsf{psame}^{\mathrm{sig}}_{\Pi}(p, q).$$

Lean4 ✓ `BEDC.FKernel.Gap.gap separation globalize`

↪ variant `BEDC.FKernel.Gap.gap separation with domain pair`

↪ variant `BEDC.FKernel.Gap.signature gap separation from witnesses`

↪ variant `BEDC.FKernel.Gap.gap separation same signature witness pair`

Proof. The two gap premises yield the admitted-source witness $\mathsf{InDom}(D, h)$ and signatures s, t with

$$\mathsf{Sig}(\Pi, h, s, \Delta), \quad \mathsf{Sig}(\Pi, h, t, \Theta),$$

and token-introduction judgments

$$\mathsf{TokIntro}(\Pi, s, p), \quad \mathsf{TokIntro}(\Pi, t, q).$$

Theorem 6.67, applied to $\mathsf{AskPolicy}(\Pi, D)$, the admitted-source witness, and the two generated signatures, gives $\mathsf{hsame}(s, t)$. The package-sameness constructor then gives $\mathsf{psame}^{\mathrm{sig}}_{\Pi}(p, q)$. □

Theorem 9199.3 (Concrete Globalize soundness)**.** *Given a witness $G : \mathsf{GeneratedSameSig}(\Pi, h, k)$, if the left generated signature object of G introduces token p and the right generated signature object of G introduces token q, then $\mathsf{psame}^{\mathrm{base}}_{\Pi}(p, q)$.*

Lean4 ✓ `BEDC.BaseReflection.GeneratedSameSig psameBase`

Proof. The witness G carries the history-sameness component between its generated signature objects. The base package-sameness constructor applied to the two token-introduction premises and that component gives $\mathsf{psame}^{\mathrm{base}}_{\Pi}(p, q)$. □

Theorem 9199.4 (Concrete Globalize completeness)**.** *Assume $\mathsf{TokUnique}(\Pi)$. Given generation judgments $\mathsf{SigGen}(\Pi, h, x, \Delta)$ and $\mathsf{SigGen}(\Pi, k, y, \Theta)$, token-introduction judgments $\mathsf{TokIntro}(\Pi, x, p)$ and $\mathsf{TokIntro}(\Pi, y, q)$, and $\mathsf{psame}^{\mathrm{base}}_{\Pi}(p, q)$, there is an element of $\mathsf{Nonempty}(\mathsf{GeneratedSameSig}(\Pi, h, k))$.*

Lean4 ✓ `BEDC.BaseReflection.PsameBase to GeneratedSameSig under tok unique`

Proof. Token-uniqueness reflection converts the base package-sameness premise, together with the two token-introduction judgments, into history-sameness of x and y. Combining that reflected sameness with the two generation judgments fills the fields of a $\mathsf{GeneratedSameSig}(\Pi, h, k)$ witness. □

9199.2 Exactness Export Contract

This chapter records the three-clause gap export used for active development. It is intentionally narrower than a full package algebra theorem.

Theorem 9199.5 (Local signature classification)**.** *Assume $\mathsf{AskPolicy}(\Pi, D)$, $\mathsf{PackageTokenPolicy}(\Pi)$,*

$$\mathsf{InGap}^{\mathrm{sig}}(\Pi, D, p, h) \quad \textit{and} \quad \mathsf{InGap}^{\mathrm{sig}}(\Pi, D, q, k).$$

Then package-sameness is classified by generated signatures:

$$\mathsf{psame}(p, q) \iff \exists s, t, \Delta, \Theta,\ \mathsf{Sig}(\Pi, h, s, \Delta) \textit{ and } \mathsf{Sig}(\Pi, k, t, \Theta) \textit{ and } \mathsf{hsame}(s, t).$$

Lean4 ✓ `BEDC.FKernel.Gap.internalized globalize classifies by signatures`

Proof. The forward direction is the concrete completeness clause applied to the two gap memberships and the package-sameness premise. For the reverse direction, unpack the two $\mathsf{InGap}^{\mathrm{sig}}$ premises. The p-membership supplies a domain witness for h, a generated signature u, and the token-introduction witness for p; the q-membership supplies a domain witness for k, a generated signature v, and the token-introduction witness for q. Separately unpack the displayed existential

into signatures s from h and t from k, together with $\mathsf{hsame}(s,t)$. Asking-policy determinacy at h gives $\mathsf{hsame}(s,u)$, and determinacy at k gives $\mathsf{hsame}(t,v)$. By symmetry and transitivity, these three history-sameness facts compose to $\mathsf{hsame}(u,v)$. The package-token policy soundness field then consumes the two token-introduction witnesses and $\mathsf{hsame}(u,v)$ to conclude $\mathsf{psame}(p,q)$. □

Theorem 9199.6 (Exact Globalize base soundness export)**.** *Assume* $\mathsf{ExactGlobalizeBase}(\Pi, D)$*. If*

$$\mathsf{InGap}^{\mathrm{sig}}(\Pi, D, p, h), \qquad \mathsf{InGap}^{\mathrm{sig}}(\Pi, D, q, k), \qquad \mathsf{GeneratedSameSig}(\Pi, h, k),$$

then $\mathsf{psame}^{\mathrm{base}}_{\Pi}(p,q)$*.*

Lean4 ✓ `BEDC.BaseReflection.ExactGlobalizeBase soundness exports base`

Proof. This is the soundness projection of $\mathsf{ExactGlobalizeBase}(\Pi, D)$ applied to the two gap memberships and the generated-sameness witness. □

Definition 9199.7 (Not-exported boundary predicate)**.** *The predicate* $\mathsf{NotExported}(\Pi, D, E)$ *records the boundary attached to an exact base Globalize witness. It holds exactly when, for all histories* h, k *and packages* p, q*, the two gap memberships*

$$\mathsf{InGap}^{\mathrm{sig}}(\Pi, D, p, h), \qquad \mathsf{InGap}^{\mathrm{sig}}(\Pi, D, q, k)$$

bound the exported statement to

$$\mathsf{psame}^{\mathrm{base}}_{\Pi}(p,q) \iff \mathsf{Nonempty}(\mathsf{GeneratedSameSig}(\Pi, h, k)).$$

Lean4 (definition) `BEDC.BaseReflection.NotExported`

Proposition 9199.8 (What is intentionally not exported)**.** *The following statements are not exported:*

1. $\mathsf{psame}^{\mathrm{eq}}_{\Pi}$*-exactness;*
2. *package-sameness transitivity without token-uniqueness hypotheses as a constructor-level theorem for* $\mathsf{psame}^{\mathrm{base}}_{\Pi}$*;*
3. *equivalence-closure exactness as a Globalize export;*
4. $\mathsf{Add}^{\uparrow}$ *certificate data as a clause of the exact Globalize export;*
5. *a full natural-number or addition construction beyond the licensed unary-continuation interface.*

Proof. Each item requires an exactness predicate whose exported relation is not $\mathsf{psame}^{\mathrm{base}}_{\Pi}$, a derived-interface certificate carried as separate naming-certificate data, or a derived-object construction that is not a field of the exact Globalize predicate. □

Lean4 ✓ `BEDC.BaseReflection.NotExported scope boundary`

Protocol 9199.9 (Export discipline)**.** *Modules cite Definition 9199.11 for the exactness predicate and Theorem 9199.16 for its field constructor. If a module needs* $\mathsf{psame}^{\mathrm{eq}}_{\Pi}$*-exactness, it must state an exactness predicate whose exported relation is* $\mathsf{psame}^{\mathrm{eq}}_{\Pi}$*, or explicitly downgrade its result from exact reflection to closure-level compatibility.*

9199.3 Checker-Friendly Exactness Predicate

Exact concrete Globalize is the base-relation exactness predicate whose data are coverage, base soundness, and base completeness between $\mathsf{psame}^{\mathrm{base}}_{\Pi}$ and $\mathsf{GeneratedSameSig}(\Pi, h, k)$, with the local iff derived from the two directional fields.

Definition 9199.10 (Generated signature sameness)**.** *For a generated probe bundle* Π*,* $\mathsf{GeneratedSameSig}(\Pi, h, k)$ *is a witness object. Its fields are signatures* s, t*, evidence objects* Δ, Θ*, generation judgments* $\mathsf{Sig}(\Pi, h, s, \Delta)$ *and* $\mathsf{Sig}(\Pi, k, t, \Theta)$*, and a sameness witness* $\mathsf{hsame}(s, t)$*.*

The existential reading is the inhabitation proposition for that object:

$$\mathsf{Nonempty}(\mathsf{GeneratedSameSig}(\Pi, h, k)) \iff \exists s, t, \Delta, \Theta,\ \mathsf{Sig}(\Pi, h, s, \Delta) \wedge \mathsf{Sig}(\Pi, k, t, \Theta) \wedge \mathsf{hsame}(s, t).$$

Thus the checker-facing data corresponding to "the two admitted histories generate the same visible signature" is the witness object itself, while classification statements use its inhabitation.

```

Definition 9199.11 (Base exact Globalize structure)**.** *For a bundle* Π *and a concrete domain policy* D*, the proposition*

$$\mathsf{ExactGlobalizeBase}(\Pi, D)$$

is the conjunction of the following three structural fields.

1. ***Coverage.***

$$\forall h,\ \mathsf{InDom}(D, h) \Rightarrow \exists p,\ \mathsf{InGap}^{\mathrm{sig}}(\Pi, D, p, h).$$

2. ***Base soundness.***

$$\forall h, k, p, q,\ \mathsf{InGap}^{\mathrm{sig}}(\Pi, D, p, h) \Rightarrow \mathsf{InGap}^{\mathrm{sig}}(\Pi, D, q, k) \Rightarrow \mathsf{GeneratedSameSig}(\Pi, h, k) \Rightarrow \mathsf{psame}^{\mathrm{base}}_{\Pi}(p, q).$$

3. ***Base completeness.***

$$\forall h, k, p, q,\ \mathsf{InGap}^{\mathrm{sig}}(\Pi, D, p, h) \Rightarrow \mathsf{InGap}^{\mathrm{sig}}(\Pi, D, q, k) \Rightarrow \mathsf{psame}^{\mathrm{base}}_{\Pi}(p, q) \Rightarrow \mathsf{Nonempty}(\mathsf{GeneratedSameSig}(\Pi, h, k)$$

The local classification equivalence is derived from soundness and completeness.

Lean4 ✓ `BEDC.BaseReflection.ExactGlobalizeBase iff fields`

↪ variant `BEDC.BaseReflection.ExactGlobalizeBase soundness`

Proposition 9199.12 (Classification is derivable from the two directions)**.** *If base soundness and base completeness hold, then for all h, k, p, q satisfying*

$$\mathsf{InGap}^{\mathrm{sig}}(\Pi, D, p, h) \quad \textit{and} \quad \mathsf{InGap}^{\mathrm{sig}}(\Pi, D, q, k),$$

one has

$$\mathsf{psame}^{\mathrm{base}}_{\Pi}(p, q) \iff \mathsf{Nonempty}(\mathsf{GeneratedSameSig}(\Pi, h, k)).$$

Lean4 ✓ `BEDC.BaseReflection.ExactGlobalizeBase classify iff from directions`

↪ variant `BEDC.BaseReflection.ExactGlobalizeBase classify directions`

Proof. The forward implication is base completeness. For the reverse implication, unpack the inhabited witness proposition and apply base soundness to the resulting $\mathsf{GeneratedSameSig}(\Pi, h, k)$ object. Coverage is not needed for this local equivalence, but it remains part of the global exactness structure because exact Globalize must also classify every admitted history, not only pairs already carrying visible packages. □

Corollary 9199.13 (Exact Globalize projections and classification)**.** *From* $\mathsf{ExactGlobalizeBase}(\Pi, D)$ *one obtains coverage, base soundness, base completeness, and the derived local classification equivalence*

$$\mathsf{InGap}^{\mathrm{sig}}(\Pi, D, p, h) \wedge \mathsf{InGap}^{\mathrm{sig}}(\Pi, D, q, k) \quad \Rightarrow \quad (\mathsf{psame}^{\mathrm{base}}_{\Pi}(p, q) \iff \mathsf{Nonempty}(\mathsf{GeneratedSameSig}(\Pi, h, k))).$$

Lean4 ✓ `BEDC.BaseReflection.ExactGlobalizeBase coverage soundness completeness and classify`

Proof. The first three clauses are the projections of $\mathsf{ExactGlobalizeBase}(\Pi, D)$. The displayed equivalence is Proposition 9199.12. □

Theorem 9199.14 (Exact Globalize self-covered classification)**.** *Let* $\mathsf{ExactGlobalizeBase}(\Pi, D)$ *hold. For every admitted history* h*, there is a package* p *covering* h *such that the local classification relates* h *to itself through the package pair* (p, p)*:*

$$\mathsf{InDom}(D, h) \quad \Rightarrow \quad \exists p,\ \mathsf{InGap}^{\mathrm{sig}}(\Pi, D, p, h) \wedge \big(\mathsf{psame}^{\mathrm{base}}_{\Pi}(p, p) \iff \mathsf{Nonempty}(\mathsf{GeneratedSameSig}(\Pi, h, h))\big).$$

Lean4 ✓ `BEDC.BaseReflection.ExactGlobalizeBase self covered classification`

Proof. Use the coverage component isolated in Corollary 9199.13 for the admitted history h. It supplies a package p with $\mathsf{InGap}^{\mathrm{sig}}(\Pi, D, p, h)$.

Apply the same corollary's local classification equivalence to the two identical displayed witnesses. With both sides instantiated by p and h, the pairwise equivalence becomes exactly the self-covered classification statement. □

Protocol 9199.15 (Exactness export discipline)**.** *Global existence cites Definition 9199.11. Pairwise classification cites Proposition 9199.12 or Corollary 9199.13 under displayed* $\mathsf{InGap}^{\mathrm{sig}}$ *witnesses. Coverage is used only when the statement must produce visible package tokens for admitted histories.*

9199.4 Exact Globalize Base Contract

The theorem packages coverage, base soundness, and base completeness at the base package relation into the concrete signature Globalize exactness predicate.

Theorem 9199.16 (Exact Globalize base target)**.** *Assume the following three field hypotheses:*

1. *coverage:*
$$\forall h,\ \mathsf{InDom}(D, h) \Rightarrow \exists p,\ \mathsf{InGap}^{\mathrm{sig}}(\Pi, D, p, h);$$
2. *soundness:*
$$\forall h, k, p, q,\ \mathsf{InGap}^{\mathrm{sig}}(\Pi, D, p, h) \Rightarrow \mathsf{InGap}^{\mathrm{sig}}(\Pi, D, q, k) \Rightarrow \mathsf{GeneratedSameSig}(\Pi, h, k) \Rightarrow \mathsf{psame}^{\mathrm{base}}_{\Pi}(p, q);$$
3. *completeness:*
$$\forall h, k, p, q,\ \mathsf{InGap}^{\mathrm{sig}}(\Pi, D, p, h) \Rightarrow \mathsf{InGap}^{\mathrm{sig}}(\Pi, D, q, k) \Rightarrow \mathsf{psame}^{\mathrm{base}}_{\Pi}(p, q) \Rightarrow \mathsf{Nonempty}(\mathsf{GeneratedSameSig}(\Pi, h, k)$$

Then
$$\mathsf{ExactGlobalizeBase}(\Pi, D).$$

↪ variant `BEDC.BaseReflection.no scaffold laundering fields and classifier`

```
↪ variant BEDC.BaseReflection.ExactGlobalizeBase covered classification
↪ variant BEDC.BaseReflection.ExactGlobalizeBase covered sound complete
↪ variant BEDC.BaseReflection.ExactGlobalizeBase covered soundness direction
↪ variant BEDC.BaseReflection.ExactGlobalizeBase covered completeness direction
↪ variant BEDC.BaseReflection.ExactGlobalizeBase covered classification directions
```

Proof. The theorem is the constructor for $\mathsf{ExactGlobalizeBase}(\Pi, D)$ from its coverage, soundness, and completeness fields. The soundness field consumes an actual $\mathsf{GeneratedSameSig}(\Pi, h, k)$ witness object; the completeness field returns the inhabited-witness proposition. □

Theorem 9199.17 (Exact Globalize admitted-pair export from fields)**.** *Assume the three field hypotheses of Theorem 9199.16. For admitted histories h and k with $\mathsf{InDom}(D, h)$ and $\mathsf{InDom}(D, k)$, there exist packages p and q such that*

$$\mathsf{ExactGlobalizeBase}(\Pi, D) \wedge \mathsf{InGap}^{\mathrm{sig}}(\Pi, D, p, h) \wedge \mathsf{InGap}^{\mathrm{sig}}(\Pi, D, q, k)$$
$$\wedge\ \left(\mathsf{psame}^{\mathrm{base}}_{\Pi}(p, q) \iff \mathsf{Nonempty}(\mathsf{GeneratedSameSig}(\Pi, h, k))\right).$$

Lean4 ✓ `BEDC.BaseReflection.ExactGlobalizeBase from fields admitted pair export`

Proof. First build the exactness witness from the three fields by Theorem 9199.16. This gives $\mathsf{ExactGlobalizeBase}(\Pi, D)$ with the same coverage, soundness, and completeness data.

Apply coverage to the displayed admission $\mathsf{InDom}(D, h)$ to obtain a package p with $\mathsf{InGap}^{\mathrm{sig}}(\Pi, D, p, h)$. Apply coverage again to $\mathsf{InDom}(D, k)$ to obtain a package q with $\mathsf{InGap}^{\mathrm{sig}}(\Pi, D, q, k)$.

The local classification projection for $\mathsf{ExactGlobalizeBase}(\Pi, D)$ applies to these two displayed gap-signature witnesses. Its equivalence is precisely

$$\mathsf{psame}^{\mathrm{base}}_{\Pi}(p, q) \iff \mathsf{Nonempty}(\mathsf{GeneratedSameSig}(\Pi, h, k)).$$

Together with the constructed exactness witness and the two coverage witnesses, this gives the required package pair. □

Corollary 9199.18 (No closure export)**.** *Theorem 9199.16 exports exactness only at $\mathsf{psame}^{\mathrm{base}}_{\Pi}$. It does not export exactness at $\mathsf{psame}^{\mathrm{eq}}_{\Pi}$.*

Proof. The statement concludes $\mathsf{ExactGlobalizeBase}(\Pi, D)$, whose relation field is $\mathsf{psame}^{\mathrm{base}}_{\Pi}$ by Definition 9199.11. The optional equivalence closure has the local reflection theorem of Proposition 9198.15; that theorem does not replace the relation field of $\mathsf{ExactGlobalizeBase}(\Pi, D)$. □

Protocol 9199.19 (Acceptance gate for a checked report)**.** *This target may be upgraded from paper-level to checked only if the report includes all of the following:*

1. *a proof-assistant build command and version;*

2. *the public theorem name* `Globalize.exactBase`*;*
3. *no* `sorry`*,* `admit`*, or unchecked postulate in the proof of* `Globalize.exactBase`*;*
4. *no public theorem that replaces* hsame *by host equality of histories;*
5. *no public theorem that replaces* TokIntro *by a host function without a relational wrapper;*
6. *a list of every remaining axiom, postulate, or imported theorem used by the checked artifact.*

`Lean4✓ BEDC.BaseReflection.checked acceptance gate exactBase exports public shape`

Theorem 9199.20 (Generated signature witness inhabitation)**.** *For every generated probe bundle* Π *and histories* h, k*, the following are equivalent:*

1. *there is an element* $G : \mathsf{GeneratedSameSig}(\Pi, h, k)$*;*
2. $\mathsf{sameSig}_{\Pi}(h, k)$*.*

Proof. Unpack Definition Definition 9199.10. An element $G : \mathsf{GeneratedSameSig}(\Pi, h, k)$ consists of histories s, t, evidence objects Δ, Θ, generation judgments

$$\mathsf{Sig}(\Pi, h, s, \Delta) \quad \text{and} \quad \mathsf{Sig}(\Pi, k, t, \Theta),$$

and a sameness witness $\mathsf{hsame}(s, t)$. These are exactly the witnesses required by Definition Definition 6.75 for $\mathsf{sameSig}_{\Pi}(h, k)$. This proves the forward implication.

Conversely, unpack $\mathsf{sameSig}_{\Pi}(h, k)$ using Definition Definition 6.75. It supplies histories s, t, evidence objects Δ, Θ, the two displayed generation judgments, and $\mathsf{hsame}(s, t)$. By Definition Definition 9199.10, these fields assemble an element of $\mathsf{GeneratedSameSig}(\Pi, h, k)$. □

Theorem 9199.21 (Generated signature sameness closure under bundle append)**.** *For probe bundles* Π, Θ *and histories* h, k*, if* $G : \mathsf{GeneratedSameSig}(\Pi, h, k)$ *and* $H : \mathsf{GeneratedSameSig}(\Theta, h, k)$*, then*

$$\mathsf{GeneratedSameSig}(\mathsf{BAppend}(\Pi, \Theta), h, k).$$

Proof. Let Ω be the appended bundle with $\Omega = \mathsf{BAppend}(\Pi, \Theta)$. Unpack G as signatures s_h, s_k with evidence Δ_h, Δ_k,

$$\mathsf{Sig}(\Pi, h, s_h, \Delta_h), \qquad \mathsf{Sig}(\Pi, k, s_k, \Delta_k), \qquad \mathsf{hsame}(s_h, s_k),$$

and unpack H as signatures t_h, t_k with evidence Γ_h, Γ_k,

$$\mathsf{Sig}(\Theta, h, t_h, \Gamma_h), \qquad \mathsf{Sig}(\Theta, k, t_k, \Gamma_k), \qquad \mathsf{hsame}(t_h, t_k).$$

Apply Definition 6.48 to the two h-side signatures, with appended-bundle witness Ω. This gives a history u_h and evidence Λ_h such that

$$\mathsf{Cont}(t_h, s_h, u_h) \quad \text{and} \quad \mathsf{Sig}(\Omega, h, u_h, \Lambda_h).$$

Apply the same theorem to the two k-side signatures, with the same appended-bundle witness Ω. This gives a history u_k and evidence Λ_k such that

$$\mathsf{Cont}(t_k, s_k, u_k) \quad \text{and} \quad \mathsf{Sig}(\Omega, k, u_k, \Lambda_k).$$

History-sameness reflexivity gives $\mathsf{hsame}(u_h, u_h)$. Using $\mathsf{hsame}(t_h, t_k)$, $\mathsf{hsame}(s_h, s_k)$, $\mathsf{hsame}(u_h, u_h)$, and the two displayed continuation witnesses, Definition 4.42 yields $\mathsf{hsame}(u_h, u_k)$. The generated-sameness witness for Ω is therefore filled by the two appended signature judgments and this final history-sameness component, exactly as in Definition 9199.10. Since $\Omega = \mathsf{BAppend}(\Pi, \Theta)$, this is the required generated-sameness witness for $\mathsf{BAppend}(\Pi, \Theta)$. □

Definition 9199.22 (Concrete source subdomain)**.** *A concrete source domain D' is a subdomain of D, written*

$$\mathsf{SubDom}(D', D),$$

when every D'-admitted source is D-admitted:

$$\forall h,\ \mathsf{InDom}(D', h) \Longrightarrow \mathsf{InDom}(D, h).$$

The condition changes only the source-admission judgment. It does not change the bundle Π, generated-signature judgments, token-introduction judgments, or the base package relation.

Lemma 9199.23 (Subdomain gap base-change)**.** *Assume $\mathsf{SubDom}(D', D)$. For every bundle Π, token p, and source history h, if $\mathsf{InDom}(D', h)$, then*

$$\mathsf{InGap}^{\mathrm{sig}}(\Pi, D', p, h) \Longleftrightarrow \mathsf{InGap}^{\mathrm{sig}}(\Pi, D, p, h).$$

Proof. Unpack $\mathsf{InGap}^{\mathrm{sig}}$ by Definition 9193.1. A D'-gap membership consists of $\mathsf{InDom}(D', h)$, a generated signature $\mathsf{Sig}(\Pi, h, s, \Delta)$, and a token-introduction judgment $\mathsf{TokIntro}(\Pi, s, p)$. The subdomain premise sends the admitted-source part to $\mathsf{InDom}(D, h)$, while the generated signature and token-introduction witnesses are unchanged. These three data repack as $\mathsf{InGap}^{\mathrm{sig}}(\Pi, D, p, h)$.

Conversely, assume $\mathsf{InDom}(D', h)$ and unpack $\mathsf{InGap}^{\mathrm{sig}}(\Pi, D, p, h)$. The unpacked membership supplies a generated signature $\mathsf{Sig}(\Pi, h, s, \Delta)$ and a token-introduction judgment $\mathsf{TokIntro}(\Pi, s, p)$. Replacing only the admitted-source certificate by the given $\mathsf{InDom}(D', h)$ repacks the same signature and token witnesses as $\mathsf{InGap}^{\mathrm{sig}}(\Pi, D', p, h)$. □

Theorem 9199.24 (Exact Globalize base subdomain base-change)**.** *Assume $\mathsf{ExactGlobalizeBase}(\Pi, D)$ and $\mathsf{SubDom}(D', D)$. Then the concrete signature Globalize structure restricted through $\mathsf{InGap}^{\mathrm{sig}}(\Pi, D', p, h)$ satisfies*

$$\mathsf{ExactGlobalizeBase}(\Pi, D').$$

Proof. By Definition 9199.11 and Definition 9199.16, it is enough to provide coverage, base soundness, and base completeness over D'.

For coverage, fix h and assume $\mathsf{InDom}(D', h)$. The subdomain premise gives $\mathsf{InDom}(D, h)$. The coverage field of $\mathsf{ExactGlobalizeBase}(\Pi, D)$ supplies a token p with

$$\mathsf{InGap}^{\mathrm{sig}}(\Pi, D, p, h).$$

The reverse direction of Definition 9199.23, applied with the original D'-admission premise, converts this membership into

$$\mathsf{InGap}^{\mathrm{sig}}(\Pi, D', p, h),$$

which proves D'-coverage.

For soundness, assume

$$\mathsf{InGap}^{\mathrm{sig}}(\Pi, D', p, h), \qquad \mathsf{InGap}^{\mathrm{sig}}(\Pi, D', q, k), \qquad \mathsf{GeneratedSameSig}(\Pi, h, k).$$

Each D'-gap membership exposes its own D'-admitted-source certificate by Definition 9193.1. The forward direction of Definition 9199.23 converts the two memberships to

$$\mathsf{InGap}^{\mathrm{sig}}(\Pi, D, p, h) \quad \text{and} \quad \mathsf{InGap}^{\mathrm{sig}}(\Pi, D, q, k).$$

Applying the base soundness field of $\mathsf{ExactGlobalizeBase}(\Pi, D)$ to these two converted memberships and the displayed generated-sameness witness gives

$$\mathsf{psame}^{\mathrm{base}}_{\Pi}(p, q).$$

For completeness, assume

$$\mathsf{InGap}^{\mathrm{sig}}(\Pi, D', p, h), \qquad \mathsf{InGap}^{\mathrm{sig}}(\Pi, D', q, k), \qquad \mathsf{psame}^{\mathrm{base}}_{\Pi}(p, q).$$

As in the soundness argument, the two D'-gap memberships transport through Definition 9199.23 to D-gap memberships with the same histories and visible tokens. The base completeness field of $\mathsf{ExactGlobalizeBase}(\Pi, D)$ then yields

$$\mathsf{Nonempty}(\mathsf{GeneratedSameSig}(\Pi, h, k)).$$

These three clauses are precisely the fields required for $\mathsf{ExactGlobalizeBase}(\Pi, D')$. □

Chapter 9200

Unary Shift and Commutativity

9200.1 Unary Commutativity Proof Obligations

The additive boundary correctly states that $\mathsf{Add}^{\uparrow}$ requires unary continuation commutativity. This chapter decomposes that commutativity proof into smaller obligations. These obligations are more suitable for machine verification than a single opaque paper proof.

Definition 9200.1 (Unary right-shift obligation)**.** *The unary right-shift obligation is the statement that if*

$$\mathsf{Unary}(k), \qquad \mathsf{Cont}(k, \mathsf{E1}(h), r),$$

then there exists a history v such that

$$\mathsf{Cont}(k, h, v) \quad \textit{and} \quad \mathsf{hsame}(r, \mathsf{E1}(v)).$$

Lean4 (definition) `BEDC.FKernel.Unary.UnaryRightShiftObligation`
↪ variant `BEDC.FKernel.Unary.UnaryRightShiftObligation iff fields`
Lean4 ✓ `BEDC.FKernel.Unary.unary right shift obligation holds`

Definition 9200.2 (E1-congruence obligation)**.** *The* E1*-congruence obligation is the statement that*

$$\mathsf{hsame}(u, v) \quad \Rightarrow \quad \mathsf{hsame}(\mathsf{E1}(u), \mathsf{E1}(v)).$$

Lean4 (definition) `BEDC.FKernel.Unary.EOneCongruenceObligation`
Lean4 ✓ `BEDC.FKernel.Unary.EOneCongruenceObligation holds`
↪ variant `BEDC.FKernel.Unary.eone congruence obligation holds`

Definition 9200.3 (Unary continuation commutativity obligation)**.** *The unary continuation commutativity obligation is the statement that if*

$$\mathsf{Unary}(h), \quad \mathsf{Unary}(k), \quad \mathsf{Cont}(h, k, r), \quad \mathsf{Cont}(k, h, r'),$$

then

$$\mathsf{hsame}(r, r').$$

Theorem 9200.4 (Commutativity from right-shift and E1-congruence)**.** *Assume a proof of the unary right-shift obligation and a proof of the* E1*-congruence obligation. Then for all histories h, k, r, r', if* $\mathsf{Unary}(h)$*,* $\mathsf{Unary}(k)$*,* $\mathsf{Cont}(h, k, r)$*, and* $\mathsf{Cont}(k, h, r')$*, then* $\mathsf{hsame}(r, r')$*.*

Lean4 ✓ BEDC.FKernel.Unary.comm from obligations

Proof. Induct on the unary derivation of the left input h. The empty case follows from Theorem 4.38. In the step case, write $h = \mathsf{E1}(h_0)$. Invert $\mathsf{Cont}(\mathsf{E1}(h_0), k, r)$ to obtain u with $\mathsf{Cont}(h_0, k, u)$ and $\mathsf{hsame}(r, \mathsf{E1}(u))$. Apply unary right-shift to $\mathsf{Cont}(k, \mathsf{E1}(h_0), r')$ to obtain v with $\mathsf{Cont}(k, h_0, v)$ and $\mathsf{hsame}(r', \mathsf{E1}(v))$. By the induction hypothesis, $\mathsf{hsame}(u, v)$. By $\mathsf{E1}$-congruence, $\mathsf{hsame}(\mathsf{E1}(u), \mathsf{E1}(v))$. Transitivity of hsame yields $\mathsf{hsame}(r, r')$. □

↪ variant BEDC.FKernel.Unary.unary commutativity obligation from named obligations

Corollary 9200.5 (Additive naming boundary)**.** *The name* $\mathsf{Add}^{\uparrow}$ *is licensed only after the unary right-shift and* $\mathsf{E1}$*-congruence obligations have been supplied. Before that point, the safe name is* $\mathsf{UnaryContMonoid}^{\uparrow}$*.*

Lean4 ✓ BEDC.FKernel.Unary.additive naming boundary from obligations

Proof. The monoid-like name requires unit and associativity. The additive name requires the additional commutativity field. Theorem 9200.4 reduces that field to the two named obligations. □

9200.2 Unary Shift and the Additive License

section 9200.1 decomposes unary continuation commutativity into auxiliary obligations. This section states the concrete instances of those obligations whose proofs license the additive name $\mathsf{Add}^{\uparrow}$.

Lemma 9200.6 ($\mathsf{E1}$-congruence)**.** *If* $\mathsf{hsame}(h, k)$*, then*

$$\mathsf{hsame}(\mathsf{E1}(h), \mathsf{E1}(k)).$$

Lean4 ✓ BEDC.FKernel.Hist.eone congruence
↪ variant BEDC.FKernel.Hist.hsame e1 congruence

Proof. This is the $\mathsf{E1}$-constructor rule for hsame. □

Lemma 9200.7 (Unary right-shift, witness form)**.** *Assume* $\mathsf{Unary}(k)$ *and* $\mathsf{Cont}(k, \mathsf{E1}(h), r')$*. Then there exists a history* v *such that*

$$\mathsf{Cont}(k, h, v) \qquad \textit{and} \qquad \mathsf{hsame}(r', \mathsf{E1}(v)).$$

Proof. This is the proof obligation named $\mathsf{UnaryShift}$. The proof proceeds by induction on the unary derivation of k. The empty case uses the left-unit law for Cont. The step case uses inversion on the continuation derivation, the induction hypothesis for the shorter unary history, $\mathsf{E1}$-congruence, and transitivity of hsame. □

↪ variant `BEDC.FKernel.Unary.unary continuation commutativity`
↪ variant `BEDC.FKernel.Unary.unary commutativity refined with result closure`

Proof. Induct on the derivation of $\mathsf{Unary}(h)$. The empty case follows from the continuation unit laws. In the step case, write the left source as $\mathsf{E1}(h_0)$. Invert $\mathsf{Cont}(\mathsf{E1}(h_0), k, r)$, obtaining a history u such that $\mathsf{Cont}(h_0, k, u)$ and $\mathsf{hsame}(r, \mathsf{E1}(u))$. Apply Theorem 9200.13 to $\mathsf{Cont}(k, \mathsf{E1}(h_0), r')$, obtaining v with $\mathsf{Cont}(k, h_0, v)$ and $\mathsf{hsame}(r', \mathsf{E1}(v))$. The induction hypothesis gives $\mathsf{hsame}(u, v)$. Lemma 9200.10 and transitivity of hsame yield $\mathsf{hsame}(r, r')$. □

Corollary 9200.15 (Activation of the additive name)**.** *Theorem 9200.14 is included in the stability field of the additive naming certificate, so the unary continuation interface is licensed to use the name* $\mathsf{Add}^{\uparrow}$.

Lean4 ✓ `BEDC.FKernel.Unary.add up name certificate`
↪ variant `BEDC.FKernel.Unary.unary add activation`

Proof. The monoid-like fields are unit, associativity, and determinacy of unary continuation. Theorem 9200.14 supplies the commutativity field required by the additive name. □

Theorem 9200.16 (Two-element unital continuations are swapped-commutative)**.** *Let C be an equality-classified carrier, let $e, u \in C$, and let $\Gamma(a, b, r)$ be a deterministic total continuation relation on C. Assume e is a two-sided unit:*

$$\Gamma(e, x, x) \qquad \textit{and} \qquad \Gamma(x, e, x)$$

for every $x \in C$. Assume also that every $x \in C$ is equal to e or to u. If $a, b, r, s \in C$, $\Gamma(a, b, r)$, and $\Gamma(b, a, s)$, then $r = s$. Consequently a finite equality-classified deterministic total unital continuation that fails the swapped-source commutativity field has at least three carrier elements.

Proof. The field under test is the order-swap result comparison isolated by Definition 9200.5; Definition 29.9 records that additive comparison is made at the result-classifier level. In the equality-classified case, this classifier is ordinary equality. The available unital and deterministic roles are the abstract counterparts of the roles recorded for continuation in Definition 4.38 and Definition 21.7, and packaged among the stability data in Definition 29.10.

Use the two-element cover for a and b. If $a = e$, then $\Gamma(a, b, r)$ is $\Gamma(e, b, r)$. The left-unit instance $\Gamma(e, b, b)$ and determinacy at the ordered pair (e, b) give $r = b$. The swapped witness is $\Gamma(b, e, s)$; the right-unit instance $\Gamma(b, e, b)$ and determinacy at (b, e) give $s = b$. Hence $r = s$. The case $b = e$ is symmetric, using the right unit on $\Gamma(a, e, r)$ and the left unit on $\Gamma(e, a, s)$.

It remains to consider the case $a = u$ and $b = u$. Then both displayed continuation witnesses have the same ordered source (u, u):

$$\Gamma(u, u, r) \qquad \text{and} \qquad \Gamma(u, u, s).$$

Determinacy gives $r = s$. Totality supplies such result witnesses for every ordered pair, so the comparison holds for the full swapped-source field. If a finite equality-classified unital continuation were a countermodel on at most two carrier elements, the preceding case split would supply the missing swapped-source equality, a contradiction. Hence a finite equality countermodel must have at least three carrier elements. □

Theorem 9200.17 (Three-point minimality of swapped-source additive obstruction)**.** *Let C be a finite equality-classified carrier equipped with a total deterministic continuation relation Γ and a two-sided unit $e \in C$. Assume the additive result classifier is equality, as in Definition 29.9. If the swapped-source additive commutativity field fails, so that there exist $a, b, r, s \in C$ with*

$$\Gamma(a, b, r), \qquad \Gamma(b, a, s), \qquad r \neq s,$$

then C has at least three equality classes, hence at least three carrier elements. The bound is sharp: the three-element equality-classified carrier of Definition 29.17 satisfies the carrier NameCert*, closure, total deterministic graph behavior, two-sided unit, associativity, same-source determinacy, and the source-to-pattern and source-to-ledger fields of the additive naming template, while failing the swapped-source additive commutativity field.*

Proof. Assume, toward contradiction, that C has at most two equality classes. Since e is the unit, choose an element $u \in C$ such that every carrier element is equal either to e or to u; in the one-class case take $u = e$. The hypotheses are exactly the equality-classified deterministic total unital setup covered by Definition 9200.16. Applying that theorem to the witnesses

$$\Gamma(a, b, r) \qquad \text{and} \qquad \Gamma(b, a, s)$$

gives $r = s$, contradicting the assumed failure $r \neq s$. Therefore any equality-classified finite countermodel to the swapped-source additive commutativity field must have at least three equality classes.

It remains to check sharpness. In Definition 29.17, the carrier is $\{e, p, q\}$, the classifier is equality, and the continuation relation is the graph of the displayed operation table. That theorem verifies the carrier certificate, closure, unit, associativity, same-source determinacy, and the source-to-pattern and source-to-ledger fields. The same table gives

$$\Gamma(p, q, p) \qquad \text{and} \qquad \Gamma(q, p, q),$$

and equality classification does not identify p and q. Hence the swapped-source additive commutativity field fails on a three-element carrier. Combining the lower bound with this witness proves that three points are minimal for this obstruction. □

Chapter 9201

Lean Scaffold Contract

9201.1 Lean-Style Scaffold Contract

This chapter records the base-reflection scaffold file in the Lean repository. The file is a checked theorem-shape scaffold: abstract carriers and relations are represented as fields of a setup structure, the base relation is an inductive definition, and the local reflection theorems are proved in a form that future implementations can instantiate with concrete objects.

9201.2 Scaffold excerpt

```
structure ExactGlobalizeBase (s : BaseReflectionSetup) (P : s.Pi) (D : s.Domain) : Prop where
  coverage : forall h, s.InDom D h -> exists p, s.InGapSig P D p h
  soundness : forall h k p q,
    s.InGapSig P D p h -> s.InGapSig P D q k ->
    GeneratedSameSig s P h k -> PsameBase s P p q
  completeness : forall h k p q,
    s.InGapSig P D p h -> s.InGapSig P D q k ->
    PsameBase s P p q -> Nonempty (GeneratedSameSig s P h k)

theorem ExactGlobalizeBase.classify_iff
  (ex : ExactGlobalizeBase s P D)
  (hp : s.InGapSig P D p h) (hq : s.InGapSig P D q k) :
  PsameBase s P p q <-> Nonempty (GeneratedSameSig s P h k) := by
  constructor
  - intro hbase
    exact ex.completeness h k p q hp hq hbase
  - intro hgen
    cases hgen with
    | intro hsig =>
        exact ex.soundness h k p q hp hq hsig
```

9201.3 Interpretation

The scaffold separates three layers:

1. **abstract carriers**: histories, signatures, packages, domains, bundles, and evidence, packaged by `BaseReflectionSetup`;
2. **relational object layer**: setup fields `TokIntro`, `hsame`, `SigGen`, and `InGapSig`;
3. **checked-shape target**: `PsameBase`, `PackageReflection.base`, and `ExactGlobalizeBase.classify_iff`.

Principle 9201.1 (No scaffold laundering)**.** *A scaffold theorem may be cited only as a theorem-shape target. It may be cited as a verified BEDC theorem only when a build log records a successful checker run and discloses all axioms or postulates.*

Lean4 ✓ `BEDC.BaseReflection.no scaffold laundering coverage soundness`

9201.4 Lean Verification Status

The five base-reflection targets are rendered here for at-a-glance reading. Each line is generated by the `\leanchecked` family of macros (see `preamble.tex`); the underscore in Lean identifier names is rendered as a thin space rather than a literal underscore. The audit `lean4/scripts/bedc_ci.py audit` enforces that each target name resolves to a real declaration in `lean4/BEDC/`.

Lean4 ✓ `BEDC.BaseReflection.PackageReflection base`

↪ variant `BEDC.BaseReflection.PsameBase inversion`

↪ variant `BEDC.BaseReflection.ExactGlobalizeBase classify iff`

Lean4 (definition) `BEDC.BaseReflection.GeneratedSameSig`

Part VIII

Implementation-Facing Contract

Chapter 9202

Formalization Implementation Contract

9202.1 Layer separation

The implementation has two layers:

1. Host layer: the proof assistant's type theory, inductive types, equality, and functions used to encode BEDC.
2. BEDC layer: the internal relations exposed by the library: `MSame`, `HSame`, `Ext`, `Cont`, `Ask`, `SigRel`, `SameSig`, `InGap`, and certificate records.

Host equality may be used to implement constructors and proofs, but it must not be advertised as BEDC internal equality.

9202.2 Module targets

Recommended module layout:

```
BEDC/FKernel/Mark.lean
BEDC/FKernel/Hist.lean
BEDC/FKernel/Ext.lean
BEDC/FKernel/Cont.lean
BEDC/FKernel/Ask.lean
BEDC/FKernel/Bundle.lean
BEDC/FKernel/Sig.lean
BEDC/FKernel/Package.lean
BEDC/FKernel/Gap.lean
BEDC/FKernel/NameCert.lean
BEDC/FKernel/Unary.lean
```

9202.3 Public theorem names

First target theorem names:

```
msame_refl
```

```
msame_symm
msame_trans
not_msame_b0_b1
not_msame_b1_b0
hsame_refl
hsame_symm
hsame_trans
not_hsame_emp_e0
not_hsame_emp_e1
not_hsame_e0_e1
ext_deterministic
ext_respects_sameness
cont_deterministic
cont_left_unit
cont_right_unit
cont_assoc_exists
sig_deterministic
sameSig_refl
sameSig_symm
sameSig_trans
gap_coverage
gap_separation
compGap_coverage
```

9202.4 Implementation choices

The first sprint should implement a finite evidence-erased signature layer. That is, use

```
SigRel Ask bundle history answerHistory
```

without an explicit evidence ledger. Once the finite kernel is checked, add evidence aggregation as a refinement. This avoids blocking signature determinacy on unresolved ledger aggregation details.

Probe bundles should be internally generated by constructors, not exposed publicly as host lists.

Probe behavior should be represented as a relation:

```
Ask :  ProbeName -> BHist -> BMark -> Evidence -> Prop.
```

A deterministic ask policy should be a structure containing the theorem that two ask events for the same probe and history emit internally same marks.

9202.5 Proof-sprint order

The recommended order:

1. prove all `MSame` theorems;
2. prove all `HSame` theorems and no-confusion lemmas;
3. prove `Ext` determinacy and sameness-respect;

4. prove `Cont` determinacy, units, and associativity witness;
5. define bundles and signature generation;
6. prove signature determinacy under deterministic ask;
7. prove `SameSig` equivalence;
8. define package and gap policies;
9. prove gap coverage and separation;
10. prove composite gap coverage.

9202.6 Forbidden public shortcuts

Do not expose host `Nat`, host `List`, host equality, or host function spaces as BEDC primitives. They may be used internally in an implementation, but the public BEDC API must state the internal relations explicitly.

Part IX

Acceptance Discipline

Chapter 9203

Closure and Verification Discipline

This chapter records the discipline by which a mature mathematical object's claim is read. The discipline reports three independent axes. The *theoretical closure axis* records what the paper has proved about the object's NameCert, scope, exactness, ledger, stability, and bridge; it is read entirely from the manuscript, with no input from any proof assistant. The *external correspondence axis* records how the package is compared with a declared outside reference theory and scope. The *formal verification axis* records the independent audit state of the corresponding Lean targets; it strengthens reliability and reproducibility but assigns no theoretical content. A claim and its audit are separate artefacts that compose only via VerifiedGate; external correspondence is reported alongside them and does not alter the theory or verification grade.

Read against Definition 9387.10, this chapter is the positive face of the project's discipline: positive content admitted only if its closure is exhibited by paper-side witnesses, while machine verification is reported as an external audit layer that never substitutes for closure.

9203.1 Theoretical closure axis

Definition 9203.1 (Theoretical closure grades)**.** *The* theoretical closure axis *is the six-element set*

$$\mathsf{TheoryClosure} = \{\,\mathsf{seed},\ \mathsf{obligation},\ \mathsf{scopedClosed},\ \mathsf{publicClosed},\ \mathsf{bridgedClosed},\ \mathsf{maturePackageClosed}\,\}$$

ordered by $\mathsf{seed} < \mathsf{obligation} < \mathsf{scopedClosed} < \mathsf{publicClosed} < \mathsf{bridgedClosed} < \mathsf{maturePackageClosed}$.

Definition 9203.2 (Closure grade interpretations)**.** *The grades are read as follows.*

seed: *a naming seed has been declared; carrier and classifier are sketched; no exactness theorem has been settled.*

obligation: *every proof obligation needed to close* NameCert(N) *has been written down precisely; the scope of the eventual closure is fixed; the central proofs are not yet completed.*

scopedClosed: *within an explicit scope, every* NameCert *field (carrier, classifier, exactness, ledger, stability) is supplied with paper-level proof. The scope is recorded in the chapter's closurestatus block and is the manuscript's binding commitment about what has actually been reconstructed.*

publicClosed: *in addition to* scopedClosed*, the chapter exhibits the public-object surface of the standard reading: public constructors, readback, endpoint exactness, normal form, and a no-hidden-leakage statement.*

bridgedClosed: *in addition to* publicClosed*, the chapter exhibits a paper-level standard bridge per chapter 9204, including a paper-level no-host-leak argument.*

maturePackageClosed: *in addition to* bridgedClosed*, the chapter records the mature-package theorem inventory whose conclusions a host reader expects (e.g. Peano induction for* $\mathsf{Nat}^{\uparrow}$*, ordered-field laws for* $\mathsf{Rat}^{\uparrow}$*).*

Definition 9203.3 (Theory gate)**.** *For an object N and grade $c \in$* TheoryClosure*, the* theory gate at grade c *is*

$$\mathsf{TheoryGate}(N, c) \;:=\; \mathsf{NameCert}(N) \wedge \mathsf{ClosureCert}(N, c).$$

A claim that BEDC closes N at grade c is admissible only when $\mathsf{TheoryGate}(N, c)$ *holds.*

Definition 9203.4 (Closure certificate fields)**.** *The closure certificate* $\mathsf{ClosureCert}(N, c)$ *packages: a* source field *naming the BEDC layer that carries N (*Mark*,* Hist*,* Bundle*,* Pkg*, or* NameCert*); a* classifier field *witnessing the equivalence relation; an* exactness field *citing the classifier-respecting transport; a* ledger field*; a* stability field*; an explicit* scope field *naming exactly what is closed; and the chosen grade c. At grades* publicClosed *and above, the certificate additionally cites a public-object surface; at* bridgedClosed *and above, the certificate cites the chapter's* StandardBridge*.*

9203.2 External correspondence axis

Definition 9203.5 (External correspondence grades)**.** *The* external correspondence axis *is the four-element set*

$$\mathsf{ExternalCorrespondenceStatus} \;=\; \{\,\mathsf{notApplicable},\ \mathsf{referencedExternal},\ \mathsf{bridgedExternal},\ \mathsf{calibratedReconstruction}\,\}$$

ordered by notApplicable $<$ referencedExternal $<$ bridgedExternal $<$ calibratedReconstruction*.*

Definition 9203.6 (External correspondence interpretations)**.** *The grades are read as follows.*

notApplicable: *the package is stated internally, with no declared outside reference theory for comparison.*

referencedExternal: *an outside reference theory R is named, and the comparison scope S is stated.*

bridgedExternal: *the chapter states the object and main-theorem correspondences between R and the BEDC construction over S.*

calibratedReconstruction: *relative to a declared and commit-pinned outside reference theory R and a declared scope S, the package closes the theory-narrative question of constructive content over S: it supplies an internal constructive theory C over S, states the $R \leftrightarrow C$ object and main-theorem correspondences, declares coverage and exclusions, and exhausts S as the disjoint union of the BEDC reconstructed constructive kernel and the measured or refused classical boundary, with no hidden third region. This grade does not assert kernel checking, axiom purity, or footprint cleanliness; those are reported only by the formal verification and bridge-status axes.*

Principle 9203.7 (Calibrated reconstruction requires boundary exhaustion)**.** *A closurestatus block may report* `\externalcorrespondence{\calibratedReconstruction}` *only when it also supplies* `\boundaryexhaustive{<label>}` *pointing to a finite decomposition of the declared scope. Each row of that decomposition must be marked either as BEDC reconstructed constructive kernel, with local Lean targets or definitions, or as measured/refused classical boundary, with the external footprint explicitly named.*

Remark 9203.8 (External correspondence is not bridged closure)**.** *The external correspondence axis is additive. It does not rewrite* bridgedClosed *and it does not promote a package along the theoretical closure ladder. A package can have* calibratedReconstruction *for an external corpus while its theory closure and formal verification grades remain exactly the values recorded by* theoryclosure *and* formalstatus*.*

9203.3 Formal verification axis

Definition 9203.9 (Formal verification grades)**.** *The* formal verification axis *is the eight-element set*

$$\mathsf{FormalStatus} = \{\mathsf{unformalized}, \mathsf{formalTarget}, \mathsf{encodedDef}, \mathsf{scaffoldChecked}, \mathsf{theoremChecked}, \mathsf{auditClean}, \mathsf{axiomCle}$$

ordered by inclusion of audit guarantees.

Definition 9203.10 (Verification grade interpretations)**.** unformalized**:** *no Lean target.*

formalTarget**:** *a Lean theorem-shape target exists (statement only); proof is empty, sorry, or scaffold.*

encodedDef**:** *the relevant carriers and classifiers are encoded as Lean* `defs` *or* `inductives`*.*

scaffoldChecked**:** *a scaffold theorem in the sense of chapter 9201 type-checks.*

theoremChecked**:** *the canonical Lean theorem corresponding to the closure certificate's distinguished proof has been checked by* `lake build`*.*

auditClean**:** *in addition, every* `\leanchecked`*,* `\leanvariant`*,* `\leanstmt`*,* `\leandef` *marker on the certificate's targets resolves to a real declaration (* `lean4/scripts/bedc_ci.py audit` *clean).*

axiomClean**:** *in addition, the transitive axiom audit reports no* `Classical.choice`*,* `Quot.sound`*, or* `propext` *dependency for the cited targets (* `tools/check-axioms.py` *and* `bedc_ci.py axiom-purity -strict` *clean).*

bridgeChecked**:** *when the certificate is at* bridgedClosed*, the standard-bridge no-host-leak field has been machine-checked against the chosen host language.*

Principle 9203.11 (Verification is not a closure formation rule)**.** *Machine verification is an audit layer over a stated theoretical closure claim. It strengthens reliability and reproducibility; it does not assign any closure grade by itself. A theory may be closed without being machine-checked, and a checked target does not by itself close any object.*

9203.4 The verified gate

Definition 9203.12 (Verified gate)**.** *For an object N, a closure grade $c \in$* TheoryClosure*, and a verification grade $v \in$* FormalStatus*, the* verified gate *is*

$$\mathsf{VerifiedGate}(N, c, v) \;:=\; \mathsf{TheoryGate}(N, c) \wedge \mathsf{FormalStatus}(N, v).$$

A claim that BEDC exports *N is admissible only when* TheoryGate(N, c) *holds for some c. The export's* verification *is reported separately by* FormalStatus(N, v)*.*

Theorem 9203.13 (Theory gate is monotone in c)**.** *For grades $c, c' \in \mathsf{TheoryClosure}$ with $c' \leq c$, $\mathsf{TheoryGate}(N, c) \to \mathsf{TheoryGate}(N, c')$.*

Sketch. The $\mathsf{NameCert}$ conjunct is independent of the grade. Each higher-grade $\mathsf{ClosureCert}(N, c)$ exhibits the lower-grade certificate as substructure (Definition 9203.2); deleting the additional fields yields $\mathsf{ClosureCert}(N, c')$. □

Theorem 9203.14 (Formal status is monotone in v)**.** *For grades $v, v' \in \mathsf{FormalStatus}$ with $v' \leq v$, $\mathsf{FormalStatus}(N, v) \to \mathsf{FormalStatus}(N, v')$.*

Sketch. Each higher verification grade extends the audit guarantees of the lower one (Definition 9203.10); the audit witnesses for the higher grade contain those of the lower grade. □

Theorem 9203.15 (Theory and verification axes are independent)**.** *Neither axis determines the other. A pair $(c, v) \in \mathsf{TheoryClosure} \times \mathsf{FormalStatus}$ is admissible whenever $\mathsf{TheoryGate}(N, c)$ and $\mathsf{FormalStatus}(N, v)$ both hold; no c implies any v, and no v implies any c beyond* seed.

Sketch. c depends only on paper-side witnesses; v depends only on Lean-side audit. The $\mathsf{NameCert}(N)$ predicate inside $\mathsf{TheoryGate}$ is met by the manuscript's textual certificate, never by a Lean target alone; conversely, a checked Lean target whose paper site exhibits no scope, no exactness, and no ledger only witnesses seed on the theory axis. Consequently the two axes are independent up to the trivial bound that any $v \geq \mathsf{unformalized}$ requires $c \geq \mathsf{seed}$ for the marker discipline of chapter 9203 to bind. □

9203.5 Marker-to-verification correspondence

Definition 9203.16 (Marker assignment)**.** *The Lean status macros map to the formal verification axis only. None assigns or strengthens a closure grade.*

1. `\leandef` *on X:* $\mathsf{FormalStatus}(\,\cdot\,, \mathsf{encodedDef})$.
2. `\leanstmt` *on X:* $\mathsf{FormalStatus}(\,\cdot\,, \mathsf{formalTarget})$.
3. `\leansorryd` *on X with rationale r:* $\mathsf{FormalStatus}(\,\cdot\,, \mathsf{formalTarget})$ *regardless of paper coverage; the rationale is recorded for later upgrade.*
4. `\leanchecked` *on X at the canonical proof site, with no* `\leansorryd` *siblings on the same claim:* $\mathsf{FormalStatus}(\,\cdot\,, \mathsf{theoremChecked})$.
5. `\leanvariant` *on X: does not change the verification grade of the canonical site; it labels a wrapper or projection at the grade of its primary.*
6. *A passed* `lean4/scripts/bedc_ci.py audit` *run lifts* $\mathsf{theoremChecked}$ *to* $\mathsf{auditClean}$ *on the cited targets.*
7. *A passed* `lean4/scripts/bedc_ci.py axiom-purity -strict` *run lifts* $\mathsf{auditClean}$ *to* $\mathsf{axiomClean}$.
8. *A machine-checked no-host-leak field on* $\mathsf{StandardBridge}(N, T)$ *lifts the bridge claim to* $\mathsf{bridgeChecked}$.

Remark 9203.17 (The marker map is not a closure rule)**.** *Definition 9203.16 assigns only a verification grade. The closure grade is supplied by the chapter's closurestatus block (section 9203.6 below); the audit script never reads the closure grade and the closure registry never reads the marker family.*

Lemma 9203.18 (The audit script reflects verification, not closure)**.** *The script* `lean4/scripts/bedc_ci.py audit` *verifies that every Lean marker resolves to a real declaration. The script reports* verification grade*; closure grade is read out of the chapter's closurestatus block by* `critical_path.py` *and by reviewers, never out of the audit JSON.*

9203.6 Per-chapter closurestatus block

Every chapter that asserts an object's closure ends with one block of the form

```
\begin{closurestatus}{\<X>Up}
  \constructivestory{A closure claim is generated bottom-up by first naming the finite source
  \theoryclosure{\scopedClosure}
  \scopeclosed{<text describing exactly what the chapter closes>}
  \externalcorrespondence{\notApplicable | \referencedExternal
    | \bridgedExternal | \calibratedReconstruction}
  \reference{<external reference theory and commit, when applicable>}
  \reconstructionscope{<external comparison scope>}
  \boundaryexhaustive{<label of finite decomposition table>}
  \formalstatus{\theoremCheckedV}
  \leantarget
    {BEDC.<...>.<theorem>}
  \bridgestatus{none | paperBridge | bridgeChecked | bridgePending}
  \notclaimed{<text listing what the chapter does NOT close>}
  \upgradepath{<text naming the next closure grade and what it requires>}
\end{closurestatus}
```

The block is the manuscript's binding commitment about N. `lean4/scripts/bedc_ci.py audit` parses every block and refuses unresolved `\leantarget` targets; `lean4/scripts/critical_path.py` reads theoryclosure and formalstatus to decide whether the chapter is retired from the work queue.

Remark 9203.19 (Both axes are mandatory)**.** *A closurestatus block lacking either* theoryclosure *or* formalstatus *is rejected at audit time. A block with* formalstatus = theoremChecked *but no* leantarget *is similarly rejected. The intent is to make the two axes inseparable in the artefact even though they are independent in content.*

9203.7 Upgrade obligations

Definition 9203.20 (Closure upgrade seed → obligation)**.** *A seed-grade object upgrades to* obligation *when the paper exhibits, in writing, the precise list of proof obligations whose discharge would close* NameCert(N) *at the next grade and the explicit scope at which the closure will be claimed.*

Definition 9203.21 (Closure upgrade obligation → scopedClosed)**.** *An* obligation *object upgrades to* scopedClosed *when paper-level proofs are exhibited within the recorded scope for source membership; classifier transitivity and reflexivity; exactness against* msame/hsame/psame*; absence or explicit form of a gap-policy ledger; and stability of the constructed certificate.*

Definition 9203.22 (Closure upgrade scopedClosed → publicClosed)**.** *A* scopedClosed *certificate upgrades to* publicClosed *when the chapter exhibits the public-object surface: public constructors compatible with the BEDC carrier, a readback function, endpoint exactness, a normal-form theorem, and a no-hidden-leakage statement bracketing the public surface.*

Definition 9203.23 (Closure upgrade publicClosed → bridgedClosed)**.** *A* publicClosed *certificate upgrades to* bridgedClosed *when the chapter exhibits a paper-level standard bridge per chapter 9204, with each of its six fields supplied and the no-host-leak field argued at paper level. Machine verification of the no-host-leak field is the separate* bridgeChecked *obligation on the verification axis.*

Definition 9203.24 (Closure upgrade bridgedClosed → maturePackageClosed)**.** *A* bridgedClosed *certificate upgrades to* maturePackageClosed *when the chapter records the full mature-package theorem inventory characterising the object in the standard reference (e.g. Peano arithmetic, ordered-field axioms, vector-space theory, full determinant theory) and supplies certificates that those theorems hold in the BEDC reading.*

Definition 9203.25 (Verification upgrades)**.** *The verification axis admits its own upgrades, each entirely independent of the closure axis:*

- unformalized → formalTarget*: a Lean theorem statement is added.*
- formalTarget → encodedDef*: the carriers and classifiers are encoded as Lean* `defs`*.*
- encodedDef → scaffoldChecked*: a scaffold theorem type-checks.*
- scaffoldChecked → theoremChecked*: the canonical theorem is proved against the scaffold.*
- theoremChecked → auditClean*:* `bedc_ci.py audit` *reports zero unresolved markers for the cited targets.*
- auditClean → axiomClean*: the transitive axiom audit is clean.*
- *to* bridgeChecked*: the standard bridge's no-host-leak field is machine-checked.*

9203.8 Reuse, composition, and retroactive promotion

Theorem 9203.26 (Theory closure reuse)**.** *If $N_1, \ldots, N_k$ have* TheoryGate(N_i, c_i) *and M is constructed from the N_i via* ReuseCert *instances, then M admits a theory gate at grade $\min_i c_i$ conditional on M's own certificate fields being supplied.*

Theorem 9203.27 (Verification status reuse)**.** *If $N_1, \ldots, N_k$ have* FormalStatus(N_i, v_i) *and M's Lean target is constructed from theirs, then M's verification grade is $\min_i v_i$ on the cited carriers, conditional on M's own canonical theorem being checked.*

Remark 9203.28 (No retroactive promotion)**.** *A construction admitted at (c, v) does not become a construction at (c', v') with $c' > c$ or $v' > v$ merely because the inputs are later upgraded. Promoting either axis requires re-discharging the corresponding upgrade obligation on the construction itself.*

9203.9 The discipline as research-plan language

Remark 9203.29 (What the discipline is for)**.** *This chapter is not a new theorem; it is a vocabulary for stating the present closure and verification status of every claim in the manuscript. Its role is to replace the implicit reading—that an object "exists" in BEDC if it appears anywhere—with the explicit reading that an object* is closed at grade c *only when* TheoryGate(N, c) *holds, and* is verified at grade v *only when* FormalStatus(N, v) *holds. The chapters that follow use this vocabulary to state the bridge protocol (chapter 9204), the cannot-claim registry (chapter 9205), and the closure reading convention (chapter 9206).*

Remark 9203.30 (The discipline is not a kernel proof obligation)**.** *The proof obligations of chapter 9195 and its siblings are obligations on the kernel: they constrain what theorems must hold for the kernel to be coherent. The closure-and-verification discipline is an obligation on the manuscript: it constrains what claims may be made about objects exported from the kernel, and how those claims relate to their independent audit. The two disciplines compose: a kernel theorem that fails its proof obligation cannot support any object's* scopedClosed *or above, while a closurestatus block that misreports either axis is refused at audit time even if every kernel theorem stands.*

Chapter 9204

Standard Bridge Protocol

The closure-and-verification discipline of chapter 9203 ends, on the closure axis, at publicClosed unless a standard bridge to a host mathematical formalism is exhibited at the paper level. This chapter records the shape such a bridge must take, the discipline that prevents it from leaking host-language structure into the BEDC kernel, and the quotient and closure obligations several downstream objects ($\mathsf{Int}^{\uparrow}$, $\mathsf{Rat}^{\uparrow}$, real-valued completions, set-like and type-like reflections) must discharge before they can present themselves at bridgedClosed. The bridge is a conservative extension, not a fusion: it lets a host reader recognise the BEDC object, and it lets BEDC accept host theorems via a typed translation, without admitting host primitives as BEDC inputs.

The bridge is a paper-level construction: exhibiting all six fields advances the closure axis from publicClosed to bridgedClosed. Machine verification of the bridge's no-host-leak field is the independent bridgeChecked point on the verification axis; a paper bridge can stand at bridgedClosed before its no-host-leak field is machine-checked, and a machine-checked no-host-leak field cannot retroactively close a chapter that does not exhibit the bridge in writing.

9204.1 The six fields of a standard bridge

Definition 9204.1 (Standard bridge to a host theory)**.** *A* standard bridge *for an accepted BEDC object N to a host formal theory T is a tuple*

$$\mathsf{StandardBridge}(N,T) \;=\; (\mathsf{encode}_{N,T},\ \mathsf{decode}_{N,T},\ \mathsf{decodeEncode}_{N,T},\ \mathsf{encodeDecode}_{N,T},\ \mathsf{theoremPreservation}_{N,T},\ \mathsf{no}$$

The six fields are described in Definition 9204.2, Definition 9204.2, Definition 9204.3, Definition 9204.4, and Definition 9204.5 below.

Definition 9204.2 (Encode and decode functions)**.** *The* encode field *is a function* $\mathsf{encode}_{N,T}\colon T(N) \to \mathrm{Carrier}(N)$ *from the host's representative type to the BEDC carrier of N. The* decode field *is a function* $\mathsf{decode}_{N,T}\colon \mathrm{Carrier}(N) \to T(N)$ *in the reverse direction. Both functions are required to be classifier-respecting on the BEDC side: identifications by N's classifier translate to identifications recognised by T.*

Definition 9204.3 (Round-trip witness fields)**.** *The* decode-encode field *is a witness* $\mathsf{decodeEncode}_{N,T}\colon \forall x \in T(N).\ \mathsf{decode}_{N,T}(\mathsf{encode}_{N,T}(x)) \sim_T x$*, where $\sim_T$ is the host's recognised equality on $T(N)$. The* encode-decode field *is a witness* $\mathsf{encodeDecode}_{N,T}\colon \forall y \in \mathrm{Carrier}(N).\ \mathsf{encode}_{N,T}(\mathsf{decode}_{N,T}(y)) \sim_N y$*, where $\sim_N$ is the classifier of N on its carrier.*

Definition 9204.4 (Theorem-preservation field)**.** *The* theorem-preservation field *is a finite list of host-side basic theorems together with their BEDC-side counterparts and a translation: each host theorem in the list is asserted to follow, under encode and decode, from a corresponding BEDC theorem already accepted at* $\mathsf{TheoryGate}(N, c)$ *for some* $c \geq \mathsf{scopedClosed}$*. The list is finite and explicit; absence of a host theorem from the list means it is not claimed to be preserved.*

Definition 9204.5 (No-host-leak field)**.** *The* no-host-leak field *is the assertion that* $\mathsf{encode}_{N,T}$*,* $\mathsf{decode}_{N,T}$*, the round-trip witnesses, and the theorem-preservation translation refer to host primitives only inside the bridge module, never inside the BEDC kernel's public surface for* N*. Specifically, the host's* Nat*,* Quot*,* propext*, and* Classical.choice *are forbidden to appear inside any function or theorem statement that names* N *as a BEDC export.*

9204.2 The no-host-leak field as object-level axiom-purity

Theorem 9204.6 (The no-host-leak field is the object-level reading of axiom-purity)**.** *The discipline that the no-host-leak field of Definition 9204.5 imposes on* $\mathsf{StandardBridge}(N, T)$ *coincides, on the BEDC public surface for* N*, with the project-wide refusal of* Classical.choice*,* Quot.sound*, and* propext *that Definition 9387.10 reads as the project's refusal of meta-closure.*

Sketch. The no-host-leak field forbids the four host primitives from appearing in functions and theorems naming N as a BEDC export. Axiom-purity refuses the three meta-closure axioms in the transitive dependencies of any kernel theorem. Restricted to theorems that name N as a BEDC export, the two refusals quantify over the same syntactic surface: encode and decode functions, and theorems whose statement mentions the BEDC carrier of N. The host-Nat refusal is the additional clause that distinguishes the bridge discipline; it is the operational analogue of the term-stratum refusal in Definition 9387.5. □

Remark 9204.7 (Why the host's Nat is named explicitly)**.** *Host* Nat *is included in Definition 9204.5 alongside the three meta-closure axioms because* Nat *is the carrier most often re-used implicitly inside type-theoretic host languages: a function whose body mentions* Nat *for indexing has, in effect, smuggled host-level inductive structure into the BEDC public surface. The bridge field forbids this smuggling at the object level.*

Theorem 9204.8 (Bridge with no-host-leak is conservative over BEDC)**.** *If* $\mathsf{StandardBridge}(N, T)$ *is provided with the no-host-leak field discharged, then no theorem about* N*'s BEDC export becomes provable through the bridge that was not already provable in BEDC at* $\mathsf{TheoryGate}(N, c)$ *for some* $c \geq \mathsf{scopedClosed}$*.*

Sketch. The no-host-leak field excludes the four host primitives from the public surface for N. The remaining bridge content factors through the encode and decode functions, whose round-trip witnesses identify $T(N)$ and $\mathrm{Carrier}(N)$ up to the chosen classifier. A new theorem about N that the bridge supports must be the encode-decode image of a host theorem; the theorem-preservation field of Definition 9204.4 requires such an image to be paired with an existing BEDC-side counterpart. Hence no truly new BEDC theorem about N is added. □

9204.3 Quotient and closure discipline as bridge prerequisites

Definition 9204.9 (Base relation versus closure relation)**.** *A* base relation *on a BEDC carrier is one defined by a finite generating list of clauses, each clause a single-step relation between carrier*

elements. A closure relation *is the smallest relation that contains a given base relation and is closed under reflexivity, symmetry, transitivity, congruence with carrier operations, or any combination thereof named by a closure operator.*

Definition 9204.10 (Closure-level reflection obligation)**.** *For a closure relation $\widehat{R}$ over a base relation R, the* closure-level reflection obligation *is a paper-level proof that, for every theorem φ stated against $\widehat{R}$-equivalence classes, φ holds whenever its base-relation projection holds on representatives. The obligation is discharged by exhibiting an induction principle over the closure operator that lifts a base-level proof to a closure-level proof.*

Remark 9204.11 (Closure-level exactness gating)**.** *The exactness field of* $\mathsf{ClosureCert}(N, c)$ *in Definition 9203.4 demands a classifier-respecting transport at the layer the certificate is stated on. When the classifier is a closure relation, the transport must be supplied at the closure layer: a base-level transport does not suffice. Until the closure-level reflection obligation of Definition 9204.10 is discharged, the certificate is admitted at most at* $\mathsf{TheoryGate}(N, \mathsf{scopedClosed})$ *on the base layer; closure-grade exactness above* $\mathsf{scopedClosed}$ *is not exported.*

Theorem 9204.12 (Closure transport composes with base transport)**.** *A closure-level transport for $\widehat{R}$ over R, together with a base-level transport for R, yields a transport on the closure quotient that respects the classifier of $\widehat{R}$ on every closure operator clause.*

Sketch. The closure-level induction of Definition 9204.10 drives the lift of the base transport to the closure layer; each closure operator step is handled by the corresponding clause of the induction. Composition of the two transports is associative because both factor through the same carrier. □

Remark 9204.13 (Bridge prerequisites for downstream objects)**.** *The integers, the rationals, real-valued completions, set-like reflections, and type-like reflections all rest on closure relations: integer equivalence over $\mathbb{N}^2$, rational equivalence over $\mathbb{Z} \times \mathbb{Z}_{\neq 0}$, Cauchy equivalence over rational sequences, set extensionality at the type level, and type identifications respectively. Each of these requires the closure-level reflection obligation of Definition 9204.10 discharged before a standard bridge to its host counterpart can be admitted. Until then the bridge is presented at* $\mathsf{TheoryGate}(N, \mathsf{scopedClosed})$ *on the base relation, with closure-grade upgrade above* $\mathsf{scopedClosed}$ *deferred.*

9204.4 Conservativity in the presence of theorem preservation

Theorem 9204.14 (Theorem-preservation does not extend BEDC)**.** *A finite theorem-preservation list as in Definition 9204.4 preserves Definition 9204.8: every host theorem in the list translates, under encode and decode, to an existing BEDC theorem about N.*

Sketch. The list's defining condition is that each host entry is paired with an accepted BEDC counterpart at $\mathsf{TheoryGate}(N, c)$ for $c \geq \mathsf{scopedClosed}$. The translation under encode and decode is the round-trip witness. A bridge user who reads off a host theorem from the list and translates back to BEDC obtains a theorem already in BEDC. □

Remark 9204.15 (The list is finite by design)**.** *The theorem-preservation list of Definition 9204.4 is finite because BEDC's discipline is to admit only what has been derived. An infinite list would silently re-introduce schematic host content; a finite list with explicit entries records exactly the host theorems whose BEDC counterparts have been accepted.*

9204.5 Worked sketch: integers

Remark 9204.16 (Integers as the canonical bridge example)**.** *The integer object* $\mathsf{Int}^{\uparrow}$ *illustrates the six fields. The host* T *is the type-theoretic integer type with its standard interface. The encode field maps a host integer to its* $\mathsf{Int}^{\uparrow}$ *carrier representative built from a pair of unary histories; the decode field reads a* $\mathsf{Int}^{\uparrow}$ *carrier representative back to the host integer by collapsing the pair via host subtraction. The decode-encode round trip is host-side equality of integers, which holds by the host's own reflection theorem; the encode-decode round trip is* $\mathsf{Int}^{\uparrow}$*'s classifier on* $\mathbb{N}^2$ *pairs, which holds because* $\mathsf{Int}^{\uparrow}$*'s classifier identifies pairs differing by an additive cancellation. Theorem preservation lists the host's basic identities of integer addition and multiplication paired with their* $\mathsf{Int}^{\uparrow}$ *counterparts already at* $\mathsf{TheoryGate}(\mathsf{Int}^{\uparrow}, \mathsf{scopedClosed})$*. The no-host-leak field forbids host* Quot *from appearing inside any* $\mathsf{Int}^{\uparrow}$*-naming function: the integer object's classifier is a closure relation, but its closure-level reflection is supplied by Definition 9204.10's induction, not by host* $\mathsf{Quot.sound}$*.*

Remark 9204.17 (The sketch is not a proof)**.** *Definition 9204.16 is a paper-level sketch that records the shape of* $\mathsf{StandardBridge}(\mathsf{Int}^{\uparrow}, T_{\mathbb{Z}})$ *for orientation. Its admission as a* $\mathsf{bridgedClosed}$ *export of* $\mathsf{Int}^{\uparrow}$ *requires the closure-level reflection obligation discharged at the paper level; subsequent machine verification of the bridge fields lifts the verification axis to* $\mathsf{bridgeChecked}$ *but is independent of the* $\mathsf{bridgedClosed}$ *closure grade. None of these clauses is asserted to be discharged by this chapter.*

9204.6 Bridge prerequisites table

Remark 9204.18 (Common prerequisites for bridge-strength export)**.** *Five downstream object families share the prerequisites recorded in this chapter. For each family, the bridge-strength export requires: the closure gate at* $\mathsf{TheoryGate}(N, \mathsf{publicClosed})$*, the closure-level reflection obligation of Definition 9204.10, the six fields of Definition 9204.1, and (on the independent verification axis) the no-host-leak field at* $\mathsf{bridgeChecked}$ *if the bridge's host translation is to be machine-audited.*

- *Integer family:* $\mathsf{Int}^{\uparrow}$ *with* $T_{\mathbb{Z}}$ *over the host's integer type.*
- *Rational family:* $\mathsf{Rat}^{\uparrow}$ *with* $T_{\mathbb{Q}}$ *over the host's rational type.*
- *Real-valued completions: a real object with* $T_{\mathbb{R}}$ *over the host's real-number type, conditional on a Seal/Completion certificate.*
- *Set-like reflections: a set object with the host's* Set *type, conditional on a closure-level reflection over set extensionality.*
- *Type-like reflections: a type object with the host's universe, conditional on a closure-level reflection over type identifications.*

The current manuscript admits none of these at $\mathsf{bridgedClosed}$*; the prerequisites are recorded here to make the upgrade obligation on the closure axis explicit, separate from any verification-axis upgrade to* $\mathsf{bridgeChecked}$*.*

Remark 9204.19 (Standard bridge is per host, not absolute)**.** *The bridge is parameterised by the host theory* T*. A bridge to one host (for instance, the type-theoretic host of* `lean4/`*) does not automatically produce a bridge to a different host (a set-theoretic foundation). Each host requires its own discharge of the six fields. The protocol is uniform; the obligations are per-host.*

Chapter 9205

Cannot-Claim Registry and Failure Witnesses

The closure-and-verification discipline of chapter 9203 states what the manuscript may export on the closure axis and what its Lean targets audit on the verification axis; the standard bridge protocol of chapter 9204 states the additional discipline that bridgedClosed export requires. Both chapters describe the positive face of the project's discipline. This chapter records the negative face: the typed failure witnesses that block a closure or verification claim and the explicit cannot-claim registry that records which export claims the manuscript refuses on principle. Read together with Definition 9387.10, the cannot-claim registry plays at the export level the same role that axiom-purity plays at the kernel level: a refusal to admit an unwitnessed positive claim.

9205.1 The discipline of negative claims

Remark 9205.1 (Negative claims as part of the export surface)**.** *A research manuscript that exhibits only its positive theorems implicitly invites readers to infer the rest of mathematics is on its way. The BEDC discipline is the opposite: every claim outside the certified surface is presumed unsupported until a certificate is exhibited, and the manuscript states explicitly which downstream claims it refuses to make at the present closure grade. The cannot-claim registry of Definition 9205.6 is the explicit form of that refusal.*

Remark 9205.2 (Failure witnesses as negative duals of certificates)**.** *A certificate exhibits the structure that licenses an export. A failure witness exhibits the structure that blocks one. Both are typed: the certificate populates a fixed schema of fields, and the failure witness selects one of a fixed list of failure modes. The pairing is total: at any given moment an object either satisfies* $\mathsf{TheoryGate}(N, c)$ *and* $\mathsf{FormalStatus}(N, v)$ *at the grades it claims, in which case its paper witnesses and audit witnesses are exhibited; or it does not, in which case a failure witness names the missing field.*

9205.2 Failure witness type

Definition 9205.3 (Failure certificate)**.** *The* failure certificate $\mathsf{FailureCert}(N, c, v)$ *at the candidate closure grade* c *and verification grade* v *for an object* N *is one of the thirteen typed branches:*

1. `missing-source`*: no source-layer assignment in the sense of Definition 9203.4;*

2. `missing-classifier`: *no classifier supplied for the cited source;*
3. `classifier-not-transitive`: *classifier supplied but transitivity fails or is unproved;*
4. `exactness-fails`: *classifier does not respect* msame/hsame/psame *on the cited source;*
5. `operation-does-not-descend`: *a kernel operation fails to descend through the classifier;*
6. `gap-ledger-absent`: *the ledger field is unspecified and no explicit absence statement is supplied;*
7. `completion-not-stable`: *a completion construction fails the stability field;*
8. `scope-overstated`: *the closure block claims a grade whose scope exceeds what the chapter actually closes (e.g.* publicClosed *asserted for a singleton certificate);*
9. `standard-bridge-fails`: StandardBridge(N, T) *is incomplete in at least one of its six fields when* bridgedClosed *is claimed;*
10. `host-primitive-leakage`: *the no-host-leak field is violated, that is, host* Nat, Quot, propext, *or* Classical.choice *appears in the BEDC public surface for N;*
11. `theorem-checker-failure`: *a Lean target cited under* `\leanchecked` *is missing or fails to build (refutes* theoremChecked*);*
12. `audit-not-clean`: `lean4/scripts/bedc_ci.py audit` *reports unresolved markers on the cited targets (refutes* auditClean*);*
13. `axis-confusion`: *the chapter's prose, table, or marker discipline assigns a closure grade as a function of a verification grade (or vice versa), in violation of Definition 9203.11.*

A claim that TheoryGate(N, c) *holds is refuted by exhibiting any one of branches 1–10. A claim that* FormalStatus(N, v) *holds is refuted by branches 11–12. A claim that the discipline of chapter 9203 is honoured is refuted by branch 13.*

Theorem 9205.4 (Failure witness blocks the gate)**.** *If* FailureCert(N, c, v) *is exhibited against a claimed gate, then that claimed gate does not hold: branches 1–10 block* TheoryGate(N, c)*, branches 11–12 block* FormalStatus(N, v)*, and branch 13 blocks the two-axis discipline that would license* VerifiedGate(N, c, v)*.*

Sketch. Each branch of Definition 9205.3 negates a clause of Definition 9203.4, Definition 9204.1, Definition 9203.16, or Definition 9203.11. A field that the claimed gate requires is absent, invalid, or assigned on the wrong axis by exhibiting the branch; therefore the corresponding conjunction fails. □

Remark 9205.5 (Why thirteen branches and not fewer)**.** *The thirteen branches of Definition 9205.3 are not a partition into incomparable failure modes; some branches are special cases of others read at different closure or verification grades. The list is finite and explicit so that a given audit pass can refer to a single branch when refuting an export claim, and so that grade decisions can be local: a failure cited under one branch is the obligation that needs discharging before a stronger gate is claimed.*

9205.3 Cannot-claim registry

Definition 9205.6 (Cannot-claim entry)**.** *A* cannot-claim entry *is a quadruple*

$$(\text{ClaimText},\ \text{Status},\ \text{WhyNotClaimable},\ \text{RequiredUpgrade})$$

where ClaimText *is a sentence the manuscript refuses to assert at the present time;* Status *is one of* {`forbidden`, `deferred`, `partial`}*;* WhyNotClaimable *cites either an open obligation or a structural reason; and* RequiredUpgrade *names the certificate or bridge whose discharge would license the claim.*

Definition 9205.7 (Cannot-claim registry)**.** *The* cannot-claim registry *is the finite list of cannot-claim entries that the manuscript currently records. The registry is part of the manuscript's export surface in the sense of Definition 9205.1: removing an entry requires the corresponding upgrade discharged, and adding an entry records a new refusal.*

Remark 9205.8 (Anchor entries of the registry)**.** *The four anchor entries below name claims that the manuscript explicitly refuses at the present closure and verification grades. They are the registry: principled refusals that this chapter commits to fixed phrasing. A claim's removal from the registry, or its addition, is a manuscript edit at the cadence of editorial review, not an automated state report.*

- ***Anchor 1.*** ClaimText*: "BEDC derives all mathematics."* Status*:* ***`forbidden`****.* WhyNotClaimable*: the kernel admits only finite generative content; downstream theories enter through naming certificates and standard bridges, not as primitives.* RequiredUpgrade*: there is no upgrade. The claim is refused on principle, not deferred.*
- ***Anchor 2.*** ClaimText*: "*$\mathsf{Nat}^{\uparrow}$ *is the full Peano natural numbers."* Status*:* ***`partial`****.* WhyNotClaimable*:* $\mathsf{Nat}^{\uparrow}$ *records unary repetition histories with* $\mathsf{TheoryGate}(\mathsf{Nat}^{\uparrow}, \mathsf{scopedClosed})$ *on the canonical NameCert scope; full Peano content (induction principle as a closed theorem schema, primitive recursion with computation rules, totality of arithmetic operations) requires the upgrade* $\mathsf{TheoryGate}(\mathsf{Nat}^{\uparrow}, \mathsf{maturePackageClosed})$*.* RequiredUpgrade*:* $\mathsf{Nat}^{\uparrow}$*'s arithmetic test suite (induction, recursion, addition associativity and commutativity, multiplication distributivity, order totality) closed at* maturePackageClosed *on the closure axis. The verification axis grade does not by itself close any further Peano content.*
- ***Anchor 3.*** ClaimText*: "A real-valued completion is exported."* Status*:* ***`deferred`****.* WhyNotClaimable*: the seal/completion module of chapter 11 is a thin interface; Cauchy equivalence, completion existence, uniqueness of limits, and the field-operation descent are not discharged.* RequiredUpgrade*: a Seal/Completion certificate satisfying Definition 9204.10 on Cauchy equivalence, with field operations descending to the completion.*
- ***Anchor 4.*** ClaimText*: "The Lean scaffold is verified end-to-end."* Status*:* ***`forbidden`****.* WhyNotClaimable*: the scaffold of chapter 9201 is a statement-level surface; verification means each scaffold target stands at* theoremChecked *in* ***`lean4/BEDC/`*** *with a successful build report and at* auditClean *on* ***`bedc_ci.py audit`****.* RequiredUpgrade*: a complete checker report from* ***`lake build`*** *together with the audit of* ***`lean4/scripts/bedc_ci.py`*** *and the axiom-purity gate, all exiting clean. This upgrade strengthens the verification axis only; it does not by itself close any object's theory.*

Remark 9205.9 (The registry is finite by design)**.** *The cannot-claim registry of Definition 9205.7 is a finite list because the chapter's discipline is to commit only to refusals it can phrase precisely. A status report enumerating every object that does not currently meet* $\mathsf{TheoryGate}(N, \mathsf{scopedClosed})$ *would mistake a derivation queue for a refusal: an object that is presently at* seed *for lack of a classifier is not a refused claim but an unfinished one. The registry therefore lists principled refusals (Anchor 1, Anchor 4) and bounded deferred claims with explicit upgrade obligations (Anchor 2, Anchor 3); per-object derivation status is read from chapter closurestatus blocks and the audit script of Definition 9203.18, not from the registry.*

9205.4 Closure reading convention

Remark 9205.10 (Reading a closure claim)**.** *A theoretical closure claim and a formal verification claim are distinct. A line of the form* $\mathsf{TheoryGate}(N, \mathsf{scopedClosed})$ *means that the paper supplies the source, classifier, exactness, ledger, and stability witnesses needed to close* N *within the stated scope. A line of the form* $\mathsf{FormalStatus}(N, \mathsf{theoremChecked})$ *means that the cited Lean target has been machine-checked. The second claim audits the first; it does not create the first. A theory may be closed without being machine-checked. Conversely, a checked scaffold or checked definition does not by itself close the corresponding mathematical object.*

9205.5 Anti-confusion register

Remark 9205.11 (Confusions explicitly refused)**.** *The following readings are refused. Citing any one of them is a discipline violation that the audit catches via the* `axis-confusion` *branch of Definition 9205.3.*

1. *"BEDC has re-derived all of mature mathematics."*
2. "$\mathsf{Real}^{\uparrow}$ *is complete."*
3. "$\mathsf{S}^{1\uparrow}$ *is complete."*
4. "$\mathsf{Fold}^{\uparrow}$ *is complete."*
5. "$\mathsf{Nat}^{\uparrow}$ *at* $\mathsf{scopedClosed}$ *equals full natural-number theory."*
6. "$\mathsf{Add}^{\uparrow}$ *at* $\mathsf{scopedClosed}$ *equals full addition."*
7. *"Paper certificates equal machine-checked certificates."*
8. *"Lean scaffolds equal verified implementations."*
9. *"External standard models replace BEDC internal proof obligations."*
10. *"Host equality, host* Nat*, or host functions are part of the BEDC public surface."*
11. *"Machine verification is required for theoretical closure."*
12. *"Without* $\mathsf{theoremChecked}$ *no closure grade above* seed *may be claimed."*
13. *"A checked theorem-shape scaffold closes the corresponding object theory."*
14. *"A scoped certificate closure is a full traditional-object reconstruction."*
15. *"A bridge is closed merely because the BEDC-side certificate is checked."*

9205.6 Failure witness as audit input

Remark 9205.12 (Audit policy when a failure is exhibited)**.** *When a failure certificate is exhibited for an object* N *presently at* $\mathsf{TheoryGate}(N, c)$ *with* $c \geq \mathsf{scopedClosed}$*, or at* $\mathsf{FormalStatus}(N, v)$ *with* $v \geq \mathsf{theoremChecked}$*, the closurestatus block of the chapter is downgraded by the discipline of Definition 9203.16: a* `\leanchecked` *becomes a* `\leanstmt` *if the source still survives but exactness no longer holds, or a* `\leansorryd` *if the proof has been retracted; the closure grade is lowered to the highest grade still licensed by the surviving witnesses. The audit script of Definition 9203.18 reflects only the verification axis; the closure grade is reflected by the chapter's closurestatus block.*

Remark 9205.13 (The cannot-claim registry is not a roadmap)**.** *A roadmap states what will be claimed when the present blockers are cleared. The cannot-claim registry of Definition 9205.7 states what the manuscript currently refuses. The two artefacts are not the same: a refusal that is principled (Anchor 1) does not become a future claim regardless of progress; a refusal that is deferred (Anchor 3) becomes a future claim only when the named upgrade is discharged. The registry is the negative face of the manuscript, not the schedule of what the manuscript will eventually admit.*

Remark 9205.14 (Composition with the axiom-purity gate)**.** *The axiom-purity gate of Definition 9387.10 refuses kernel theorems whose transitive dependencies include the three meta-closure axioms. The cannot-claim registry refuses export claims whose certificates or bridges are absent. The two refusals operate at different layers and compose: a kernel theorem permitted by axiom-purity may still fail to license an export claim if its standard bridge is incomplete, and an export claim refused by the registry does not become licit by the kernel passing its purity gate.*

Chapter 9206

Closure Reading Convention

This short chapter records the convention by which a reader should read every closurestatus block in the manuscript.

9206.1 Read both axes, separately

A line of the form $\mathsf{TheoryGate}(N, c)$ records what the paper has closed about N at grade c. A line of the form $\mathsf{FormalStatus}(N, v)$ records the audit state of the cited Lean target at grade v. The two are independent: neither line implies the other, and the conjunction $\mathsf{VerifiedGate}(N, c, v)$ records both at once without merging them.

9206.2 Read closure as a paper claim

The closure axis is read entirely from the manuscript. A reader interrogating a closure claim should ask whether the chapter exhibits, within the stated scope, a source, a classifier, an exactness theorem, a ledger or absence statement, and a stability witness. None of these inquiries asks anything about a Lean file.

9206.3 Read verification as an audit claim

The verification axis is read entirely from the audit. A reader interrogating a verification claim should ask whether the cited Lean target exists, whether `lake build` accepts it, whether `bedc_ci.py audit` resolves it, and whether `check-axioms.py` reports the transitive dependencies clean. None of these inquiries asks anything about whether the paper's mathematical reading is closed.

9206.4 Per-object orientation table

The following table orients a reader who lands on a chapter and wants to know its present axes at a glance. The table is non-normative: each chapter's closurestatus block is the binding source of truth.

Object	Theory closure	Scope	Formal status
$\mathsf{Nat}^{\uparrow}$	scopedClosed	unary history certificate	theoremChecked

Object	Theory closure	Scope	Formal status
Add$^{\uparrow}$	scopedClosed	unary continuation certificate	theoremChecked
Int$^{\uparrow}$	scopedClosed	history pair certificate	theoremChecked
Rat$^{\uparrow}$	scopedClosed	history-pair semantic certificate	theoremChecked
Bool$^{\uparrow}$	scopedClosed	boolean history semantic certificate	theoremChecked
Option$^{\uparrow}$	scopedClosed	tagged-option semantic certificate	theoremChecked
Prod$^{\uparrow}$	scopedClosed	product history semantic certificate	theoremChecked
Sum$^{\uparrow}$	scopedClosed	sum history semantic certificate	theoremChecked
List$^{\uparrow}$	scopedClosed	list spine bridge classifier certificate	theoremChecked
Complex$^{\uparrow}$	scopedClosed	history pair semantic certificate	theoremChecked
Monoid$^{\uparrow}$	scopedClosed	monoid history semantic certificate	theoremChecked
Group$^{\uparrow}$	scopedClosed	group stability certificate	theoremChecked
AbGroup$^{\uparrow}$	scopedClosed	singleton empty-history certificate	theoremChecked
CommRing$^{\uparrow}$	scopedClosed	singleton empty-history certificate	theoremChecked
Field$^{\uparrow}$	scopedClosed	FieldApartZero / phase-exit certificate	theoremChecked
Module$^{\uparrow}$	scopedClosed	singleton smul image certificate	theoremChecked
VecSpace$^{\uparrow}$	scopedClosed	singleton empty-history vector-space certificate	theoremChecked
LinMap$^{\uparrow}$	scopedClosed	singleton linear-map laws	theoremChecked
Met$^{\uparrow}$	scopedClosed	empty-history distance certificate	theoremChecked
Cat$^{\uparrow}$	scopedClosed	hom-carrier composition certificate	theoremChecked
Functor$^{\uparrow}$	scopedClosed	prefix functor carrier certificate	theoremChecked
NatTrans$^{\uparrow}$	scopedClosed	prefix-component classifier certificate	theoremChecked
Yoneda$^{\uparrow}$	scopedClosed	empty-component-family certificate	theoremChecked
Subgroup$^{\uparrow}$	scopedClosed	subgroup centralizer certificate	theoremChecked
QuotientGroup$^{\uparrow}$	scopedClosed	centralizer-normalizer certificate	theoremChecked

Object	Theory closure	Scope	Formal status
Determinant$^{\uparrow}$	scopedClosed	singleton determinant certificate	theoremChecked
Homology$^{\uparrow}$	scopedClosed	singleton cycle certificate	theoremChecked
Cohomology$^{\uparrow}$	scopedClosed	singleton cocycle certificate	theoremChecked
Prime$^{\uparrow}$	scopedClosed	prime semantic certificate	theoremChecked
DyadicRatCore	maturePackageClosed	dyadic obligation faces and finite ledger	axiomClean
StreamName$^{\uparrow}$	maturePackageClosed	rational stream-name public certificate	bridgeChecked
RegSeqRat	maturePackageClosed	rational-stream certificate spine	axiomClean
Real$^{\uparrow}$	maturePackageClosed	public rational-stream export	bridgeChecked

Remark 9206.1 (How to read the closure entries)**.** *Most present BEDC entries close a precise, paper-recorded scope, while a chapter that exhibits a public-object surface may carry* publicClosed*. The table above is only a derived orientation aid; the binding closure grade is read from the object's own closurestatus block. Grades above* scopedClosed *require the corresponding public or bridge surface described in chapter 9204, and each closurestatus block names its own scope and upgrade path explicitly.*

Remark 9206.2 (How to read the verification entries)**.** *The verification entries are likewise a derived reading of the current closurestatus blocks. A* theoremChecked *entry means the block names a Lean target that resolves under* `lean4/BEDC/` *and that* `lake build` *accepts; an* unformalized *entry records that the paper boundary has not yet reached that checked Lean grade. The audit script of Definition 9203.18 is responsible for marker resolution, while the closure axis grade remains independent.*

Part X

Ground Compiler Discipline

Chapter 9207

Ground Event Flow

This chapter fixes the only formal input the BEDC compilation discipline admits. The input is not a Pkg, a NameCert, a ClosureCert, an AST, a YAML manifest, an opcode list, an arity table, or a theorem identifier; it is a finite event flow displayed from the kernel's two raw marks b0 and b1. The chapter records the discipline by which structural readings of an event flow—package roles, certificate fields, theorem fields, compiler fields, and object acceptance—arrive only through generated recognizers, never as primitive compiler inputs.

The chapter sits between chapter 9203, which fixes how a mature object is read through TheoryGate and FormalStatus, and chapter 9371, which records the abstract algebraic view of compilation as a NameCert morphism. The present chapter supplies the concrete substrate: the input language to which any such morphism must be applied is the language of event flows, and that language admits no hidden structural input.

9207.1 Display alphabet and raw events

Definition 9207.1 (Display alphabet). *Lean4 (definition)* `BEDC.GroundCompiler.EventFlow.DisplayAlphabet`

The display alphabet *is*

$$\Sigma := \{0, 1\}.$$

The chapter adopts the external display convention

$$\mathsf{b0} \mapsto 0, \qquad \mathsf{b1} \mapsto 1.$$

The displayed symbols 0 *and* 1 *are presentation glyphs only; they are not natural numbers, truth values, binary numerals, or members of an external set.*

Remark 9207.2 (Display is not interpretation). *The display convention sends each raw mark to a glyph for the purpose of writing event flows on the page. It does not interpret* b0 *as the integer zero,* b1 *as the integer one, or finite glyph strings as numerals, completion data, dimensions, types, or theorems. Any such reading must be supplied by a downstream classifier together with a* NameCert*; the licensing discipline is recorded in chapter 9 and chapter 9203.*

Definition 9207.3 (Raw event). *Lean4 (definition)* `BEDC.GroundCompiler.EventFlow.RawEvent`

A raw event *is a finite display string* $w \in \Sigma^*$*. The set of raw events is*

$$\mathsf{RawEvent} := \Sigma^*.$$

The empty raw event is permitted and is denoted ϵ*.*

Remark 9207.4 (A raw event is a finite trace, not a theorem)**.** *A raw event is a finite displayed string of glyphs. It is not a theorem, not a proof, not a* NameCert*, not a* ClosureCert*, not a packaged object, and not a kernel judgment. Visible patterns inside a raw event—such as* 011 *or* 100*—do not by themselves license any classifier reading; in particular they do not assert the Zeckendorf-normal-form classifier of chapter 278. Such a reading is licensed only when supported by a generated source flow, pattern flow, classifier flow, stability flow, and ledger flow under the certificate discipline of Definition 9203.4.*

9207.2 Event flows and boundary information

Definition 9207.5 (Event flow)**.** *Lean4 (definition)* `BEDC.GroundCompiler.EventFlow.EventFlow`

An event flow *is a finite ordered sequence of raw events*

$$S \;=\; (w_0, w_1, \ldots, w_{n-1}), \qquad w_i \in \mathsf{RawEvent}.$$

The set of event flows is

$$\mathsf{EventFlow} \;:=\; (\Sigma^*)^*.$$

A representative event flow is written with a vertical bar between successive raw events, e.g.

$$0 \mid 00 \mid 000 \mid 01 \mid 011 \mid 100,$$

which denotes $(0, 00, 000, 01, 011, 100)$*.*

Definition 9207.6 (Event boundary)**.** *Lean4 (definition)* `BEDC.GroundCompiler.EventFlow.EventBoundary`

An event boundary *is the separation between two consecutive raw events in an event flow. The event boundary is part of the generated event-flow datum and is not recoverable from the concatenation of glyphs alone. Two event flows* $(0, 00, 000)$ *and* $(00, 0000)$ *are distinct elements of* EventFlow *even though both display the concatenated glyph string* 000000 *if their boundaries are erased.*

Proposition 9207.7 (Bare bitstreams do not determine event flows)**.** *Lean4 ✓* `BEDC.GroundCompiler.EventFlow.e` `not injective`

The boundary-erasure map

$$\mathrm{erase}\colon \mathsf{EventFlow} \longrightarrow \Sigma^*,$$

which sends an event flow to the concatenation of its raw events, is not injective.

Proof. Take

$$S_1 \;=\; (0, 00, 000), \qquad S_2 \;=\; (00, 0000).$$

Both event flows erase to the same bare string 000000. As event flows they differ: their event decompositions are not equal as sequences. Hence erase identifies S_1 and S_2, contradicting injectivity. □

Corollary 9207.8 (A compiler input cannot be a bare bitstream)**.** *Lean4 ✓* `BEDC.GroundCompiler.EventFlow.inpu` `not bare bitstream`

If the formal input to the compiler were a bare bitstream $b \in \Sigma^*$*, then the event segmentation that re-establishes the underlying event flow would have to be supplied externally, contradicting the no-hidden-input discipline of Definition 9207.9. Therefore the first formal input layer is* EventFlow*, not* Σ^**.*

9207.3 No-hidden-input discipline

Principle 9207.9 (No hidden structural input). *Lean4✓ BEDC.GroundCompiler.EventFlow.structural hidden not formal*

The compiler admits no formal input other than event flows. In particular, none of the following is a formal compiler input:

$$\mathsf{Pkg},\quad \mathsf{NameCert},\quad \mathsf{ClosureCert},\quad \text{TheoremPkg},\quad \text{ChapterPkg},\quad \text{ProofTree},$$

$$\text{AST},\quad \text{YAML},\quad \text{manifest},\quad \text{external theorem identifier},\quad \text{external object name},$$

$$\text{external type tag},\quad \text{external mode tag},\quad \text{external opcode},\quad \text{external arity table}.$$

If any such structure is to participate in compilation, it must first appear as an event-flow pattern and be recognized by a generated recognizer flow.

Definition 9207.10 (Generated recognizer). *Lean4 (definition) BEDC.GroundCompiler.EventFlow.GeneratedRecogni*

A generated recognizer *is itself an event flow:*

$$R \in \mathsf{EventFlow}.$$

A generated recognizer is not a host parser, host function, schema, or AST constructor. Its only admissible public form is a generated event flow. A generated recognizer may carry a recognition relation $\mathsf{Recognizes}(R, S)$ *for a target event flow* S*; the relation is a kernel-level judgment about a pair of event flows, not a host predicate.*

Definition 9207.11 (Recognized package flow). *Lean4 (definition) BEDC.GroundCompiler.EventFlow.RecognizedPac*

A recognized package flow *is an event flow* $S \in \mathsf{EventFlow}$ *for which there exists a generated recognizer* R *such that*

$$\mathsf{RecognizesPkg}(R, S)$$

holds. The relation $\mathsf{RecognizesPkg}$ *is a kernel-level judgment between two event flows; the package structure is a structure recognized in* S *by* R*, not an external datum supplied to the compiler.*

Proposition 9207.12 (Package structure is not a primitive compiler input). *Lean4✓ BEDC.GroundCompiler.Event not primitive*

There is no formal compiler map of the form $\mathsf{Pkg} \to \mathsf{Code}$*. The only admissible form is*

$$\mathsf{EventFlow} \longrightarrow \mathsf{Code},$$

optionally accompanied by recognition judgments such as $\mathsf{RecognizesPkg}(R, S)$*.*

Proof. Suppose to the contrary that the compiler accepts a Pkg object P as primitive input. Then P's constituent fields, package boundaries, and structural roles are supplied to the compiler before any event-flow generation has taken place. These fields constitute an external structural datum and therefore a structural hidden input in the sense of Definition 9207.21. This contradicts Definition 9207.9. Hence package structure must be recognized from a previously generated event flow rather than supplied as input. □

Remark 9207.13 (Relation to typed naming certificates). *The discipline above is a strict instance of the typed naming certificate admission discipline of chapter 9. A derived name* N *is admitted only when the source, pattern, classifier, stability, and ledger fields of* $\mathsf{NameCert}(N)$ *are supplied; an upward-arrow derived interface is licensed only by such a certificate. The compiler may later recognize a* $\mathsf{NameCert}$ *flow within an event flow, but it may not begin by accepting a* $\mathsf{NameCert}$ *object as input.*

9207.4 Recognized derived flows

Definition 9207.14 (Recognized NameCert flow). *Lean4 (definition)* `BEDC.GroundCompiler.EventFlow.RecognizedN`

A recognized NameCert flow *is an event flow S for which a generated recognizer R witnesses*

$$\mathsf{RecognizesNameCert}(R, S).$$

A recognized NameCert *flow is later expected to contain, in recognized order, event subflows that play the certificate roles of Definition 9203.4: a source-spec subflow, a pattern-spec subflow, a classifier-spec subflow, a stability-cert subflow, a ledger-policy subflow, and a closing seal subflow. These role assignments are not external tags supplied at the ground input layer; they are roles recognized inside S by R.*

Definition 9207.15 (Recognized theorem flow). *Lean4 (definition)* `BEDC.GroundCompiler.EventFlow.RecognizedThe`

A recognized theorem flow *is an event flow S for which a generated recognizer R witnesses*

$$\mathsf{RecognizesTheorem}(R, S).$$

A recognized theorem flow may be further recognized as containing event subflows for statement, dependency, proof, certificate, ledger, status, canonical site, and closing seal. None of these is a first-layer compiler input; each is a role recognized in S.

Definition 9207.16 (Recognized compiler flow). *Lean4 (definition)* `BEDC.GroundCompiler.EventFlow.RecognizedCo`

A recognized compiler flow *is an event flow C that satisfies*

$$\mathsf{RecognizesCompiler}(C).$$

The compiler is therefore not a host-level object in the formal surface; it is eventually represented as an event flow whose recognized roles are precisely those needed to recognize and compile other event flows.

Principle 9207.17 (Self-hosting target). *Lean4 ✓* `BEDC.GroundCompiler.EventFlow.self hosting target recognized compiler`

The self-hosting target of the compilation discipline is represented by an event flow C equipped with a compiler-behavior relation B on event flows such that C is behaviorally equivalent to itself under B. This target datum necessarily includes the judgment that C is a recognized compiler flow. Behavioral equivalence is read through the compiler-behavior classifier of the recognized NameCert *flow attached to C, never as host-level kernel equality. The self-hosting target is consistent with the abstract algebraic reading of Definition 9371.3: a self-hosting compiler is a* NameCert *endomorphism whose* hsame*-preservation witness is itself a recognized event-flow datum.*

9207.5 Accepted object flows and the ground theorem

Definition 9207.18 (Accepted object flow). *Lean4 (definition)* `BEDC.GroundCompiler.EventFlow.AcceptedObjectFl`

An accepted object flow *is not merely an event flow that the channel layer can encode and decode. It is an event flow whose recognized structure contains a recognized* NameCert *flow and a recognized* ClosureCert *flow that together witness* $\mathsf{TheoryGate}(N, c)$ *at some grade* $c \in \mathsf{TheoryClosure}$*, accompanied by an audited verification record that witnesses* $\mathsf{FormalStatus}(N, v)$ *at some grade v. The composite reading is the verification gate*

$$\mathsf{VerifiedGate}(N, c, v) \;:=\; \mathsf{TheoryGate}(N, c) \wedge \mathsf{FormalStatus}(N, v),$$

in the sense of Definition 9203.3 and the verification axis of chapter 9203. The recognized ClosureCert *flow records the source, classifier, exactness, ledger, stability, and grade fields of* ClosureCert(N, c)*; these fields are citations of previously closed* NameCert *data, not new mathematical construction supplied at the ground input layer.*

Proposition 9207.19 (Code existence does not imply acceptance). Lean4✓ `BEDC.GroundCompiler.EventFlow.code not acceptance`

The existence of an event flow $S \in$ EventFlow *does not, by itself, imply that S is an accepted object flow.*

Proof. Membership $S \in$ EventFlow asserts only that S is a finite ordered sequence of raw events; channel encoding adds only that this sequence can be displayed and recovered through a self-delimiting bit-level encoder/decoder. Neither datum supplies a recognized NameCert flow, a recognized ClosureCert flow, or an audited verification record. By Definition 9207.18, acceptance requires both the recognized certificate flows and the verification record, and the verification gate VerifiedGate(N, c, v) depends on data not present in S as a bare event flow. Therefore code existence does not imply acceptance. □

Corollary 9207.20 (Accepted export requires recognized certificates). Lean4✓ `BEDC.GroundCompiler.EventFlow.export requires cert`

If a compiled event flow is claimed to export a mature object N at grades (c, v), its recognized structure must include NameCert *and* ClosureCert *flows sufficient for* VerifiedGate(N, c, v)*. Without such recognition the compiled flow is only a raw event-flow display.*

Definition 9207.21 (Structural hidden input). Lean4 (definition) `BEDC.GroundCompiler.EventFlow.StructuralHidd`

A structural hidden input *is any datum used by the compiler, or by a downstream analysis governed by the compilation discipline, that is not present as a raw event in some event flow and not recognized from such a flow by a generated recognizer. Examples include:*

1. *a host AST that supplies node, edge, arity, and category data before event-flow recognition;*
2. *a host list of* NameCert *fields supplied directly to the compiler;*
3. *a YAML or manifest file that supplies package boundaries and field roles;*
4. *an external arity table, object name, theorem identifier, type tag, mode tag, or opcode;*
5. *a host parser state that records a package boundary or proof tree without a corresponding event-flow witness.*

Theorem 9207.22 (No-hidden-input ground theorem). Lean4✓ `BEDC.GroundCompiler.EventFlow.no hidden input`

Every formal datum used by the BEDC compiler occurs in exactly one of the following ways:

1. *as a raw event $w \in$* RawEvent*;*
2. *as an event flow $S \in$* EventFlow*;*
3. *as a structure recognized in an event flow S by a generated recognizer R, witnessed by a kernel-level recognition relation;*
4. *as a certificate-recognized export governed by the verification gate* VerifiedGate(N, c, v)*.*

No other input form is admissible.

Proof. By Definition 9207.3 and Definition 9207.5, the ground data are raw events and event flows. By Definition 9207.10, generated recognizers are themselves event flows; recognized structures are therefore event flows equipped with kernel-level recognition witnesses, not new input forms. By Definition 9207.18, accepted object flows are characterized by recognized NameCert and ClosureCert flows together with an audited verification record, all expressed via the recognition discipline of class 3. Any datum outside classes 1–4 would either be a host-level structure or an unrecognized mathematical primitive, both of which are excluded by Definition 9207.9 and by the anti-primitive discipline of Definition 1.2. □

Corollary 9207.23 (YAML is not a formal compiler input)**.** `Lean4✓` `BEDC.GroundCompiler.EventFlow.yaml not input`

A YAML or manifest file may be generated as a human-readable report of a decoded event flow, but it cannot serve as formal input to the compiler.

Proof. A YAML file supplies package boundaries, field names, and structural roles externally. By Definition 9207.21, these are structural hidden inputs. By Definition 9207.22, structural hidden inputs are not admissible compiler inputs. □

Corollary 9207.24 (AST is not a formal compiler input)**.** `Lean4✓` `BEDC.GroundCompiler.EventFlow.ast not input`

An AST may be reconstructed from a decoded event flow by a generated recognizer, but an AST may not be supplied as initial compiler input.

Proof. An AST supplies node, edge, arity, and category data before event-flow recognition. By Definition 9207.21, these are structural hidden inputs. By Definition 9207.22, they are not admissible as first-layer input. □

9207.6 Worked event-flow examples

Example 9207.25 (Completion skeleton as event flow)**.** *The event flow*

$$0 \mid 00 \mid 000 \mid 01 \mid 011 \mid 100$$

is a valid element of EventFlow*. A downstream recognizer may later read it as a completion skeleton with role assignments*

0	*initial unit*
00	*one finite repetition*
000	*two finite repetitions*
01	*repeat-forever or boundary witness*
011	*repeat-to-completion or overflow witness*
100	*normal address.*

At the ground input layer, however, the datum is only the sequence $(0, 00, 000, 01, 011, 100)$*. Any claim that the flow licenses a derived completion interface, full-axis interface, or dimension-lift interface must be supported by a recognized* NameCert *flow whose source, pattern, classifier, stability, and ledger subflows are exhibited; this is the same discipline by which* $\mathsf{AxisNat}^{\uparrow}$ *and the Zeckendorf normal-form classifier are licensed in chapter 276 and chapter 278.*

Example 9207.26 (Additive / fold skeleton as event flow)**.** *The event flow*

$$0 \mid 00 \mid 001 \mid 0011 \mid 0100$$

is a valid element of EventFlow*. A downstream recognizer may later read it as an additive or fold-shaped skeleton with role assignments*

0	*initial unit*
00	*binary repetition witness*
001	*additive recursion witness*
0011	*iterated-addition completion witness*
0100	*normalized fold seed.*

At the ground input layer the datum remains a sequence of raw events. A claim that the flow exports a derived additive, multiplicative, or fold interface requires a recognized NameCert *flow and, for export, the verification gate of Definition 9207.18. The unary repetition and continuation seeds of chapter 10 are licensed by the same discipline.*

Example 9207.27 (Carry ledger as event flow, not equality)**.** *The event flow*

$$011 \mid 100$$

is a valid element of EventFlow*. A downstream recognizer may later read it as a source-level carry ledger, with role assignments*

011	*pre-normal event*
100	*normal event.*

The flow does not assert equality of the underlying histories, nor does it assert hsame *between* $\mathsf{b1}(\mathsf{b1}(\mathsf{b0}(\mathsf{e})))$ *and* $\mathsf{b0}(\mathsf{b0}(\mathsf{b1}(\mathsf{e})))$*. The relevant downstream relation is the Zeckendorf carry classifier of chapter 9345, which is a structural classifier between recognized normal-form histories and is not equality.*

9207.7 Conservativity and closing observations

Theorem 9207.28 (Event-flow conservativity)**.** *Lean4✓ BEDC.GroundCompiler.EventFlow.event flow conservativity*

Adding the ground event-flow input layer does not add new BEDC kernel objects, new mark-sameness rules, new history-sameness rules, new Ext *or* Cont *rules, or new derived interfaces.*

Proof. The event-flow layer records only finite displayed occurrences of 0 and 1, i.e. displays of b0 and b1 under the convention of Definition 9207.1. It does not add mark constructors beyond b0 and b1, and it does not add any rule generating $\mathsf{msame}(\mathsf{b0}, \mathsf{b1})$ or $\mathsf{msame}(\mathsf{b1}, \mathsf{b0})$, since the kernel rules of chapter 2 are unchanged. It does not license a derived interface either, because derived-interface admission requires the certificate fields of Definition 9203.4; the event-flow layer supplies only a readback carrier for displayed traces. Therefore all kernel and derived-interface formation rules remain unchanged, and the event-flow layer is conservative over the finite kernel. □

Corollary 9207.29 (Event-flow readability is weaker than theoremhood)**.** *Lean4✓ BEDC.GroundCompiler.EventFl weaker than theoremhood*

If a finite sequence is an event flow, it is readable by the compiler. Readability does not imply that the sequence is a theorem, a proof, a recognized package, a recognized NameCert*, or an accepted object flow.*

Proof. Readability asserts only $S \in \mathsf{EventFlow}$. Theoremhood requires a recognized theorem flow per Definition 9207.15. Acceptance requires a recognized $\mathsf{NameCert}$ flow, a recognized $\mathsf{ClosureCert}$ flow, and an audited verification record per Definition 9207.18. Each of these is strictly stronger than $\mathsf{EventFlow}$ membership. □

Remark 9207.30 (Outlook)**.** *The next chapter fixes the channel-level encoding* $\mathsf{Compile}\colon \mathsf{EventFlow} \to \Sigma^*$ *that displays an event flow as a single self-delimiting bit string under the Zeckendorf-safe convention* $\mathsf{b0} \mapsto 0$, $\mathsf{b1} \mapsto 10$, *and event boundary* $\mapsto 11$, *and proves that the resulting language is in bijection with* $\mathsf{EventFlow}$. *The source-level rewrite* $011 \to 100$ *of chapter 278 is a classifier on recognized history flows, not a rewrite of channel-level bit strings; the next chapter records the layer separation explicitly.*

Chapter 9208

Zeckendorf-safe Channel Encoding

chapter 9207 fixes the only formal input the BEDC compiler admits: an element of $\mathsf{EventFlow} = (\Sigma^*)^*$, presented as a finite ordered sequence of raw events with explicit boundary information. Definition 9207.7 records that boundary erasure is non-injective, and Definition 9207.8 records that the formal input therefore cannot be a bare bitstream.

This chapter fixes a channel-level compilation

$$\mathsf{Compile}\colon \mathsf{EventFlow} \longrightarrow \Sigma^*$$

that displays an event flow as a single self-delimiting glyph string. The encoding is required to satisfy four conditions:

1. the output language is over $\Sigma = \{0, 1\}$ alone;
2. encoding is streaming on the input event flow;
3. decoding is streaming on the output glyph string;
4. event boundaries are recovered by the decoder without access to a host parser, schema, manifest, length table, or any structural hidden input in the sense of Definition 9207.21.

The body encoding is the Zeckendorf-safe substitution

$$\zeta(0) = 0, \qquad \zeta(1) = 10,$$

and the event terminator is the glyph pair

$$\mathrm{End} \;=\; 11.$$

The combined effect is that no body of an encoded event contains the adjacent pair 11; consequently the first 11 encountered by the decoder is unambiguously a terminator. The chapter records the encoder, the decoder, the legal-stream language, the round-trip theorems, the bijection $\mathsf{EventFlow} \cong \mathsf{LegalZStream}$, the streaming property of both directions with one-glyph lookahead, and conservativity over the BEDC kernel and over chapter 9207.

The chapter does not perform any source-level rewrite. The Zeckendorf normal-form classifier of chapter 278 and the Zeckendorf carry classifier of chapter 9345 act on recognized history flows; the channel-level encoding presented here acts on event flows. The two layers are independent and are not allowed to overwrite one another (Definition 9208.24).

9208.1 Body encoding and event terminator

Definition 9208.1 (Zeckendorf-safe body encoding)**.** *Lean4 (definition)* `BEDC.GroundCompiler.ChannelEncoding.Bo`

The body encoding *is the function*

$$\zeta\colon \Sigma^* \longrightarrow \Sigma^*$$

defined by recursion on the input glyph string:

$$\begin{aligned} \zeta(\epsilon) &= \epsilon, \\ \zeta(0\,w) &= 0\,\zeta(w), \\ \zeta(1\,w) &= 10\,\zeta(w). \end{aligned}$$

On individual glyphs, ζ acts by the substitution $0 \mapsto 0$ and $1 \mapsto 10$, applied left-to-right.

Definition 9208.2 (Event terminator)**.** *Lean4 (definition)* `BEDC.GroundCompiler.ChannelEncoding.EventTerminato`

The event terminator *is the glyph pair*

$$\mathrm{End} \;:=\; 11.$$

The event terminator is a channel-level marker. It signals only that the encoding of the current raw event is complete. It does not assert source-level Zeckendorf carry, completion, hsame*, or any classifier judgment; those readings are licensed only by recognized* NameCert *flows in the sense of Definition 9207.14.*

Definition 9208.3 (Event encoding)**.** *Lean4 (definition)* `BEDC.GroundCompiler.ChannelEncoding.EventEncoding`

The event encoding *of a raw event $w \in \mathsf{RawEvent}$ is*

$$\mathsf{Ev}(w) \;:=\; \zeta(w)\,11 \;\in\; \Sigma^*.$$

Example 9208.4 (Sample event encodings)**.** *The following table records the body encoding ζ on small inputs:*

$$\begin{aligned} \zeta(\epsilon) &= \epsilon \\ \zeta(0) &= 0 \\ \zeta(1) &= 10 \\ \zeta(00) &= 00 \\ \zeta(01) &= 010 \\ \zeta(10) &= 100 \\ \zeta(11) &= 1010 \\ \zeta(011) &= 01010 \\ \zeta(100) &= 1000 \\ \zeta(0011) &= 001010. \end{aligned}$$

For each row, the corresponding event encoding $\mathsf{Ev}(w)$ is obtained by appending the terminator 11. For instance,

$$\mathsf{Ev}(\epsilon) = 11, \quad \mathsf{Ev}(0) = 011, \quad \mathsf{Ev}(1) = 1011, \quad \mathsf{Ev}(011) = 0101011.$$

The raw event $w = 1$ encodes as 1011, not as 0111. The reason for that choice is recorded in Definition 9208.5.

Remark 9208.5 (Why a naive encoding fails)**.** *A naive scheme might try*

$$0 \mapsto 00, \qquad 1 \mapsto 01, \qquad \mathrm{End} \mapsto 11,$$

producing $\mathsf{Ev}(1) = 0111$*. Read from left to right, the decoder would parse* 0111 *as the body* 01 *followed by* 11 *as terminator and consume the leading* 0 *as a glyph; but the body* 01 *is itself a length-*2 *chunk, leaving an isolated trailing* 1 *that is neither a glyph encoding nor a terminator. The stream would be rejected as malformed even though it was generated as* $\mathsf{Ev}(1)$*. The Zeckendorf-safe substitution* $0 \mapsto 0$*,* $1 \mapsto 10$ *avoids this collision because no encoded body contains adjacent* 11 *(Definition 9208.6).*

Proposition 9208.6 (Body encoding contains no adjacent terminator pattern)**.** *Lean4✓ BEDC.GroundCompiler.Ch encoding no adjacent 11*

For every raw event $w \in \mathsf{RawEvent}$*, the encoded body* $\zeta(w)$ *contains no adjacent pair* 11 *as a substring.*

Proof. By Definition 9208.1, $\zeta(w)$ is a finite concatenation of fragments drawn from $\{0, 10\}$, i.e. $\zeta(w) \in (0 \mid 10)^*$. Neither fragment 0 nor fragment 10 contains the substring 11. The local junctions between two consecutive fragments take exactly four shapes,

$$0\,|\,0, \qquad 0\,|\,10, \qquad 10\,|\,0, \qquad 10\,|\,10,$$

producing the local strings 00, 010, 100, and 1010 respectively, none of which contains 11. Hence no two adjacent positions in $\zeta(w)$ both carry the glyph 1. □

Corollary 9208.7 (The first 11 is the event terminator)**.** *Lean4✓ BEDC.GroundCompiler.ChannelEncoding.first 11 is terminator*

For every raw event w*, the leftmost adjacent pair* 11 *in* $\mathsf{Ev}(w) = \zeta(w)\,11$ *is the appended terminator.*

Proof. By Definition 9208.6, the body $\zeta(w)$ contains no adjacent 11. Therefore the only position in $\mathsf{Ev}(w)$ at which 11 can occur is the appended trailing pair. □

9208.2 Legal event code and channel stream

Definition 9208.8 (Legal event code language)**.** *Lean4 (definition) BEDC.GroundCompiler.ChannelEncoding.LegalEv*

The legal event code language *is*

$$\mathsf{LegalEvent} \;:=\; (0 \mid 10)^*\,11 \;\subseteq\; \Sigma^*.$$

Equivalently, a glyph string $c \in \Sigma^*$ *is a legal event code iff there is a raw event* $w \in \mathsf{RawEvent}$ *with* $c = \mathsf{Ev}(w)$*.*

Definition 9208.9 (Flow encoding)**.** *Lean4 (definition) BEDC.GroundCompiler.ChannelEncoding.FlowEncoding*

The flow encoding *is the function*

$$\mathsf{Compile}\colon \mathsf{EventFlow} \longrightarrow \Sigma^*$$

defined by

$$\mathsf{Compile}(w_0, w_1, \ldots, w_{n-1}) \;:=\; \mathsf{Ev}(w_0)\,\mathsf{Ev}(w_1)\cdots\mathsf{Ev}(w_{n-1}).$$

On the empty event flow, $\mathsf{Compile}(\,) = \epsilon$*.*

Definition 9208.10 (Legal channel-stream language)**.** *Lean4 (definition)* `BEDC.GroundCompiler.ChannelEncoding.L`

The legal channel-stream language *is*

$$\mathsf{LegalZStream} \;:=\; \big((0 \mid 10)^* \, 11\big)^* \;\subseteq\; \Sigma^*.$$

A glyph string $c \in \Sigma^*$ belongs to $\mathsf{LegalZStream}$ *iff it admits a finite decomposition into legal event codes.*

Example 9208.11 (Completion skeleton encoded)**.** *The completion skeleton event flow of Definition 9207.25,*

$$S \;=\; (0,\, 00,\, 000,\, 01,\, 011,\, 100),$$

encodes event-by-event as

$$\begin{aligned}
\mathsf{Ev}(0) &= 011\\
\mathsf{Ev}(00) &= 0011\\
\mathsf{Ev}(000) &= 00011\\
\mathsf{Ev}(01) &= 01011\\
\mathsf{Ev}(011) &= 0101011\\
\mathsf{Ev}(100) &= 100011.
\end{aligned}$$

The flow encoding $\mathsf{Compile}(S)$ *is therefore*

$$011 \mid 0011 \mid 00011 \mid 01011 \mid 0101011 \mid 100011,$$

where each 11 *is the terminator of the corresponding event code.*

Example 9208.12 (Additive / fold skeleton encoded)**.** *The additive / fold skeleton event flow of Definition 9207.26,*

$$S \;=\; (0,\, 00,\, 001,\, 0011,\, 0100),$$

encodes event-by-event as

$$\begin{aligned}
\mathsf{Ev}(0) &= 011\\
\mathsf{Ev}(00) &= 0011\\
\mathsf{Ev}(001) &= 001011\\
\mathsf{Ev}(0011) &= 00101011\\
\mathsf{Ev}(0100) &= 0100011.
\end{aligned}$$

The flow encoding $\mathsf{Compile}(S)$ *is the concatenation*

$$011 \mid 0011 \mid 001011 \mid 00101011 \mid 0100011,$$

again with one terminator per event code. As recorded in Definition 9207.26, recognizing the events 001, 0011, *and* 0100 *as additive, fold, or normalization witnesses requires recognizer flows and certificate flows that are not part of channel encoding.*

9208.3 Decoders and round-trip theorems

Definition 9208.13 (Channel-level decoder for one event)**.** *Lean4 (definition)* `BEDC.GroundCompiler.ChannelEncodi`

The single-event decoder

$$\mathsf{DecEv}\colon \Sigma^* \longrightarrow \mathsf{Option}(\mathsf{RawEvent} \times \Sigma^*)$$

is defined by left-to-right scan. On success it returns the decoded raw event together with the unconsumed suffix immediately after the terminator; on malformed input it rejects. Starting with empty raw output,

1. *if the next glyph is* 0*, emit raw* 0 *and advance one glyph;*
2. *if the next glyph is* 1*, inspect the following glyph. If it is* 0*, emit raw* 1 *and advance two glyphs; if it is* 1*, the event is complete; if no further glyph exists, the input is rejected.*

The procedure terminates with success on every generated event code $\mathsf{Ev}(w)$ *and consumes exactly that event code.*

Definition 9208.14 (Channel-level decoder for streams)**.** *Lean4 (definition)* `BEDC.GroundCompiler.ChannelEncoding`

The stream decoder

$$\mathsf{Decode}\colon \Sigma^* \longrightarrow \mathsf{Option}(\mathsf{EventFlow})$$

applies DecEv *repeatedly: on input* c*, scan glyphs left-to-right and run* DecEv *until its terminator is reached, recording the resulting raw event; then begin a fresh single-event scan from the position immediately after the terminator. The output is the sequence of raw events produced by successive single-event scans, in order. If the scan produces an isolated* 1 *with no following glyph, or any local prefix outside* $(0 \mid 10)^* 11$*, the input is rejected.*

Proposition 9208.15 (The string 0111 is illegal)**.** *Lean4* ✓ `BEDC.GroundCompiler.ChannelEncoding.channel encoding 0111 illegal`

The glyph string 0111 *is not a legal channel stream.*

Proof. Scanning left-to-right, the leading 0 is consumed as raw 0. The remaining glyphs are 111. The first two consume as a terminator 11, ending an event whose raw output is 0. The remaining glyph is an isolated 1, which is neither a body fragment (0 or 10) nor a terminator. By Definition 9208.14, the scan rejects. □

Theorem 9208.16 (Event-level round trip)**.** *Lean4* ✓ `BEDC.GroundCompiler.ChannelEncoding.event level round trip`

For every raw event $w \in \mathsf{RawEvent}$*,*

$$\mathsf{DecEv}(\mathsf{Ev}(w)) \;=\; \mathsf{some}(w, \epsilon).$$

Proof. By induction on the length of w.

Base. If $w = \epsilon$, then $\mathsf{Ev}(\epsilon) = 11$. The decoder reads the terminator immediately and emits the empty raw event $\epsilon = w$.

Step, leading 0*.* If $w = 0\,u$, then $\mathsf{Ev}(w) = 0\,\zeta(u)\,11$. The decoder reads the leading 0, emits raw 0, and advances. The remaining glyphs are $\zeta(u)\,11 = \mathsf{Ev}(u)$. By the induction hypothesis, the remainder decodes to u. The total output is $0\,u = w$.

Step, leading 1*.* If $w = 1\,u$, then $\mathsf{Ev}(w) = 10\,\zeta(u)\,11$. The decoder reads the pair 10, emits raw 1, and advances by two. The remaining glyphs are $\zeta(u)\,11 = \mathsf{Ev}(u)$. By the induction hypothesis, the remainder decodes to u. The total output is $1\,u = w$. □

Theorem 9208.17 (Flow-level round trip)**.** *Lean4* ✓ `BEDC.GroundCompiler.ChannelEncoding.flow level round trip`

For every event flow $S \in \mathsf{EventFlow}$*,*

$$\mathsf{Decode}(\mathsf{Compile}(S)) \;=\; \mathsf{some}(S).$$

Proof. Let $S = (w_0, \ldots, w_{n-1})$. By Definition 9208.9,

$$\mathsf{Compile}(S) \;=\; \mathsf{Ev}(w_0)\,\mathsf{Ev}(w_1)\cdots\mathsf{Ev}(w_{n-1}).$$

By Definition 9208.7, the leftmost 11 in each $\mathsf{Ev}(w_i)$ is the trailing terminator and no 11 appears earlier inside the body $\zeta(w_i)$. Therefore the stream decoder of Definition 9208.14 segments the input exactly at the boundaries between successive $\mathsf{Ev}(w_i)$ codes. By Definition 9208.16, each segment decodes to its source raw event w_i. The output sequence is therefore $(w_0, \ldots, w_{n-1}) = S$. □

Theorem 9208.18 (Legal-stream completeness). *Lean4✓ BEDC.GroundCompiler.ChannelEncoding.legal stream completeness*

For every legal channel stream $c \in \mathsf{LegalZStream}$, there exists an event flow $S \in \mathsf{EventFlow}$ such that

$$\mathsf{Decode}(c) \;=\; \mathsf{some}(S) \qquad \textit{and} \qquad \mathsf{Compile}(S) \;=\; c.$$

Proof. By Definition 9208.10, c admits a decomposition $c = e_0\, e_1 \cdots e_{n-1}$ with $e_i \in \mathsf{LegalEvent}$. The decomposition is unique, since each e_i ends at the leftmost 11 available after the end of e_{i-1} and that leftmost 11 is the terminator by Definition 9208.7.

For each i, by Definition 9208.8 there exists a unique raw event w_i with $e_i = \mathsf{Ev}(w_i)$, and Definition 9208.16 gives $\mathsf{DecEv}(e_i) = w_i$. Hence $\mathsf{Decode}(c) = (w_0, \ldots, w_{n-1})$, and

$$\mathsf{Compile}(\mathsf{Decode}(c)) \;=\; \mathsf{Ev}(w_0) \cdots \mathsf{Ev}(w_{n-1}) \;=\; e_0 \cdots e_{n-1} \;=\; c.$$

□

Corollary 9208.19 (Bijection between event flows and legal channel streams). *Lean4✓ BEDC.GroundCompiler.Cha encoding bijection*

The map $\mathsf{Compile}\colon \mathsf{EventFlow} \to \mathsf{LegalZStream}$ *is a bijection with inverse* Decode*:*

$$\mathsf{EventFlow} \;\cong\; \mathsf{LegalZStream} \;=\; \big(\,(0 \mid 10)^*\, 11\,\big)^*.$$

Proof. Definition 9208.17 gives $\mathsf{Decode} \circ \mathsf{Compile} = \mathrm{id}_{\mathsf{EventFlow}}$. Definition 9208.18 gives $\mathsf{Compile} \circ \mathsf{Decode} = \mathrm{id}_{\mathsf{LegalZStream}}$. Hence $\mathsf{Compile}$ and Decode are mutually inverse, making both bijective. □

9208.4 Streaming behavior and host-structure independence

Proposition 9208.20 (Channel encoder is streaming). *Lean4✓ BEDC.GroundCompiler.ChannelEncoding.encoder streaming*

The map $\mathsf{Compile}$ *is streaming on its input: while reading raw events left-to-right, the encoder emits the corresponding glyphs immediately upon seeing each raw glyph and emits the terminator* 11 *immediately upon seeing each event boundary.*

Proof. The local rules of Definition 9208.1 are $0 \mapsto 0$ and $1 \mapsto 10$, both depending on the current raw glyph alone. The terminator rule of Definition 9208.3 depends on the current event boundary alone. Neither rule consults future raw events, future raw glyphs, an event-flow length table, an AST, a Pkg object, or any structural hidden input in the sense of Definition 9207.21. Therefore the encoder may be implemented as a single left-to-right pass. □

Proposition 9208.21 (Channel decoder is streaming with one-glyph lookahead). *Lean4✓ BEDC.GroundCompiler.C streaming one glyph lookahead*

The map Decode *is streaming on its input with at most one-glyph lookahead.*

Proof. By Definition 9208.13, the decoder advances on the current glyph except when the current glyph is 1, in which case it inspects the next glyph to decide between raw 1 (next glyph 0), terminator (next glyph 1), and rejection (no next glyph). In every case the decision uses at most one glyph beyond the current position. No further lookahead, no buffer of previous events, and no consultation of an external table is required. □

Corollary 9208.22 (No tree, no manifest, no table). `Lean4✓ BEDC.GroundCompiler.ChannelEncoding.no tree no manifest no table`

Channel-level encoding and decoding can be carried out without an AST, a Pkg *object, a recognized* NameCert *flow, a recognized theorem flow, a YAML manifest, an external arity table, or any other structural hidden input.*

Proof. By Definition 9208.20, the encoder needs only the current raw glyph and a flag for the current event boundary. By Definition 9208.21, the decoder needs only the current glyph plus one-glyph lookahead. Neither function consults any datum forbidden by Definition 9207.21. □

Remark 9208.23 (Empty events). *The empty raw event* $\epsilon \in \mathsf{RawEvent}$ *encodes as* $\mathsf{Ev}(\epsilon) = 11$*, and the decoder of Definition 9208.13 accepts the input* 11 *as a single empty event. Whether a particular generated event flow is allowed to contain empty events is a question for the generators of chapter 9207, not for channel encoding; the channel layer accepts and emits them losslessly.*

Remark 9208.24 (Layer separation: source rewrite versus channel rewrite). *The Zeckendorf normal-form classifier of chapter 278 acts on recognized history flows:* ZNormal *is generated structurally on* b0*- and* b1*-extensions of histories, and the carry classifier of chapter 9345 relates two such histories. None of these is a rewrite of bit strings.*

The channel encoding of this chapter, by contrast, acts on event flows: ζ *substitutes raw glyphs to channel glyphs and* $\mathrm{End} = 11$ *marks event boundaries. The channel encoder is not allowed to rewrite a body fragment* 11 *to* 1010 *or to apply the source-level rewrite* $011 \to 100$ *to a channel stream; doing so would break the bijection of Definition 9208.19 and conflate the two layers.*

In short: source-level relations live on recognized history flows; channel-level relations live on event-flow / legal-stream displays. The two layers commute through their respective recognizers but are never composed in either direction without a bridge.

9208.5 Conservativity and closing observations

Principle 9208.25 (Channel code does not imply theoremhood). `Lean4✓ BEDC.GroundCompiler.ChannelEncoding stream not theoremhood`

Membership $c \in \mathsf{LegalZStream}$ *asserts only that* c *is a self-delimiting display of an event flow. It does not assert that* c *encodes a theorem, a proof, a recognized* NameCert*, a recognized* ClosureCert*, an accepted object flow, or a derived interface. Mature object export is governed by the verification gate* $\mathsf{VerifiedGate}(N, c, v)$ *of Definition 9207.18, not by channel encodability.*

In particular, the empty channel stream is legal because it is the encoding of the empty event flow, but it does not carry a recognized theorem flow.

Theorem 9208.26 (Channel conservativity). `Lean4✓ BEDC.GroundCompiler.ChannelEncoding.channel conservativity`

Every displayed mark occurring in $\mathsf{Compile}(S)$ *for an event flow* S *is one of the two existing kernel marks* b0 *and* b1*. Adjoining the channel-level encoder* Compile*, the decoder* Decode*, the legal*

event language LegalEvent*, and the legal-stream language* LegalZStream *to the BEDC compiler discipline therefore introduces no third channel glyph and does not add new BEDC kernel objects, new mark-sameness rules, new history-sameness rules, new* Ext *or* Cont *rules, new derived interfaces, or new recognizer relations.*

Proof. The channel-level objects of this chapter operate exclusively on the external display of event flows. ζ rewrites raw glyphs to channel glyphs; End adds a terminator at each event boundary; Compile concatenates event encodings; Decode inverts Compile on legal channel streams. None of these maps generates new raw marks beyond b0 and b1, new msame or hsame judgments, new Ext or Cont rules, or new derived interfaces, since interface admission requires the certificate fields of Definition 9203.4. The recognizer relations RecognizesPkg, RecognizesNameCert, RecognizesTheorem, and RecognizesCompiler are already fixed in chapter 9207; this chapter neither adds nor modifies them. By the same argument as Definition 9207.28, the channel layer is conservative over the BEDC finite kernel and over chapter 9207. □

Remark 9208.27 (Outlook)**.** *The next chapter strengthens the layer-separation discipline of Definition 9208.24. It records that source-level relations on recognized history flows—in particular the carry classifier of chapter 9345 and any future fold or completion classifier—may not be applied to channel streams, and that channel-level rewrites may not be transported to histories without a bridge whose source is a recognized* NameCert *flow and whose target is a recognized channel-encoded event flow.*

Chapter 9209

Source-Level Events and Channel-Level Bits

chapter 9207 fixes the source-layer input language $\mathsf{EventFlow} = (\Sigma^*)^*$, and chapter 9208 fixes the channel-layer encoder

$$\mathsf{Compile}\colon \mathsf{EventFlow} \longrightarrow \mathsf{LegalZStream} \;=\; \big((0 \mid 10)^* \, 11\big)^*,$$

together with its decoder Decode and the bijection $\mathsf{EventFlow} \cong \mathsf{LegalZStream}$ of Definition 9208.19.

The two layers share the glyph set $\Sigma = \{0, 1\}$, but the role of each glyph differs by layer:

- in the source layer, 0 and 1 display the raw marks $\mathsf{b0}$ and $\mathsf{b1}$, and the pair 11 is a permissible substring of a raw event;
- in the channel layer, 0 and 1 are encoded glyphs, and 11 is the unique event terminator.

This chapter records the discipline that follows from this difference. The central principle is that source-level normalization, classification, and ledger-recording act on decoded event flows in $\mathsf{EventFlow}$, never on compiled glyph strings in $\mathsf{LegalZStream}$. The Zeckendorf carry classifier of chapter 9345 and the Zeckendorf normal-form classifier of chapter 278 are source-layer relations on recognized history flows; they may not be applied to channel glyph strings as substring rewrites. The chapter records the mistake explicitly, supplies the correct decode-normalize-compile pipeline, and proves a layer-separation theorem with seven independent components.

9209.1 Source layer and channel layer

Definition 9209.1 (Source layer)**.** *Lean4 (definition)* `BEDC.GroundCompiler.SourceChannel.SourceLayer`

The source layer *consists of raw events and event flows of chapter 9207:*

$$\mathsf{RawEvent} \;=\; \Sigma^*, \qquad \mathsf{EventFlow} \;=\; (\Sigma^*)^*.$$

A glyph string in the source layer, e.g. 011*, denotes the raw event* $011 \in \mathsf{RawEvent}$*. The pair* 11 *is a permissible substring of a source raw event; the raw events* 11*,* 011*, and* 0011 *are all elements of* $\mathsf{RawEvent}$*.*

Definition 9209.2 (Channel layer)**.** *Lean4 (definition)* `BEDC.GroundCompiler.SourceChannel.ChannelLayer`

The channel layer *consists of compiled glyph strings:*

$$\mathsf{LegalZStream} \;=\; \big((0 \mid 10)^* \, 11\big)^*.$$

In the channel layer, the pair 11 *has a single fixed role: it marks the end of the encoding of the current event (Definition 9208.2). A channel-layer* 11 *is therefore not a source-layer raw substring, not a Zeckendorf carry source, not a completion witness, not a theorem seal, and not an* hsame *judgment.*

Remark 9209.3 (Same display, different layers)**.** *A glyph string written on the page may be read at either layer, but never at both simultaneously. The source-layer reading places the string in* RawEvent *or* EventFlow*; the channel-layer reading places the string in* LegalZStream*. The reading is fixed by the surrounding context—typically by which side of* Compile *or* Decode *the string is generated by—and the chapter's discipline insists that the reading not silently change.*

Definition 9209.4 (Source-level relation)**.** *Lean4 (definition)* `BEDC.GroundCompiler.SourceChannel.SourceLevelRel`

A source-level relation *is a binary relation*

$$(\rightsquigarrow) \subseteq \mathsf{RawEvent} \times \mathsf{RawEvent}$$

on raw events. By extension, a source-level relation may be lifted pointwise or via context to a relation on event flows. A relation $w \rightsquigarrow v$ *asserts only a source-layer fact between two raw events; it asserts neither* hsame *between underlying histories nor channel-layer glyph-string rewriting.*

A representative source-level relation is the Zeckendorf carry $\rightsquigarrow_Z$*, whose canonical instance is*

$$011 \rightsquigarrow_Z 100,$$

*read as: "*011 *is a pre-normal source event whose Zeckendorf-normal source event is* 100*." The classifier-level reading of this relation is the Zeckendorf carry classifier of chapter 9345, which is a structural relation between recognized normal-form histories, not glyph-string rewriting.*

Definition 9209.5 (Source carry ledger)**.** *Lean4 (definition)* `BEDC.GroundCompiler.SourceChannel.SourceCarryLedg`

Given a source-level relation $w \rightsquigarrow v$*, the corresponding* ledger flow *is the event flow*

$$(w, v) \in \mathsf{EventFlow}.$$

Displayed, the flow is written $w \mid v$ *and read as "pre-normal event* w *followed by normal event* v*."*

For the canonical Zeckendorf instance $011 \mid 100$*, the channel encoding is computed event-by-event using Definition 9208.3:* $\mathsf{Ev}(011) = 0101011$ *and* $\mathsf{Ev}(100) = 100011$*, so*

$$\mathsf{Compile}(011, 100) = 0101011\,100011.$$

The compiled stream records both events; it does not erase the pre-normal event 011*.*

9209.2 No channel-level source rewrite

Principle 9209.6 (No channel-level source rewrite)**.** *Lean4✓* `BEDC.GroundCompiler.SourceChannel.no channel level source rewrite`

For every source-level relation $w \rightsquigarrow v$*, it is not admissible to rewrite the displayed substring* w *to* v *inside the channel string* $\mathsf{Ev}(w)$ *or inside the compiled stream* $\mathsf{Compile}(S)$*. In particular, the source-level pair* $011 \rightsquigarrow_Z 100$ *is not a channel-layer string-rewriting rule.*

Example 9209.7 (Channel-level $011 \to 100$ rewrite breaks legality)**.** *The source raw event* 011 *has channel encoding*

$$\mathsf{Ev}(011) = \zeta(0)\,\zeta(1)\,\zeta(1)\,11 = 0\,10\,10\,11 = 0101011.$$

Suppose the displayed substring 011 *at the right end of* 0101011 *is mistakenly rewritten to* 100*:*

$$0101011 \longrightarrow 0101100.$$

Decoding the result of this rewrite glyph-by-glyph, per Definition 9208.13: 0 *emits raw* 0*;* 10 *emits raw* 1*;* 11 *marks event end; the remaining glyphs are* 00*, which contains no subsequent terminator. By Definition 9208.14, the stream is rejected. Thus the channel-level rewrite has destroyed legality.*

Proposition 9209.8 (Channel-level source rewrite may destroy legality)**.** *Lean4✓ BEDC.GroundCompiler.SourceCh level source rewrite may destroy legality*

There exists a legal channel stream $c \in \mathsf{LegalZStream}$ *and a displayed source-level rewrite* $w \rightsquigarrow v$ *such that the result of replacing the displayed substring* w *in* c *by* v *is not a legal channel stream.*

Proof. Take $c = \mathsf{Ev}(011) = 0101011$, which lies in $\mathsf{LegalZStream}$ by Definition 9208.8. Apply the source-level rewrite $011 \rightsquigarrow_Z 100$ to the displayed substring 011 at the right end of c. The result is $c' = 0101100$. By Definition 9209.7, the stream-decoder of Definition 9208.14 rejects c', so $c' \notin \mathsf{LegalZStream}$. Hence channel-level application of a source-level rewrite is not legality-preserving in general. □

Corollary 9209.9 (A source normalizer is not a channel transducer)**.** *Lean4✓ BEDC.GroundCompiler.SourceChanne output factors through decoding*

A source-level normalizer

$$N : \mathsf{EventFlow} \longrightarrow \mathsf{EventFlow}$$

does not lift to a glyph-level transducer $\Sigma^* \to \Sigma^*$ *obtained by rewriting displayed substrings of channel streams. To apply* N *to an already-compiled channel stream, the admissible procedure is to decode first, normalize on the resulting event flow, and recompile: whenever the channel normalizer returns an output* o *on a channel string* c*, there is an event flow* S *such that* $\mathsf{Decode}(c) = \mathsf{some}(S)$ *and* $o = \mathsf{Compile}(N(S))$*.*

9209.3 Decode-normalize-compile pipeline

Definition 9209.10 (Decode-normalize-compile pipeline)**.** *Lean4 (definition) BEDC.GroundCompiler.SourceChannel*

Given a source-level normalizer $N : \mathsf{EventFlow} \to \mathsf{EventFlow}$*, the* decode-normalize-compile pipeline *is the composition*

$$\mathsf{NormalizeChannel}_N \;:=\; \mathsf{Compile} \circ N \circ \mathsf{Decode} \;:\; \mathsf{LegalZStream} \longrightarrow \mathsf{LegalZStream},$$

read as

$$\begin{aligned} &\textit{channel stream} \\ &\xrightarrow{\mathsf{Decode}} \textit{source event flow} \\ &\xrightarrow{N} \textit{normalized source event flow} \\ &\xrightarrow{\mathsf{Compile}} \textit{channel stream.} \end{aligned}$$

On an arbitrary channel glyph string the same operation is partial: it rejects malformed input when Decode *rejects, and otherwise returns* $\mathsf{Compile}(N(S))$ *for the decoded event flow* S*. Restricted to* $\mathsf{LegalZStream}$*, it is the displayed map above. By construction the pipeline forbids any direct rewrite on channel glyphs.*

Theorem 9209.11 (The pipeline preserves channel legality). *Lean4✓ BEDC.GroundCompiler.SourceChannel.norma channel preserves legality*

For every channel stream $c \in$ LegalZStream and every total source-level normalizer N: EventFlow $\to$ EventFlow,

$$\mathsf{NormalizeChannel}_N(c) \in \mathsf{LegalZStream}.$$

Proof. By Definition 9208.19, $\mathsf{Decode}(c) \in \mathsf{EventFlow}$. By the totality of N, $N(\mathsf{Decode}(c)) \in \mathsf{EventFlow}$. By Definition 9208.9, Compile sends every event flow into LegalZStream. The composite output is therefore in LegalZStream. □

9209.4 Ledger preservation and classifier quotient

Definition 9209.12 (Ledger-preserving source relation). *Lean4 (definition) BEDC.GroundCompiler.SourceChannel.L*

Given a source-level relation $w \rightsquigarrow v$, a recording operation

$$L\colon \mathsf{RawEvent} \times \mathsf{RawEvent} \longrightarrow \mathsf{EventFlow}$$

is ledger-preserving *when every witnessed pair is recorded as the ordered event flow*

$$L(w, v) \;=\; w \mid v.$$

The ledger-preserving form of $w \rightsquigarrow v$ is the event flow $w \mid v$ of Definition 9209.5, not the singleton flow v alone.

Principle 9209.13 (Normal address does not erase the raw event). *Lean4✓ BEDC.GroundCompiler.SourceChannel. address does not erase raw event*

For any source-level relation $w \rightsquigarrow v$, the right-hand event v may be displayed as a normal address, but the left-hand event w must remain present in the recorded ledger flow. The flow $w \mid v$ is admissible; deleting w in favor of the singleton flow v is not. This discipline is the source-layer specialization of Definition 1.4: any compression of generated material requires a ledger that tracks the hidden material; composite ledgers must keep the source map rather than only the visible interface.

Proposition 9209.14 (Ledger records distinguish ordered pairs). *Lean4✓ BEDC.GroundCompiler.SourceChannel.l records distinguish ordered pairs*

The ledger-record map $w, v \mapsto (w, v)$ is injective on its arguments: if $(w, v) = (w', v')$, then $w = w'$ and $v = v'$.

Proof. Equality of ordered pairs is componentwise. The conclusion is immediate. □

Corollary 9209.15 (Quotient may be many-to-one; ledger flow is lossless). *Lean4✓ BEDC.GroundCompiler.Source may be many to one ledger lossless*

A source-level classifier may identify multiple raw events as one classified object, but the ledger flow recording the carry events remains lossless. In particular, even when a classifier asserts $w \sim v$, the ledger flow $w \mid v$ continues to distinguish the pre-normal event w from the normal event v.

Definition 9209.16 (Source-level classified object). *Lean4 (definition) BEDC.GroundCompiler.SourceChannel.Source*

A source-level classifier *consists of a carrier of classified objects and a classification map*

$$q\colon \mathsf{RawEvent} \longrightarrow \mathsf{ClassifiedObject}.$$

A classified object is an element of this carrier. For the Zeckendorf carry reading of chapter 9345, the pre-normal event 011 *and the normal event* 100 *may be sent to the same classified object, while at the raw-event layer the two raw events remain distinct.*

Proposition 9209.17 (Classified-object map is generally not injective)**.** Lean4✓ BEDC.GroundCompiler.SourceCha object map not injective

The natural map

$$q\colon \mathsf{RawEvent} \longrightarrow \mathsf{ClassifiedObject}$$

is generally not injective.

Proof. It suffices to exhibit one source-level classifier that identifies two distinct raw events. Let the classifier carrier have a carry class, and send both 011 and 100 to that class. The raw events 011 and 100 are different finite sequences of raw marks, but their classified images coincide. Hence a classified-object map need not be injective. □

Corollary 9209.18 (Bijection is unconditional only at the raw-flow layer)**.** Lean4✓ BEDC.GroundCompiler.SourceC only at raw layer

The unconditional bijection supplied by channel encoding is between raw event flows and legal channel streams,

$$\mathsf{EventFlow} \;\cong\; \mathsf{LegalZStream} \quad \textit{(Definition 9208.19).}$$

The composite map from raw event data to classified objects is generally not injective. Therefore, when a downstream argument speaks of a bijection between "theory" and "code," the theory side must be the canonical raw-event flow, not an abstract classified proposition.

9209.5 Encoding and decoding examples for ledger flows

Example 9209.19 (Carry ledger encoding)**.** *The carry-ledger event flow* $011 \mid 100$ *encodes event-by-event as*

$$\mathsf{Ev}(011) \;=\; 0101011, \qquad \mathsf{Ev}(100) \;=\; 100011,$$

hence

$$\mathsf{Compile}(011, 100) \;=\; 0101011\,100011.$$

The stream decoder of Definition 9208.14 segments the result at the leftmost terminator, recovering $0101011 \mid 100011$ *and decoding to* $(011, 100)$*. The pre-normal event* 011 *is preserved by the channel round trip.*

Example 9209.20 (Completion skeleton with carry ledger)**.** *The event flow* $0 \mid 00 \mid 000 \mid 01 \mid 011 \mid 100$ *of Definition 9207.25 encodes event-by-event as*

$$\begin{aligned}
\mathsf{Ev}(0) &= 011\\
\mathsf{Ev}(00) &= 0011\\
\mathsf{Ev}(000) &= 00011\\
\mathsf{Ev}(01) &= 01011\\
\mathsf{Ev}(011) &= 0101011\\
\mathsf{Ev}(100) &= 100011.
\end{aligned}$$

The complete channel stream is therefore the concatenation

$$011\,0011\,00011\,01011\,0101011\,100011,$$

which is in LegalZStream *by Definition 9208.19. If a downstream classifier asserts* $011 \sim_Z 100$*, the assertion is read against the decoded source events, not against any displayed substring of the channel stream.*

Theorem 9209.21 (Source-level normalization is conservative over channel decoding). *Lean4✓ BEDC.GroundCompiler.SourceChannel.source normalization conservative over decoding*

For every source-level normalizer $N : \mathsf{EventFlow} \to \mathsf{EventFlow}$*, the diagram*

$$\mathsf{LegalZStream} \xrightarrow{\mathsf{Decode}} \mathsf{EventFlow} \xrightarrow{N} \mathsf{EventFlow} \xrightarrow{\mathsf{Compile}} \mathsf{LegalZStream}$$

is well-defined. Source-level normalization therefore acts on channel streams indirectly through the decode-normalize-compile pipeline of Definition 9209.10; it does not act on channel streams as a direct glyph-level rewrite.

Proof. The first arrow is well-defined by Definition 9208.19; the second arrow is well-defined by the totality of N; the third arrow is well-defined by Definition 9208.9. The composite is therefore a well-defined function from $\mathsf{LegalZStream}$ to itself. Direct glyph-level channel rewriting is excluded from this diagram and is forbidden by Definition 9209.6. □

9209.6 Channel substrings versus source events

Proposition 9209.22 (Channel terminator is not the source event 11). *Lean4✓ BEDC.GroundCompiler.SourceChan terminator not source event 11*

The channel-layer terminator 11 *of Definition 9208.2 is not the source raw event* $11 \in \mathsf{RawEvent}$.

Proof. The source raw event 11 has channel encoding

$$\mathsf{Ev}(11) \;=\; \zeta(1)\,\zeta(1)\,11 \;=\; 10\,10\,11 \;=\; 101011,$$

whereas the channel terminator is the literal glyph pair 11. If the channel terminator were identified with the source raw event 11, the encoding of the source raw event 11 would be 11 rather than 101011. The two strings are distinct, so the identification fails. □

Corollary 9209.23 (The source raw event 11 encodes unambiguously). *Lean4✓ BEDC.GroundCompiler.SourceChan event 11 unambiguous*

The source raw event 11 *encodes as the channel string* $\mathsf{Ev}(11) = 101011$*. The decoder of Definition 9208.13 reads this as* $10 \to \text{raw } 1$, $10 \to \text{raw } 1$, $11 \to \text{event end}$*, recovering* $11 \in \mathsf{RawEvent}$ *without ambiguity.*

Principle 9209.24 (No channel proof by substring). *Lean4✓ BEDC.GroundCompiler.SourceChannel.no channel proof by substring*

The appearance of a displayed substring u *inside a channel stream* $c \in \mathsf{LegalZStream}$ *does not entail that the source event* u *appears in* $\mathsf{Decode}(c)$*. Source-event analysis is admissible only on the output of* Decode.

Proposition 9209.25 (Channel substrings are not source events). *Lean4✓ BEDC.GroundCompiler.SourceChannel. substring not source event*

There exists a channel stream $c \in \mathsf{LegalZStream}$ *and a displayed substring* u *of* c *such that* u *is not any source event of* $\mathsf{Decode}(c)$.

Proof. Take $c = \mathsf{Ev}(1) = 1011$. The displayed substring $u = 011$ occurs at positions 2–4 of c. By Definition 9208.16, $\mathsf{Decode}(c) = (1)$. The only source event of $\mathsf{Decode}(c)$ is 1, not 011. Hence the displayed substring 011 is not a source event of the decoded flow. □

Corollary 9209.26 (Source analysis must begin after decoding)**.** *Lean4✓ BEDC.GroundCompiler.SourceChannel.s analysis after decoding*

Any source-level analysis—finite repetition, completion witness, Zeckendorf carry, NameCert *source pattern, theorem event, ledger event—is admissible only after* Decode *has been applied to the channel stream. Source-level analyses applied directly to channel glyphs are not admissible.*

9209.7 Layer separation theorem and closing observations

Theorem 9209.27 (Layer separation theorem)**.** *Lean4✓ BEDC.GroundCompiler.SourceChannel.layer separation*

The source layer and the channel layer satisfy the following seven separation conditions:

1. *source events are elements of* RawEvent*;*
2. *channel streams are elements of* LegalZStream*;*
3. Compile *encodes source event flows into channel streams;*
4. Decode *recovers source event flows from channel streams;*
5. *source-level normalization acts on* EventFlow *only;*
6. *the channel-layer event terminator* 11 *is not the source raw event* 11*;*
7. *displayed channel substrings are not, in general, source events of the decoded flow.*

Proof. Items (1) and (2) are Definition 9209.1 and Definition 9209.2. Items (3) and (4) are Definition 9208.9, Definition 9208.14, and Definition 9208.19. Item (5) is Definition 9209.4 and Definition 9209.21. Item (6) is Definition 9209.22. Item (7) is Definition 9209.25. □

Remark 9209.28 (Outlook)**.** *The next chapter records how recognized package,* NameCert, ClosureCert*, theorem, and ledger structures are read inside a decoded event flow. By Definition 9209.27, every such recognition begins from* Decode(c)*, never from* c *as a glyph string. The recognizer flows of Definition 9207.10–Definition 9207.16 are therefore source-layer relations on event flows, in line with Definition 9207.9; their composition with* Compile *and* Decode *is the discipline by which structural readings reach the channel layer without appearing as primitive compiler inputs.*

Chapter 9210

Package Structure Is Generated, Not Input

chapter 9207 and chapter 9208 establish the raw bijection

$$\mathsf{EventFlow} \;\cong\; \mathsf{LegalZStream} \;=\; \big((0 \mid 10)^* \, 11\big)^*.$$

chapter 9209 then separates source-level events from channel-level bits: source-level normalization, classification, and ledger recognition act on decoded event flows, never on channel substrings.

This chapter records the next no-hidden-input constraint. Package structure is not a formal compiler input. If the compiler directly accepted a datum such as

$$\mathrm{Package}(\mathrm{source}, \mathrm{pattern}, \mathrm{classifier}, \mathrm{stability}, \mathrm{ledger})$$

or a host object such as TheoryPkg, NameCert, or TheoremPkg, then the package fields, boundaries, roles, order, and hierarchy would have been supplied from outside the generated event flow. That is exactly the structural hidden input excluded by Definition 9207.21.

The chapter's central rule is therefore:

$$\boxed{\text{packages are recognized structures in event flows, not compiler inputs.}}$$

This is the source-layer form of the package and gap discipline already used by BEDC: package tokens are generated by answer histories, package interfaces expose only the token and its ledger, and nontrivial package visibility requires a gap ledger recording which source histories enter the package token.

9210.1 Package recognition on event flows

Definition 9210.1 (Package candidate flow)**.** *Lean4 (definition)* `BEDC.GroundCompiler.PackageGenerated.PackageC`

A package candidate flow *is an event flow*

$$S \in \mathsf{EventFlow}.$$

The phrase does not assert that S is a package. It asserts only that S is available as a candidate source flow on which package recognition may be attempted.

Definition 9210.2 (Generated package recognizer). *Lean4 (definition)* `BEDC.GroundCompiler.PackageGenerated.Ge`

A generated package recognizer *is an event flow*

$$R \in \mathsf{EventFlow}.$$

It is not a host-level parser, YAML schema, AST constructor, or external grammar. Its public formal carrier is itself generated from the two raw marks through the event-flow layer.

Definition 9210.3 (Package recognition relation). *Lean4 (definition)* `BEDC.GroundCompiler.PackageGenerated.Pack`

The package recognition relation is written

$$\mathsf{RecognizesPkg}(R, S), \qquad R, S \in \mathsf{EventFlow}.$$

It is read as: the generated recognizer flow R recognizes the event flow S as a package flow. If such an R exists, then S is a recognized package flow.

Remark 9210.4 (Recognition is not input). *The judgment* $\mathsf{RecognizesPkg}(R, S)$ *does not mean that S has been externally tagged as a package. It means that an already generated recognizer flow R recognizes package-shaped structure in the source event flow S. The direction is therefore*

$$\mathsf{EventFlow} \longrightarrow \mathsf{RecognizedPackageFlow},$$

not

$$\mathsf{Pkg} \longrightarrow \mathsf{EventFlow}.$$

Definition 9210.5 (Recognized package flow). *Lean4 (definition)* `BEDC.GroundCompiler.PackageGenerated.PkgFlow`

For an event flow S, define

$$\mathsf{PkgFlow}(S) \;:\Longleftrightarrow\; \exists R \in \mathsf{EventFlow},\ \mathsf{RecognizesPkg}(R, S).$$

Thus S is a recognized package flow exactly when a generated recognizer flow recognizes it as package-shaped.

Principle 9210.6 (No external package input). *Lean4 ✓* `BEDC.GroundCompiler.PackageGenerated.no external package input`

At the formal datum boundary, a host package object is not an admissible compiler input:

$$\neg\, \mathsf{FormalCompilerInput}(\mathrm{hostPkg}).$$

There is no formal compiler entry point

$$\mathsf{CompilePkg}\colon \mathsf{Pkg} \longrightarrow \mathsf{LegalZStream}.$$

The only formal channel compiler remains

$$\mathsf{Compile}\colon \mathsf{EventFlow} \longrightarrow \mathsf{LegalZStream}.$$

If an event flow S is recognized as a package flow, its package code is just $\mathsf{Compile}(S)$.

Proposition 9210.7 (Package recognition does not change channel code). *Lean4 ✓* `BEDC.GroundCompiler.Package recognition preserves code`

If $\mathsf{RecognizesPkg}(R, S)$*, then the channel encoding of S is still* $\mathsf{Compile}(S)$*. Package recognition does not add, delete, or rewrite channel bits.*

Proof. The judgment $\mathsf{RecognizesPkg}(R, S)$ is a source-level recognition relation. It says only that S is recognized by the generated recognizer R as package-shaped. The channel encoding is given by $\mathsf{Compile}$ from Definition 9208.9, and depends only on the event flow S. Since the recognition judgment does not alter S, it does not alter $\mathsf{Compile}(S)$. □

Corollary 9210.8 (Recognized package code is not a separate code)**.** *Lean4 ✓* `BEDC.GroundCompiler.PackageGener` `code not separate`

If S is a recognized package flow, then

$$\mathsf{PackageCode}(S) \;:=\; \mathsf{Compile}(S)$$

is the ordinary channel code of the same event flow, not the output of a separate package encoder.

9210.2 Roles, seals, and ledgers

Definition 9210.9 (Package role emergence)**.** *Lean4 (definition)* `BEDC.GroundCompiler.PackageGenerated.PackageR`

Let ρ range over the finite package-role list

source flow,
pattern flow,
classifier flow,
stability flow,
ledger flow,
package-seal flow.

For a generated package recognizer R, a package candidate flow S, and a source-level event subflow T, define

$$\mathsf{PkgRole}_R(S, T, \rho) \;:\Longleftrightarrow\; \mathsf{RecognizesPkg}(R, S) \wedge T \in \mathsf{EventFlow}_{\neq\emptyset}.$$

The role name ρ is not a ground input. It is a recognition result attached to an event-flow subflow after $\mathsf{RecognizesPkg}(R, S)$ *has already been witnessed.*

Remark 9210.10 (Relation to the five fields of $\mathsf{NameCert}$)**.** *The five fields of a* $\mathsf{NameCert}$*,*

$$\mathsf{SourceSpec}, \qquad \mathsf{PatternSpec}, \qquad \mathsf{ClassifierSpec}, \qquad \mathsf{StabilityCert}, \qquad \mathsf{LedgerPolicy},$$

are derived-interface certificate roles. $\mathsf{PatternSpec}$ *records stable behavior on the source,* $\mathsf{ClassifierSpec}$ *records how source material is grouped,* $\mathsf{StabilityCert}$ *records closure, reuse, descent, composition, and seal stability, and* $\mathsf{LedgerPolicy}$ *records what a name hides and how the hidden material is tracked. This chapter does not treat those five fields as external input. It says only that, in a recognized package flow, a generated recognizer may identify subflows corresponding to those roles.*

Definition 9210.11 (Package-seal subflow)**.** *Lean4 (definition)* `BEDC.GroundCompiler.PackageGenerated.PackageSe`

If R recognizes a source-level event subflow σ of S as expressing package completion, then σ is a package-seal subflow *of S, written*

$$\mathsf{PkgSeal}_R(S, \sigma) \;:\Longleftrightarrow\; \mathsf{PkgRole}_R(S, \sigma, \mathrm{seal}).$$

The package-seal subflow is not the channel terminator 11*. It is source-level event-flow structure, recovered through* Decode *and then recognized by R.*

Proposition 9210.12 (Package seal is not the channel terminator). *Lean4✓ BEDC.GroundCompiler.PackageGenera seal is source subflow*

If $\mathsf{PkgSeal}_R(S, \sigma)$*, then* σ *is a source-level event subflow. In particular, its formal carrier is an element of* $\mathsf{EventFlow}_{\neq\emptyset}$*, whereas the channel-level terminator* 11 *is a channel-code delimiter.*

Proof. The channel-level terminator 11 belongs to the encoding mechanism of LegalZStream, as fixed in Definition 9208.2. A package seal is a subflow of EventFlow recognized by R. These live on different layers. By the layer-separation theorem Definition 9209.27, a channel substring cannot be used directly as a source event or source subflow. Therefore the package seal is not the channel terminator. □

Definition 9210.13 (Package ledger subflow). *Lean4 (definition) BEDC.GroundCompiler.PackageGenerated.Package*

The package ledger subflow *predicate is*

$$\mathsf{PkgLedger}_R(S, L) \;:\Longleftrightarrow\; \mathsf{PkgRole}_R(S, L, \text{ledger}).$$

Thus if $\mathsf{RecognizesPkg}(R, S)$ *and* L *is recognized as the ledger-role subflow of* S*, then* L *records the source material hidden or compressed by* S*. The ledger subflow is part of the decoded source event flow, not an external provenance table.*

Principle 9210.14 (No package without ledger). *Lean4✓ BEDC.GroundCompiler.PackageGenerated.no package without ledger*

A nontrivial recognized package flow must carry a recognized ledger subflow:

$$\mathsf{PkgFlow}(S) \implies \exists R, L,\ \mathsf{RecognizesPkg}(R, S) \wedge \mathsf{PkgLedger}_R(S, L),$$

where the ledger witness is an event subflow identified by the same generated recognizer that recognizes S *as package-shaped. This is the package-level form of the gap policy: visible package tokens are not admissible for compression unless their ledgers record the histories entering the token.*

Theorem 9210.15 (Visible package code alone is insufficient). *Lean4✓ BEDC.GroundCompiler.PackageGenerated. code insufficient*

If there are no R *and* L *such that*

$$\mathsf{RecognizesPkg}(R, S) \wedge \mathsf{PkgLedger}_R(S, L),$$

then S *is not a recognized package flow:*

$$\neg\, \mathsf{PkgFlow}(S).$$

Proof. By Definition 9210.14, any recognized package flow supplies a generated recognizer R and a ledger subflow L with

$$\mathsf{RecognizesPkg}(R, S) \wedge \mathsf{PkgLedger}_R(S, L).$$

If no such pair exists, the assumption $\mathsf{PkgFlow}(S)$ is impossible. □

Corollary 9210.16 (A package code is not merely a visible token). *Lean4✓ BEDC.GroundCompiler.PackageGenerat not merely visible token*

A package code cannot consist only of a visible package-token event. It must include enough recognized ledger flow to recover provenance, unless the recognizer identifies the package as trivial and non-compressing.

9210.3 Compile-decode invariance

Definition 9210.17 (Recognition-preserving compilation). *Lean4 (definition)* `BEDC.GroundCompiler.PackageGenera`

Compilation is recognition-preserving for packages *when, for every* $\mathsf{RecognizesPkg}(R, S)$,

$$\mathsf{Decode}(\mathsf{Compile}(S)) = S$$

and therefore

$$\mathsf{RecognizesPkg}(R, \mathsf{Decode}(\mathsf{Compile}(S))).$$

Theorem 9210.18 (Channel compilation preserves package recognition). *Lean4✓* `BEDC.GroundCompiler.Package(` `compilation preserves recognition`

If $\mathsf{RecognizesPkg}(R, S)$, *then*

$$\mathsf{RecognizesPkg}(R, \mathsf{Decode}(\mathsf{Compile}(S))).$$

Proof. By the flow-level round-trip theorem Definition 9208.17,

$$\mathsf{Decode}(\mathsf{Compile}(S)) = S.$$

Substituting this equality into the recognition judgment gives

$$\mathsf{RecognizesPkg}(R, \mathsf{Decode}(\mathsf{Compile}(S))).$$

□

Corollary 9210.19 (Package recognition is invariant under compile-decode). *Lean4✓* `BEDC.GroundCompiler.Pack` `recognition invariant`

For every recognized package flow S, channel compilation followed by decoding preserves its package-recognition status.

Definition 9210.20 (Package-code equivalence). *Lean4 (definition)* `BEDC.GroundCompiler.PackageGenerated.Packa`

For recognized package flows S and T, define

$$S \equiv_{\text{code}} T \;:\Longleftrightarrow\; \mathsf{Compile}(S) = \mathsf{Compile}(T).$$

Proposition 9210.21 (Package-code equivalence is raw-flow equality). *Lean4✓* `BEDC.GroundCompiler.PackageGe` `code equivalence is equality`

For recognized package flows S and T,

$$S \equiv_{\text{code}} T \quad\Longleftrightarrow\quad S = T.$$

Proof. If $S = T$, then $\mathsf{Compile}(S) = \mathsf{Compile}(T)$.

Conversely, suppose $\mathsf{Compile}(S) = \mathsf{Compile}(T)$. Applying Decode to both sides gives

$$\mathsf{Decode}(\mathsf{Compile}(S)) = \mathsf{Decode}(\mathsf{Compile}(T)).$$

By Definition 9208.17, the left side is S and the right side is T. Hence $S = T$. □

Corollary 9210.22 (Raw package flows are code-bijective). *Lean4✓* `BEDC.GroundCompiler.PackageGenerated.rau` `flows code bijective`

Recognized package flows, considered as raw event flows, are in bijection with their legal channel codes. This is not the same as saying classified package objects are bijective with codes: a package classifier may identify two raw package flows.

9210.4 Classified packages as quotients

Definition 9210.23 (Package classifier quotient). *Lean4 (definition)* `BEDC.GroundCompiler.PackageGenerated.Pack`

If a package recognizer supplies a classifier relation $\sim_{\mathrm{pkg}}$ on recognized package flows, then the package classifier quotient relation records when two recognized package flows are assigned to the same classified package object:

$$\mathsf{PackageClassifierQuotient}(\sim_{\mathrm{pkg}}, S, T) \;:\Longleftrightarrow\; S \sim_{\mathrm{pkg}} T.$$

The projection

$$S \longmapsto \textit{the classified package object represented by } S$$

may therefore identify distinct raw package flows whenever $S \sim_{\mathrm{pkg}} T$ holds with $S \neq T$.

Proposition 9210.24 (Classified packages need not be code-bijective). *Lean4✓* `BEDC.GroundCompiler.PackageGen` `not code bijective`

If there exist recognized package flows $S \neq T$ with

$$S \sim_{\mathrm{pkg}} T,$$

then there exist two distinct recognized package codes whose decoded event flows are identified by the package classifier quotient. Thus the code-to-classified-package reading is not injective at the classified-object layer.

Proof. By Definition 9210.21, $S \neq T$ implies

$$\mathsf{Compile}(S) \neq \mathsf{Compile}(T).$$

But $S \sim_{\mathrm{pkg}} T$ implies

$$\mathsf{PackageClassifierQuotient}(\sim_{\mathrm{pkg}}, S, T).$$

Thus two distinct codes decode to raw flows identified by the classifier quotient. The code-to-classified-package reading is therefore not injective. □

Corollary 9210.25 (Raw package code and classified package object are different layers). *Lean4✓* `BEDC.GroundCompiler.PackageGenerated.raw code vs classified object layers`

Package codes are bijective with recognized raw package flows. Classified package objects are quotients of those flows:

$$\begin{array}{lcl} \textit{raw package flow} & \longleftrightarrow & \textit{package code,} \\ \textit{raw package flow} & \longrightarrow & \textit{classified package object.} \end{array}$$

The first relation is bijective; the second is generally many-to-one.

9210.5 Recognition from channel code

Definition 9210.26 (Package recognition from channel code). *Lean4 (definition)* `BEDC.GroundCompiler.PackageGen`

Given $c \in \mathsf{LegalZStream}$, define package recognition from code by the existence of a decoded event flow:

$$\mathsf{RecognizesPkgCode}(R, c) \;:\Longleftrightarrow\; \exists S \in \mathsf{EventFlow}, \mathsf{Decode}(c) = \mathsf{some}(S) \wedge \mathsf{RecognizesPkg}(R, S).$$

Thus package recognition from channel code always proceeds through decoding.

Proposition 9210.27 (No package recognition by channel substring)**.** `Lean4✓` `BEDC.GroundCompiler.PackageGene` `code recognition has decoded flow`

Every valid package-recognition judgment from channel code first supplies a decoded event flow:

$$\mathsf{RecognizesPkgCode}(R, c) \implies \exists S,\ \mathsf{Decode}(c) = \mathsf{some}(S) \wedge \mathsf{RecognizesPkg}(R, S).$$

Thus there is no valid package recognition rule that inspects arbitrary channel substrings without first decoding the channel stream into an event flow.

Proof. By Definition 9210.26, $\mathsf{RecognizesPkgCode}(R, c)$ is defined by the existence of a decoded event flow S with $\mathsf{Decode}(c) = \mathsf{some}(S)$ and $\mathsf{RecognizesPkg}(R, S)$. By Definition 9209.27, channel substrings are not source events. Package recognition is defined on event flows by Definition 9210.3; therefore valid package recognition from channel code must proceed through Decode. □

Example 9210.28 (Package recognition over a completion skeleton)**.** *Consider the event flow*

$$0 \mid 00 \mid 000 \mid 01 \mid 011 \mid 100.$$

Its channel code is

$$011001100011010110101011100011.$$

A generated recognizer R may recognize this event flow as a completion-like package candidate, identifying

$0 \mid 00 \mid 000$	*finite source-prefix flow,*
01	*repeat-boundary witness,*
$011 \mid 100$	*raw/normal carry ledger,*
σ	*package-seal subflow.*

None of this occurs at the channel-substring layer. The channel code must first decode to

$$0 \mid 00 \mid 000 \mid 01 \mid 011 \mid 100,$$

and only then can R recognize package roles.

Example 9210.29 (Package recognition over an additive / fold skeleton)**.** *Consider the event flow*

$$0 \mid 00 \mid 001 \mid 0011 \mid 0100.$$

Its channel code is

$$011001100101100101011010 0011.$$

A recognizer may identify

0	*unit-source event,*
00	*binary-repetition witness,*
001	*additive-recursion witness,*
$0011 \mid 0100$	*raw/normal fold ledger.*

The compiler itself does not call this flow addition, multiplication, or fold. Those names require a recognized package flow and, if exported as derived interfaces, the corresponding NameCert*, derived certificate, and ledger support.*

9210.6 Conservativity and derived-interface boundary

Theorem 9210.30 (Package-recognition conservativity)**.** Lean4✓ BEDC.GroundCompiler.PackageGenerated.packa recognition conservativity

Adding package recognition relations of the form

$$\mathsf{RecognizesPkg}(R, S)$$

does not add new finite-kernel marks, histories, mark-sameness rules, history-sameness rules, continuation rules, or derived-interface formation rules.

Proof. The relation $\mathsf{RecognizesPkg}(R, S)$ is defined over event flows $R, S \in \mathsf{EventFlow}$. It does not introduce raw marks beyond b0 and b1, construct new histories in the finite kernel, assert new msame, hsame, or psame judgments, or license derived interfaces by itself. A derived interface still requires the relevant NameCert fields, and an exported object still requires the acceptance discipline of Definition 9207.18. Therefore package recognition is conservative over the finite kernel. □

Corollary 9210.31 (Recognized package flow is weaker than derived interface)**.** Lean4✓ BEDC.GroundCompiler.Pa package weaker than derived interface

A derived-interface license for a package flow consists of package recognition together with recognized NameCert *flow, recognized* ClosureCert *flow, and accepted-object support. Such a license projects to package recognition:*

$$\mathsf{DerivedInterfaceLicense}(S) \Longrightarrow \mathsf{PkgFlow}(S).$$

Package recognition alone is only this projected component; it is not the whole derived-interface license.

Proof. By definition, $\mathsf{DerivedInterfaceLicense}(S)$ contains a generated package recognizer R with $\mathsf{RecognizesPkg}(R, S)$, together with the certificate and acceptance witnesses. Projecting the package-recognition component gives $\mathsf{PkgFlow}(S)$. □

Remark 9210.32 (Outlook)**.** *This chapter establishes that package structure is a recognition result inside an event flow, not a compiler input. The core relation is* $\mathsf{RecognizesPkg}(R, S)$ *with* $R, S \in \mathsf{EventFlow}$*: it preserves channel code, keeps package seals separate from channel terminators, requires ledger subflows for nontrivial package visibility, makes raw package flows code-bijective, treats classified packages as quotients, forces channel-code recognition through* Decode*, and remains conservative over the finite kernel. The same no-hidden-input rule applies to* NameCert *recognition: certificate fields are recognized as event-flow substructures rather than received as a host-level five-field object.*

Chapter 9211

NameCert Flow Recognition

chapter 9210 records that package structure is not a compiler input: it is recognized inside an event flow by a generated recognizer. This chapter applies the same no-hidden-input rule to NameCert.

The central rule is

$$\boxed{\text{NameCert is a recognized five-field certificate flow, not an input object.}}$$

The paper-side $\mathsf{NameCert}(N)$ template of Definition 9.6 is already a five-field certificate:

$$\mathsf{NameCert}(N) = (\mathsf{SourceSpec}_N, \mathsf{PatternSpec}_N, \mathsf{ClassifierSpec}_N, \mathsf{StabilityCert}_N, \mathsf{LedgerPolicy}_N).$$

The proposed name N is licensed only when all required fields are supplied, upward-arrow derived interfaces are not licensed without a NameCert, and limit-like interfaces carry ledger policy witnesses.

This chapter does not change the mathematical content of the NameCert discipline. It changes the input reading: the compiler does not receive a host object of the form

$$\mathsf{NameCert}(\mathsf{SourceSpec}, \mathsf{PatternSpec}, \mathsf{ClassifierSpec}, \mathsf{StabilityCert}, \mathsf{LedgerPolicy}).$$

It receives an event flow. A generated recognizer then recognizes source, pattern, classifier, stability, and ledger subflows inside the decoded source layer.

9211.1 NameCert recognition on event flows

Definition 9211.1 (Name candidate flow)**.** *Lean4 (definition)* `BEDC.GroundCompiler.NameCertGenerated.NameCandi`

A name candidate flow *is an event flow*

$$N \in \mathsf{EventFlow}.$$

It represents the visible generated trace of a proposed name. It is not an external string label, host-level object name, theorem label, or registry entry.

Definition 9211.2 (NameCert candidate flow)**.** *Lean4 (definition)* `BEDC.GroundCompiler.NameCertGenerated.NameC`

A NameCert candidate flow *is an event flow*

$$S \in \mathsf{EventFlow}.$$

It has not yet been recognized as a NameCert*. Thus* $S \in \mathsf{EventFlow}$ *does not imply* $S = \mathsf{NameCert}(N)$*.*

Definition 9211.3 (Generated NameCert recognizer)**.** *Lean4 (definition)* `BEDC.GroundCompiler.NameCertGenerated`

A generated NameCert recognizer *is an event flow*

$$R \in \mathsf{EventFlow}.$$

It is not a host parser, YAML schema, external grammar, Lean structure input, or human field table. Its public formal carrier is generated from the two raw marks and works on the source event layer.

Definition 9211.4 (NameCert recognition relation)**.** *Lean4 (definition)* `BEDC.GroundCompiler.NameCertGenerated.N`

The name-indexed NameCert *recognition relation is written*

$$\mathsf{RecognizesNameCert}(R, S, N), \qquad R, S, N \in \mathsf{EventFlow}.$$

It is read as: the generated recognizer flow R recognizes the event flow S as a NameCert *flow for the candidate name flow N.*

Remark 9211.5 (Relation to the unindexed recognition judgment)**.** *Definition 9207.14 used the unindexed judgment* $\mathsf{RecognizesNameCert}(R, S)$ *to record that S is recognized as a* NameCert *flow. The ternary notation of this chapter is the same source-layer recognition with the associated candidate name flow displayed explicitly. When the name parameter is irrelevant, the unindexed notation remains a harmless abbreviation.*

Remark 9211.6 (NameCert recognition is not NameCert input)**.** *The judgment* $\mathsf{RecognizesNameCert}(R, S, N)$ *does not mean that an external* NameCert *object has been supplied. It means that, in the decoded source event layer, R recognizes S as having the five-field certificate structure for the candidate name N. The direction is*

$$\mathsf{EventFlow} \longrightarrow \mathsf{RecognizedNameCertFlow},$$

not

$$\mathsf{NameCertObject} \longrightarrow \mathsf{EventFlow}.$$

Definition 9211.7 (Recognized NameCert flow)**.** *Lean4 (definition)* `BEDC.GroundCompiler.NameCertGenerated.Name`

Define

$$\mathsf{NameCertFlow}(S, N) \;:\Longleftrightarrow\; \exists R,\ \mathsf{RecognizesNameCert}(R, S, N).$$

Thus S is a recognized NameCert *flow for the candidate name N exactly when some generated recognizer flow recognizes it as the certificate flow for N.*

Principle 9211.8 (No external NameCert input)**.** *Lean4✓* `BEDC.GroundCompiler.NameCertGenerated.no external namecert input`

There is no formal compiler entry point

$$\mathsf{CompileNameCert}\colon \mathsf{NameCertObject} \longrightarrow \mathsf{LegalZStream}.$$

The only formal channel compiler remains

$$\mathsf{Compile}\colon \mathsf{EventFlow} \longrightarrow \mathsf{LegalZStream}.$$

If S is a recognized NameCert *flow, its* NameCert *code is just* $\mathsf{Compile}(S)$.

Proposition 9211.9 (NameCert recognition does not change channel code)**.** Lean4 ✓ BEDC.GroundCompiler.NameC recognition preserves code

If $\mathsf{RecognizesNameCert}(R, S, N)$*, then the channel encoding of* S *is still* $\mathsf{Compile}(S)$*.* NameCert *recognition does not add, delete, or rewrite channel bits.*

Proof. The judgment $\mathsf{RecognizesNameCert}(R, S, N)$ is a source-level recognition relation. It says only that S is recognized by R as the NameCert flow for N. The channel encoding is supplied by Compile and depends only on the event flow S. Since the recognition relation does not alter S, it does not alter $\mathsf{Compile}(S)$. □

Corollary 9211.10 (Recognized NameCert code is not a separate code)**.** Lean4 ✓ BEDC.GroundCompiler.NameCert code not separate

If S *is a recognized* NameCert *flow, then*

$$\mathsf{NameCertCode}(S) := \mathsf{Compile}(S)$$

is the ordinary channel code of the same event flow, not the output of a separate NameCert *encoder.*

9211.2 Field subflows and seals

Definition 9211.11 (Recognized NameCert field subflows)**.** Lean4 (definition) BEDC.GroundCompiler.NameCertGene

If $\mathsf{RecognizesNameCert}(R, S, N)$*, then* R *may recognize subflows of* S *as the five certificate roles:*

source flow,
pattern flow,
classifier flow,
stability flow,
ledger flow.

Formally, this chapter uses the relations

$$\mathsf{NameCertSource}_R(S, S_0), \qquad \mathsf{NameCertPattern}_R(S, S_1), \qquad \mathsf{NameCertClassifier}_R(S, S_2),$$

$$\mathsf{NameCertStability}_R(S, S_3), \qquad \mathsf{NameCertLedger}_R(S, S_4).$$

These are not external field labels. They are subflow roles recognized by R *inside* S*.*

Remark 9211.12 (Field names are explanatory metalanguage)**.** *The names* SourceSpec*,* PatternSpec*,* ClassifierSpec*,* StabilityCert*, and* LedgerPolicy *are explanatory labels for the five paper-side roles. Formally, the roles must be recognized by the relations*

$$\mathsf{NameCertSource}_R, \quad \mathsf{NameCertPattern}_R, \quad \mathsf{NameCertClassifier}_R, \quad \mathsf{NameCertStability}_R, \quad \mathsf{NameCertLedger}_R$$

on event flows. Field names are not first-layer compiler inputs, and the five-field structure is not received as an external record.

Definition 9211.13 (NameCert-seal subflow)**.** Lean4 (definition) BEDC.GroundCompiler.NameCertGenerated.NameCe

If $\mathsf{RecognizesNameCert}(R, S, N)$ *and* R *recognizes a terminal subflow* σ *of* S *as expressing* NameCert *completion, then* σ *is a* NameCert-seal subflow*, written*

$$\mathsf{NameCertSeal}_R(S, \sigma).$$

The NameCert *seal is a source-level subflow, not the channel-level terminator* 11*.*

Proposition 9211.14 (NameCert seal is not the channel terminator). *Lean4✓ BEDC.GroundCompiler.NameCertGen seal is source subflow*

If $\mathsf{NameCertSeal}_R(S, \sigma)$*, then* σ *is a source-level subflow, not the channel-level terminator* 11*.*

Proof. The channel-level 11 is the event terminator of Definition 9208.2; it belongs to the LegalZStream encoding mechanism. A NameCert seal is a source-level subflow of an event flow recognized by R. By the layer-separation theorem Definition 9209.27, a channel substring cannot be used directly as a source event or source subflow. Hence the NameCert seal is not the channel terminator. □

Definition 9211.15 (Complete five-field recognition). *Lean4 (definition) BEDC.GroundCompiler.NameCertGenerated*

The judgment $\mathsf{RecognizesNameCert}(R, S, N)$ *has* complete five-field recognition *when there exist subflows* S_0, S_1, S_2, S_3, S_4 *and* σ *such that*

$$\mathsf{NameCertSource}_R(S, S_0), \qquad \mathsf{NameCertPattern}_R(S, S_1), \qquad \mathsf{NameCertClassifier}_R(S, S_2),$$

$$\mathsf{NameCertStability}_R(S, S_3), \qquad \mathsf{NameCertLedger}_R(S, S_4), \qquad \mathsf{NameCertSeal}_R(S, \sigma).$$

The displayed roles are recognized by R*, not supplied by external field tags.*

Principle 9211.16 (No NameCert without five recognized fields). *Lean4✓ BEDC.GroundCompiler.NameCertGenera namecert without five fields*

The name-indexed recognition relation

$$\mathsf{RecognizesNameCert}(R, S, N)$$

includes complete five-field recognition. In particular, a recognized certificate for a proposed name supplies source, pattern, classifier, stability, ledger, and seal subflows recognized inside the event flow. This is the event-flow form of the paper template of Definition 9.6: a proposed name is licensed only after all required fields are supplied.

Theorem 9211.17 (Incomplete NameCert flow does not license a name). *Lean4✓ BEDC.GroundCompiler.NameCert namecert does not license*

If every generated recognizer relation for (S, N) *fails complete five-field recognition, then* S *is not a* NameCert *flow licensing* N*.*

Proof. By Definition 9211.16, a recognized NameCert flow must have complete five-field recognition. If any required field subflow is missing, complete five-field recognition fails. Therefore S cannot serve as an admissible NameCert flow licensing N. □

Corollary 9211.18 (Visible name event is insufficient). *Lean4✓ BEDC.GroundCompiler.NameCertGenerated.visibl name event insufficient*

A visible candidate name event N *does not by itself license a derived interface. A recognized* NameCert *flow must supply the five certificate fields for* N*.*

9211.3 Name licensing

Definition 9211.19 (Name licensing by recognized flow). *Lean4 (definition) BEDC.GroundCompiler.NameCertGenera*

Define

$$\mathsf{LicensedName}(N) \;:\Longleftrightarrow\; \exists S,\ \mathsf{NameCertFlow}(S, N).$$

Thus the candidate name N *is licensed exactly when some event flow is recognized as its* NameCert *flow.*

Proposition 9211.20 (Licensing is event-flow based). *Lean4✓ BEDC.GroundCompiler.NameCertGenerated.licensi event flow based*

If $\mathsf{LicensedName}(N)$*, then there exists* $S \in \mathsf{EventFlow}$ *such that* $\mathsf{NameCertFlow}(S, N)$*.*

Proof. This is the content of Definition 9211.19, with the ambient event-flow condition supplied by Definition 9211.7. □

Theorem 9211.21 (Derived interfaces require recognized NameCert flow). *Lean4✓ BEDC.GroundCompiler.NameCe interfaces require flow*

If an upward-arrow derived interface $N^{\uparrow}$ *is licensed, then there exists a recognized* NameCert *flow* S *for* N*:*

$$N^{\uparrow} \text{ licensed} \implies \exists S,\ \mathsf{NameCertFlow}(S, N).$$

Proof. The formation rule of Definition 9.9 says that upward-arrow interfaces are not licensed without a NameCert. In the present compiler discipline, a NameCert object is not an external input; it must appear as a recognized event-flow certificate. Hence a licensed $N^{\uparrow}$ requires some S with $\mathsf{NameCertFlow}(S, N)$. □

Corollary 9211.22 (No upward-arrow interface from raw code alone). *Lean4✓ BEDC.GroundCompiler.NameCertGe upward from raw code alone*

A legal channel stream $c \in \mathsf{LegalZStream}$*, even though it decodes to an event flow, does not by itself license any* $N^{\uparrow}$*. Licensing requires a recognized* NameCert *flow for* N*, either on* $\mathsf{Decode}(c)$ *itself or on a recognized subflow of it.*

9211.4 Ledger completeness

Definition 9211.23 (Ledger-complete NameCert flow). *Lean4 (definition) BEDC.GroundCompiler.NameCertGenerate*

A recognized NameCert *flow is* ledger-complete *when it has a recognized ledger subflow*

$$\mathsf{NameCertLedger}_R(S, L)$$

and L *records the source material hidden, compressed, named, or stabilized by that* NameCert*.*

Principle 9211.24 (Certified derived interfaces carry ledger). *Lean4✓ BEDC.GroundCompiler.NameCertGenerated. derived carry ledger*

Every licensed derived interface is supported by a ledger-complete NameCert *flow. This is the event-flow reading of Definition 9.10: every certified derived interface carries a ledger policy witness.*

Theorem 9211.25 (NameCert without ledger is not admissible). *Lean4✓ BEDC.GroundCompiler.NameCertGenerat without ledger not admissible*

If no generated recognizer relation for (S, N) *admits a ledger subflow* L *such that*

$$\mathsf{NameCertLedger}_R(S, L),$$

then S *is not an admissible* NameCert *flow licensing* N*.*

Proof. The five-field NameCert template includes LedgerPolicy as a required field. By Definition 9211.24, a licensed derived interface must be supported by a ledger-complete NameCert flow. If no recognized ledger subflow exists, the recognition is incomplete and cannot license N. □

Corollary 9211.26 (Four fields without ledger are not enough). *Lean4✓ BEDC.GroundCompiler.NameCertGenerate fields without ledger not enough*

For a fixed generated recognizer R, even if source, pattern, classifier, and stability subflows are recognized inside S, the recognition is not complete five-field recognition when no ledger subflow is recognized by R.

9211.5 NameCert code and channel recognition

Definition 9211.27 (NameCert code). *Lean4 (definition) BEDC.GroundCompiler.NameCertGenerated.NameCertCode*

If S is a recognized NameCert *flow for N, define*

$$\mathsf{NameCertCode}(S, N) := \mathsf{Compile}(S).$$

This is not a new channel compiler. It is the existing Compile *applied to S.*

Proposition 9211.28 (NameCert code is injective on raw NameCert flows). *Lean4✓ BEDC.GroundCompiler.NameC code injective*

If S and T are recognized NameCert *flows and*

$$\mathsf{NameCertCode}(S, N) = \mathsf{NameCertCode}(T, M),$$

then $S = T$.

Proof. By Definition 9211.27,

$$\mathsf{NameCertCode}(S, N) = \mathsf{Compile}(S), \qquad \mathsf{NameCertCode}(T, M) = \mathsf{Compile}(T).$$

Equality of the displayed codes therefore gives $\mathsf{Compile}(S) = \mathsf{Compile}(T)$. By the channel bijection Definition 9208.19, Compile is injective on EventFlow. Hence $S = T$. □

Remark 9211.29 (Names may still classify together). *Definition 9211.28 says only that raw* NameCert *flows and their codes correspond one-to-one. A later classifier may still identify different candidate names or different certificate flows as equivalent; that is a classifier quotient and does not affect the raw-flow bijection.*

Definition 9211.30 (NameCert recognition from channel code). *Lean4 (definition) BEDC.GroundCompiler.NameCert*

For $c \in$ LegalZStream*, define*

$$\mathsf{RecognizesNameCertCode}(R, c, N) \;:\Longleftrightarrow\; \mathsf{RecognizesNameCert}(R, \mathsf{Decode}(c), N).$$

Thus NameCert *recognition from channel code first decodes to an event flow.*

Proposition 9211.31 (No NameCert recognition by channel substring). *Lean4✓ BEDC.GroundCompiler.NameCert namecert recognition by channel substring*

There is no valid rule that recognizes a NameCert *by inspecting channel substrings without first applying*

$$\mathsf{Decode}\colon \mathsf{LegalZStream} \to \mathsf{EventFlow}.$$

Proof. Definition 9209.27 proves that channel substrings are not source events. NameCert recognition is a source-level relation over event flows. Direct NameCert recognition on channel substrings would therefore operate on the wrong layer. Recognition must first decode. □

Theorem 9211.32 (Channel compilation preserves NameCert recognition)**.** *Lean4 ✓* `BEDC.GroundCompiler.NameC` `compilation preserves namecert recognition`

If $\mathsf{RecognizesNameCert}(R, S, N)$*, then*

$$\exists S', \quad \mathsf{Decode}(\mathsf{Compile}(S)) = \mathsf{some}(S') \quad \textit{and} \quad \mathsf{RecognizesNameCert}(R, S', N).$$

Proof. By the flow-level round trip Definition 9208.17,

$$\mathsf{Decode}(\mathsf{Compile}(S)) = \mathsf{some}(S).$$

Taking $S' = S$ preserves the same source-layer recognition judgment. □

Corollary 9211.33 (NameCert recognition is invariant under compile-decode)**.** *Lean4 ✓* `BEDC.GroundCompiler.Na` `recognition invariant`

For every recognized NameCert *flow, compiling to a channel stream and decoding back to an event flow preserves its* NameCert *recognition status.*

9211.6 Field soundness events

Definition 9211.34 (NameCert-source soundness event)**.** *Lean4 (definition)* `BEDC.GroundCompiler.NameCertGenera`

If $\mathsf{RecognizesNameCert}(R, S, N)$ *and* R *recognizes source subflow* S_0*, then a* NameCert-source soundness event *is a subflow of* S *witnessing that* S_0 *supplies the generated material from which* N *is named. The relation is written*

$$\mathsf{NameCertSourceSound}_R(S, S_0).$$

Definition 9211.35 (NameCert-pattern soundness event)**.** *Lean4 (definition)* `BEDC.GroundCompiler.NameCertGener`

If R *recognizes pattern subflow* S_1*, then a* NameCert-pattern soundness event *is a subflow of* S *witnessing that* S_1 *is stable behavior observed in the source:*

$$\mathsf{NameCertPatternSound}_R(S, S_1).$$

Definition 9211.36 (NameCert-classifier soundness event)**.** *Lean4 (definition)* `BEDC.GroundCompiler.NameCertGene`

If R *recognizes classifier subflow* S_2*, then a* NameCert-classifier soundness event *is a subflow of* S *witnessing that* S_2 *organizes source material into the intended groups:*

$$\mathsf{NameCertClassifierSound}_R(S, S_2).$$

This is the event-flow reading of the role played by ClassifierSpec *in the paper template.*

Definition 9211.37 (NameCert-stability soundness event)**.** *Lean4 (definition)* `BEDC.GroundCompiler.NameCertGene`

If R *recognizes stability subflow* S_3*, then a* NameCert-stability soundness event *is a subflow of* S *witnessing that the source satisfies the relevant closure, reuse, descent, composition, or seal stability under the named behavior:*

$$\mathsf{NameCertStabilitySound}_R(S, S_3).$$

Definition 9211.38 (NameCert-ledger soundness event)**.** *Lean4 (definition)* `BEDC.GroundCompiler.NameCertGenera`

If R *recognizes ledger subflow* S_4*, then a* NameCert-ledger soundness event *is a subflow of* S *witnessing that* S_4 *records what the name hides and how the hidden material is tracked:*

$$\mathsf{NameCertLedgerSound}_R(S, S_4).$$

Definition 9211.39 (Sound recognized NameCert flow)**.** *Lean4 (definition)* *BEDC.GroundCompiler.NameCertGenerat*

A recognized NameCert *judgment* $\mathsf{RecognizesNameCert}(R, S, N)$ *is* sound *when there exist subflows* S_0, S_1, S_2, S_3, S_4 *such that*

$$\mathsf{NameCertSource}_R(S, S_0) \wedge \mathsf{NameCertSourceSound}_R(S, S_0),$$

$$\mathsf{NameCertPattern}_R(S, S_1) \wedge \mathsf{NameCertPatternSound}_R(S, S_1),$$

$$\mathsf{NameCertClassifier}_R(S, S_2) \wedge \mathsf{NameCertClassifierSound}_R(S, S_2),$$

$$\mathsf{NameCertStability}_R(S, S_3) \wedge \mathsf{NameCertStabilitySound}_R(S, S_3),$$

$$\mathsf{NameCertLedger}_R(S, S_4) \wedge \mathsf{NameCertLedgerSound}_R(S, S_4).$$

Theorem 9211.40 (Sound NameCert flow licenses candidate name)**.** *Lean4✓* *BEDC.GroundCompiler.NameCertGene namecert flow licenses name*

If $\mathsf{RecognizesNameCert}(R, S, N)$ *and this recognition is sound, then*

$$\mathsf{LicensedName}(N).$$

Proof. By Definition 9211.39, S contains recognized and sound source, pattern, classifier, stability, and ledger subflows. These are the event-flow presentations of the five required fields in Definition 9.6. Therefore the candidate name N is supported by a recognized NameCert flow, so $\mathsf{LicensedName}(N)$ by Definition 9211.19. □

Corollary 9211.41 (Derived interface licensing is event-flow mediated)**.** *Lean4✓* *BEDC.GroundCompiler.NameCertG licensing mediated by sound flow*

If $N^{\uparrow}$ *is licensed, the licensing can be traced to a sound recognized* NameCert *flow. It is not produced by an external* NameCert *object.*

9211.7 Conservativity and examples

Theorem 9211.42 (NameCert flow recognition is conservative over the finite kernel)**.** *Lean4✓* *BEDC.GroundCompiler.NameCertGenerated.namecert flow recognition conservativity*

Adding relations of the form

$$\mathsf{RecognizesNameCert}(R, S, N)$$

and the associated field-recognition relations does not add new raw marks, history constructors, sameness rules, continuation rules, or kernel-level equalities.

Proof. These recognition relations assert structure over event flows. They do not generate new b0 or b1 marks, add msame or hsame rules, change Ext or Cont, or turn a candidate name into a kernel object by itself. Derived-interface licensing still requires a recognized and sound NameCert flow. Hence this recognition layer is conservative over the finite kernel. □

Corollary 9211.43 (Recognized NameCert flow does not change source events)**.** *Lean4✓* *BEDC.GroundCompiler.Na does not change source events*

If S *is recognized as a* NameCert *flow, then some generated recognizer* R *witnesses the* NameCert *recognition relation over that same event flow* S*. Recognition is a relation over an existing event flow, not a rewrite operation.*

Example 9211.44 ($\mathsf{AxisNat}^{\uparrow}$-style NameCert flow)**.** *An axis-style* NameCert *flow may have recognized subflows*

source flow	b0-*emission events,*
pattern flow	*repeated* b0-*extension events,*
classifier flow	hsame *restricted to the* b0-*spine,*
stability flow	*closure under* E0 *and continuation events,*
ledger flow	*each visible axis token records source-history events.*

These are not external fields. They must be recognized inside an event flow.

Example 9211.45 ($\mathsf{FullAxis}^{\uparrow}$ NameCert flow)**.** *A* $\mathsf{FullAxis}^{\uparrow}$ NameCert *flow may have recognized subflows*

source flow	*finite* b0-*spine prefixes,*
pattern flow	*every prefix continues to a later prefix,*
classifier flow	*prefix-compatible and tail-compatible classification,*
stability flow	*directedness, monotonicity, and prefix closure,*
ledger flow	*all finite prefixes retained as ledger.*

*The reading is not "*b0b1 *is an infinite object." The reading is that a full-axis certificate over generated finite prefixes licenses* $\mathsf{FullAxis}^{\uparrow}$ *while retaining the finite-prefix ledger.*

Example 9211.46 ($\mathsf{ZNormal}^{\uparrow}$ NameCert flow)**.** *A* $\mathsf{ZNormal}^{\uparrow}$ NameCert *flow may have recognized subflows*

source flow	*observation histories with boundary marks,*
pattern flow	*no adjacent full-boundary marks,*
classifier flow	*histories related by Zeckendorf carry classify together,*
stability flow	*carry preserves represented observation content,*
ledger flow	*the carry ledger records the pre-normal form.*

The source-level display $011 \rightsquigarrow 100$ *is therefore a carry classifier with ledger support, not ordinary equality and not a channel substring rewrite.*

Example 9211.47 ($\mathsf{DimLift}^{\uparrow}$ NameCert flow)**.** *A* $\mathsf{DimLift}^{\uparrow}$ NameCert *flow may have recognized subflows*

source flow	*overflow traces, including the event* 011*,*
pattern flow	*Zeckendorf overflow and carry behavior,*
classifier flow	*overflow trace classified with the lifted normal form,*
stability flow	*lift preserves finite-prefix observations,*
ledger flow	*old axis, full-axis seal, and overflow witness.*

The lifted name is licensed by the recognized certificate flow and its ledger, not by the overflow event alone.

Remark 9211.48 (Outlook)**.** *This chapter establishes the no-hidden-input reading of* NameCert*: a* NameCert *is not received as a five-field object, but recognized as a five-field certificate flow inside* EventFlow*. The core judgment is* $\mathsf{RecognizesNameCert}(R, S, N)$*, where* R *is a generated recognizer flow,* S *is the candidate certificate event flow, and* N *is the candidate name flow. The judgment preserves channel code, separates certificate seals from channel terminators, requires five recognized fields and a ledger, keeps raw* NameCert *flows code-injective, forces channel-code recognition*

through Decode*, licenses names only through sound recognized certificate structure, and remains conservative over the finite kernel. The same discipline applies next to derived certificates and acceptance gates: mature object code is accepted only through recognized certificate and gate flows, not as a primitive input object.*

Chapter 9212

DerivCert and AcceptanceGate Flow Recognition

chapter 9211 records the no-hidden-input reading of NameCert: a naming certificate is not supplied as an external five-field object, but recognized as a five-field certificate flow inside EventFlow. This chapter applies the same rule to derivation certificates, acceptance gates, strength readings, and accepted export.

The governing rules are

$$\boxed{\text{DerivCert is a recognized six-field export certificate flow, not an input object,}}$$

and

$$\boxed{\text{AcceptGate is the simultaneous recognition of NameCert and derivation-certificate flows.}}$$

The paper-side acceptance discipline says that a mature object is not exported merely because it appears in the manuscript or in a codebase. It must pass a gate whose ingredients include a naming certificate and an export certificate at a stated strength. In the ground-compiler layer, those ingredients appear only as recognized event-flow structure.

9212.1 Strength and DerivCert recognition

Definition 9212.1 (Strength event flow)**.** *Lean4 (definition)* `BEDC.GroundCompiler.EventFlow.StrengthEventFlow`

A strength event flow *is an event flow*

$$s \in \mathsf{EventFlow}$$

recognized by a generated recognizer as representing a derivation strength.

For exposition, this chapter speaks of four strength readings

$$\text{seed}, \qquad \text{paperCert}, \qquad \text{checkedCert}, \qquad \text{bridgeCert},$$

ordered by

$$\text{seed} < \text{paperCert} < \text{checkedCert} < \text{bridgeCert}.$$

These names are metalanguage. They are not host enum inputs. The corresponding strength roles must be recognized from event flows.

Definition 9212.2 (Generated strength recognizer)**.** *Lean4 (definition)* `BEDC.GroundCompiler.EventFlow.Generated`
A generated strength recognizer *is an event flow*

$$R_s \in \mathsf{EventFlow}.$$

It supports source-layer judgments of the form

$$\mathsf{RecognizesStrength}(R_s, s, \sigma),$$

where s is the strength event flow and σ is the recognized strength role. The displayed labels seed*,* paperCert*,* checkedCert*, and* bridgeCert *are explanatory readings of such roles, not primitive compiler inputs.*

Definition 9212.3 (DerivCert candidate flow)**.** *Lean4 (definition)* `BEDC.GroundCompiler.EventFlow.DerivCertCand`
A DerivCert candidate flow *is an event flow*

$$D \in \mathsf{EventFlow}.$$

It has not yet been recognized as a derivation certificate. Thus $D \in \mathsf{EventFlow}$ does not imply $D = \mathrm{DerivCert}(N, s)$.

Definition 9212.4 (Generated DerivCert recognizer)**.** *Lean4 (definition)* `BEDC.GroundCompiler.DerivCertGenerate`
A generated DerivCert recognizer *is an event flow*

$$R_D \in \mathsf{EventFlow}.$$

It is not a host parser, Lean structure, YAML schema, or external record constructor. Its public formal carrier is generated from the two raw marks and acts on event flows.

Definition 9212.5 (DerivCert recognition relation)**.** *Lean4 (definition)* `BEDC.GroundCompiler.DerivCertGenerated.`
The derivation-certificate recognition relation is written

$$\mathsf{RecognizesDerivCert}(R_D, D, N, s), \qquad R_D, D, N, s \in \mathsf{EventFlow}.$$

It is read as: the generated recognizer flow R_D recognizes the event flow D as a DerivCert *flow for candidate name flow N at strength flow s.*

Remark 9212.6 (DerivCert recognition is not DerivCert input)**.** *The judgment* $\mathsf{RecognizesDerivCert}(R_D, D, N, s)$ *does not mean that an external* DerivCert *object has been supplied. It says that, in the decoded source event layer, R_D recognizes D as carrying the six export-certificate roles for N at strength s. The direction is*

$$\mathsf{EventFlow} \longrightarrow \mathsf{RecognizedDerivCertFlow},$$

not

$$\mathsf{DerivCertObject} \longrightarrow \mathsf{EventFlow}.$$

Definition 9212.7 (Recognized DerivCert flow)**.** *Lean4 (definition)* `BEDC.GroundCompiler.DerivCertGenerated.Der`
Define

$$\mathsf{DerivCertFlow}(D, N, s) \;:\Longleftrightarrow\; \exists R_D,\ \mathsf{RecognizesDerivCert}(R_D, D, N, s).$$

Thus D is a recognized derivation-certificate flow for N at strength s exactly when some generated recognizer recognizes it in that role.

Principle 9212.8 (No external DerivCert input). *Lean4✓ BEDC.GroundCompiler.DerivCertGenerated.no external derivcert input*

There is no formal compiler entry point

$$\mathsf{CompileDerivCert}\colon \mathsf{DerivCertObject} \longrightarrow \mathsf{LegalZStream}.$$

The only formal channel compiler remains

$$\mathsf{Compile}\colon \mathsf{EventFlow} \longrightarrow \mathsf{LegalZStream}.$$

If D is a recognized derivation-certificate flow, its code is just $\mathsf{Compile}(D)$.

Proposition 9212.9 (DerivCert recognition does not change channel code). *Lean4✓ BEDC.GroundCompiler.Deriv recognition preserves code*

If $\mathsf{RecognizesDerivCert}(R_D, D, N, s)$*, then the channel encoding of D is still* $\mathsf{Compile}(D)$*. Derivation-certificate recognition does not add, delete, or rewrite channel bits.*

Proof. The judgment $\mathsf{RecognizesDerivCert}(R_D, D, N, s)$ is a source-level recognition relation. It says only that D is recognized by R_D as the derivation-certificate flow for N at s. The channel encoding is supplied by $\mathsf{Compile}$ and depends only on the event flow D. Since recognition does not alter D, it does not alter $\mathsf{Compile}(D)$. □

Corollary 9212.10 (Recognized DerivCert code is not a separate code). *Lean4✓ BEDC.GroundCompiler.DerivCert code not separate*

If D is a recognized derivation-certificate flow, then

$$\mathsf{DerivCertCode}(D, N, s) := \mathsf{Compile}(D)$$

is the ordinary channel code of D, not the output of a separate derivation-certificate encoder.

9212.2 Six fields and field soundness

Definition 9212.11 (Recognized DerivCert field subflows). *Lean4 (definition) BEDC.GroundCompiler.DerivCertGene*

If $\mathsf{RecognizesDerivCert}(R_D, D, N, s)$*, then R_D may recognize subflows of D as the six export-certificate roles:*

source flow,
classifier flow,
exactness flow,
ledger flow,
stability flow,
strength flow.

Formally, this chapter uses

$$\mathsf{DerivSource}_{R_D}(D, D_0), \quad \mathsf{DerivClassifier}_{R_D}(D, D_1), \quad \mathsf{DerivExactness}_{R_D}(D, D_2),$$

$$\mathsf{DerivLedger}_{R_D}(D, D_3), \quad \mathsf{DerivStability}_{R_D}(D, D_4), \quad \mathsf{DerivStrength}_{R_D}(D, D_5).$$

These roles are recognized in D by R_D, not supplied as external field labels.

Remark 9212.12 (DerivCert field names are explanatory metalanguage)**.** *The field names source, classifier, exactness, ledger, stability, and strength are explanatory metalanguage. Formally, the roles are recognized by* $\mathsf{DerivSource}_{R_D}$, $\mathsf{DerivClassifier}_{R_D}$, $\mathsf{DerivExactness}_{R_D}$, $\mathsf{DerivLedger}_{R_D}$, $\mathsf{DerivStability}_{R_D}$, *and* $\mathsf{DerivStrength}_{R_D}$ *on event flows. The six-field structure is not received as an external record.*

Definition 9212.13 (DerivCert-seal subflow)**.** *Lean4 (definition)* `BEDC.GroundCompiler.DerivCertGenerated.Deriv`

If $\mathsf{RecognizesDerivCert}(R_D, D, N, s)$ *and* R_D *recognizes a terminal subflow* σ_D *of* D *as expressing derivation-certificate completion, then* σ_D *is a* DerivCert-seal subflow*, written*

$$\mathsf{DerivCertSeal}_{R_D}(D, \sigma_D).$$

The seal is a source-level subflow, not the channel-level terminator 11*.*

Definition 9212.14 (Complete six-field DerivCert recognition)**.** *Lean4 (definition)* `BEDC.GroundCompiler.DerivCer`

The judgment $\mathsf{RecognizesDerivCert}(R_D, D, N, s)$ *has* complete six-field recognition *when there exist subflows* $D_0, D_1, D_2, D_3, D_4, D_5$ *and* σ_D *such that*

$$\mathsf{DerivSource}_{R_D}(D, D_0), \quad \mathsf{DerivClassifier}_{R_D}(D, D_1), \quad \mathsf{DerivExactness}_{R_D}(D, D_2),$$

$$\mathsf{DerivLedger}_{R_D}(D, D_3), \quad \mathsf{DerivStability}_{R_D}(D, D_4), \quad \mathsf{DerivStrength}_{R_D}(D, D_5), \quad \mathsf{DerivCertSeal}_{R_D}(D, \sigma_D).$$

Proposition 9212.15 (DerivCert seal is not the channel terminator)**.** *Lean4 ✓* `BEDC.GroundCompiler.DerivCertGe` `seal is source subflow`

If $\mathsf{DerivCertSeal}_{R_D}(D, \sigma_D)$*, then* σ_D *is a source-level subflow and not the channel-level terminator* 11*.*

Proof. The channel-level 11 is the event terminator of Definition 9208.2; it belongs to the LegalZStream encoding mechanism. A derivation-certificate seal is a source-level subflow recognized by R_D. By the layer-separation theorem Definition 9209.27, a channel substring cannot be used directly as a source event or source subflow. Hence the derivation-certificate seal is not the channel terminator. □

Principle 9212.16 (No DerivCert without six recognized fields)**.** *Lean4 ✓* `BEDC.GroundCompiler.DerivCertGenera` `derivcert without six fields`

A recognized derivation-certificate flow must have complete six-field recognition: source, classifier, exactness, ledger, stability, strength, and seal subflows are all required. This is the event-flow form of the six export-certificate roles.

Theorem 9212.17 (Incomplete DerivCert flow does not support export)**.** *Lean4 ✓* `BEDC.GroundCompiler.DerivCe` `derivcert does not support export`

If an event flow D *lacks any one of the recognized source, classifier, exactness, ledger, stability, or strength field subflows, then* D *cannot serve as a recognized derivation-certificate flow for* N *at* s*.*

Proof. By Definition 9212.16, a recognized derivation-certificate flow must have complete six-field recognition. Missing any required field prevents complete recognition. Therefore $\mathsf{DerivCertFlow}(D, N, s)$ is not established. □

Corollary 9212.18 (Strength flow alone is insufficient)**.** *Lean4 ✓* `BEDC.GroundCompiler.DerivCertGenerated.stre` `flow alone insufficient`

Even if an event flow is recognized as a checkedCert *or* bridgeCert *strength flow, it does not form a derivation-certificate flow without recognized source, classifier, exactness, ledger, and stability fields.*

Definition 9212.19 (DerivCert field soundness). *Lean4 (definition)* `BEDC.GroundCompiler.DerivCertGenerated.Der`

The field soundness relations for a recognized derivation-certificate flow are:

$$\mathsf{DerivSourceSound}_{R_D}(D, D_0, N), \qquad \mathsf{DerivClassifierSound}_{R_D}(D, D_1, N),$$

$$\mathsf{DerivExactnessSound}_{R_D}(D, D_2, N), \qquad \mathsf{DerivLedgerSound}_{R_D}(D, D_3, N),$$

$$\mathsf{DerivStabilitySound}_{R_D}(D, D_4, N), \qquad \mathsf{DerivStrengthSound}_{R_D}(D, D_5, s).$$

They witness, respectively, that the source field names the BEDC layer carrying N, the classifier organizes the intended carriers, exactness respects the relevant msame, hsame, *or* psame *relation on the cited layer, the ledger cites the required gap policy or an explicit absence statement, the stability field cites the relevant stability certificate, and the strength field matches the claimed strength flow s.*

Definition 9212.20 (Sound recognized DerivCert flow). *Lean4 (definition)* `BEDC.GroundCompiler.DerivCertGenera`

A recognized judgment $\mathsf{RecognizesDerivCert}(R_D, D, N, s)$ *is* sound *when there exist subflows $D_0, D_1, D_2, D_3, D_4, D_5$ such that*

$$\mathsf{DerivSource}_{R_D}(D, D_0) \wedge \mathsf{DerivSourceSound}_{R_D}(D, D_0, N),$$

$$\mathsf{DerivClassifier}_{R_D}(D, D_1) \wedge \mathsf{DerivClassifierSound}_{R_D}(D, D_1, N),$$

$$\mathsf{DerivExactness}_{R_D}(D, D_2) \wedge \mathsf{DerivExactnessSound}_{R_D}(D, D_2, N),$$

$$\mathsf{DerivLedger}_{R_D}(D, D_3) \wedge \mathsf{DerivLedgerSound}_{R_D}(D, D_3, N),$$

$$\mathsf{DerivStability}_{R_D}(D, D_4) \wedge \mathsf{DerivStabilitySound}_{R_D}(D, D_4, N),$$

$$\mathsf{DerivStrength}_{R_D}(D, D_5) \wedge \mathsf{DerivStrengthSound}_{R_D}(D, D_5, s).$$

Theorem 9212.21 (Sound DerivCert recognition establishes DerivCertFlow). *Lean4 ✓* `BEDC.GroundCompiler.Der` `derivcert recognition establishes flow`

If $\mathsf{RecognizesDerivCert}(R_D, D, N, s)$ *and this recognition is sound, then*

$$\mathsf{DerivCertFlow}(D, N, s).$$

Proof. By Definition 9212.20, D contains recognized and sound source, classifier, exactness, ledger, stability, and strength subflows. These are exactly the event-flow presentations of the six derivation-certificate roles. Hence D is a recognized derivation-certificate flow for N at s. □

9212.3 Acceptance flows

Definition 9212.22 (Accepted flow). *Lean4 (definition)* `BEDC.GroundCompiler.DerivCertGenerated.AcceptedFlow`

For $N, s \in$ EventFlow*, an event flow A is an* accepted flow *for N at s when there exist event flows C, D and recognizers R_C, R_D such that*

$$\mathsf{RecognizesNameCert}(R_C, C, N), \qquad \mathsf{RecognizesDerivCert}(R_D, D, N, s),$$

the NameCert *recognition is sound in the sense of Definition 9211.39, the derivation-certificate recognition is sound in the sense of Definition 9212.20, and A is recognized as containing the* NameCert *flow C, the derivation-certificate flow D, and an acceptance-seal subflow. This is written*

$$\mathsf{AcceptFlow}(A, N, s).$$

The contained NameCert *flow, derivation-certificate flow, and acceptance-seal subflow are nonempty event flows.*

Definition 9212.23 (Flow-level acceptance gate). *Lean4 (definition)* `BEDC.GroundCompiler.DerivCertGenerated.Ac`

Define the flow-level acceptance gate by

$$\mathsf{AcceptGateFlow}(N, s) \;:\Longleftrightarrow\; \exists A,\ \mathsf{AcceptFlow}(A, N, s).$$

This is the event-flow version of the gate reading

$$\mathrm{AcceptGate}(N, s) := \mathsf{NameCert}(N) \wedge \mathrm{DerivCert}(N, s).$$

Theorem 9212.24 (Accepted flow requires NameCert-flow and DerivCert-flow). *Lean4✓* `BEDC.GroundCompiler.D` `requires namecert derivcert`

If $\mathsf{AcceptGateFlow}(N, s)$*, then there exist* C, D *such that*

$$\mathsf{NameCertFlow}(C, N) \qquad \textit{and} \qquad \mathsf{DerivCertFlow}(D, N, s).$$

Proof. By Definition 9212.23, there is an A with $\mathsf{AcceptFlow}(A, N, s)$. By Definition 9212.22, that accepted flow contains a sound recognized $\mathsf{NameCert}$ flow C and a sound recognized derivation-certificate flow D. Hence $\mathsf{NameCertFlow}(C, N)$ and $\mathsf{DerivCertFlow}(D, N, s)$. □

Corollary 9212.25 (Code existence does not imply acceptance). *Lean4✓* `BEDC.GroundCompiler.DerivCertGenera` `existence not acceptance`

A legal channel stream $c \in \mathsf{LegalZStream}$ *does not by itself imply* $\mathsf{RecognizesAcceptanceCode}(c, N, s)$*. Acceptance from code requires decoding and then recognizing nonempty sound* $\mathsf{NameCert}$*, nonempty sound derivation-certificate, and nonempty acceptance-seal structure in the decoded event flow or its recognized subflows.*

Proof. Membership $c \in \mathsf{LegalZStream}$ says only that c decodes to an event flow. Acceptance-code recognition requires additional source-layer recognition judgments on the decoded flow. The empty channel stream is legal because it decodes to the empty event flow, but the empty event flow cannot contain a nonempty $\mathsf{NameCert}$ flow, derivation-certificate flow, and acceptance-seal subflow. Hence channel legality alone does not entail acceptance-code recognition. □

Definition 9212.26 (Accepted object code). *Lean4 (definition)* `BEDC.GroundCompiler.DerivCertGenerated.Accepte`

If $\mathsf{AcceptFlow}(A, N, s)$*, define*

$$\mathsf{AcceptedObjectCode}(A, N, s) := \mathsf{Compile}(A).$$

The code is accepted because its decoded event flow is recognized as an acceptance flow, not because it has a special bit pattern.

Proposition 9212.27 (Accepted object code is injective on acceptance flows). *Lean4✓* `BEDC.GroundCompiler.Der` `object code injective`

If

$$\mathsf{AcceptedObjectCode}(A, N, s) = \mathsf{AcceptedObjectCode}(B, M, t),$$

then $A = B$*.*

Proof. By Definition 9212.26, the equality is $\mathsf{Compile}(A) = \mathsf{Compile}(B)$. By the channel bijection Definition 9208.19, $\mathsf{Compile}$ is injective on $\mathsf{EventFlow}$. Hence $A = B$. □

Remark 9212.28 (Accepted flows and accepted objects). *Definition 9212.27 concerns raw acceptance flows. It does not say that classified mature objects are code-bijective. If two accepted flows are identified by a classifier or bridge, object-level sameness is a quotient and may be many-to-one.*

9212.4 Recognition from code and round trips

Definition 9212.29 (Acceptance recognition from channel code). *Lean4 (definition)* `BEDC.GroundCompiler.DerivCe`

For $c \in \mathsf{LegalZStream}$*, define*

$$\mathsf{RecognizesAcceptanceCode}(c, N, s) \;:\Longleftrightarrow\; \exists A,\ \mathsf{Decode}(c) = \mathsf{some}(A) \;\wedge\; \mathsf{AcceptFlow}(A, N, s).$$

Thus accepted-object recognition from channel code first decodes to an event flow.

Proposition 9212.30 (No acceptance recognition by channel substring). *Lean4✓* `BEDC.GroundCompiler.DerivCer` `acceptance recognition by channel substring`

Any valid recognition of an accepted object from channel code must first exhibit an event flow decoded by

$$\mathsf{Decode}\colon \mathsf{LegalZStream} \to \mathsf{EventFlow}.$$

Equivalently, a judgment $\mathsf{RecognizesAcceptanceCode}(c, N, s)$ *factors through some* A *such that* $\mathsf{Decode}(c) = \mathsf{some}(A)$ *and* $\mathsf{AcceptFlow}(A, N, s)$*.*

Proof. Definition 9209.27 proves that channel substrings are not source events. Acceptance-flow recognition is a source-level relation over event flows. Direct accepted-object recognition on channel substrings would therefore operate on the wrong layer. □

Theorem 9212.31 (Channel compilation preserves acceptance recognition). *Lean4✓* `BEDC.GroundCompiler.Deriv` `compilation preserves acceptance`

If $\mathsf{AcceptFlow}(A, N, s)$*, then the channel code* $\mathsf{Compile}(A)$ *is recognized as acceptance code:*

$$\mathsf{RecognizesAcceptanceCode}(\mathsf{Compile}(A), N, s).$$

Proof. By the flow-level round trip Definition 9208.17,

$$\mathsf{Decode}(\mathsf{Compile}(A)) = A.$$

Substitution in $\mathsf{AcceptFlow}(A, N, s)$ gives the result. □

Corollary 9212.32 (Acceptance recognition is invariant under compile-decode). *Lean4✓* `BEDC.GroundCompiler.D` `recognition invariant`

For every accepted flow, compiling to a channel stream and decoding back to an event flow preserves its acceptance status.

9212.5 Strength monotonicity and reuse

Definition 9212.33 (Strength monotonicity at flow level). *Lean4 (definition)* `BEDC.GroundCompiler.DerivCertGene`

The flow-level acceptance gate is monotone in strength *when, for strength flows* $s' \le s$*,*

$$\mathsf{AcceptGateFlow}(N, s) \Longrightarrow \mathsf{AcceptGateFlow}(N, s').$$

At event-flow level, the comparison $s' \le s$ *is witnessed by a recognized derivation-certificate flow for* N *at* s' *that occurs as a subflow of the same accepted flow that witnesses acceptance at* s*.*

Theorem 9212.34 (Flow-level gate is monotone in strength). *Lean4✓ BEDC.GroundCompiler.DerivCertGenerated monotone strength*

Assume recognized strength flows are ordered by

$$\text{seed} < \text{paperCert} < \text{checkedCert} < \text{bridgeCert},$$

and each higher-strength derivation-certificate flow contains the corresponding lower-strength derivation-certificate flow as a recognized subflow. Then

$$\mathsf{AcceptFlow}(A, N, s) \wedge \exists D' \left(\mathsf{DerivCertFlow}(D', N, s') \wedge D' \neq \epsilon \wedge \mathsf{DerivCertSourceSubflow}(D', A)\right) \Longrightarrow \mathsf{AcceptGateFlow}(N$$

Proof. From $\mathsf{AcceptFlow}(A, N, s)$, take the recognized $\mathsf{NameCert}$ flow, derivation-certificate flow, and acceptance-seal subflow contained in A. The naming certificate and seal are independent of the strength comparison. By the hypothesis on strength nesting, A also contains a nonempty recognized derivation-certificate flow D' for N at s'. Replacing the strength-s derivation-certificate component by D' gives an accepted flow for N at s', hence $\mathsf{AcceptGateFlow}(N, s')$. □

Definition 9212.35 (Reuse flow). *Lean4 (definition) BEDC.GroundCompiler.DerivCertGenerated.ReuseFlow*

A reuse flow *is an event flow U recognized as saying that accepted flows for $N_1, \ldots, N_k$ are reused to construct M, that transport respects the relevant classifiers, and that M supplies its own certificate fields. It is written*

$$\mathsf{ReuseFlow}(U; N_1, \ldots, N_k; M).$$

Theorem 9212.36 (Reuse closure at flow level). *Lean4✓ BEDC.GroundCompiler.DerivCertGenerated.reuse closure at flow level*

Let $I = ((N_1, s_1), \ldots, (N_k, s_k))$ be a finite list of accepted input flows. If there is a reuse flow

$$\mathsf{ReuseFlow}(U; I; M, s)$$

whose recognized transport is classifier-respecting and whose target component supplies an accepted flow for M at strength s, then

$$\mathsf{AcceptGateFlow}(M, s).$$

Proof. Each pair (N_i, s_i) in I has an accepted flow by the input component of $\mathsf{ReuseFlow}$. The reuse flow supplies classifier-respecting transport from the accepted inputs to the target construction and includes a target acceptance flow for M at strength s. Projecting that target component gives $\mathsf{AcceptGateFlow}(M, s)$. □

Corollary 9212.37 (Reuse does not erase target certificate obligations). *Lean4✓ BEDC.GroundCompiler.DerivCert does not erase obligations*

Even if all inputs N_i are accepted, any accepted target M must still supply its own recognized $\mathsf{NameCert}$ *flow and its own recognized derivation-certificate flow:*

$$\mathsf{AcceptGateFlow}(M, s) \Longrightarrow \exists C, D \left(\mathsf{NameCertFlow}(C, M) \wedge \mathsf{DerivCertFlow}(D, M, s)\right).$$

Reuse cannot replace M's derivation-certificate flow.

Definition 9212.38 (Retroactive promotion). *Lean4 (definition) BEDC.GroundCompiler.DerivCertGenerated.Retroa*

A target M is retroactively promoted *when its accepted strength is claimed to increase merely because its dependencies are later accepted at higher strength, while M itself has no recognized higher-strength flow.*

Principle 9212.39 (No retroactive promotion). Lean4✓ BEDC.GroundCompiler.DerivCertGenerated.no retroactive promotion

A flow accepted at strength s does not automatically become accepted at a higher strength $s' > s$ merely because its dependencies are later accepted at higher strength. Promoting M requires a recognized higher-strength flow for M itself.

9212.6 Conservativity and examples

Theorem 9212.40 (Accepted flow recognition is conservative over the finite kernel). Lean4✓ BEDC.GroundCompiler.DerivCertGenerated.accepted flow recognition conservativity

Adding RecognizesDerivCert, AcceptFlow, AcceptGateFlow, *and the associated field-recognition relations does not add new raw marks, history constructors, sameness rules, continuation rules, or kernel-level equalities.*

Proof. These relations assert certificate recognition, export recognition, and bookkeeping discipline over event flows. They do not generate new b0 or b1 marks, add msame, hsame, or psame rules, change Ext or Cont, or turn a mature object into a kernel primitive. Export still requires recognized NameCert and derivation-certificate flows. Hence the recognition layer is conservative over the finite kernel. □

Corollary 9212.41 (Accepted object code is weaker than object equality). Lean4✓ BEDC.GroundCompiler.DerivCe object code weaker than object equality

If two accepted object codes are identified by a classifier or bridge as the same mature object, that does not imply equality of their raw acceptance flows. Equivalently, a classifier may identify distinct accepted flows by a coarser event-flow reading. Raw-flow equality is controlled by channel code equality; mature-object sameness is controlled by classifier and bridge structure.

Example 9212.42 ($\mathsf{AxisNat}^{\uparrow}$ acceptance flow). *An* $\mathsf{AxisNat}^{\uparrow}$ *acceptance flow contains a* NameCert *flow with* b0*-emission source histories, repeated* b0*-extension pattern,* hsame *restricted to the* b0*-spine, closure under* E0 *and continuation, and a source-history ledger. It also contains a derivation-certificate flow naming the layer carrying* $\mathsf{AxisNat}^{\uparrow}$*, the axis classifier, exactness for the relevant sameness relation, the axis ledger, the stability certificate, and the recognized strength flow. The channel code is* Compile *of that whole accepted flow, not a local event such as* 0*,* 00*, or* 01*.*

Example 9212.43 ($\mathsf{FullAxis}^{\uparrow}$ acceptance flow). *A* $\mathsf{FullAxis}^{\uparrow}$ *acceptance flow recognizes finite* b0*-spine prefixes as source, later-prefix continuation as pattern, prefix-compatible and tail-compatible classification, directedness and prefix closure as stability, and all finite prefixes as ledger. Its derivation-certificate flow still supplies source layer, classifier exactness, ledger citation, stability citation, and strength. The visible overflow skeleton alone does not export* $\mathsf{FullAxis}^{\uparrow}$*.*

Example 9212.44 ($\mathsf{DimLift}^{\uparrow}$ acceptance flow). *A* $\mathsf{DimLift}^{\uparrow}$ *acceptance flow recognizes overflow traces such as* 011*, Zeckendorf overflow and carry behavior, the lifted normal-form classifier, finite-prefix preservation, and the ledger consisting of old axis, full-axis seal, and overflow witness. Its derivation-certificate flow then recognizes the six export roles. The event* 011 *alone is not the lifted object.*

Remark 9212.45 (Outlook). *This chapter establishes that derivation certificates and acceptance gates are not compiler inputs. The core judgments are* $\mathsf{RecognizesDerivCert}(R_D, D, N, s)$*,* $\mathsf{AcceptFlow}(A, N, s)$*, and* $\mathsf{AcceptGateFlow}(N, s)$*. Derivation-certificate recognition preserves channel code, requires six recognized fields, rejects strength-only export, and is conservative over the*

finite kernel. Acceptance requires both recognized NameCert *and derivation-certificate flows, code existence alone does not imply acceptance, accepted object code is injective only on raw acceptance flows, recognition from code must pass through* Decode*, strength monotonicity and reuse are flow-level disciplines, and no higher-strength export appears without a recognized higher-strength flow for the target itself. The next ground-compiler chapter applies the same rule to theorem flow recognition: theorems are not external theorem labels or proof objects, but recognized statement, dependency, proof, certificate, ledger, status, and seal flows.*

Chapter 9213

Theorem Flow Recognition

chapter 9212 records the no-hidden-input reading of derivation certificates and acceptance gates: a DerivCert is recognized as a six-field export-certificate flow, and an acceptance gate is the simultaneous recognition of naming and derivation-certificate flows. This chapter applies the same rule to theorems themselves.

The governing rule is

$$\boxed{\text{a theorem is recognized event-flow structure, not an external label.}}$$

The compiler therefore has no formal entry point for theorem objects, theorem labels, proposition objects, proof trees, Lean theorem names, external theorem identifiers, external statement strings, or host proof checkers. A theorem enters this layer only as an event flow recognized by a generated theorem recognizer.

9213.1 Theorem recognition

Definition 9213.1 (Theorem candidate flow)**.** *Lean4 (definition)* `BEDC.GroundCompiler.TheoremGenerated.Theorem`

A theorem candidate flow *is an event flow*

$$T \in \mathsf{EventFlow}.$$

It has not yet been recognized as a theorem. Thus $T \in \mathsf{EventFlow}$ *does not imply that* T *is a theorem, has a proof, carries a status, or satisfies any certificate or acceptance condition.*

Definition 9213.2 (Generated theorem recognizer)**.** *Lean4 (definition)* `BEDC.GroundCompiler.TheoremGenerated.Ge`

A generated theorem recognizer *is an event flow*

$$R_T \in \mathsf{EventFlow}.$$

It is not a host-level proof checker, theorem table, external parser, proof-object constructor, or theorem manifest. Its public formal carrier is itself generated from the two raw marks and acts on decoded event flows.

Definition 9213.3 (Theorem recognition relation)**.** *Lean4 (definition)* `BEDC.GroundCompiler.TheoremGenerated.The`

The theorem recognition relation is written

$$\mathsf{RecognizesTheorem}(R_T, T), \qquad R_T, T \in \mathsf{EventFlow}.$$

It is read as: the generated theorem recognizer flow R_T *recognizes the event flow* T *as a theorem flow.*

Remark 9213.4 (Recognition is not theorem input)**.** *The judgment* $\mathsf{RecognizesTheorem}(R_T, T)$ *does not say that an external theorem object has been supplied. It says that, in the decoded source event layer,* R_T *recognizes* T *as having theorem-flow structure. The direction is*

$$\mathsf{EventFlow} \longrightarrow \mathsf{RecognizedTheoremFlow},$$

not

$$\mathsf{TheoremObject} \longrightarrow \mathsf{EventFlow}.$$

Definition 9213.5 (Recognized theorem flow)**.** *Lean4 (definition)* `BEDC.GroundCompiler.TheoremGenerated.Theorem`

Define

$$\mathsf{TheoremFlow}(T) \;:\Longleftrightarrow\; \exists R_T, \mathsf{RecognizesTheorem}(R_T, T) \wedge \mathsf{CompleteTheoremFlowRecognition}(R_T, T).$$

Thus T *is a recognized theorem flow exactly when some generated recognizer recognizes it in that role and recognizes the complete theorem-role structure inside it.*

Principle 9213.6 (No external theorem input)**.** *Lean4* ✓ `BEDC.GroundCompiler.TheoremGenerated.no external theorem input`

There is no formal compiler entry point

$$\mathsf{CompileTheorem} : \mathsf{TheoremObject} \to \mathsf{LegalZStream}.$$

The only formal compiler entry point remains

$$\mathsf{Compile} : \mathsf{EventFlow} \to \mathsf{LegalZStream}.$$

If T *is recognized as a theorem flow, its theorem code is just* $\mathsf{Compile}(T)$.

Proposition 9213.7 (Recognition preserves channel code)**.** *Lean4* ✓ `BEDC.GroundCompiler.TheoremGenerated.the recognition preserves code`

If $\mathsf{RecognizesTheorem}(R_T, T)$*, then the channel encoding of* T *is still*

$$\mathsf{Compile}(T).$$

Theorem recognition does not add, delete, or rewrite channel bits.

Proof. The judgment $\mathsf{RecognizesTheorem}(R_T, T)$ is a source-level recognition relation. It says only that T is recognized by R_T as a theorem flow. The channel encoding is supplied by $\mathsf{Compile}$ and depends only on the event flow T. Since recognition does not alter T, it does not alter $\mathsf{Compile}(T)$. □

Corollary 9213.8 (Recognized theorem code is not a new code)**.** *Lean4* ✓ `BEDC.GroundCompiler.TheoremGenerated code not separate`

If T *is a recognized theorem flow, then*

$$\mathsf{TheoremCode}(T) := \mathsf{Compile}(T)$$

is the channel code of the same event flow T*, not the output of a separate theorem compiler.*

9213.2 Theorem roles

Definition 9213.9 (Recognized theorem subflows). *Lean4 (definition)* `BEDC.GroundCompiler.TheoremGenerated.The`

If $\mathsf{RecognizesTheorem}(R_T, T)$*, then* R_T *may recognize subflows of* T *as theorem roles:*

$$\begin{array}{ll} \mathsf{ThmStatement}_{R_T}(T, T_0), & \mathsf{ThmDependencies}_{R_T}(T, T_1), \\ \mathsf{ThmProof}_{R_T}(T, T_2), & \mathsf{ThmCertificates}_{R_T}(T, T_3), \\ \mathsf{ThmLedger}_{R_T}(T, T_4), & \mathsf{ThmStatus}_{R_T}(T, T_5), \\ \mathsf{ThmCanonicalSite}_{R_T}(T, T_6), & \mathsf{ThmSeal}_{R_T}(T, \sigma_T). \end{array}$$

These are not external field labels. They are source-level subflow roles recognized inside T *by* R_T*.*

Remark 9213.10 (Theorem field names are explanatory metalanguage). *The words statement, dependency, proof, certificate, ledger, status, canonical site, and seal are explanatory metalanguage. Formally, the roles must be recognized in event flows by relations such as*

$$\mathsf{ThmStatement}_{R_T}, \quad \mathsf{ThmDependencies}_{R_T}, \quad \mathsf{ThmProof}_{R_T}, \quad \mathsf{ThmCertificates}_{R_T},$$
$$\mathsf{ThmLedger}_{R_T}, \quad \mathsf{ThmStatus}_{R_T}, \quad \mathsf{ThmCanonicalSite}_{R_T}, \quad \mathsf{ThmSeal}_{R_T}.$$

This preserves the no-hidden-input rule: theorem fields are not first-layer inputs, and theorem structure is not an external record supplied to the compiler.

Definition 9213.11 (Complete theorem-flow recognition). *Lean4 (definition)* `BEDC.GroundCompiler.TheoremGenera`

The judgment $\mathsf{RecognizesTheorem}(R_T, T)$ *has* complete theorem-flow recognition *when there exist subflows*

$$T_0, T_1, T_2, T_3, T_4, T_5, T_6, \sigma_T$$

such that

$$\mathsf{ThmStatement}_{R_T}(T, T_0), \quad \mathsf{ThmDependencies}_{R_T}(T, T_1), \quad \mathsf{ThmProof}_{R_T}(T, T_2),$$
$$\mathsf{ThmCertificates}_{R_T}(T, T_3), \quad \mathsf{ThmLedger}_{R_T}(T, T_4), \quad \mathsf{ThmStatus}_{R_T}(T, T_5),$$
$$\mathsf{ThmCanonicalSite}_{R_T}(T, T_6), \quad \mathsf{ThmSeal}_{R_T}(T, \sigma_T).$$

Intuitively, T_0 *is the statement flow,* T_1 *the dependency flow,* T_2 *the proof flow,* T_3 *the certificate flow,* T_4 *the ledger flow,* T_5 *the status flow,* T_6 *the canonical-site flow, and* σ_T *the theorem-seal flow. These roles are recognized by* R_T*, not supplied by an external theorem package.*

Principle 9213.12 (No theorem without complete recognized flow). *Lean4 ✓* `BEDC.GroundCompiler.TheoremGener` `theorem without complete recognition`

A recognized theorem flow must have complete theorem-flow recognition. Thus

$$\mathsf{TheoremFlow}(T) \Longrightarrow \exists R_T, \mathsf{RecognizesTheorem}(R_T, T) \wedge \mathsf{CompleteTheoremFlowRecognition}(R_T, T),$$

with recognized statement, dependency, proof, certificate, ledger, status, canonical-site, and seal subflows.

Theorem 9213.13 (Incomplete theorem flow is not a theorem flow). *Lean4 ✓* `BEDC.GroundCompiler.TheoremGener` `theorem flow not theorem`

If, for every generated theorem recognizer R_T *that recognizes* T*, complete theorem-flow recognition fails, then* T *is not a theorem flow.*

Proof. By Definition 9213.12, a recognized theorem flow must have complete theorem-flow recognition. If any required subflow is absent, complete recognition fails. Therefore $\mathsf{TheoremFlow}(T)$ cannot be used for that incomplete flow. □

Corollary 9213.14 (Statement alone is not a theorem)**.** Lean4 ✓ `BEDC.GroundCompiler.TheoremGenerated.statem` `alone not theorem`

If an event flow carries a recognized statement subflow but no generated theorem recognizer recognizes a proof subflow for it, then the event flow is not a theorem flow.

Corollary 9213.15 (Proof alone is not a theorem)**.** Lean4 ✓ `BEDC.GroundCompiler.TheoremGenerated.proof` `alone not theorem`

A recognized proof flow does not by itself constitute a theorem flow. It must be recognized as proving a statement flow under dependency, certificate, ledger, status, and canonical-site structure.

9213.3 Proof, certificate, ledger, status, and site soundness

Definition 9213.16 (Generated proof checker flow)**.** Lean4 (definition) `BEDC.GroundCompiler.TheoremGenerated.Ge`

A generated proof checker flow *is an event flow*

$$R_P \in \mathsf{EventFlow}.$$

It is not a host proof checker, Lean kernel, or external verifier. It is itself generated as an event flow.

Definition 9213.17 (Proof checking relation)**.** Lean4 (definition) `BEDC.GroundCompiler.TheoremGenerated.ChecksP`

The proof checking relation is written

$$\mathsf{ChecksProof}(R_P, T_0, T_1, T_2).$$

It is read as: the generated proof checker flow R_P checks that proof-flow T_2 proves statement-flow T_0 using dependency-flow T_1. This is a source-level recognition or verification judgment, not host-level proof checking supplied as compiler input.

Definition 9213.18 (Proof-sound theorem recognition)**.** Lean4 (definition) `BEDC.GroundCompiler.TheoremGenerate`

The judgment $\mathsf{RecognizesTheorem}(R_T, T)$ *is* proof-sound *when there exist T_0, T_1, T_2 and a generated proof checker flow R_P such that*

$$\mathsf{ThmStatement}_{R_T}(T, T_0), \qquad \mathsf{ThmDependencies}_{R_T}(T, T_1), \qquad \mathsf{ThmProof}_{R_T}(T, T_2),$$
$$\mathsf{ChecksProof}(R_P, T_0, T_1, T_2).$$

Definition 9213.19 (Certificate soundness)**.** Lean4 (definition) `BEDC.GroundCompiler.TheoremGenerated.Certifica`

The judgment $\mathsf{RecognizesTheorem}(R_T, T)$ *is* certificate-sound *when there is a certificate subflow T_3 recognized inside T by R_T and a generated certificate recognizer R_C such that*

$$\mathsf{ThmCertificates}_{R_T}(T, T_3) \quad \textit{and} \quad \mathsf{Recognizes}(R_C, T_3, T_3)$$

hold. The certificate subflow may itself be recognized as containing required NameCert *flows, derivation-certificate flows, proof-certificate flows, or other certificate flows; the certificate datum is recognized from the theorem event flow, not supplied externally.*

Definition 9213.20 (Ledger-sound theorem recognition)**.** *Lean4 (definition)* `BEDC.GroundCompiler.TheoremGenerat`

The judgment $\mathsf{RecognizesTheorem}(R_T, T)$ *is* ledger-sound *when*

$$\mathsf{ThmLedger}_{R_T}(T, T_4)$$

and T_4 *records the source material hidden or cited by the statement, dependencies, proof, certificates, status, and canonical-site subflows.*

Definition 9213.21 (Status-sound theorem recognition)**.** *Lean4 (definition)* `BEDC.GroundCompiler.TheoremGenerate`

The judgment $\mathsf{RecognizesTheorem}(R_T, T)$ *is* status-sound *when*

$$\mathsf{ThmStatus}_{R_T}(T, T_5)$$

and T_5 *is recognized by a generated status recognizer as the theorem's derivation status, strength, or proof status. The status is not a host enum; it is an event-flow role.*

Definition 9213.22 (Site-sound theorem recognition)**.** *Lean4 (definition)* `BEDC.GroundCompiler.TheoremGenerated.`

The judgment $\mathsf{RecognizesTheorem}(R_T, T)$ *is* site-sound *when*

$$\mathsf{ThmCanonicalSite}_{R_T}(T, T_6)$$

and T_6 *records the theorem flow's canonical site, namely the recognized place where the theorem package occurs in the theory-dependency flow. This prevents the same statement, wrapper, or proof from being confused with the same raw theorem flow merely because their statement readings coincide.*

Definition 9213.23 (Sound theorem flow)**.** *Lean4 (definition)* `BEDC.GroundCompiler.TheoremGenerated.SoundTheor`

A recognized theorem judgment

$$\mathsf{RecognizesTheorem}(R_T, T)$$

is sound *when it has complete theorem-flow recognition and is proof-sound, certificate-sound, ledger-sound, status-sound, and site-sound.*

Theorem 9213.24 (Sound flow establishes theoremhood)**.** *Lean4 ✓* `BEDC.GroundCompiler.TheoremGenerated.soun` `theorem flow establishes theoremhood`

If $\mathsf{RecognizesTheorem}(R_T, T)$ *and this recognition is sound, then*

$$\mathsf{TheoremFlow}(T),$$

and T *is available as a source-level event flow for theorem package code.*

Proof. Complete theorem-flow recognition supplies statement, dependency, proof, certificate, ledger, status, canonical-site, and theorem-seal subflows. Proof-soundness recognizes the proof flow as proving the statement flow using the dependency flow. Certificate-soundness recognizes the required certificate flows and their own soundness. Ledger-soundness records hidden and cited source material. Status-soundness and site-soundness record the theorem's strength and canonical occurrence. Hence T satisfies the flow-level conditions for theoremhood, and its theorem package code is obtained from the ordinary channel compiler. □

9213.4 Theorem code and quotients

Definition 9213.25 (Theorem code)**.** *Lean4 (definition)* `BEDC.GroundCompiler.TheoremGenerated.TheoremCode`

If T is a sound recognized theorem flow, define

$$\mathsf{TheoremCode}(T) := \mathsf{Compile}(T).$$

This code is the channel compilation of T. It is not a proof, theorem object, theorem label, or separate theorem compiler output.

Proposition 9213.26 (Theorem code is injective on raw theorem flows)**.** *Lean4✓* `BEDC.GroundCompiler.TheoremG` `code injective`

If T and U are sound recognized theorem flows and

$$\mathsf{TheoremCode}(T) = \mathsf{TheoremCode}(U),$$

then $T = U$.

Proof. By definition, $\mathsf{TheoremCode}(T) = \mathsf{Compile}(T)$ and $\mathsf{TheoremCode}(U) = \mathsf{Compile}(U)$. Equality of theorem codes gives

$$\mathsf{Compile}(T) = \mathsf{Compile}(U).$$

By the channel bijection of Definition 9208.19, $\mathsf{Compile}$ is injective on event flows. Hence $T = U$. □

Corollary 9213.27 (Raw theorem flows and theorem codes are bijective)**.** *Lean4✓* `BEDC.GroundCompiler.Theorem` `code bijective`

The theorem-flow carrier, considered at the raw event-flow layer, is in bijection with its theorem codes:

$$\mathsf{TheoremCandidateFlow} \cong \mathsf{LegalTheoremCode}_{01}.$$

Sound recognition is an additional source-level predicate on this carrier; it does not change the underlying channel code map.

Remark 9213.28 (Abstract propositions are not theorem flows)**.** *An abstract proposition is not the same thing as a theorem flow. The same proposition can have multiple statement presentations, proofs, dependency unfoldings, certificate strengths, ledgers, canonical sites, bridge statuses, and wrapper theorem flows. Thus*

$$\textit{proposition} \ncong \textit{raw theorem code}$$

in general. The bijection is between canonical raw theorem flows and their theorem codes.

Proposition 9213.29 (The same statement can have multiple theorem flows)**.** *Lean4✓* `BEDC.GroundCompiler.The` `statement multiple flows`

There may be theorem flows T and U whose statement subflows are identified by the same statement classifier, while $T \neq U$.

Proof. Take two theorem flows with classifier-equivalent statement flows but different proof, dependency, ledger, status, or canonical-site subflows. As complete event flows, they are distinct. Their statements may nevertheless be equivalent under the statement classifier. Hence one classified statement can be carried by multiple raw theorem flows. □

Corollary 9213.30 (Code equality refines statement equivalence). *Lean4 ✓ BEDC.GroundCompiler.TheoremGenerat equality refines statement equivalence*

If

$$\mathsf{TheoremCode}(T) = \mathsf{TheoremCode}(U),$$

then $T = U$, so the full statement, proof, dependencies, certificates, ledger, status, and canonical-site structure agree at the raw-flow layer. Statement-flow equivalence alone does not imply theorem-code equality.

Definition 9213.31 (Theorem classifier quotient). *Lean4 (definition) BEDC.GroundCompiler.TheoremGenerated.Theo*

If a theorem classifier $\sim_{\mathrm{thm}}$ identifies theorem flows, the classified theorem object is an equivalence class

$$[T]_{\sim_{\mathrm{thm}}}.$$

The projection

$$T \longmapsto [T]_{\sim_{\mathrm{thm}}}$$

need not be injective.

Proposition 9213.32 (Classified theorem objects need not be code-bijective). *Lean4 ✓ BEDC.GroundCompiler.Theo theorem objects not code bijective*

If there are sound theorem flows $T \neq U$ with

$$T \sim_{\mathrm{thm}} U,$$

then the map from theorem codes to classified theorem objects is not injective.

Proof. By Definition 9213.26, $T \neq U$ implies

$$\mathsf{TheoremCode}(T) \neq \mathsf{TheoremCode}(U).$$

But $T \sim_{\mathrm{thm}} U$ implies

$$[T]_{\sim_{\mathrm{thm}}} = [U]_{\sim_{\mathrm{thm}}}.$$

Thus two distinct theorem codes map to one classified theorem object. □

Corollary 9213.33 (The theorem-flow layer and theorem-object layer differ). *Lean4 ✓ BEDC.GroundCompiler.Theo flow object layer differ*

The raw-flow layer and classified-object layer have different maps:

$$\textit{theorem flow} \leftrightarrow \textit{theorem code}, \qquad \textit{theorem flow} \longrightarrow \textit{classified theorem object}.$$

The first is bijective; the second is generally a quotient.

9213.5 Recognition from code

Definition 9213.34 (Theorem recognition from channel code). *Lean4 (definition) BEDC.GroundCompiler.TheoremGe*

For a legal channel stream $c \in \mathsf{LegalZStream}$, define

$$\mathsf{RecognizesTheoremCode}(R_T, c) \;:\Longleftrightarrow\; \exists T,\ \mathsf{Decode}(c) = T \wedge \mathsf{RecognizesTheorem}(R_T, T).$$

Recognition from channel code therefore proceeds through decoding.

Proposition 9213.35 (No theorem recognition by channel substring). *Lean4✓ BEDC.GroundCompiler.TheoremGen theorem recognition by channel substring*

There is no valid rule that recognizes a theorem by inspecting arbitrary channel substrings without first decoding the channel stream into an event flow. A channel-code recognition judgment factors through a decoded event flow T and a source-level judgment $\mathsf{RecognizesTheorem}(R_T, T)$.

Proof. Definition 9209.27 proves that channel substrings are not source events. Theorem recognition is a source-level relation over event flows. Any theorem recognition rule acting directly on channel substrings would therefore operate on the wrong layer. Valid recognition must first apply Decode. □

Theorem 9213.36 (Compile-decode preserves recognition). *Lean4✓ BEDC.GroundCompiler.TheoremGenerated.co decode preserves recognition*

If $\mathsf{RecognizesTheorem}(R_T, T)$, *then*

$$\mathsf{RecognizesTheoremCode}(R_T, \mathsf{Compile}(T)).$$

Proof. By the flow-level round trip Definition 9208.17,

$$\mathsf{Decode}(\mathsf{Compile}(T)) = T.$$

Together with $\mathsf{RecognizesTheorem}(R_T, T)$, this supplies the decoded witness required by $\mathsf{RecognizesTheoremCode}(R$ □

Corollary 9213.37 (Theorem recognition is invariant under compile-decode). *Lean4✓ BEDC.GroundCompiler.Theo invariant under compile decode*

For every recognized theorem flow, its theorem code is recognized after the compile-decode round trip.

9213.6 Acceptance and seals

Definition 9213.38 (Accepted theorem flow). *Lean4 (definition) BEDC.GroundCompiler.TheoremGenerated.Accepte*

A theorem flow T is an accepted theorem flow *when:*

1. *T is a sound recognized theorem flow;*
2. *the required* NameCert, *derivation-certificate, or proof-certificate flows in its certificate subflow are soundly recognized;*
3. *whenever the theorem claims mature-object export, the corresponding acceptance-gate flow of Definition 9212.23 is recognized.*

This is written $\mathsf{AcceptedTheoremFlow}(T)$.

Proposition 9213.39 (Theorem code existence does not imply accepted theorem). *Lean4✓ BEDC.GroundCompiler code existence not accepted*

There exists a legal theorem code $c \in \mathsf{LegalTheoremCode}_{01}$ whose decoded event flow is not an accepted theorem flow. Thus legal channel-code existence alone does not imply

$$\mathsf{AcceptedTheoremFlow}(T)$$

for the decoded theorem-candidate flow T.

Proof. Legal channel membership says only that c decodes to an event flow. Accepted theoremhood requires theorem recognition, proof-soundness, certificate-soundness, ledger-soundness, status-soundness, and, where export is claimed, an acceptance-gate flow. Channel legality supplies none of those recognition judgments. □

Corollary 9213.40 (Code is not proof). Lean4✓ `BEDC.GroundCompiler.TheoremGenerated.theorem code is not proof`

Theorem code records a theorem flow. It does not replace the proof-flow, generated proof checker, or proof-soundness judgment.

Definition 9213.41 (Theorem seal subflow). Lean4 (definition) `BEDC.GroundCompiler.TheoremGenerated.TheoremSe`

If $\mathsf{RecognizesTheorem}(R_T, T)$ *and* R_T *recognizes a terminal subflow* σ_T *of* T *as expressing theorem-package completion, then* σ_T *is a* theorem-seal subflow*, written*

$$\mathsf{ThmSeal}_{R_T}(T, \sigma_T).$$

The theorem seal is a source-level subflow, not the channel-level terminator 11*.*

Proposition 9213.42 (Theorem seal is not the channel terminator). Lean4✓ `BEDC.GroundCompiler.TheoremGener seal is source subflow`

If $\mathsf{ThmSeal}_{R_T}(T, \sigma_T)$*, then* σ_T *is a source-level subflow of* T*, not a channel-level terminator datum.*

Proof. The channel-level 11 is the event terminator of Definition 9208.2; it belongs to the LegalZStream encoding mechanism. A theorem seal is recognized inside a decoded event flow. By the layer-separation theorem Definition 9209.27, a channel substring cannot be used directly as a source subflow. Hence the theorem seal is not the channel terminator. □

9213.7 Conservativity and examples

Theorem 9213.43 (Theorem-flow recognition is conservative over the finite kernel). Lean4✓ `BEDC.GroundCompiler.TheoremGenerated.theorem flow recognition conservativity`

Adding RecognizesTheorem*,* ChecksProof*,* AcceptedTheoremFlow*, and the associated role-recognition relations does not add new raw marks, history constructors, sameness rules, continuation rules, or kernel-level equalities.*

Proof. These relations assert theorem recognition, proof checking, certificate recognition, ledger discipline, status recognition, site recognition, and acceptance bookkeeping over event flows. They do not generate new b0 or b1 marks, add msame, hsame, or psame rules, change Ext or Cont, or turn theorem objects into kernel primitives. Theorem acceptance still depends on recognized proof, certificate, ledger, status, and acceptance flows. Hence the recognition layer is conservative over the finite kernel. □

Example 9213.44 (Channel round-trip theorem as theorem flow). *The channel round-trip theorem can be represented by a theorem flow whose statement subflow reads* $\mathsf{Decode}(\mathsf{Compile}(S)) = S$*, whose dependencies include event encoding, decoding, the no-internal-*11 *lemma, and event-level round trip, and whose proof flow is an induction over the event flow. Its certificate subflow records the compiler definitions and decoder-correctness evidence; its ledger records both* S *and* $\mathsf{Compile}(S)$*; its status subflow records the recognized strength; and its canonical site points to the channel-encoding theorem site. The theorem code is* Compile *of that whole theorem flow, not the channel code of the displayed statement alone.*

Example 9213.45 (Zeckendorf carry theorem as theorem flow)**.** *A source-level carry theorem may have a statement subflow saying that* 011 *and* 100 *are related by a Zeckendorf carry relation. Its dependencies include source-event definitions, a normal-form recognizer, the no-adjacent-boundary pattern, and the carry classifier. Its proof flow supplies the classifier witness, and its ledger records both the pre-normal event* 011 *and the normal event* 100*. This theorem flow does not assert* $011 = 100$ *or* $\mathsf{hsame}(011, 100)$*; it asserts a classifier-level carry relation with ledger support.*

Example 9213.46 ($\mathsf{FullAxis}^{\uparrow}$ theorem as theorem flow)**.** *A* $\mathsf{FullAxis}^{\uparrow}$ *theorem flow can state that* $\mathsf{FullAxis}^{\uparrow}$ *is licensed by finite-prefix source, compatible-thread pattern, prefix-compatible classifier, seal stability, and tail ledger. Its dependencies include* $\mathsf{AxisNat}^{\uparrow}$ *flow, finite-prefix flow, thread flow, seal-certificate flow, and* $\mathsf{NameCert}$ *flow. Its proof flow verifies the five-field certificate structure, while its ledger retains* 0, 00, 000*, the repeat-boundary witness, the seal witness, and all finite prefixes. Such a theorem flow is not the bare event* 011*; that event can only be a local witness inside the flow.*

Remark 9213.47 (Outlook)**.** *This chapter establishes that a theorem is not an external label or proof object, but a recognized theorem flow. The core judgments are* $\mathsf{RecognizesTheorem}(R_T, T)$ *and* $\mathsf{ChecksProof}(R_P, T_0, T_1, T_2)$*. Theorem recognition preserves channel code, theorem code is just* $\mathsf{Compile}(T)$*, complete theorem flow requires statement, dependencies, proof, certificates, ledger, status, canonical site, and seal, statement alone and proof alone are insufficient, sound theorem flow establishes theoremhood at the flow level, theorem code is injective only on raw theorem flows, classified theorem objects are quotients, recognition from code must pass through* Decode*, code existence does not imply accepted theoremhood, code is not proof, theorem seals are not channel terminators, and theorem-flow recognition is conservative over the finite kernel. The next ground-compiler chapter applies the same rule to chapter flow recognition.*

Chapter 9214

Chapter Flow Recognition

chapter 9213 records the no-hidden-input reading of theoremhood: a theorem is not an external theorem label or proof object, but a recognized statement, dependency, proof, certificate, ledger, status, canonical-site, and seal structure inside an event flow. This chapter lifts the same rule to chapter structure.

The governing rule is

a chapter is recognized event-flow structure, not a manifest, outline, or external package.

The formal compiler therefore does not accept a chapter package, manifest, YAML file, Markdown heading tree, LaTeX section tree, external chapter identifier, chapter title string, definition list, theorem list, proof-tree list, certificate table, cannot-claim table, or status table. A chapter enters this layer only as an event flow recognized by a generated chapter recognizer.

9214.1 Chapter recognition

Definition 9214.1 (Chapter candidate flow)**.** *Lean4 (definition)* `BEDC.GroundCompiler.ChapterFlow.ChapterCandid`

A chapter candidate flow *is an event flow*

$$C \in \mathsf{EventFlow}.$$

It has not yet been recognized as a chapter. Thus $C \in \mathsf{EventFlow}$ *does not imply that* C *is a chapter, contains definitions, lemmas, theorems, proofs, certificates, ledgers, status data, or carries a chapter seal.*

Definition 9214.2 (Generated chapter recognizer)**.** *Lean4 (definition)* `BEDC.GroundCompiler.ChapterFlow.Generate`

A generated chapter recognizer *is an event flow*

$$R_C \in \mathsf{EventFlow}.$$

It is not a YAML parser, Markdown parser, LaTeX section parser, host-level AST constructor, or external chapter manifest. Its public formal carrier is itself generated from the two raw marks and acts on decoded event flows.

Definition 9214.3 (Chapter recognition relation)**.** *Lean4 (definition)* `BEDC.GroundCompiler.ChapterFlow.Recognize`

The chapter recognition relation is written

$$\mathsf{RecognizesChapter}(R_C, C), \qquad R_C, C \in \mathsf{EventFlow}.$$

It is read as: the generated chapter recognizer flow R_C *recognizes the event flow* C *as a chapter flow.*

Remark 9214.4 (Recognition is not chapter input)**.** *The judgment* $\mathsf{RecognizesChapter}(R_C, C)$ *does not say that an external chapter object has been supplied. It says that, in the decoded source event layer,* R_C *recognizes* C *as having chapter-flow structure. The direction is*

$$\mathsf{EventFlow} \longrightarrow \mathsf{RecognizedChapterFlow},$$

not

$$\mathsf{ChapterPkg} \longrightarrow \mathsf{EventFlow}.$$

Definition 9214.5 (Recognized chapter flow)**.** *Lean4 (definition)* `BEDC.GroundCompiler.ChapterFlow.ChapterFlow`

Define

$$\mathsf{ChapterFlow}(C) \;:\Longleftrightarrow\; \exists R_C,\ \mathsf{CompleteChapterRecognition}(R_C, C).$$

Thus C *is a recognized chapter flow exactly when some generated chapter recognizer recognizes it with the complete chapter-role structure recorded below.*

Principle 9214.6 (No external chapter input)**.** *Lean4 ✓* `BEDC.GroundCompiler.ChapterFlow.no external chapter input`

There is no formal compiler entry point

$$\mathsf{CompileChapter} : \mathsf{ChapterPkg} \to \mathsf{LegalZStream}.$$

The only formal compiler entry point remains

$$\mathsf{Compile} : \mathsf{EventFlow} \to \mathsf{LegalZStream}.$$

If C *is recognized as a chapter flow, its chapter code is just* $\mathsf{Compile}(C)$*.*

Proposition 9214.7 (Recognition preserves channel code)**.** *Lean4 ✓* `BEDC.GroundCompiler.ChapterFlow.chapter recognition preserves code`

If $\mathsf{RecognizesChapter}(R_C, C)$*, then the channel encoding of* C *is still*

$$\mathsf{Compile}(C).$$

Chapter recognition does not add, delete, or rewrite channel bits.

Proof. The judgment $\mathsf{RecognizesChapter}(R_C, C)$ is a source-level recognition relation. It says only that C is recognized by R_C as a chapter flow. The channel encoding is supplied by $\mathsf{Compile}$ and depends only on the event flow C. Since recognition does not alter C, it does not alter $\mathsf{Compile}(C)$. □

Corollary 9214.8 (Recognized chapter code is not a new code)**.** *Lean4 ✓* `BEDC.GroundCompiler.ChapterFlow.chap code not new code`

If C *is a recognized chapter flow, then*

$$\mathsf{ChapterCode}(C) := \mathsf{Compile}(C)$$

is the channel code of the same event flow C*, not the output of a separate chapter compiler.*

9214.2 Chapter roles

Definition 9214.9 (Recognized chapter subflows). *Lean4 (definition)* `BEDC.GroundCompiler.ChapterFlow.ChapterSt`

If $\mathsf{RecognizesChapter}(R_C, C)$*, then* R_C *may recognize subflows of* C *as chapter roles:*

$$\begin{array}{ll} \mathsf{ChapStart}_{R_C}(C, C_0), & \mathsf{ChapDependencies}_{R_C}(C, C_1), \\ \mathsf{ChapDefinitions}_{R_C}(C, C_2), & \mathsf{ChapLemmas}_{R_C}(C, C_3), \\ \mathsf{ChapTheorems}_{R_C}(C, C_4), & \mathsf{ChapProofs}_{R_C}(C, C_5), \\ \mathsf{ChapCertificates}_{R_C}(C, C_6), & \mathsf{ChapLedger}_{R_C}(C, C_7), \\ \mathsf{ChapCannotClaims}_{R_C}(C, C_8), & \mathsf{ChapStatus}_{R_C}(C, C_9), \\ \mathsf{ChapSeal}_{R_C}(C, \sigma_C). & \end{array}$$

These are not external field labels. They are source-level subflow roles recognized inside C *by* R_C*.*

Remark 9214.10 (Chapter field names are explanatory metalanguage). *The words chapter-start, dependencies, definitions, lemmas, theorems, proofs, certificates, ledger, cannot-claims, status, and chapter-seal are explanatory metalanguage. Formally, the roles must be recognized in event flows by the corresponding* $\mathsf{Chap}\cdots_{R_C}$ *relations. This preserves the no-hidden-input rule: chapter fields are not first-layer inputs, and chapter structure is not an external record supplied to the compiler.*

Definition 9214.11 (Complete chapter-flow recognition). *Lean4 (definition)* `BEDC.GroundCompiler.ChapterFlow.Co`

The judgment $\mathsf{RecognizesChapter}(R_C, C)$ *has* complete chapter-flow recognition *when there exist subflows*

$$C_0, C_1, \ldots, C_9, \sigma_C$$

such that

$$\begin{array}{ccc} \mathsf{ChapStart}_{R_C}(C, C_0), & \mathsf{ChapDependencies}_{R_C}(C, C_1), & \mathsf{ChapDefinitions}_{R_C}(C, C_2), \\ \mathsf{ChapLemmas}_{R_C}(C, C_3), & \mathsf{ChapTheorems}_{R_C}(C, C_4), & \mathsf{ChapProofs}_{R_C}(C, C_5), \\ \mathsf{ChapCertificates}_{R_C}(C, C_6), & \mathsf{ChapLedger}_{R_C}(C, C_7), & \mathsf{ChapCannotClaims}_{R_C}(C, C_8), \\ \multicolumn{3}{c}{\mathsf{ChapStatus}_{R_C}(C, C_9), \qquad \mathsf{ChapSeal}_{R_C}(C, \sigma_C).} \end{array}$$

Intuitively, C_0 *is the chapter-start flow,* C_1 *the dependency flow,* C_2 *the definition flow,* C_3 *the lemma flow,* C_4 *the theorem flow,* C_5 *the proof flow,* C_6 *the certificate flow,* C_7 *the ledger flow,* C_8 *the cannot-claim flow,* C_9 *the status flow, and* σ_C *the chapter-seal flow. These roles are recognized by* R_C*, not supplied by an external chapter package.*

Principle 9214.12 (No chapter without complete recognized flow). *Lean4 ✓* `BEDC.GroundCompiler.ChapterFlow.n` `chapter without complete recognition`

A recognized chapter flow must have complete chapter-flow recognition. Thus

$$\mathsf{ChapterFlow}(C) \Longrightarrow \exists R_C,\ \mathsf{CompleteChapterRecognition}(R_C, C),$$

with recognized chapter-start, dependency, definition, lemma, theorem, proof, certificate, ledger, cannot-claim, status, and seal subflows.

Theorem 9214.13 (Incomplete chapter flow is not a chapter flow). *Lean4 ✓* `BEDC.GroundCompiler.ChapterFlow.in` `chapter flow not chapter`

If, for every generated chapter recognizer R_C*, the complete recognition judgment*

$$\mathsf{CompleteChapterRecognition}(R_C, C)$$

fails, then C cannot be used as a recognized chapter flow. In particular, an event flow that lacks any one of the recognized chapter-start, dependency, definition, lemma, theorem, proof, certificate, ledger, cannot-claim, status, or chapter-seal subflows for every candidate recognizer is not a chapter flow.

Proof. By definition, $\mathsf{ChapterFlow}(C)$ means that some generated recognizer R_C supplies CompleteChapterRecognitio If every such complete recognition judgment fails, the existential witness required for $\mathsf{ChapterFlow}(C)$ cannot exist. □

Corollary 9214.14 (Title alone is not a chapter)**.** Lean4 ✓ BEDC.GroundCompiler.ChapterFlow.title alone not chapter

A chapter-start flow or title-like event does not by itself constitute a chapter flow. If no generated chapter recognizer supplies complete chapter-flow recognition for the same candidate flow, then the candidate flow is not a chapter flow. It still needs dependencies, definitions, lemmas, theorems, proofs, certificates, ledger, cannot-claims, status, and chapter seal.

Corollary 9214.15 (Theorem list alone is not a chapter)**.** Lean4 ✓ BEDC.GroundCompiler.ChapterFlow.theorem list alone not chapter

Even if an event flow contains recognized theorem flows, that alone does not constitute a chapter flow. If no generated chapter recognizer supplies complete chapter-flow recognition for the same candidate flow, then the candidate flow is not a chapter flow. The chapter still needs dependency, definition, proof, certificate, ledger, cannot-claim, status, and chapter-seal structure.

9214.3 Soundness of chapter structure

Definition 9214.16 (Dependency soundness)**.** Lean4 (definition) BEDC.GroundCompiler.ChapterFlow.DependencySo

The judgment $\mathsf{RecognizesChapter}(R_C, C)$ *is* dependency-sound *when*

$$\mathsf{ChapDependencies}_{R_C}(C, C_1)$$

for some recognized dependency subflow C_1. The ordering, deferred-claim marks, cannot-claim marks, and open-obligation marks are carried by this event subflow, not by an external dependency manifest.

Definition 9214.17 (Definition soundness)**.** Lean4 (definition) BEDC.GroundCompiler.ChapterFlow.DefinitionSoun

The judgment $\mathsf{RecognizesChapter}(R_C, C)$ *is* definition-sound *when*

$$\mathsf{ChapDefinitions}_{R_C}(C, C_2)$$

and each definition flow inside C_2 is generated from prior dependencies, raw events, recognized package flows, recognized NameCert *flows, or earlier definitions. If a definition introduces a derived name, the corresponding* NameCert *flow must be recognized, unless the definition is explicitly marked as candidate-only.*

Definition 9214.18 (Theorem soundness)**.** Lean4 (definition) BEDC.GroundCompiler.ChapterFlow.TheoremSound

The judgment $\mathsf{RecognizesChapter}(R_C, C)$ *is* theorem-sound *when*

$$\mathsf{ChapTheorems}_{R_C}(C, C_4)$$

and each theorem subflow inside C_4 is recognized by a generated theorem recognizer as a sound theorem flow in the sense of Definition 9213.23.

Definition 9214.19 (Proof soundness). *Lean4 (definition)* `BEDC.GroundCompiler.ChapterFlow.ProofSound`
The judgment $\mathsf{RecognizesChapter}(R_C, C)$ *is* proof-sound *when*

$$\mathsf{ChapProofs}_{R_C}(C, C_5)$$

and each proof subflow inside C_5 *is checked by a generated proof checker flow, or else is explicitly marked as a proof obligation, paper-level proof, or unchecked proof status.*

Definition 9214.20 (Certificate soundness). *Lean4 (definition)* `BEDC.GroundCompiler.ChapterFlow.CertificateSou`
The judgment $\mathsf{RecognizesChapter}(R_C, C)$ *is* certificate-sound *when*

$$\mathsf{ChapCertificates}_{R_C}(C, C_6)$$

and each certificate subflow inside C_6 *is recognized by its appropriate recognizer, for example as a* NameCert *flow, derivation-certificate flow, acceptance-gate flow, seal-certificate flow, reuse-certificate flow, or bridge-certificate flow, or else is explicitly marked as an open certificate obligation.*

Definition 9214.21 (Ledger soundness). *Lean4 (definition)* `BEDC.GroundCompiler.ChapterFlow.LedgerSound`
The judgment $\mathsf{RecognizesChapter}(R_C, C)$ *is* ledger-sound *when*

$$\mathsf{ChapLedger}_{R_C}(C, C_7)$$

and C_7 *records the source material hidden or cited by the chapter's definitions, theorems, proofs, certificates, cannot-claims, status flow, and dependency flow. If the chapter uses nontrivial packaging, compression, classifier quotients, normalization, completion, or bridge structure, the ledger flow records the corresponding provenance.*

Definition 9214.22 (Cannot-claim soundness). *Lean4 (definition)* `BEDC.GroundCompiler.ChapterFlow.CannotClaim`
The judgment $\mathsf{RecognizesChapter}(R_C, C)$ *is* cannot-claim-sound *when*

$$\mathsf{ChapCannotClaims}_{R_C}(C, C_8)$$

and C_8 *records the claims the chapter is not allowed to make. Typical examples are bare code equals theorem, bare event equals mature object, source-level carry equals* hsame*, channel-level* 11 *participates in source-level carry, derived interface without certificate, completion without ledger, and export without acceptance gate. These cannot-claim items must be consistent with the chapter's definitions, theorems, certificates, and status flow.*

Definition 9214.23 (Status soundness). *Lean4 (definition)* `BEDC.GroundCompiler.ChapterFlow.StatusSound`
The judgment $\mathsf{RecognizesChapter}(R_C, C)$ *is* status-sound *when*

$$\mathsf{ChapStatus}_{R_C}(C, C_9)$$

and C_9 *records the status of each main definition, theorem, certificate, bridge, and implementation target in the chapter. Explanatory status readings include* seed, paperCert, checkedCert, bridgeCert*, open obligation, and cannot-claim. These status readings are not automatically upgraded by channel code; they must be supplied by recognized status flows.*

Definition 9214.24 (Sound recognized chapter flow). *Lean4 (definition)* `BEDC.GroundCompiler.ChapterFlow.SoundR`
A recognized chapter judgment

$$\mathsf{RecognizesChapter}(R_C, C)$$

is sound *when it has complete chapter-flow recognition and is dependency-sound, definition-sound, theorem-sound, proof-sound, certificate-sound, ledger-sound, cannot-claim-sound, and status-sound.*

Theorem 9214.25 (Sound flow establishes chapterhood). *Lean4✓ BEDC.GroundCompiler.ChapterFlow.sound establishes chapterhood*

If $\mathsf{RecognizesChapter}(R_C, C)$ *and this recognition is sound, then*

$$\mathsf{ChapterFlow}(C),$$

and C *is available as a source-level event flow for chapter code.*

Proof. Complete chapter-flow recognition supplies chapter-start, dependency, definition, lemma, theorem, proof, certificate, ledger, cannot-claim, status, and chapter-seal subflows. Dependency-soundness records the well-founded dependency order. Definition-soundness prevents definitions from adding unlicensed external primitives. Theorem-soundness and proof-soundness recognize theorem and proof subflows in the required sense. Certificate-soundness recognizes the supporting certificate structure. Ledger-soundness tracks hidden and cited material. Cannot-claim-soundness records the claims not licensed by the chapter. Status-soundness records the chapter's strength and implementation status. Hence C satisfies the flow-level conditions for chapterhood, and its chapter code is obtained from the ordinary channel compiler. □

9214.4 Chapter code and quotients

Definition 9214.26 (Chapter code). *Lean4 (definition) BEDC.GroundCompiler.ChapterFlow.ChapterCode*

If C *is a sound recognized chapter flow, define*

$$\mathsf{ChapterCode}(C) := \mathsf{Compile}(C).$$

This code is the channel compilation of C*. It is not a chapter object, YAML file, manifest, or human-readable chapter tree.*

Proposition 9214.27 (Chapter code is injective on raw chapter flows). *Lean4✓ BEDC.GroundCompiler.ChapterFlo code injective*

If C *and* D *are sound recognized chapter flows and*

$$\mathsf{ChapterCode}(C) = \mathsf{ChapterCode}(D),$$

then $C = D$*.*

Proof. By definition, $\mathsf{ChapterCode}(C) = \mathsf{Compile}(C)$ and $\mathsf{ChapterCode}(D) = \mathsf{Compile}(D)$. Equality of chapter codes gives

$$\mathsf{Compile}(C) = \mathsf{Compile}(D).$$

By the channel bijection of Definition 9208.19, $\mathsf{Compile}$ is injective on event flows. Hence $C = D$. □

Corollary 9214.28 (Raw chapter flows and chapter codes are bijective). *Lean4✓ BEDC.GroundCompiler.ChapterFl code bijective*

Sound recognized chapter flows, considered as raw event flows, are in bijection with their chapter codes:

$$\mathsf{SoundChapterFlow} \cong \mathsf{LegalChapterCode}_{01}.$$

Remark 9214.29 (Chapter topic is not chapter flow)**.** *An abstract chapter topic is not the same thing as a chapter flow. A chapter about* NameCert *may have multiple proof orders, lemma organizations, cannot-claim presentations, ledger unfoldings, status reports, and bridge readings. Thus*

$$\textit{chapter topic} \ncong \textit{raw chapter code.}$$

The bijection is between canonical raw chapter flows and their chapter codes.

Definition 9214.30 (Chapter classifier quotient)**.** *Lean4 (definition)* `BEDC.GroundCompiler.ChapterFlow.ChapterCl`

A chapter classifier relation $\sim_{\text{chap}}$ is a source-level relation on chapter candidate flows. The classified chapter object relation is represented by

$$\mathsf{ChapterClassifierQuotient}_{\sim_{\text{chap}}}(C, D) \ :\Longleftrightarrow\ C \sim_{\text{chap}} D.$$

The classified projection

$$C \longmapsto [C]_{\sim_{\text{chap}}}$$

need not be injective.

Proposition 9214.31 (Classified chapter objects need not be code-bijective)**.** *Lean4✓* `BEDC.GroundCompiler.Chap` `chapter objects not code bijective`

If there are sound chapter flows $C \neq D$ with

$$C \sim_{\text{chap}} D,$$

then the map from chapter codes to classified chapter objects is not injective.

Proof. By Definition 9214.27, $C \neq D$ implies

$$\mathsf{ChapterCode}(C) \neq \mathsf{ChapterCode}(D).$$

But $C \sim_{\text{chap}} D$ implies

$$[C]_{\sim_{\text{chap}}} = [D]_{\sim_{\text{chap}}}.$$

Thus two distinct chapter codes map to one classified chapter object. □

Corollary 9214.32 (The chapter-flow layer and chapter-object layer differ)**.** *Lean4✓* `BEDC.GroundCompiler.Chapt` `flow object layer differ`

The raw-flow layer and classified-object layer have different maps:

$$\textit{chapter flow} \leftrightarrow \textit{chapter code}, \qquad \textit{chapter flow} \longrightarrow \textit{classified chapter object.}$$

The first is bijective; the second is generally a quotient.

9214.5 Recognition from code and readable views

Definition 9214.33 (Chapter recognition from channel code)**.** *Lean4 (definition)* `BEDC.GroundCompiler.ChapterFlo`

For a legal channel stream $c \in \mathsf{LegalZStream}$, define

$$\mathsf{RecognizesChapterCode}(R_C, c) \ :\Longleftrightarrow\ \exists C,\ \mathsf{Decode}(c) = C \ \wedge\ \mathsf{RecognizesChapter}(R_C, C).$$

Recognition from channel code therefore proceeds through decoding.

Proposition 9214.34 (No chapter recognition by channel substring). Lean4✓ BEDC.GroundCompiler.ChapterFlow chapter recognition by channel substring

There is no valid rule that recognizes a chapter by inspecting arbitrary channel substrings without first decoding the channel stream into an event flow.

Proof. Definition 9209.27 proves that channel substrings are not source events. Chapter recognition is a source-level relation over event flows. Any chapter recognition rule acting directly on channel substrings would therefore operate on the wrong layer. Valid recognition must first apply Decode. □

Theorem 9214.35 (Compile-decode preserves chapter recognition). Lean4✓ BEDC.GroundCompiler.ChapterFlow. decode preserves chapter recognition

If $\mathsf{RecognizesChapter}(R_C, C)$, *then*

$$\mathsf{RecognizesChapterCode}(R_C, \mathsf{ChapterCode}(C)).$$

Proof. By the flow-level round trip Definition 9208.17,

$$\mathsf{Decode}(\mathsf{ChapterCode}(C)) = C.$$

Together with $\mathsf{RecognizesChapter}(R_C, C)$, this supplies the decoded witness required by RecognizesChapterCode. □

Corollary 9214.36 (Chapter recognition is invariant under compile-decode). Lean4✓ BEDC.GroundCompiler.Chap recognition invariant

For every recognized chapter flow, compiling to a channel stream and decoding back to an event flow preserves its chapter-recognition status.

Definition 9214.37 (Human-readable chapter view). Lean4 (definition) BEDC.GroundCompiler.ChapterFlow.HumanR

A human-readable chapter view *is a display generated from a decoded and recognized chapter flow, such as Markdown, LaTeX, YAML, JSON, an outline, a theorem-status table, or a dependency graph. These views are output presentations, not input structure.*

Principle 9214.38 (YAML is output, not input). Lean4✓ BEDC.GroundCompiler.ChapterFlow.chapter yaml output not input

YAML, manifests, and outlines may be generated from a decoded and recognized chapter flow, but they cannot serve as formal compiler input.

Proposition 9214.39 (YAML input would be hidden structure). Lean4✓ BEDC.GroundCompiler.ChapterFlow.cha yaml input hidden structure

If YAML were accepted as formal input, then chapter boundaries, field names, theorem order, certificate slots, ledger slots, and status labels would be supplied externally. Such input is structural hidden input.

Proof. YAML explicitly supplies chapter structure: field names, nesting, lists, order, labels, and status readings. These are not recognized from a generated event flow over b0 and b1; they are passed in as external structure. This violates the no-hidden-input rule. □

Corollary 9214.40 (YAML may be a report). Lean4✓ BEDC.GroundCompiler.ChapterFlow.yaml may report

If a decoded and recognized chapter flow C *is already available, YAML is a human-readable chapter view generated as a report*

$$C \longrightarrow \mathrm{YAMLView}(C).$$

The reverse direction is not a formal compiler input.

9214.6 Dependencies and seals

Definition 9214.41 (Chapter-level dependency order). *Lean4 (definition)* `BEDC.GroundCompiler.ChapterFlow.Chap`

The dependency order of a chapter flow is the recognized dependency subflow

$$\mathsf{ChapDependencies}_{R_C}(C, C_1).$$

Each referenced flow is carried with one of the admissible dependency markers: earlier generated, earlier recognized, deferred obligation, cannot-claim item, open obligation, or future bridge. The unmarked-forward case is not a valid dependency-order entry.

Theorem 9214.42 (No forward dependency without marker). *Lean4✓* `BEDC.GroundCompiler.ChapterFlow.no forward dependency without marker`

If a chapter flow C refers to a flow X through the dependency subflow C_1, and the reference is assigned the unmarked-forward marker, then it is not a valid chapter-level dependency-order entry.

Proof. By Definition 9214.41, a valid dependency-order entry requires a marker different from the unmarked-forward marker. The displayed reference has exactly that excluded marker, so it cannot satisfy the dependency-order predicate. □

Corollary 9214.43 (Chapter flow must record open obligations). *Lean4✓* `BEDC.GroundCompiler.ChapterFlow.ope obligations recorded`

If a chapter flow has complete chapter-flow recognition, then its recognized structure includes a cannot-claim flow, a status flow, and a ledger flow. Any unfinished certificate, proof, bridge, or recognizer that the chapter depends on must be recorded through this recognized obligation structure.

Definition 9214.44 (Chapter seal subflow). *Lean4 (definition)* `BEDC.GroundCompiler.ChapterFlow.ChapSeal`

If $\mathsf{RecognizesChapter}(R_C, C)$ *and* R_C *recognizes an event flow* σ_C *as the chapter-completion role for* C*, then* σ_C *is a* chapter-seal subflow*, written*

$$\mathsf{ChapSeal}_{R_C}(C, \sigma_C).$$

The chapter seal is a source-level event flow carrying a recognized role, not the channel-level terminator 11*.*

Proposition 9214.45 (Chapter seal is not the channel terminator). *Lean4✓* `BEDC.GroundCompiler.ChapterFlow.c seal is event flow`

If $\mathsf{ChapSeal}_{R_C}(C, \sigma_C)$*, then* σ_C *is a source-level event flow recognized as nonempty formal event-flow input. The seal judgment is therefore not a claim about the channel-level terminator* 11*.*

Proof. The channel-level 11 is the event terminator of Definition 9208.2; it belongs to the LegalZStream encoding mechanism. A chapter seal is recognized inside a decoded event flow. By the layer-separation theorem Definition 9209.27, a channel substring cannot be used directly as a source subflow. Hence the chapter seal is not the channel terminator. □

9214.7 Conservativity and examples

Theorem 9214.46 (Chapter-flow recognition is conservative over the finite kernel). *Lean4✓* `BEDC.GroundCompiler.ChapterFlow.chapter flow conservativity`

Adding RecognizesChapter*,* ChapterFlow*,* SoundChapterFlow*, and the associated role-recognition relations does not add new raw marks, history constructors, sameness rules, continuation rules, or kernel-level equalities.*

Proof. These relations assert chapter recognition, theorem inclusion, certificate recognition, ledger tracking, cannot-claim tracking, and status bookkeeping over event flows. They do not generate new b0 or b1 marks, add msame, hsame, or psame rules, change Ext or Cont, or turn chapter objects into kernel primitives. Hence the recognition layer is conservative over the finite kernel. □

Example 9214.47 (NameCert chapter as chapter flow)**.** *A* NameCert *chapter flow may contain a chapter-start flow for the chapter opening, dependency flows for raw events, package and gap flows, classifier flows, and ledger flows, definition flows for candidate certificates and five-field recognition, lemma flows saying that incomplete certificates do not license names and that ledgers are required, theorem flows saying that sound* NameCert *flows license candidate names and that recognition is conservative, certificate flows for supporting recognizers, ledger flows for field provenance and hidden source material, cannot-claim flows excluding code-alone licensing and channel-substring recognition, status flows for theorem targets, and a chapter-seal flow. Its channel code is* $\mathsf{Compile}(C_{\mathrm{NameCertChapter}})$*, not a YAML outline or chapter manifest.*

Example 9214.48 (Channel compiler chapter as chapter flow)**.** *A channel compiler chapter flow may contain a chapter-start flow, dependency flows for event-flow definitions, definition flows for* ζ*, event encoding,* Compile*,* LegalZStream*, and* Decode*, lemma flows for no internal* 11*, first-*11 *termination, and illegality of* 0111*, theorem flows for event-level and flow-level round trips and the bijection* $\mathsf{EventFlow} \cong \mathsf{LegalZStream}$*, proof flows by induction on raw events and event flows, certificate flows for conservativity and source-channel separation, ledgers retaining both raw event and compiled stream, cannot-claim flows excluding code-as-theorem and channel-substring-as-source, status flows for proof and Lean target status, and a chapter seal.*

Remark 9214.49 (Outlook)**.** *This chapter establishes that a chapter is not YAML, a manifest, or a chapter package, but a recognized chapter flow. The core judgment is* $\mathsf{RecognizesChapter}(R_C, C)$*. Chapter recognition preserves channel code, chapter code is just* $\mathsf{Compile}(C)$*, complete chapter flow requires chapter-start, dependencies, definitions, lemmas, theorems, proofs, certificates, ledger, cannot-claims, status, and seal, title alone and theorem list alone are insufficient, sound chapter flow establishes chapterhood at the flow level, chapter code is injective only on raw chapter flows, chapter topics and classified chapter objects are quotients, recognition from code must pass through* Decode*, YAML is an output view rather than formal input, forward dependencies require explicit markers, chapter seals are not channel terminators, and chapter-flow recognition is conservative over the finite kernel. The next ground-compiler chapter applies the same rule to recognizer flows themselves.*

Chapter 9215

Recognizer Flows

The preceding chapters established that packages, naming certificates, derivation certificates, acceptance gates, theorems, and chapters are not compiler inputs. They enter the system only as structures recognized inside event flows. This creates the next no-hidden-input question: are the recognizers themselves hidden inputs?

If package, certificate, theorem, or chapter recognition were supplied by a host parser, host function, AST constructor, YAML schema, or Lean meta-level object, the hidden structure would merely move from the object being recognized to the recognizer. The governing rule of this chapter is therefore

$$\boxed{\text{a recognizer is not an external parser; a recognizer is itself an event flow.}}$$

Package recognizers, NameCert recognizers, derivation-certificate recognizers, theorem recognizers, chapter recognizers, proof checkers, status recognizers, ledger recognizers, and compiler recognizers must be generated recognizer flows.

9215.1 Recognizer candidates and roles

Definition 9215.1 (Recognizer candidate flow)**.** *Lean4 (definition)* `BEDC.GroundCompiler.EventFlow.RecognizerCan`

A recognizer candidate flow *is an event flow*

$$R \in \mathsf{EventFlow}.$$

It has not yet been accepted as a recognizer. Thus $R \in \mathsf{EventFlow}$ *does not imply that* R *recognizes packages, recognizes theorems, checks proofs, or compiles itself. Such capabilities must be supported by recognizer-certificate flows.*

Definition 9215.2 (Recognizer role)**.** *Lean4 (definition)* `BEDC.GroundCompiler.EventFlow.RecognitionRole`

A recognizer role *is a source-level description of a recognition task. Explanatory examples include package recognition,* NameCert *recognition, derivation-certificate recognition, theorem recognition, chapter recognition, compiler recognition, proof checking, status recognition, and ledger recognition.*

These role names are metalanguage. Formally, a role is not a host enum input; it must be represented and recognized inside the relevant recognizer-certificate flow.

Definition 9215.3 (Recognition relation schema)**.** *Lean4 (definition)* `BEDC.GroundCompiler.EventFlow.Recognizes`

Given a recognizer candidate flow R, a target event flow S, and a recognition role ρ represented by event-flow structure, the generic recognition judgment is written

$$\mathsf{Recognizes}(R, \rho, S).$$

It is read as: the generated flow R recognizes the event flow S under recognition role ρ.

The concrete judgments used earlier are instances or refinements of this schema:

$$\mathsf{RecognizesPkg}(R, S), \qquad \mathsf{RecognizesNameCert}(R, S, N), \qquad \mathsf{RecognizesDerivCert}(R, D, N, s),$$
$$\mathsf{RecognizesTheorem}(R, T), \qquad \mathsf{RecognizesChapter}(R, C), \qquad \mathsf{RecognizesCompiler}(R).$$

These are source-level event-flow judgments, not external parser calls.

Remark 9215.4 (Recognition is not host parsing)**.** *The judgment* $\mathsf{Recognizes}(R, \rho, S)$ *does not mean that a host parser has parsed S, nor that a Lean meta function has accepted it. It means that the event flow R acts in the BEDC source layer as a recognizer witness for the target event flow S under role ρ. Thus the formal system does not allow* RecognizesPkg *to abbreviate an external parser result, or* RecognizesTheorem *to abbreviate host proof-checker output.*

9215.2 Recognizer certificates

Definition 9215.5 (Recognizer certificate candidate)**.** *Lean4 (definition)* `BEDC.GroundCompiler.RecognizerFlows.Re`

A recognizer certificate candidate *is an event flow*

$$C_R \in \mathsf{EventFlow}.$$

It claims to supply recognition-capability evidence for a recognizer candidate R, but has not yet been recognized as a sound recognizer certificate.

Definition 9215.6 (Recognizer certificate recognition)**.** *Lean4 (definition)* `BEDC.GroundCompiler.RecognizerFlows.`

The recognizer-certificate recognition relation is written

$$\mathsf{RecognizesRecognizerCert}(Q, C_R, R, \rho), \qquad Q, C_R, R, \rho \in \mathsf{EventFlow}.$$

It is read as: the generated meta-recognizer flow Q recognizes C_R as a recognizer certificate for recognizer flow R under recognition role ρ. The meta-recognizer Q is also an event flow.

Remark 9215.7 (Layered bootstrapping, not external regress)**.** *Definition 9215.6 raises an apparent regress: who recognizes the recognizer certificate, and who recognizes that recognizer? The answer is not an external parser. The discipline uses a layered bootstrap:*

$$C_0,\ C_1,\ C_2,\ C_3,\ C_4,\ C_5,\ C_\infty,$$

where the lower layers cover channel decoding and basic event-flow recognition, later layers cover package, certificate, theorem, chapter, and compiler recognition, and the limiting target is a self-hosted compiler flow. Lower recognizers recognize finite certificate structure for higher recognizers, retaining ledgers and failure records at each step.

Definition 9215.8 (Certified recognizer flow)**.** *Lean4 (definition)* `BEDC.GroundCompiler.RecognizerFlows.Certifie`

A recognizer candidate flow R is a certified recognizer flow *for role ρ, written*

$$\mathsf{CertifiedRecognizer}(R, \rho),$$

when there exist a recognizer certificate flow C_R and meta-recognizer flow Q such that

$$\mathsf{RecognizesRecognizerCert}(Q, C_R, R, \rho)$$

and C_R is a sound recognizer-certificate flow.

Definition 9215.9 (Recognizer certificate fields). *Lean4 (definition)* `BEDC.GroundCompiler.RecognizerFlows.Recogn`

If

$$\mathsf{RecognizesRecognizerCert}(Q, C_R, R, \rho),$$

then Q may recognize subflows of C_R as the certificate roles

$$\begin{array}{lll} \mathsf{RecDom}_Q(C_R, D), & \mathsf{RecTarget}_Q(C_R, T), & \mathsf{RecRole}_Q(C_R, \rho), \\ \mathsf{RecSoundness}_Q(C_R, \mathrm{Snd}), & \mathsf{RecCompleteness}_Q(C_R, \mathrm{Cmp}), & \mathsf{RecLedger}_Q(C_R, L), \\ \mathsf{RecFailure}_Q(C_R, F), & \mathsf{RecStability}_Q(C_R, \mathrm{St}), & \mathsf{RecSeal}_Q(C_R, \sigma_R). \end{array}$$

These are not external field labels. They are subflow roles recognized by Q inside C_R.

Definition 9215.10 (Recognizer soundness). *Lean4 (definition)* `BEDC.GroundCompiler.RecognizerFlows.RecSound`

A recognizer R is sound *for role ρ when every flow it recognizes under that role satisfies the structure required by the role:*

$$\mathsf{RecSound}(R, \rho) \;:\Longleftrightarrow\; \forall S,\ \mathsf{Recognizes}(R, \rho, S) \Rightarrow \mathsf{RoleOK}(\rho, S).$$

For example, a sound NameCert *recognizer may recognize only flows that contain the required source, pattern, classifier, stability, and ledger structure and satisfy the associated soundness checks.*

Definition 9215.11 (Recognizer completeness). *Lean4 (definition)* `BEDC.GroundCompiler.RecognizerFlows.RecComp`

A recognizer R is complete relative to a domain D *for role ρ when*

$$\mathsf{RoleOK}(\rho, S) \wedge S \in D \Longrightarrow \mathsf{Recognizes}(R, \rho, S).$$

Completeness is always relative to a recognized domain flow. No finite recognizer is required to recognize every possible structure without a specified domain.

Definition 9215.12 (Recognizer failure ledger). *Lean4 (definition)* `BEDC.GroundCompiler.RecognizerFlows.RecFail`

A recognizer-certificate flow must contain a failure flow

$$\mathsf{RecFailure}_Q(C_R, F)$$

recording why candidate flows are rejected: format failure, missing field, missing ledger, soundness failure, status mismatch, or ill-founded dependency. This is the recognizer-level form of cannot-claim and audit discipline.

Definition 9215.13 (Recognizer ledger). *Lean4 (definition)* `BEDC.GroundCompiler.RecognizerFlows.RecLedger`

A recognizer-certificate flow must contain a ledger flow

$$\mathsf{RecLedger}_Q(C_R, L)$$

recording the source events used by R, the subflows assigned to roles, the source material compressed by recognition, the raw and normal forms related by the recognizer, and the failure branches excluded. If a recognizer hides source structure without such a ledger, it is not admissible.

Principle 9215.14 (No recognizer without certificate). *Lean4✓ BEDC.GroundCompiler.RecognizerFlows.formal recognition evidence requires certified*

A recognizer flow may be used as a formal recognizer only when it is certified for the relevant role. Formal recognition evidence is the paired datum consisting of the recognition judgment

$$\mathsf{Recognizes}(R, \rho, S)$$

and the certificate judgment

$$\mathsf{CertifiedRecognizer}(R, \rho).$$

Hence any formal recognition evidence for R, ρ, and S projects to $\mathsf{CertifiedRecognizer}(R, \rho)$.

Theorem 9215.15 (Uncertified recognizer cannot license recognition). *Lean4✓ BEDC.GroundCompiler.Recognizer cannot license*

If $\neg\mathsf{CertifiedRecognizer}(R, \rho)$*, then there is no formal recognition evidence for R, ρ, and S. Equivalently, the system cannot use the bare judgment*

$$\mathsf{Recognizes}(R, \rho, S)$$

as formal evidence that S has role ρ.

Proof. By Definition 9215.14, formal recognition requires a certified recognizer. If R is not certified for ρ, its output has no recognized soundness, completeness, ledger, or failure-flow support. Hence that output cannot be used as formal evidence for the role. □

Corollary 9215.16 (Host parser output is inadmissible). *Lean4✓ BEDC.GroundCompiler.RecognizerFlows.host parser output inadmissible*

Recognition supplied only by a host parser, YAML schema, external grammar, Lean meta-level elaborator, or file manifest is not admissible as a BEDC recognition judgment unless it is backed by a certified recognizer flow.

9215.3 Conservativity and hierarchy

Definition 9215.17 (Recognizer conservativity). *Lean4 (definition) BEDC.GroundCompiler.RecognizerFlows.Recogn*

A certified recognizer R is kernel-conservative *for role ρ when* $\mathsf{Recognizes}(R, \rho, S)$ *does not add new raw marks, history constructors, sameness rules, continuation rules, or derived-interface formation rules.*

Theorem 9215.18 (Certified recognizers are recognition-only). *Lean4✓ BEDC.GroundCompiler.RecognizerFlows. recognition only*

If $\mathsf{CertifiedRecognizer}(R, \rho)$ *and its certificate contains a kernel-conservativity subflow, then the recognition judgments of R do not change the finite kernel.*

Proof. The kernel-conservativity subflow records that R recognizes structure inside source event flows rather than generating new kernel rules. It does not add b0 or b1, does not add msame, hsame, or psame rules, does not change Ext or Cont, and does not license derived interfaces. Derived interfaces still require NameCert flow; accepted objects still require acceptance-gate flow. Hence R is conservative over the finite kernel. □

Definition 9215.19 (Recognizer hierarchy). *Lean4 (definition)* `BEDC.GroundCompiler.RecognizerFlows.Recognizer`

A recognizer hierarchy *is a finite list of event flows*

$$R_0, R_1, \ldots, R_n$$

with corresponding roles

$$\rho_0, \rho_1, \ldots, \rho_n$$

such that R_0 handles channel decoding and event-flow recognition, each recognizer certificate for R_{i+1} is recognized by R_i or earlier recognizers, each R_i recognizes only the finite structure required by its role, and every level retains ledger and failure-flow data.

Definition 9215.20 (Bootstrap base recognizer). *Lean4 (definition)* `BEDC.GroundCompiler.RecognizerFlows.Bootst`

The bootstrap base recognizer *R_0 recognizes legal channel streams and event flows:*

$$\mathsf{RecognizesLegalZStream}(R_0, c), \qquad \mathsf{RecognizesEventFlow}(R_0, S).$$

It corresponds to the channel compiler and decoder bijection

$$\mathsf{EventFlow} \cong \mathsf{LegalZStream}.$$

Its role covers event boundaries, raw 0, raw 1, legal event codes, and legal event flows.

Proposition 9215.21 (Bootstrap base does not recognize mathematical structure). *Lean4 ✓* `BEDC.GroundCompiler` `base no math structure`

The base recognizer R_0 recognizes only channel legality and event-flow structure. It does not recognize packages, NameCert *flows, theorem flows, chapter flows, proof flows, accepted objects, or mature interfaces.*

Proof. The role of R_0 is channel grammar and event-flow decoding. Packages, certificates, theorems, chapters, and accepted objects require higher recognizers with field recognition, ledger recognition, soundness checks, and failure flows. Those roles are not part of the base recognizer. □

Definition 9215.22 (Package recognizer level). *Lean4 (definition)* `BEDC.GroundCompiler.RecognizerFlows.Package`

A package recognizer level *is a level R_i in a recognizer hierarchy whose role is package recognition. It supports judgments of the form*

$$\mathsf{RecognizesPkg}(R_i, S),$$

but only after $\mathsf{CertifiedRecognizer}(R_i, \rho_{\mathrm{pkg}})$ *has been established.*

Definition 9215.23 (Certificate recognizer level). *Lean4 (definition)* `BEDC.GroundCompiler.RecognizerFlows.Certi`

A certificate recognizer level *is a level R_i in a recognizer hierarchy that recognizes* NameCert *flows, derivation-certificate flows, or acceptance flows. It supports judgments such as*

$$\mathsf{RecognizesNameCert}(R_i, S, N),$$
$$\mathsf{RecognizesDerivCert}(R_i, D, N, s),$$
$$\mathsf{RecognizesAcceptance}(R_i, A, N, s).$$

Definition 9215.24 (Theorem recognizer level). *Lean4 (definition)* `BEDC.GroundCompiler.RecognizerFlows.Theorem`

A theorem recognizer level *is a level R_i in a recognizer hierarchy that recognizes theorem flows:*

$$\mathsf{RecognizesTheorem}(R_i, T).$$

Its certificate records soundness for statement, proof, dependency, certificate, ledger, status, canonical-site, and theorem-seal recognition.

Definition 9215.25 (Chapter recognizer level). *Lean4 (definition)* `BEDC.GroundCompiler.RecognizerFlows.Chapter`

A chapter recognizer level *is a level R_i in a recognizer hierarchy that recognizes chapter flows:*

$$\mathsf{RecognizesChapter}(R_i, C).$$

Its certificate records soundness for definitions, lemmas, theorems, proofs, certificates, ledger, cannot-claims, status, and chapter-seal recognition.

Theorem 9215.26 (Recognizer hierarchy removes structural hidden input). *Lean4 ✓* `BEDC.GroundCompiler.Recog` `hierarchy removes hidden input`

If the recognition judgments for package, NameCert*, derivation-certificate, theorem, and chapter structures are supplied by certified recognizers in a recognizer hierarchy, then these structures are not hidden structural inputs.*

Proof. Hidden structural input is structure that enters the system without being generated as event flow and without being recognized by generated recognizers. In a certified recognizer hierarchy, every such structural use is supported by some event flow R_i and its recognizer certificate. The structure is therefore recognized from event-flow data rather than supplied as external input. □

Corollary 9215.27 (YAML, ASTs, and theorem labels remain inadmissible). *Lean4 ✓* `BEDC.GroundCompiler.Reco` `views inadmissible`

Even in the presence of a recognizer hierarchy, YAML files, ASTs, external theorem labels, and external package records remain inadmissible as formal inputs. They may at most be human-readable output views generated from decoded event flows.

9215.4 Self-description and self-hosting

Definition 9215.28 (Recognizer self-description flow). *Lean4 (definition)* `BEDC.GroundCompiler.RecognizerFlows.R`

A self-description flow *for a recognizer R is an event flow*

$$D_R \in \mathsf{EventFlow}$$

recording which role R recognizes, which domain it requires, which recognition judgments it returns, which ledger and failure branches it records, which earlier recognizer certifies it, and which kernel constraints it preserves. If D_R is recognized by R or by a later compiler recognizer, then R has self-description structure.

Definition 9215.29 (Compiler recognizer flow). *Lean4 (definition)* `BEDC.GroundCompiler.RecognizerFlows.Compile`

A compiler recognizer flow *is an event flow C that recognizes channel compiler definitions, event encoder and decoder structure, the recognizer hierarchy, recognizer certificates, theorem and chapter code construction, and self-description flows. This is written*

$$\mathsf{RecognizesCompiler}(C).$$

Definition 9215.30 (Compiler behavior classifier). *Lean4 (definition)* `BEDC.GroundCompiler.RecognizerFlows.Comp`

Define the compiler behavior classifier by

$$C \equiv_{\text{comp}} C'$$

when C and C' produce the same recognized outputs on all recognized event-flow compilation tasks and preserve the same ledger and failure-flow behavior. This is not raw event-flow equality and not hsame*; it is a classifier for compiler behavior.*

Definition 9215.31 (Self-hosting compiler flow). *Lean4 (definition)* `BEDC.GroundCompiler.RecognizerFlows.SelfHo`

A compiler recognizer flow C is self-hosting *when* $\mathsf{RecognizesCompiler}(C)$*, C compiles its own compiler flow to some C', the result is behaviorally equivalent to C, and the self-compilation ledger records raw C, compiled code, decoded C', and the behavior-classifier witness. Formally,* $\mathsf{SelfHosting}(C)$ *holds when there exists C' such that*

$$\mathsf{Compiles}_C(C, C') \qquad \textit{and} \qquad C' \equiv_{\text{comp}} C.$$

Proposition 9215.32 (Self-hosting is not kernel equality). *Lean4✓* `BEDC.GroundCompiler.RecognizerFlows.self hosting projects behavior classifier`

If $\mathsf{SelfHosting}(C)$*, then there exists a compiled flow C' together with a formal self-compilation judgment* $\mathsf{Compiles}_C(C, C')$ *and a compiler-behavior classifier witness*

$$C' \equiv_{\text{comp}} C.$$

Thus self-hosting records compiler-behavior stability through a classifier witness; it does not record raw event-flow equality or kernel-level sameness as the self-hosting datum.

Proof. Definition 9215.31 requires $C' \equiv_{\text{comp}} C$. By Definition 9215.30, $\equiv_{\text{comp}}$ is a behavior classifier, not raw equality or kernel sameness. Hence self-hosting does not imply $C = C'$ as raw event flows. □

Theorem 9215.33 (Self-hosting removes compiler-as-hidden-input). *Lean4✓* `BEDC.GroundCompiler.RecognizerFl hosting removes compiler as hidden input`

If there is a self-hosting compiler flow C, and its recognizer hierarchy recognizes package, NameCert*, derivation-certificate, theorem, chapter, and compiler flows, then the compiler is not a host-level hidden input.*

Proof. Under self-hosting, the compiler C is itself an event flow and its compiler status is recognized by $\mathsf{RecognizesCompiler}(C)$. It compiles itself to a behavior-equivalent flow C' and records the self-compilation ledger. Thus its structure, behavior, and reuse discipline are supported by event-flow recognition and behavior classification, not by a host-level parser or external compiler assumption. □

Corollary 9215.34 (Full no-hidden-input needs self-hosting or a bootstrap boundary). *Lean4✓* `BEDC.GroundCompiler.RecognizerFlows.full no hidden input needs self hosting`

Before a self-hosting compiler flow is available, the system cannot assert a full no-hidden-input self-hosting claim. A full no-hidden-input claim must include a self-hosting compiler flow; any remaining external compiler dependence belongs in the bootstrap-obligation layer.

Definition 9215.35 (Bootstrap obligation). *Lean4 (definition)* `BEDC.GroundCompiler.RecognizerFlows.BootstrapO`

A bootstrap obligation *is a cannot-claim style record saying that a recognizer or compiler component still depends on an external implementation or on structure not yet discharged by self-hosting event flow. It records claim text, status, why the obligation is not discharged, and the required upgrade.*

Theorem 9215.36 (Bootstrap obligation blocks full self-hosting claim). *Lean4✓* `BEDC.GroundCompiler.Recognize obligation blocks full self hosting claim`

If any bootstrap obligation remains undischarged, the system cannot claim that the compiler is fully no-hidden-input self-hosting.

Proof. A full self-hosting claim requires compiler and recognizer structure to be generated, recognized, and self-hosted as event-flow structure. An undischarged bootstrap obligation records that some recognizer or compiler component still depends on an external implementation or uncertified structure. Therefore the full no-hidden-input self-hosting claim is not available. □

9215.5 Examples and conservativity

Example 9215.37 (Channel compiler as base recognizer)**.** *The channel compiler and decoder can serve as R_0. They recognize raw* 0 *as channel* 0*, raw* 1 *as channel* 10*, event end as channel* 11*, and the bijection between legal streams and event flows. Their soundness theorem is* $\mathsf{Decode}(\mathsf{Compile}(S)) = S$*, and their completeness theorem is that legal* c *satisfies* $\mathsf{Compile}(\mathsf{Decode}(c)) = c$*. This base does not recognize packages, theorems, or* NameCert *flows.*

Example 9215.38 (NameCert recognizer certificate)**.** *A* NameCert *recognizer certificate records a domain of certificate-candidate flows, target* NameCert *flows, the role of* NameCert *recognition, soundness saying that recognized flows have source, pattern, classifier, stability, and ledger structure, domain-relative completeness, ledgers for the field and seal subflows, failure branches for missing fields and malformed seals, stability under compile-decode round trip, and a recognizer-certificate seal.*

Example 9215.39 (Theorem recognizer certificate)**.** *A theorem recognizer certificate records theorem-candidate flows, theorem-flow targets, theorem-recognition role, soundness for statement, dependencies, proof, certificates, ledger, status, canonical site, and theorem seal, domain-relative completeness, ledgers for statement, proof, dependency, and certificate subflows, failure branches for missing statement, missing proof, bad proof checker, missing ledger, status mismatch, and missing canonical site, plus compile-decode stability and a recognizer-certificate seal.*

Example 9215.40 (Chapter recognizer certificate)**.** *A chapter recognizer certificate records chapter-candidate flows, recognized chapter-flow targets, chapter-recognition role, soundness for start, dependencies, definitions, lemmas, theorems, proofs, certificates, ledger, cannot-claims, status, and seal, domain-relative completeness, ledgers for dependency order and recognized lists, failure branches for forward dependency without marker, theorem without proof, missing certificate, missing ledger, and missing cannot-claim entry, plus compile-decode stability and a recognizer-certificate seal.*

Theorem 9215.41 (Recognizer flows are conservative over the finite kernel)**.** `Lean4✓ BEDC.GroundCompiler.Recog flows conservative over kernel`

Adding certified recognizer flows, recognizer-certificate flows, and self-hosting compiler flows does not add new raw marks, history constructors, sameness rules, continuation rules, or kernel-level equalities.

Proof. Recognizer flows are event flows. Recognition judgments are relations over event flows and certificates of such relations. They do not generate new b0 or b1, do not add msame, hsame, or psame rules, do not alter Ext or Cont, and do not license derived interfaces by themselves. Derived interfaces still require recognized NameCert flows; exports still require acceptance-gate flows. Self-hosting establishes behavior classification of compiler flows, not kernel equality. Hence recognizer flows are conservative over the finite kernel. □

Corollary 9215.42 (Recognizer existence does not imply recognized object existence)**.** *The existence of a recognizer flow R does not imply the existence of an event flow S such that* $\mathsf{Recognizes}(R, \rho, S)$*. A recognizer flow is a possible recognizer; actual recognized structures still require target event flows and recognition judgments.*

Corollary 9215.43 (Recognition does not imply acceptance)**.** `Lean4✓` `BEDC.GroundCompiler.RecognizerFlows.re` `not acceptance`

Even if R recognizes S as a package, NameCert*, theorem, or chapter flow, acceptance of mature objects still requires recognized* NameCert *flow, recognized derivation-certificate flow, and acceptance-gate flow where applicable.*

Remark 9215.44 (Outlook)**.** *This chapter establishes that recognizers are not external parsers, but event flows. The core judgments are* $\mathsf{Recognizes}(R, \rho, S)$ *and* $\mathsf{CertifiedRecognizer}(R, \rho)$*. A recognizer candidate flow is not automatically a recognizer; formal use requires a recognizer certificate with domain, target, role, soundness, completeness, ledger, failure, stability, and seal subflows. Uncertified recognizers and host-parser outputs are inadmissible. A certified recognizer hierarchy removes hidden structural input for package, certificate, theorem, and chapter recognition. Self-hosting compiler flow removes compiler-as-hidden-input, but self-hosting is behavior classification, not kernel equality. Undischarged bootstrap obligations block full self-hosting claims. Recognizer flows remain conservative over the finite kernel, recognizer existence does not imply recognized-object existence, and recognition does not imply acceptance. The next ground-compiler chapter gives the detailed self-hosting construction path from the channel base recognizer to a compiler flow that can compile and recognize itself.*

Lemma 9215.45 (Certified recognizer certificates expose ledger and failure)**.** *Let R, ρ, S, C_R, and Q be event flows. Suppose there is formal recognition evidence for R, ρ, and S, and suppose its certificate side is backed by*

$$\mathsf{RecognizesRecognizerCert}(Q, C_R, R, \rho).$$

Then there are event flows L and F such that

$$\mathsf{RecLedger}_Q(C_R, L),$$
$$\mathsf{RecFailure}_Q(C_R, F).$$

In particular, the evidence cannot use R as a formal recognizer while hiding either the recognizer ledger or the recognizer failure record.

Proof. By Definition 9215.14, formal recognition evidence for R, ρ, and S includes the certificate judgment $\mathsf{CertifiedRecognizer}(R, \rho)$. By Definition 9215.8, such a certification is witnessed by a recognizer-certificate flow and a meta-recognizer flow, and the assumed judgment

$$\mathsf{RecognizesRecognizerCert}(Q, C_R, R, \rho)$$

identifies C_R as the certificate flow recognized by Q for this role. The recognized certificate field surface in Definition 9215.9 includes the ledger and failure roles. The ledger requirement in Definition 9215.13 supplies an event flow L with $\mathsf{RecLedger}_Q(C_R, L)$, and the failure-ledger requirement in Definition 9215.12 supplies an event flow F with $\mathsf{RecFailure}_Q(C_R, F)$. These are finite subflows of the same recognized recognizer certificate C_R, so the formal recognition evidence exposes both fields. □

Chapter 9216

Self-Hosting Compiler Flow

chapter 9215 records the no-hidden-input reading of recognizers: a recognizer is not an external parser, but an event flow. This raises the next question. If package, NameCert, derivation-certificate, theorem, and chapter recognizers are themselves generated event flows, who recognizes those recognizers?

The answer is layered bootstrapping, with an explicit boundary until a self-hosting compiler flow is available. The governing rule is

the compiler is not an external program; ultimately it must be a recognizable, compilable, reproducible event flo

The intended ladder is

channel compiler $\longrightarrow$ event-flow recognizer $\longrightarrow$ package recognizer $\longrightarrow$ certificate recognizers $\longrightarrow$ theorem and chapter recognizers $\longrightarrow$ compiler recognizer $\longrightarrow$ self-hosting compiler flow.

This chapter does not claim that the base is already fully self-hosted. It distinguishes a visible bootstrap boundary from self-hosting discharge. Any compiler component not yet discharged by event-flow self-hosting must be recorded as a bootstrap obligation, not hidden in the implementation layer.

9216.1 Compiler candidates and behavior

Definition 9216.1 (Compiler candidate flow)**.** *Lean4 (definition)* `BEDC.GroundCompiler.SelfHostingCompilerFlow.`

A compiler candidate flow *is an event flow*

$$C \in \mathsf{EventFlow}.$$

It has not yet been accepted as a compiler. Thus $C \in \mathsf{EventFlow}$ does not imply that C compiles event flows, recognizes packages, recognizes theorems, or recognizes itself. Such capabilities must be supported by compiler recognizer and compiler certificate flows.

Definition 9216.2 (Compiler recognition relation)**.** *Lean4 (definition)* `BEDC.GroundCompiler.SelfHostingCompilerF`

The compiler recognition relation is written

$$\mathsf{RecognizesCompiler}(R_C, C), \qquad R_C, C \in \mathsf{EventFlow}.$$

It is read as: the generated compiler recognizer flow R_C recognizes the event flow C as a compiler flow. If some R_C satisfies this relation, then C is a recognized compiler flow.

Definition 9216.3 (Compiler behavior relation). *Lean4 (definition)* `BEDC.GroundCompiler.SelfHostingCompilerFlo`
The compiler behavior relation is written

$$\mathsf{Compiles}_C(S, T), \qquad C, S, T \in \mathsf{EventFlow}.$$

It is read as: compiler flow C compiles input event flow S into output event flow T. The compiler, input, and output are all event flows, not host programs, ASTs, or package objects.

Remark 9216.4 (Compiler behavior is a source-level relation). *The judgment* $\mathsf{Compiles}_C(S, T)$ *is a source-level relation over event flows. It is not a channel-level bit rewrite and not a host-level function call. To obtain channel presentations of S and T, one applies* $\mathsf{Compile}(S)$ *and* $\mathsf{Compile}(T)$ *separately.*

Definition 9216.5 (Compiler task domain). *Lean4 (definition)* `BEDC.GroundCompiler.SelfHostingCompilerFlow.Co`
The task domain *of a compiler flow C is a recognized event-flow class*

$$\mathsf{TaskDom}(C, D),$$

where $D \in$ EventFlow *represents the input-flow range that C is licensed to handle. A channel compiler has only the event-flow and channel-flow task domain; it does not thereby handle theorem recognition or* NameCert *recognition.*

Definition 9216.6 (Compiler target domain). *Lean4 (definition)* `BEDC.GroundCompiler.SelfHostingCompilerFlow.C`
The target domain *of a compiler flow C is a recognized event-flow class*

$$\mathsf{TargetDom}(C, T),$$

recording the kind of output flow C is meant to produce, such as channel-code flow, package-recognizer flow, NameCert*-recognizer flow, theorem-recognizer flow, or compiler flow.*

9216.2 Compiler certificates

Definition 9216.7 (Compiler certificate candidate flow). *Lean4 (definition)* `BEDC.GroundCompiler.SelfHostingComp`
A compiler certificate candidate flow *is an event flow*

$$K_C \in \mathsf{EventFlow}.$$

It claims to supply compilation-capability evidence for a compiler candidate C, but has not yet been recognized as a sound compiler certificate.

Definition 9216.8 (Compiler certificate recognition). *Lean4 (definition)* `BEDC.GroundCompiler.SelfHostingCompile`
The compiler-certificate recognition relation is written

$$\mathsf{RecognizesCompilerCert}(R_K, K_C, C), \qquad R_K, K_C, C \in \mathsf{EventFlow}.$$

It is read as: the generated recognizer flow R_K recognizes the event flow K_C as a compiler certificate for compiler flow C.

Definition 9216.9 (Compiler certificate fields). *Lean4 (definition)* `BEDC.GroundCompiler.SelfHostingCompilerFlow`
If

$$\mathsf{RecognizesCompilerCert}(R_K, K_C, C),$$

then R_K may recognize subflows of K_C as compiler-certificate roles:

$$\begin{aligned}
&\mathsf{CompInputDom}_{R_K}(K_C, D_{\text{in}}), && \mathsf{CompOutputDom}_{R_K}(K_C, D_{\text{out}}),\\
&\mathsf{CompEncodingRule}_{R_K}(K_C, E), && \mathsf{CompDecodingRule}_{R_K}(K_C, D),\\
&\mathsf{CompRoundTrip}_{R_K}(K_C, P), && \mathsf{CompRecognizerHierarchy}_{R_K}(K_C, H),\\
&\mathsf{CompLedger}_{R_K}(K_C, L), && \mathsf{CompFailure}_{R_K}(K_C, F),\\
&\mathsf{CompKernelConservativity}_{R_K}(K_C, K), && \mathsf{CompSelfDescription}_{R_K}(K_C, \mathrm{SD}),\\
&\mathsf{CompSeal}_{R_K}(K_C, \sigma_C).
\end{aligned}$$

These are not external field labels. They are subflow roles recognized by R_K inside K_C.

Definition 9216.10 (Certified compiler flow)**.** *Lean4 (definition)* `BEDC.GroundCompiler.SelfHostingCompilerFlow.C`

A compiler candidate C is a certified compiler flow*, written*

$$\mathsf{CertifiedCompiler}(C),$$

when there exist a compiler certificate flow K_C and recognizer R_K such that

$$\mathsf{RecognizesCompilerCert}(R_K, K_C, C)$$

and the recognized certificate flow is sound.

Principle 9216.11 (No compiler without compiler certificate)**.** *Lean4 ✓* `BEDC.GroundCompiler.SelfHostingCompil` `compilation requires certificate`

A compiler flow may be used as a formal compiler only when it is certified. Before the judgment

$$\mathsf{Compiles}_C(S, T)$$

is used formally, the system must have

$$\mathsf{CertifiedCompiler}(C).$$

Otherwise C remains only a compiler candidate flow.

Theorem 9216.12 (Uncertified compiler cannot be used as compiler)**.** *Lean4 ✓* `BEDC.GroundCompiler.SelfHosting` `cannot compile`

If $\neg\mathsf{CertifiedCompiler}(C)$, then for every compiler behavior relation

$$\mathsf{Compiles}_C(S, T)$$

the pair

$$\mathsf{CertifiedCompiler}(C) \;\wedge\; \mathsf{Compiles}_C(S, T)$$

cannot hold. Thus the system cannot use $\mathsf{Compiles}_C(S, T)$ as formal evidence that C compiles S into T unless the certificate component of the formal compiler judgment is present.

Proof. By Definition 9216.11, a formal compiler judgment contains the certified-compiler component together with the behavior component. If $\neg\mathsf{CertifiedCompiler}(C)$, then the certified-compiler component is impossible, so the conjunction $\mathsf{CertifiedCompiler}(C) \wedge \mathsf{Compiles}_C(S, T)$ is impossible. Hence $\mathsf{Compiles}_C(S, T)$ cannot be used as a formal compilation judgment by itself. □

Corollary 9216.13 (Host compiler output is inadmissible without event-flow certificate)**.** *Lean4 ✓* `BEDC.GroundCompiler.SelfHostingCompilerFlow.host output inadmissible without certificate`

If a compilation result comes only from a host compiler, script, external parser, build tool, YAML manifest, or meta-level program, and has no certified compiler flow, then it is not admissible as a formal BEDC compiler judgment.

9216.3 Bootstrap boundary

Definition 9216.14 (Bootstrap compiler). *Lean4 (definition)* `BEDC.GroundCompiler.SelfHostingCompilerFlow.Boo`

A bootstrap compiler *is a compiler component explicitly recorded as part of the bootstrap boundary before self-hosting is discharged. It is written*

$$\mathsf{Bootstrap}(C, \rho),$$

where ρ records the bootstrap role, such as channel encoder and decoder, first event-flow recognizer, or first recognizer-certificate checker.

Definition 9216.15 (Bootstrap obligation). *Lean4 (definition)* `BEDC.GroundCompiler.SelfHostingCompilerFlow.Bo`

A bootstrap obligation *is an event flow B whose recognized content records the bootstrap component, its role, why it is assumed, which part is not yet self-hosted, the required discharge condition, status, and ledger. It is written*

$$\mathsf{BootstrapObligation}(B, C, \rho).$$

Principle 9216.16 (Bootstrap must be explicit). *Lean4 ✓* `BEDC.GroundCompiler.SelfHostingCompilerFlow.boots` `must be explicit`

Before full self-hosting is established, every compiler component that depends on external implementation must be recorded by a bootstrap obligation. The component cannot be hidden in host functions, YAML, Lean meta code, proof scripts, or implementation details.

Theorem 9216.17 (Hidden bootstrap violates no-hidden-input discipline). *Lean4 ✓* `BEDC.GroundCompiler.SelfHo` `bootstrap violates`

If a compiler component C is used in a formal compilation judgment, but is neither a certified compiler flow nor recorded by a bootstrap obligation, then the system violates the no-hidden-input discipline.

Proof. Formal compilation judgments are supported by certified compiler flows, except at an explicit bootstrap boundary. If C is neither certified nor recorded as a bootstrap obligation, then the source of its behavior is outside the event-flow system and has no ledger. It is therefore a hidden input. □

9216.4 Self-compilation and self-hosting

Definition 9216.18 (Compiler behavior classifier). *Lean4 (definition)* `BEDC.GroundCompiler.SelfHostingCompilerF`

The compiler behavior classifier is written

$$C \equiv_{\mathrm{comp}} C'$$

when C and C' have the same recognized behavior on the same recognized task domain and preserve the same ledger and failure-flow behavior. The classifier records input-domain agreement, output-domain agreement, encoding behavior, decoding behavior, round-trip theorem behavior, failure-flow behavior, ledger behavior, and kernel-conservativity behavior. It is not raw event-flow equality, kernel equality, or hsame.

Definition 9216.19 (Self-compilation). *Lean4 (definition)* `BEDC.GroundCompiler.SelfHostingCompilerFlow.SelfCo`

A compiler flow C self-compiles *when there exists an event flow C' such that*

$$\mathsf{Compiles}_C(C, C') \qquad \textit{and} \qquad C' \equiv_{\mathrm{comp}} C.$$

This is written $\mathsf{SelfCompiles}(C)$.

Definition 9216.20 (Self-hosting compiler flow). *Lean4 (definition)* `BEDC.GroundCompiler.SelfHostingCompilerFlo`

A compiler flow C is self-hosting, *written* $\mathsf{SelfHosting}(C)$, *when:*

1. $\mathsf{CertifiedCompiler}(C)$;
2. $\mathsf{RecognizesCompiler}(R_C, C)$ *for some generated compiler recognizer* R_C;
3. $\mathsf{SelfCompiles}(C)$;
4. *the self-compilation ledger records raw C, compiled code, decoded output C', and the behavior-classifier witness $C' \equiv_{\text{comp}} C$.*

Proposition 9216.21 (Self-hosting is not raw equality). *Lean4 ✓* `BEDC.GroundCompiler.SelfHostingCompilerFlou` *`hosting yields behavior classifier`*

If $\mathsf{SelfHosting}(C)$, *then for some event flow C' one obtains*

$$C' \equiv_{\text{comp}} C,$$

as a compiler-behavior classifier witness. The self-hosting judgment therefore exposes behavior classification as its equality-like datum, rather than raw event-flow equality.

Proof. Definition 9216.20 contains a self-compilation output C' together with the behavior-classifier witness $C' \equiv_{\text{comp}} C$. By Definition 9216.18, this classifier is a relation on compiler behavior, not raw event-flow equality. □

Corollary 9216.22 (Self-hosting does not imply kernel equality). *Lean4 ✓* `BEDC.GroundCompiler.SelfHostingComp` *`hosting not kernel equality`*

Since $C' \equiv_{\text{comp}} C$ is a compiler-behavior classifier, self-hosting asserts no new kernel-level equality, hsame, *or* msame *judgment.*

Definition 9216.23 (Self-hosting ledger). *Lean4 (definition)* `BEDC.GroundCompiler.SelfHostingCompilerFlow.Selfl`

A self-hosting ledger *for C is an event flow L_C recording raw compiler flow C, compiled channel code* $\mathsf{Compile}(C)$, *decoded output flow C', the compiler-behavior classifier witness $C' \equiv_{\text{comp}} C$, failure branches, discharged or remaining bootstrap obligations, and kernel-conservativity witness. This is written*

$$\mathsf{SelfHostingLedger}(C, L_C).$$

Principle 9216.24 (No self-hosting without ledger). *Lean4 ✓* `BEDC.GroundCompiler.SelfHostingCompilerFlow.se` *`hosting requires ledger`*

A self-hosting claim requires a self-hosting ledger:

$$\mathsf{SelfHosting}(C) \Longrightarrow \exists L_C,\ \mathsf{SelfHostingLedger}(C, L_C).$$

This is the compiler-level form of the BEDC ledger discipline: recognition, compression, and behavior equivalence must retain provenance.

Theorem 9216.25 (Self-hosting removes compiler-as-hidden-input). *Lean4 ✓* `BEDC.GroundCompiler.SelfHosting(` *`hosting removes hidden input`*

If $\mathsf{SelfHosting}(C)$ *and the recognizer hierarchy of C recognizes package,* NameCert, *derivation-certificate, theorem, chapter, and compiler flows, then the compiler is no longer a host-level hidden input.*

Proof. Self-hosting gives a certified compiler flow C and a self-compilation output C' with $C' \equiv_{\text{comp}} C$. The self-hosting ledger records the raw flow, compiled code, decoded output, behavior equivalence, and failure behavior. The recognizer hierarchy recognizes package, certificate, theorem, chapter, and compiler structures by generated recognizer flows. The system therefore no longer needs a host compiler, parser, AST, or manifest as formal input; compiler behavior is supported by event-flow certificate and self-compilation ledger. □

Corollary 9216.26 (Full no-hidden-input claim requires self-hosting or declared bootstrap)**.** Lean4✓ `BEDC.GroundCompiler.SelfHostingCompilerFlow.full claim requires boundary`

If SelfHosting(C) *has not been established, then the system cannot claim a full no-hidden-input compiler unless every non-self-hosted component is recorded as a bootstrap obligation.*

9216.5 Bootstrap ladder

Definition 9216.27 (Channel compiler C_0)**.** Lean4 (definition) `BEDC.GroundCompiler.SelfHostingCompilerFlow.Ch`

The lowest channel compiler C_0 is the event-flow table

$$C_0 := (0,\ 10,\ 11).$$

Its three raw events record the channel codewords

$$\textit{raw } 0 \mapsto 0, \qquad \textit{raw } 1 \mapsto 10, \qquad \textit{event end} \mapsto 11,$$

and its channel-only behavior sends an input event flow S to the one-event flow whose raw event is Compile(S)*. This behavior supports the bijection*

$$\mathsf{EventFlow} \cong \mathsf{LegalZStream}.$$

It recognizes legal event codes, event boundaries, raw event reconstruction, and flow round trips. It does not recognize packages, NameCert *flows, derivation-certificate flows, theorem flows, chapter flows, or compiler flows.*

Proposition 9216.28 (C_0 is not a full compiler)**.** Lean4✓ `BEDC.GroundCompiler.SelfHostingCompilerFlow.channe` `compiler not full`

The channel compiler C_0 is not a full self-hosting compiler under the channel-only behavior above.

Proof. The behavior of C_0 is limited to event-channel encoding and decoding. When applied to C_0 itself, it returns the channel code flow Compile(C_0) rather than a compiler flow behaviorally classifying back to C_0. Thus the self-hosting classifier required for a full compiler cannot be obtained from the channel-only behavior. □

Definition 9216.29 (Compiler bootstrap ladder)**.** Lean4 (definition) `BEDC.GroundCompiler.SelfHostingCompilerFl`

A compiler bootstrap ladder *is a sequence*

$$C_0, C_1, C_2, C_3, C_4, C_5$$

with roles:

C_0 : *channel compiler,*
C_1 : *event-flow and basic recognizer compiler,*
C_2 : *package recognizer compiler,*
C_3 : NameCert *and derivation-certificate recognizer compiler,*
C_4 : *theorem and chapter recognizer compiler,*
C_5 : *compiler recognizer and self-hosting compiler.*

Each transition to C_{i+1} must be compiled or recognized using prior stages and must carry a certificate flow documenting the transition.

Definition 9216.30 (Ladder soundness). Lean4 (definition) BEDC.GroundCompiler.SelfHostingCompilerFlow.Ladde

A compiler bootstrap ladder is sound *when every transition*

$$C_i \to C_{i+1}$$

has an event-flow certificate containing input domain, output domain, compiler behavior, round-trip or recognition soundness, ledger, failure-flow, kernel-conservativity, status, and seal.

Theorem 9216.31 (Sound ladder discharges staged hidden inputs). Lean4✓ BEDC.GroundCompiler.SelfHostingC ladder discharges

If $C_0, \ldots, C_5$ is a sound compiler bootstrap ladder and C_5 is a self-hosting compiler flow, then the lower recognizer and compiler structures are generated, recognized, compiled, or self-hosted by event-flow structure rather than supplied as external hidden inputs.

Proof. By ladder soundness, each stage C_{i+1} is supported by prior stages and a transition certificate flow. By self-hosting of C_5, the final compiler compiles and behaviorally reproduces itself. Thus the recognizer hierarchy and compiler behavior are supported by event flows and ledgers rather than by an external parser, AST, manifest, or host compiler as formal input. □

Definition 9216.32 (Remaining bootstrap boundary). Lean4 (definition) BEDC.GroundCompiler.SelfHostingCompil

Before C_5 is self-hosting, the remaining bootstrap boundary *is the recorded collection of components not yet discharged by the sound ladder:*

$$\mathsf{BootBoundary} = \{\, C_i \mid C_i \text{ is not yet certified or not yet self-hosted, and has a bootstrap-obligation flow} \,\}.$$

Principle 9216.33 (Bootstrap boundary must be visible). Lean4✓ BEDC.GroundCompiler.SelfHostingCompilerFl bootstrap boundary visible

Every element of BootBoundary *must have a bootstrap-obligation event flow. Hidden bootstrap is not allowed.*

Theorem 9216.34 (Invisible bootstrap blocks compiler certification). Lean4✓ BEDC.GroundCompiler.SelfHosting bootstrap blocks certification

If some $C_i \in$ BootBoundary lacks a bootstrap-obligation flow, then the compiler part cannot be certified as no-hidden-input.

Proof. A component in the bootstrap boundary depends on external implementation or unproven recognition behavior. If it lacks a bootstrap-obligation flow, that dependence is not recorded in the event-flow ledger. Hidden input remains, so no-hidden-input certification fails. □

9216.6 Compiler theorem packages

Definition 9216.35 (Compiler theorem package). Lean4 (definition) BEDC.GroundCompiler.SelfHostingCompilerFl

A compiler theorem package *is a recognized theorem flow whose statement is witnessed as belonging to a compiler-theorem topic. The topic may be channel round trip, decode-encode behavior, recognizer soundness, recognizer completeness, compiler self-hosting, or bootstrap discharge. Each such package must be a recognized theorem flow in the sense of chapter 9213.*

Proposition 9216.36 (Compiler theorem code is theorem-flow code). Lean4✓ `BEDC.GroundCompiler.SelfHosting theorem code is theorem code`

The code of a compiler theorem is

$$\mathsf{Compile}(T),$$

where T is the recognized compiler theorem flow. It is not a host theorem name, Lean theorem identifier, or theorem label.

Proof. By Definition 9213.25, theorem code is the channel compilation of theorem flow. Compiler theorems are theorem flows whose statements concern compiler behavior. Therefore their code is $\mathsf{Compile}(T)$. □

Example 9216.37 (Channel round-trip compiler theorem). *A channel round-trip theorem flow may contain statement flow* $\mathsf{Decode}(\mathsf{Compile}(S)) = S$*, dependency flows for ζ, event encoding,* Compile*, and* Decode*, a proof flow by induction on event flow, a ledger containing raw S, compiled stream, and decoded stream, a status flow, a canonical-site flow in the channel compiler chapter, and a theorem-seal flow. Its code is* $\mathsf{Compile}(T_{\mathrm{roundtrip}})$.

Example 9216.38 (Recognizer soundness compiler theorem). *A recognizer soundness theorem flow may state that if R recognizes S under role ρ, then S satisfies* $\mathsf{RoleOK}(\rho)$*. Its dependencies include recognizer-certificate definitions, the role definition, and the ledger definition. Its proof flow projects the soundness subflow from the recognizer certificate, and its ledger records R, S, and the certificate flow.*

Example 9216.39 (Self-hosting theorem flow). *A self-hosting theorem flow may state* $\mathsf{SelfHosting}(C)$*. Its dependencies include* $\mathsf{CertifiedCompiler}(C)$*,* $\mathsf{RecognizesCompiler}(R_C, C)$*,* $\mathsf{Compiles}_C(C, C')$*,* $C' \equiv_{\mathrm{comp}} C$*, and* $\mathsf{SelfHostingLedger}(C, L_C)$*. Its ledger records raw C,* $\mathsf{Compile}(C)$*, decoded C', the behavior-classifier witness, and remaining bootstrap obligations.*

Theorem 9216.40 (Self-hosting theorem is not required for channel bijection). Lean4✓ `BEDC.GroundCompiler.Self hosting channel bijection independent`

The channel bijection

$$\mathsf{EventFlow} \cong \mathsf{LegalZStream}$$

does not require a self-hosting compiler theorem. It requires only the channel encoder and decoder definitions and their round-trip proofs.

Proof. The channel bijection is established at the C_0 layer by the definitions of ζ, event encoding, Compile, and Decode, plus round-trip proofs. Self-hosting concerns the compiler flow itself as a generated object capable of reproducing its behavior. These are logically distinct. □

Corollary 9216.41 (Channel correctness and no-hidden-input completeness are separate). Lean4✓ `BEDC.GroundCompiler.SelfHostingCompilerFlow.channel correctness separate`

The system may have a correct channel compiler while still carrying bootstrap obligations for higher recognizers. Full no-hidden-input status requires both channel correctness and discharge of recognizer and compiler bootstrap obligations.

9216.7 Conservativity

Theorem 9216.42 (Compiler-flow recognition is conservative over the finite kernel)**.** Lean4✓ `BEDC.GroundCompiler.SelfHostingCompilerFlow.compiler flow recognition conservativity`

Adding compiler candidate flows, compiler certificate flows, compiler behavior relations, self-hosting relations, and bootstrap obligations does not add new raw marks, history constructors, sameness rules, continuation rules, or kernel-level equalities.

Proof. All compiler-related objects in this chapter are event flows or relations over event flows. They do not generate new b0 or b1, do not add msame, hsame, or psame rules, do not change Ext or Cont, and do not license derived interfaces by themselves. Compiler behavior equivalence is a classifier over compiler flows, not kernel equality. Therefore compiler-flow recognition is conservative over the finite kernel. □

Corollary 9216.43 (Self-hosting compiler is not a BEDC primitive)**.** *Even if* $\mathsf{SelfHosting}(C)$ *holds, C is not a new primitive. It is a certified event flow with behavior classifier and ledger.*

Remark 9216.44 (Outlook)**.** *This chapter establishes that the compiler is not an external program; ultimately it must be an event flow. The core relations are* $\mathsf{CertifiedCompiler}(C)$, $\mathsf{Compiles}_C(S,T)$, $C' \equiv_{\mathrm{comp}} C$, *and* $\mathsf{SelfHosting}(C)$. *A compiler candidate flow is not automatically a compiler; formal use requires a compiler certificate. Hidden bootstrap violates the no-hidden-input discipline. Self-hosting is behavior classification, not raw equality or kernel equality, and it requires a self-hosting ledger. Self-hosting removes compiler-as-hidden-input, while C_0 channel correctness remains separate from full no-hidden-input completeness. A sound bootstrap ladder discharges staged hidden inputs; invisible bootstrap blocks certification. Compiler theorem packages are theorem flows, and compiler-flow recognition is conservative over the finite kernel. The next chapter turns from compiler foundations to semantic motif analysis of event flows and channel codes.*

Chapter 9217

Semantic Motif Analysis

The preceding chapters establish a no-hidden-input compiler discipline:

$$\mathsf{b0}, \mathsf{b1} \text{ event flows} \longrightarrow \text{Zeckendorf-safe channel codes} \longrightarrow \text{generated recognizers}$$
$$\longrightarrow \text{package, certificate, theorem, chapter, and compiler recognition} \longrightarrow \text{self-hosting compiler flow.}$$

This chapter begins to use that discipline to compare mathematical theories at the event-flow layer.

The guiding observation is

traditionally distinct theories may share the same generating motifs in their underlying event flows.

Objects such as $\mathsf{Nat}^{\uparrow}$, $\mathsf{List}^{\uparrow}$, $\mathsf{Add}^{\uparrow}$, categorical composition, completion, real-number structure, circle or phase structure, complex-number structure, and topological structure can have different names and certificates while sharing finite repetition, continuation, seal, carry, classifier quotient, ledger compression, or reuse motifs.

The no-hidden-input rule remains unchanged:

a motif is not an external pattern; it is a stable subflow recognized by a generated motif recognizer.

Thus finite repetition, completion, carry, reuse, classifier, and ledger motifs may not be attached to code by external tags or regular expressions. They must be recognized inside decoded event flows by generated recognizer flows.

9217.1 Motif recognition

Definition 9217.1 (Subflow). *Lean4 (definition)* `BEDC.GroundCompiler.SemanticMotif.Subflow`

Let

$$S = (w_0, w_1, \ldots, w_{n-1}) \in \mathsf{EventFlow}.$$

A contiguous subflow *is a segment*

$$S[i : j] = (w_i, w_{i+1}, \ldots, w_{j-1}), \qquad 0 \le i \le j \le n.$$

An indexed subflow *is an order-preserving selection*

$$(w_{i_0}, w_{i_1}, \ldots, w_{i_{k-1}}), \qquad i_0 < i_1 < \cdots < i_{k-1}.$$

Contiguous subflows support local motif recognition. Indexed subflows support ledgers, dependencies, reuse, and other cross-position structure.

Definition 9217.2 (Motif candidate flow). *Lean4 (definition)* `BEDC.GroundCompiler.SemanticMotif.MotifCandidate`

A motif candidate flow *is a subflow*

$$M \subseteq S$$

of an event flow. It has not yet been recognized as a motif. Thus $M \subseteq S$ does not imply that M is a repetition motif, carry motif, completion motif, classifier motif, or any other semantic motif.

Definition 9217.3 (Generated motif recognizer). *Lean4 (definition)* `BEDC.GroundCompiler.SemanticMotif.Generate`

A generated motif recognizer *is an event flow*

$$R_M \in \mathsf{EventFlow}.$$

It is not an external pattern matcher, regular expression, host-level algorithm, or YAML-defined motif table. It is itself generated from the two raw marks and supported by recognizer-certificate structure.

Definition 9217.4 (Motif recognition relation). *Lean4 (definition)* `BEDC.GroundCompiler.SemanticMotif.Recognize`

The motif recognition relation is written

$$\mathsf{RecognizesMotif}(R_M, S, M, \mu), \qquad R_M, S, M, \mu \in \mathsf{EventFlow}.$$

It is read as: the generated motif recognizer flow R_M recognizes subflow M of S as motif role μ. Explanatory roles include finite repetition, continuation, seal, carry, classifier quotient, ledger compression, reuse, and bridge. Formally, μ is not a host enum; it is role-flow structure represented in event-flow form.

Remark 9217.5 (Motif recognition is not regex matching). *The judgment* $\mathsf{RecognizesMotif}(R_M, S, M, \mu)$ *is not a search for a bit substring or host pattern. It takes place on decoded source event flow and is witnessed by generated recognizer flow R_M. Its certificate discipline must retain domain, ledger, failure branches, and stability conditions.*

Definition 9217.6 (Motif occurrence). *Lean4 (definition)* `BEDC.GroundCompiler.SemanticMotif.MotifOccurrence`

If

$$\mathsf{RecognizesMotif}(R_M, S, M, \mu),$$

then M is a motif occurrence *in S, written*

$$M \preceq_{\mu, R_M} S.$$

This means that, under recognizer R_M, the subflow M occurs in S as motif role μ.

Principle 9217.7 (No external motif input). *Lean4 ✓* `BEDC.GroundCompiler.SemanticMotif.no external motif input`

There is no formal input motif table, pattern list, or regular-expression rule that defines motifs. Motifs are recognized from event flows by generated motif recognizers.

Definition 9217.8 (Motif ledger). *Lean4 (definition)* `BEDC.GroundCompiler.SemanticMotif.MotifLedger`

If $\mathsf{RecognizesMotif}(R_M, S, M, \mu)$*, a* motif ledger *is an event subflow L_M recording the raw events of M, its positions in S, why it is recognized as μ, whether normalization or classifier quotienting is involved, whether source material is hidden, and why adjacent candidate subflows fail. It is written*

$$\mathsf{MotifLedger}_{R_M}(S, M, \mu, L_M).$$

The formal core of the relation requires L_M to be an event flow attached to the recognition witness and carried as a subflow of the same source flow.

Principle 9217.9 (No motif without ledger). *Lean4✓ BEDC.GroundCompiler.SemanticMotif.no motif without ledger*

Every motif recognition carries a motif ledger. The support flow M supplies the minimal ledger witness, and richer analyses may recognize a larger ledger subflow:

$$\mathsf{RecognizesMotif}(R_M, S, M, \mu) \Longrightarrow \exists L_M,\ \mathsf{MotifLedger}_{R_M}(S, M, \mu, L_M).$$

Theorem 9217.10 (Motif recognition is source-level). *Lean4✓ BEDC.GroundCompiler.SemanticMotif.motif recognition source level*

If $\mathsf{RecognizesMotif}(R_M, S, M, \mu)$*, then S, M, and μ are source-level event-flow objects, not channel-level bit substrings.*

Proof. By Definition 9217.4, the arguments of RecognizesMotif are event flows. Event flows are source-level objects. By the source-channel separation theorem Definition 9209.27, channel substrings cannot be used directly as source events or source subflows. Hence motif recognition is a source-level relation. □

Corollary 9217.11 (Motif analysis must decode first). *Lean4✓ BEDC.GroundCompiler.SemanticMotif.motif analysis decodes first*

For a legal channel stream $c \in \mathsf{LegalZStream}$, motif analysis must first form

$$\mathsf{Decode}(c) = S$$

and then recognize motifs in S. It cannot search channel bits directly.

9217.2 Basic motif forms

Definition 9217.12 (Finite repetition motif). *Lean4 (definition) BEDC.GroundCompiler.SemanticMotif.FiniteRepet*

A finite repetition motif *is a recognized event subflow of the explanatory form*

$$M = (x, xx, xxx, \ldots, x^k),$$

where x is a raw event and each term is recognized as a source-level extension of the previous term. For example, $0 \mid 00 \mid 000$ *can be a finite repetition candidate, but it becomes a motif only through a judgment*

$$\mathsf{RecognizesMotif}(R_M, S, M, \mu_{\mathrm{rep}}).$$

Definition 9217.13 (Continuation motif). *Lean4 (definition) BEDC.GroundCompiler.SemanticMotif.ContinuationM*

A continuation motif *is a recognized event subflow expressing continuation, composition, append, or combination behavior. Explanatory shapes include*

$$x, \quad y, \quad xy$$

or a larger input-flow, continuation-result-flow, and continuation-witness-flow. A candidate such as $00 \mid 000 \mid 00000$ *becomes a continuation motif only when the recognizer supplies the continuation witness and ledger.*

Definition 9217.14 (Seal motif). *Lean4 (definition) BEDC.GroundCompiler.SemanticMotif.SealMotif*

A seal motif *is a recognized event subflow expressing finite stages, a repeat-boundary or completion witness, and tail ledger. A candidate such as*

$$0 \mid 00 \mid 000 \mid 01 \mid 011$$

may be recognized as completion-like, but the local event 011 *is not by itself a completed object. Completion requires seal, certificate, and ledger structure.*

Definition 9217.15 (Carry motif). *Lean4 (definition)* `BEDC.GroundCompiler.SemanticMotif.CarryMotif`

A carry motif *is a recognized subflow*

$$w \mid v$$

where w is a pre-normal event, v is a normal event, and a source-level classifier or normalization relation relates w to v. The candidate $011 \mid 100$ *can be a Zeckendorf carry motif. It is not equality; it must retain a ledger for both raw pre-normal and normal events.*

Definition 9217.16 (Classifier quotient motif). *Lean4 (definition)* `BEDC.GroundCompiler.SemanticMotif.Classifie`

A classifier quotient motif *is a recognized event structure in which multiple raw event flows are placed in one class by a classifier:*

$$S_1 \sim S_2.$$

It contains raw-flow ledgers for S_1 and S_2, classifier witness, exactness witness, and failure cases.

Definition 9217.17 (Ledger compression motif). *Lean4 (definition)* `BEDC.GroundCompiler.SemanticMotif.LedgerCo`

A ledger compression motif *is a recognized structure in which a visible event or package token hides source material while a ledger subflow preserves provenance. It contains visible token flow, hidden source material flow, ledger flow, pullback or source-map flow, and compression seal flow. This is the motif-level form of the package and gap ledger discipline.*

Definition 9217.18 (Reuse motif). *Lean4 (definition)* `BEDC.GroundCompiler.SemanticMotif.ReuseMotif`

A reuse motif *is a recognized structure in which a new flow references accepted or recognized flows $N_1, \ldots, N_k$ and uses a reuse witness while still supplying its own certificate obligations. It contains input accepted-flow references, transport witness, new source-flow, classifier-flow, ledger-flow, certificate-flow, and strength bound. Reuse does not erase the target object's own certificate obligations.*

Definition 9217.19 (Bridge motif). *Lean4 (definition)* `BEDC.GroundCompiler.SemanticMotif.BridgeMotif`

A bridge motif *is a recognized structure establishing conservative correspondence between a BEDC flow and a standard-side mathematical description. It contains BEDC source flow, standard-side target description flow, translation flow, soundness flow, reflection or completeness flow where available, no-host-leak ledger, and bridge seal. The external object is not a primitive input; it appears only through certified correspondence flow.*

9217.3 Code behavior

Proposition 9217.20 (Motif recognition does not change channel code). *Lean4 ✓* `BEDC.GroundCompiler.Semantic` `recognition preserves code`

If $\mathsf{RecognizesMotif}(R_M, S, M, \mu)$, *then the channel code of S is still*

$$\mathsf{Compile}(S).$$

Proof. Motif recognition is a source-level relation over an existing event flow S. It does not change the events of S. The channel code is defined by $\mathsf{Compile}(S)$ and depends only on S. Therefore motif recognition does not change channel code. □

Corollary 9217.21 (Motif code is not a separate code). *Lean4 ✓* `BEDC.GroundCompiler.SemanticMotif.motif` `code not separate`

The code of a motif occurrence M is the ordinary channel compilation $\mathsf{Compile}(M)$ *of its raw subflow. It is not produced by a separate motif compiler.*

Theorem 9217.22 (Motif recognition is invariant under compile-decode). *Lean4 ✓ BEDC.GroundCompiler.Semanti compile decode invariant*

If $\mathsf{RecognizesMotif}(R_M, S, M, \mu)$*, then*

$$\mathsf{RecognizesMotif}(R_M, \mathsf{Decode}(\mathsf{Compile}(S)), M, \mu).$$

Proof. By the channel round-trip theorem Definition 9208.17,

$$\mathsf{Decode}(\mathsf{Compile}(S)) = S.$$

Substitution into the recognition judgment gives the claim. □

9217.4 Profiles, overlap, and prefixes

Definition 9217.23 (Motif profile). *Lean4 (definition) BEDC.GroundCompiler.SemanticMotif.MotifProfile*

Given an event flow S *and a family of motif recognizers* $\mathcal{R}$*, define the* motif profile *of* S *by*

$$\mathsf{Profile}_{\mathcal{R}}(S) = \{\, (\mu, M, L_M) \mid \exists R_M \in \mathcal{R},\ \mathsf{RecognizesMotif}(R_M, S, M, \mu) \wedge \mathsf{MotifLedger}_{R_M}(S, M, \mu, L_M) \,\}.$$

Thus the profile records recognized motif occurrences together with their ledgers.

Remark 9217.24 (Motif profile depends on recognizer family). *The profile* $\mathsf{Profile}_{\mathcal{R}}(S)$ *depends on* $\mathcal{R}$*. If* $\mathcal{R}$ *contains no carry recognizer, carry motifs will not be reported; if it contains no seal recognizer, completion-like motifs will not be reported. A motif profile is analysis relative to a generated and certified recognizer family, not every truth about a bare event flow.*

Definition 9217.25 (Motif support). *Lean4 (definition) BEDC.GroundCompiler.SemanticMotif.MotifSupport*

If

$$(\mu, M, L_M) \in \mathsf{Profile}_{\mathcal{R}}(S),$$

then M *is the* support subflow *of the motif occurrence and* L_M *is its* support ledger*.*

Definition 9217.26 (Motif overlap). *Lean4 (definition) BEDC.GroundCompiler.SemanticMotif.MotifOverlap*

For event flows S *and* T*, their motif overlap is*

$$\mathsf{Overlap}_{\mathcal{R}}(S, T) = \mathsf{Profile}_{\mathcal{R}}(S) \cap \mathsf{Profile}_{\mathcal{R}}(T),$$

where the comparison is by motif role, support shape, and ledger-compatible equivalence, not by bare channel substring.

Proposition 9217.27 (Channel substring overlap is insufficient). *Lean4 ✓ BEDC.GroundCompiler.SemanticMotif.c substring overlap insufficient*

If two channel codes share a bit substring, that alone does not imply that their source flows share a motif.

Proof. Channel substrings are not source events. For example, a channel code may contain a substring shaped like 011 even when its decoded event is the raw event 1. Therefore channel substring overlap cannot serve as source motif overlap. Motif overlap must proceed by decoding and recognition. □

Definition 9217.28 (Event-level common prefix). *Lean4 (definition)* `BEDC.GroundCompiler.SemanticMotif.EventCo`

For event flows

$$S = (s_0, \ldots, s_{m-1}), \qquad T = (t_0, \ldots, t_{n-1}),$$

an event-level common prefix of length k *is the assertion that* $k \le m$, $k \le n$, *and*

$$s_i = t_i \quad \text{for all } 0 \le i < k.$$

It is written $\mathsf{PrefixLen}(S, T, k)$.

Definition 9217.29 (Recognized semantic prefix). *Lean4 (definition)* `BEDC.GroundCompiler.SemanticMotif.Recogni`

A recognized semantic prefix *of* S *and* T *is a common event-level prefix* P *such that a generated motif recognizer recognizes* P *inside both flows under the same motif role. Raw prefix equality alone is not semantic prefix equality, because the semantic datum includes the recognized role.*

Proposition 9217.30 (Same raw prefix need not imply same semantic prefix). *Lean4 ✓* `BEDC.GroundCompiler.Sem` `raw prefix not unique semantic prefix`

Two event flows can share the same raw prefix while that prefix is recognized under different motif roles. Thus raw prefix equality does not determine a unique semantic prefix role.

Proof. The one-event prefix 0 is a common event-level prefix of the two displayed one-event flows 0 and 0. A generated motif recognizer may recognize that prefix under the finite-repetition role in one occurrence and under the continuation role in another occurrence. These roles are distinct event-flow roles, so the shared raw prefix does not determine a unique semantic prefix role. □

9217.5 Motif metrics

Definition 9217.31 (Seal depth). *Lean4 (definition)* `BEDC.GroundCompiler.SemanticMotif.SealDepth`

For a recognizer family $\mathcal{R}$, *the* seal depth $\mathsf{SealDepth}_{\mathcal{R}}(S)$ *is the number of ledger-distinct motif occurrences in* S *recognized as seal motifs.*

Definition 9217.32 (Carry index). *Lean4 (definition)* `BEDC.GroundCompiler.SemanticMotif.CarryIndex`

The carry index $\mathsf{CarryIndex}_{\mathcal{R}}(S)$ *is the number of ledger-distinct motif occurrences in* S *recognized as carry motifs. A recognized occurrence* $011 \mid 100$ *contributes at least one carry occurrence.*

Definition 9217.33 (Ledger depth). *Lean4 (definition)* `BEDC.GroundCompiler.SemanticMotif.LedgerDepth`

The ledger depth $\mathsf{LedgerDepth}_{\mathcal{R}}(S)$ *is the maximum recognized dependency nesting depth of motif ledgers, package ledgers,* $\mathsf{NameCert}$ *ledgers, derivation-certificate ledgers, and theorem ledgers inside* S.

Definition 9217.34 (Classifier compression ratio). *Lean4 (definition)* `BEDC.GroundCompiler.SemanticMotif.Classi`

If $\mathcal{R}$ *recognizes a classifier quotient motif in* S *placing raw flows* $M_1, \ldots, M_k$ *into* r *recognized classes with* $r > 0$, *define*

$$\mathsf{CompressionRatio}_{\mathcal{R}}(S) = \frac{k}{r}.$$

This metric is defined only when classifier recognition and exactness ledger are both present.

Definition 9217.35 (Reuse depth). *Lean4 (definition)* `BEDC.GroundCompiler.SemanticMotif.ReuseDepth`

The reuse depth $\mathsf{ReuseDepth}_{\mathcal{R}}(S)$ *is the length of the longest dependency chain of reuse motifs in* S. *It measures how many layers of accepted or recognized objects the flow depends on.*

Definition 9217.36 (Motif distance). *Lean4 (definition)* `BEDC.GroundCompiler.SemanticMotif.MotifDistance`

For event flows S and T, a motif distance $\mathsf{Dist}_{\mathcal{R}}(S,T)$ *is any distance function based on their motif profiles. A simple Jaccard-style choice is*

$$\mathsf{Dist}_{\mathcal{R}}(S,T) = 1 - \frac{|\mathsf{Profile}_{\mathcal{R}}(S) \cap \mathsf{Profile}_{\mathcal{R}}(T)|}{|\mathsf{Profile}_{\mathcal{R}}(S) \cup \mathsf{Profile}_{\mathcal{R}}(T)|}.$$

Applications may choose distances better suited to ledger, role, and support-shape comparisons.

Theorem 9217.37 (Motif metrics are code-invariant under round trip). *Lean4 ✓* `BEDC.GroundCompiler.SemanticM` `metrics roundtrip invariant`

If $c = \mathsf{Compile}(S)$, then for every recognizer family $\mathcal{R}$,

$$\mathsf{Profile}_{\mathcal{R}}(S) = \mathsf{Profile}_{\mathcal{R}}(\mathsf{Decode}(c)).$$

Consequently seal depth, carry index, ledger depth, compression ratio, reuse depth, and motif-distance values defined from profiles are invariant under compile-decode round trip.

Proof. By channel round trip, $\mathsf{Decode}(\mathsf{Compile}(S)) = S$. Hence S and $\mathsf{Decode}(c)$ are the same source event flow. Motif recognizers act on source event flows, so their profiles agree. Metrics defined from those profiles agree as well. □

Corollary 9217.38 (Motif analysis can be performed on decoded code). *Lean4 ✓* `BEDC.GroundCompiler.SemanticM` `analysis on decoded code`

Given $c \in \mathsf{LegalZStream}$, one can decode $S = \mathsf{Decode}(c)$ and compute $\mathsf{Profile}_{\mathcal{R}}(S)$. This is the same source-level analysis as applying the recognizers to the original event flow.

9217.6 Examples

Example 9217.39 (Completion skeleton motif profile). *The event flow*

$$0 \mid 00 \mid 000 \mid 01 \mid 011 \mid 100$$

may be recognized as containing finite repetition $0 \mid 00 \mid 000$*, a repeat-boundary motif* 01*, a seal motif* 011*, a carry motif* $011 \mid 100$*, and the larger completion skeleton. Its channel code is*

$$011001100011010110101011100011.$$

Motif recognition must decode back to source event flow before identifying 011 *or* 100 *as source-level events.*

Example 9217.40 (Add and fold skeleton motif profile). *The event flow*

$$0 \mid 00 \mid 001 \mid 0011 \mid 0100$$

may be recognized as unit source 0*, binary repetition* 00*, additive recursion* 001*, iterated-addition raw completion* 0011*, fold normal address* 0100*, and carry or normalization ledger* $0011 \mid 0100$*. Compared with the completion skeleton, it shares the finite-source prefix* $0 \mid 00$ *but then branches toward binary combination and fold rather than seal-style completion.*

Example 9217.41 ($\mathsf{List}^{\uparrow}$ and $\mathsf{Nat}^{\uparrow}$ motif relation)**.** *A* $\mathsf{List}^{\uparrow}$ *flow can contain a finite spine motif for nil, cons, cons-cons, and so on. Under bottom readback this overlaps with the finite repetition and finite-length motifs of* $\mathsf{Nat}^{\uparrow}$*. The list flow also carries payload classifier, constructor-shape ledger, length ledger, and source-carrier reuse. Thus* $\mathsf{List}^{\uparrow}$ *is not merely* $\mathsf{Nat}^{\uparrow}$*; it is finite repetition plus payload and constructor ledger structure.*

Example 9217.42 ($\mathsf{Add}^{\uparrow}$ and categorical composition)**.** *An* $\mathsf{Add}^{\uparrow}$ *event flow may recognize binary continuation, unit behavior, and associativity behavior. A category-composition flow may recognize arrow composition, identity behavior, and associativity behavior. Their motif profiles can overlap in continuation, unit, and associativity ledgers, while category structure also carries object and arrow sorting, domain and codomain compatibility, and identity-arrow ledger.*

Example 9217.43 ($\mathsf{Real}^{\uparrow}$ and completion)**.** *Completion flows and* $\mathsf{Real}^{\uparrow}$ *flows can both contain finite approximation stages, compatible thread, tail classifier, seal motif, and ledger retaining finite stages. The* $\mathsf{Real}^{\uparrow}$ *flow also carries arithmetic descent, order or metric compatibility, field-operation ledger, and Cauchy or regularity classifier. Thus* $\mathsf{Real}^{\uparrow}$ *is not a bare completion motif; it is completion plus algebra, order, and metric certificate stack.*

Example 9217.44 ($\mathsf{DimLift}^{\uparrow}$ and circle or phase structure)**.** *A* $\mathsf{DimLift}^{\uparrow}$ *flow may contain completion witness, overflow witness, carry motif, lifted normal address, and old-axis ledger. Circle or phase structure may contain periodic closure, phase carry, lifted coordinate, unit-constraint ledger, and topological classifier. Shared carry shapes such as* $011 \mid 100$ *or higher carry motifs can reveal common carry and lift structure without implying that the mature objects are the same.*

9217.7 Limits of motif analysis

Theorem 9217.45 (Motif similarity does not imply object equality)**.** *Lean4✓ BEDC.GroundCompiler.SemanticMoti similarity not object equality*

If two event flows S *and* T *have nonempty motif overlap,*

$$\mathsf{Overlap}_{\mathcal{R}}(S,T) \neq \emptyset,$$

one cannot conclude that they are the same source flow, represent the same accepted object, or are equivalent under any classifier.

Proof. Motif overlap says only that the event flows contain recognized motif occurrences with compatible roles and ledgers. Two distinct source flows can share such an occurrence. Object equality or accepted-object equivalence further requires the appropriate classifier, bridge, exactness, and acceptance-gate recognition. Motif overlap does not supply those judgments. □

Corollary 9217.46 (Motif analysis is explanatory, not proof of identity)**.** *Motif analysis can explain generating similarity between theories, but it does not replace proof, classifier exactness,* NameCert*, derivation-certificate, or acceptance-gate structure.*

Theorem 9217.47 (Motif recognition is conservative over the finite kernel)**.** *Lean4✓ BEDC.GroundCompiler.Seman generated conservativity*

Adding RecognizesMotif*,* Profile*,* SealDepth*,* CarryIndex*,* LedgerDepth*, and* ReuseDepth *does not add new raw marks, history constructors, sameness rules, continuation rules, or kernel-level equalities.*

Proof. All these relations act on event flows or recognized subflows. They record, recognize, and compare source-level event structures already present. They do not generate new b0 or b1, add msame, hsame, or psame rules, change Ext or Cont, or license derived interfaces. Derived interfaces still require NameCert flow; accepted objects still require acceptance-gate flow. Hence motif analysis is conservative over the finite kernel. □

Corollary 9217.48 (Motif analysis cannot license mature objects). Lean4 ✓ `BEDC.GroundCompiler.SemanticMotif.analysis cannot license mature objects`

A flow showing completion, carry, phase, or quotient motifs is not thereby licensed as $\mathsf{Real}^{\uparrow}$*, circle structure,* $\mathsf{Complex}^{\uparrow}$*, topology, or any other mature object. Mature objects still require recognized* NameCert*, derivation-certificate, and acceptance-gate flows.*

Definition 9217.49 (Motif report). Lean4 (definition) `BEDC.GroundCompiler.SemanticMotif.MotifReport`

A motif report *is a human-readable output view generated from an event flow S and recognizer family $\mathcal{R}$. It may list recognized motifs, support subflows, motif ledgers, metrics, overlaps with other flows, and failure cases. It is not formal input, proof, or certificate.*

Principle 9217.50 (Motif reports are output, not input). Lean4 ✓ `BEDC.GroundCompiler.SemanticMotif.motif reports output not input`

Motif reports, similarity tables, distance matrices, diagrams, and YAML or JSON reports cannot serve as formal motif-analysis input or formal compiler input. They are outputs of event-flow analysis.

Remark 9217.51 (Outlook). *This chapter establishes that motifs are not external patterns, but stable subflows recognized by generated motif recognizers. The core judgment is* $\mathsf{RecognizesMotif}(R_M, S, M, \mu)$*. Motif recognition is source-level, requires decoding before analysis, preserves channel code, and is invariant under compile-decode round trip. Channel substring overlap does not imply motif overlap, and raw prefix equality does not imply semantic prefix equality. Motif profiles support seal depth, carry index, ledger depth, compression ratio, reuse depth, and motif distance, all relative to a recognizer family. Motif similarity explains generative relation but does not prove object equality or license mature objects. Motif analysis is conservative over the finite kernel, and motif reports are outputs rather than inputs. The next chapter applies this framework to concrete flow comparisons among* $\mathsf{Nat}^{\uparrow}$*,* $\mathsf{List}^{\uparrow}$*,* $\mathsf{Add}^{\uparrow}$*, completion, and Zeckendorf axis skeletons.*

Chapter 9218

First Case Studies: Finite Repetition, Add/Fold, List, and Completion

chapter 9217 establishes the no-hidden-input form of semantic motif analysis: motifs are not external patterns, but stable subflows recognized by generated motif recognizers. This chapter begins the first concrete comparisons. The goal is not to prove that any mature object has already been accepted. The goal is to show how already-generated event flows can be compared at the underlying $\mathsf{b0}, \mathsf{b1}$ layer.

The case studies are finite repetition skeletons, Nat-like skeletons, Add and fold skeletons, List-like skeletons, and Completion or $\mathsf{FullAxis}^{\uparrow}$-like skeletons. The guiding rule is

$$\boxed{\text{different traditional theories can share event motifs without becoming the same object.}}$$

For example, $\mathsf{Nat}^{\uparrow}$ and $\mathsf{List}^{\uparrow}$ can share finite-spine motifs; $\mathsf{Add}^{\uparrow}$ and fold or composition can share continuation motifs; completion and $\mathsf{FullAxis}^{\uparrow}$ can share seal and tail-ledger motifs; Zeckendorf carry and $\mathsf{DimLift}^{\uparrow}$ can share carry and normal-address motifs. These are motif-level relations. Mature export still requires recognized $\mathsf{NameCert}$ flow, derivation-certificate flow, ledger flow, and acceptance-gate flow.

9218.1 Case-study flows

Definition 9218.1 (Case-study flow)**.** *Lean4 (definition)* `BEDC.GroundCompiler.CaseStudies.CaseStudyFlow`

A case-study flow *is an event flow*

$$S \in \mathsf{EventFlow}$$

equipped with an explanatory target such as finite repetition skeleton, Add and fold skeleton, Completion skeleton, or List skeleton. The explanatory target is not input structure. Formally the flow is still just

$$S = (w_0, \ldots, w_{n-1}),$$

and its theoretical reading must be recognized by generated recognizer flow.

Definition 9218.2 (Skeleton code)**.** *Lean4 (definition)* `BEDC.GroundCompiler.CaseStudies.SkeletonCode`

For a case-study flow $S = (w_0, \ldots, w_{n-1})$, define its skeleton code *by*

$$\mathsf{SkCode}(S) := \mathsf{Compile}(S).$$

This is not object code and not accepted theorem code. It is the channel code of the event flow.

Remark 9218.3 (Skeletons are weaker than certificates)**.** *A skeleton flow can display a motif such as finite repetition, carry, or seal structure, but it is not thereby a* NameCert *flow, derivation-certificate flow, or accepted-object flow. For example,*

$$0 \mid 00 \mid 000 \mid 01 \mid 011 \mid 100$$

can be a Completion or $\mathsf{FullAxis}^{\uparrow}$ *skeleton, but a full* $\mathsf{FullAxis}^{\uparrow}$ *certificate still requires recognized source, pattern, classifier, stability, and ledger fields.*

9218.2 Finite repetition skeleton

Definition 9218.4 (Finite repetition skeleton)**.** *Lean4 (definition)* `BEDC.GroundCompiler.CaseStudies.FiniteRepet`

Let

$$S_{\mathrm{rep}}^{(k)} = (0, 00, 000, \ldots, 0^k)$$

be the event flow consisting of the first k finite b0*-repetition events. For example,*

$$S_{\mathrm{rep}}^{(3)} = (0, 00, 000).$$

Its explanatory reading is starting unit, one repetition, two repetitions, and so on. Formally it is only an event flow.

Example 9218.5 (Finite repetition skeleton code)**.** *For*

$$0 \mid 00 \mid 000,$$

the event encodings are

$$0 \mapsto 011, \qquad 00 \mapsto 0011, \qquad 000 \mapsto 00011.$$

Hence

$$\mathsf{Compile}(0 \mid 00 \mid 000) = 011001100011,$$

displayed by event as

$$011 \mid 0011 \mid 00011.$$

Definition 9218.6 (Finite repetition motif recognition)**.** *Lean4 (definition)* `BEDC.GroundCompiler.CaseStudies.Fin`

Given a motif recognizer R_{rep}, if

$$\mathsf{RecognizesMotif}(R_{\mathrm{rep}}, S, M, \mu_{\mathrm{rep}})$$

and M has event shape

$$(x, xx, xxx, \ldots, x^k),$$

then M is recognized in S as a finite repetition motif. When $x = 0$, this is the finite b0*-axis repetition motif.*

Proposition 9218.7 (Finite repetition skeleton contains repetition motif)**.** *Lean4 ✓* `BEDC.GroundCompiler.CaseSt` `skeleton has motif`

If R_{rep} is certified as a finite-repetition recognizer and

$$S_{\mathrm{rep}}^{(k)} = (0, 00, \ldots, 0^k),$$

then

$$\mathsf{RecognizesMotif}(R_{\mathrm{rep}}, S_{\mathrm{rep}}^{(k)}, S_{\mathrm{rep}}^{(k)}, \mu_{\mathrm{rep}})$$

holds.

Proof. By definition, each successor event in $S_{\mathrm{rep}}^{(k)}$ is obtained from the preceding event by source-level appending of 0:

$$0^i \mapsto 0^{i+1}.$$

This is exactly the source-level pattern certified for the finite-repetition recognizer. Hence R_{rep} recognizes the skeleton as a finite repetition motif. □

Corollary 9218.8 (Finite repetition motif does not imply $\mathsf{Nat}^{\uparrow}$)**.** *Lean4✓ BEDC.GroundCompiler.CaseStudies.repe skeleton not repeat rule*

The finite repetition skeleton

$$0 \mid 00 \mid 000$$

does not by itself contain the Nat-like repeat-rule witness

$$01.$$

Thus finite repetition motif data alone cannot be read as $\mathsf{Nat}^{\uparrow}$*. A derived interface such as* $\mathsf{Nat}^{\uparrow}$ *still requires recognized* NameCert *flow with source, pattern, classifier, stability, and ledger fields.*

9218.3 Nat-like skeleton

Definition 9218.9 (Nat-like skeleton)**.** *Lean4 (definition) BEDC.GroundCompiler.CaseStudies.NatLikeSkeleton*

A Nat-like skeleton *is an event flow*

$$S_{\mathrm{NatSkel}} = (0, 00, 000, \ldots, 0^k, 01),$$

whose initial segment is a finite repetition skeleton and whose final event 01 *is a candidate repeat-rule witness. Formally it remains just an event flow.*

Example 9218.10 (Nat-like skeleton code)**.** *For*

$$0 \mid 00 \mid 000 \mid 01,$$

the event encodings are

$$0 \mapsto 011, \quad 00 \mapsto 0011, \quad 000 \mapsto 00011, \quad 01 \mapsto 01011.$$

Thus the skeleton code is

$$01100110001101011.$$

Definition 9218.11 (Repeat-rule motif)**.** *Lean4 (definition) BEDC.GroundCompiler.CaseStudies.RepeatRuleMotif*

A repeat-rule motif *is a recognized structure consisting of finite repetition source plus repeat-rule witness. An explanatory shape is*

$$0 \mid 00 \mid 000 \mid 01,$$

where $0 \mid 00 \mid 000$ *is the finite repetition source and* 01 *is the repeat-rule witness candidate.*

Proposition 9218.12 (Nat-like skeleton extends finite repetition skeleton)**.** *Lean4✓ BEDC.GroundCompiler.CaseSt like extends repetition*

The Nat-like skeleton S_{NatSkel} *contains* $S_{\mathrm{rep}}^{(k)}$ *as a prefix subflow.*

Proof. By definition,

$$S_{\mathrm{NatSkel}} = (0, 00, \ldots, 0^k, 01).$$

Its first k repetition events are exactly

$$S_{\mathrm{rep}}^{(k)} = (0, 00, \ldots, 0^k).$$

□

Corollary 9218.13 (Nat-like and repetition skeletons share a prefix motif)**.** Lean4 ✓ BEDC.GroundCompiler.CaseSt repetition share prefix

If the finite repetition recognizer is certified, then the Nat-like skeleton and the finite repetition skeleton share the finite repetition motif.

Remark 9218.14 (Existing $\mathsf{Nat}^{\uparrow}$ and $\mathsf{AxisNat}^{\uparrow}$)**.** *In existing BEDC development,* $\mathsf{Nat}^{\uparrow}$ *can arise from unary repetition direction, while the Zeckendorf-axis reading can separately consider the* $\mathsf{b0}$ *direction as* $\mathsf{AxisNat}^{\uparrow}$*. This chapter does not identify them as the same object. It only records that, when both use finite repetition as source, their motif profiles share finite repetition or spine structure.*

9218.4 Add and fold skeletons

Definition 9218.15 (Add skeleton)**.** Lean4 (definition) BEDC.GroundCompiler.CaseStudies.AddSkeleton

The Add-like skeleton is

$$S_{\mathrm{AddSkel}} = (0, 00, 001).$$

The explanatory reading is starting unit, binary repetition or binary combination witness, and binary recursion witness. The event 001 *is not bare addition; it is an Add-style local witness candidate.*

Example 9218.16 (Add skeleton code)**.** *The event encodings are*

$$0 \mapsto 011, \qquad 00 \mapsto 0011, \qquad 001 \mapsto 001011.$$

Therefore

$$\mathsf{SkCode}(S_{\mathrm{AddSkel}}) = 0110011001011.$$

Definition 9218.17 (Fold or MulSeed skeleton)**.** Lean4 (definition) BEDC.GroundCompiler.CaseStudies.FoldSkelet

The fold-like or MulSeed-like skeleton is

$$S_{\mathrm{FoldSkel}} = (0, 00, 001, 0011, 0100).$$

The explanatory reading is starting unit, binary repetition, Add-style recursion witness, iterated-addition completion witness, and normal-address candidate.

Example 9218.18 (Fold or MulSeed skeleton code)**.** *The event encodings are*

$$0 \mapsto 011, \qquad 00 \mapsto 0011, \qquad 001 \mapsto 001011,$$
$$0011 \mapsto 00101011, \qquad 0100 \mapsto 0100011.$$

Thus

$$\mathsf{SkCode}(S_{\mathrm{FoldSkel}}) = 011001100101100101011010 0011.$$

Definition 9218.19 (Additive recursion motif). *Lean4 (definition)* `BEDC.GroundCompiler.CaseStudies.AdditiveRec`

An additive recursion motif *is a recognized event structure containing unit source, binary repetition witness, and binary recursion witness. An explanatory shape is*

$$0 \mid 00 \mid 001.$$

Definition 9218.20 (Fold completion motif). *Lean4 (definition)* `BEDC.GroundCompiler.CaseStudies.FoldCompletio`

A fold completion motif *is a recognized event structure containing additive recursion witness, raw iterated-addition completion witness, and normal fold address. An explanatory shape is*

$$001 \mid 0011 \mid 0100,$$

where $0011 \mid 0100$ *may be recognized as source-level carry or normalization ledger.*

Proposition 9218.21 (Fold skeleton extends Add skeleton). *Lean4 ✓* `BEDC.GroundCompiler.CaseStudies.fold skeleton extends add`

The fold skeleton S_{FoldSkel} *contains* S_{AddSkel} *as a prefix subflow.*

Proof. By definition,

$$S_{\mathrm{FoldSkel}} = (0, 00, 001, 0011, 0100).$$

Its first three events are $(0, 00, 001) = S_{\mathrm{AddSkel}}$. □

Corollary 9218.22 (Fold skeleton reuses Add skeleton). *Lean4 ✓* `BEDC.GroundCompiler.CaseStudies.fold reuses add`

At the motif-profile layer, the fold or MulSeed skeleton reuses the Add skeleton's additive recursion motif and adds fold completion or normalization motifs.

Theorem 9218.23 (Add and fold skeletons do not license $\mathsf{Add}^{\uparrow}$ or $\mathsf{Mul}^{\uparrow}$). *Lean4 ✓* `BEDC.GroundCompiler.CaseStud fold not license`

There exist Add-like and fold-like case-study readings whose flows are

$$S_{\mathrm{AddSkel}} \quad \textit{and} \quad S_{\mathrm{FoldSkel}},$$

with S_{AddSkel} *a prefix subflow of* S_{FoldSkel}*, while their case-study targets are distinct. Thus recognizing additive or fold motifs does not by itself license* $\mathsf{Add}^{\uparrow}$ *or* $\mathsf{Mul}^{\uparrow}$*.*

Proof. Add and fold skeletons are source-level motifs. The formal witness is the pair of case-study flows tagged by distinct Add-like and fold-like target readings, together with the prefix inclusion of S_{AddSkel} in S_{FoldSkel}. Derived interfaces such as $\mathsf{Add}^{\uparrow}$ and $\mathsf{Mul}^{\uparrow}$ require recognized $\mathsf{NameCert}$ flows; mature export further requires derivation-certificate and acceptance-gate flows. Motif recognition supplies none of these certificates. □

9218.5 List-like skeleton

Definition 9218.24 (List spine skeleton). *Lean4 (definition)* `BEDC.GroundCompiler.CaseStudies.ListSpineSkeleto`

Given a source event a*, define the list-spine skeleton*

$$S_{\mathrm{ListSkel}}(a, k) = (a, aa, aaa, \ldots, a^k).$$

Its explanatory reading is one-element spine, two-element spine, three-element spine, and so on. Formally this is a finite repetition motif over a*. If* $a = 0$*, then* $0 \mid 00 \mid 000$ *is also the minimal finite repetition skeleton.*

Definition 9218.25 (List constructor ledger motif). *Lean4 (definition)* `BEDC.GroundCompiler.CaseStudies.ListCon`

A list constructor ledger motif *is ledger structure over a finite spine motif recording nil or cons shape, length, payload source, payload classifier, and constructor decomposition. This motif is not provided by bare finite repetition; it must be recognized by a list recognizer flow.*

Proposition 9218.26 (List spine skeleton shares finite repetition with Nat-like skeleton). *Lean4✓* `BEDC.GroundCompiler.CaseStudies.list spine shares repetition with nat`

If $a = 0$, then

$$S_{\mathrm{ListSkel}}(0, k) = S^{(k)}_{\mathrm{rep}}.$$

Hence a List-like finite spine skeleton and a Nat-like finite repetition skeleton have the same raw finite repetition motif.

Proof. By definition,

$$S_{\mathrm{ListSkel}}(0, k) = (0, 00, \ldots, 0^k),$$

which is exactly $S^{(k)}_{\mathrm{rep}}$. □

Corollary 9218.27 ($\mathsf{List}^{\uparrow}$ is finite repetition plus constructor ledger). *Lean4✓* `BEDC.GroundCompiler.CaseStudies finite plus ledger`

If a list constructor ledger motif is recognized, then it contains a recognized reuse-spine motif and a nonempty ledger flow. When $\mathsf{List}^{\uparrow}$ *uses finite spine as source, its motif profile may share finite repetition structure with Nat-like skeletons, but it still needs constructor ledger, payload classifier, length ledger, and source-carrier certificate. Thus it is not* $\mathsf{Nat}^{\uparrow}$*; it is finite-spine motif plus list-specific ledger and classifier structure.*

Theorem 9218.28 (Same finite spine does not imply same object). *Lean4✓* `BEDC.GroundCompiler.CaseStudies.s finite spine not same object`

There exist two case-study readings whose event flows share the same finite spine motif, and even the same underlying finite-spine flow, while their case-study targets are distinct. Hence finite-spine sharing alone does not determine object identity.

Proof. The same finite spine motif can serve as Nat-like source, List-like spine, finite index carrier, matrix index carrier, or polynomial coefficient list. The formal witness is a pair of case-study flows with identical finite-spine event flow and distinct target tags. Object identity is determined by classifier, ledger, $\mathsf{NameCert}$, and derivation-certificate structure. Sharing finite spine records source-level motif overlap only. □

9218.6 Completion and FullAxis skeleton

Definition 9218.29 (Completion skeleton). *Lean4 (definition)* `BEDC.GroundCompiler.CaseStudies.CompletionSkele`

The Completion or $\mathsf{FullAxis}^{\uparrow}$*-like skeleton is*

$$S_{\mathrm{CompSkel}} = (0, 00, 000, 01, 011, 100).$$

The explanatory reading is starting unit, one repetition, two repetitions, repeat-boundary witness, repeat-to-completion or overflow witness, and normal-address candidate.

Example 9218.30 (Completion skeleton code). *The event encodings are*

$$0 \mapsto 011, \qquad 00 \mapsto 0011, \qquad 000 \mapsto 00011, \qquad 01 \mapsto 01011,$$
$$011 \mapsto 0101011, \qquad 100 \mapsto 100011.$$

Therefore

$$\mathsf{SkCode}(S_{\mathrm{CompSkel}}) = 011001100011010110101011100011.$$

Definition 9218.31 (Completion motif)**.** *Lean4 (definition)* `BEDC.GroundCompiler.CaseStudies.CompletionMotif`

A completion motif *is a recognized structure containing finite stages, repeat-boundary witness, seal or completion witness, normal-address witness, and tail ledger. The explanatory shape is*

$$0 \mid 00 \mid 000 \mid 01 \mid 011 \mid 100.$$

Proposition 9218.32 (Completion skeleton contains finite repetition motif)**.** *Lean4✓* `BEDC.GroundCompiler.Case` `skeleton contains repetition`

The completion skeleton contains $(0, 00, 000)$ *as a prefix subflow, and hence contains a finite repetition motif candidate.*

Proof. By definition,

$$S_{\mathrm{CompSkel}} = (0, 00, 000, 01, 011, 100).$$

Its first three events are $(0, 00, 000)$. □

Proposition 9218.33 (Completion skeleton contains carry ledger candidate)**.** *Lean4✓* `BEDC.GroundCompiler.Case` `skeleton contains carry`

The completion skeleton contains

$$011 \mid 100$$

as a source-level carry ledger candidate.

Proof. By definition, the last two events of S_{CompSkel} are $(011, 100)$. Hence the carry ledger candidate appears as a subflow. □

Corollary 9218.34 (Completion skeleton splits from Add and fold skeleton)**.** *Lean4✓* `BEDC.GroundCompiler.CaseS` `completion split`

The Add and fold skeleton

$$0 \mid 00 \mid 001 \mid 0011 \mid 0100$$

and the Completion skeleton

$$0 \mid 00 \mid 000 \mid 01 \mid 011 \mid 100$$

share the prefix $0 \mid 00$ *and then branch. The former turns toward additive recursion and fold; the latter turns toward repeat-boundary, seal, and carry.*

Theorem 9218.35 (Completion skeleton does not license $\mathsf{FullAxis}^{\uparrow}$)**.** *Even if* S_{CompSkel} *is recognized as a completion motif, one cannot infer* $\mathsf{FullAxis}^{\uparrow}$*.*

Proof. A completion motif supplies source-level event structure. The derived interface $\mathsf{FullAxis}^{\uparrow}$ requires recognized $\mathsf{NameCert}$ flow: finite-prefix source, compatible-thread pattern, prefix-compatible classifier, seal stability, and tail ledger. Motif recognition is not $\mathsf{NameCert}$ recognition. □

9218.7 Cross-theory comparison

Definition 9218.36 (Skeleton overlap). *Lean4 (definition)* `BEDC.GroundCompiler.CaseStudies.SkeletonOverlap`

For skeleton flows S and T, their raw prefix overlap is $\mathsf{PrefixLen}(S, T)$, *and their recognized motif overlap is*

$$\mathsf{Overlap}_{\mathcal{R}}(S, T),$$

the set of motif occurrences shared under recognizer family $\mathcal{R}$.

Proposition 9218.37 (Add and fold skeleton and Completion skeleton share finite source). *Lean4✓* `BEDC.GroundCompiler.CaseStudies.fold completion prefix`

Let

$$S_{\text{FoldSkel}} = (0, 00, 001, 0011, 0100)$$

and

$$S_{\text{CompSkel}} = (0, 00, 000, 01, 011, 100).$$

Then

$$\mathsf{PrefixLen}(S_{\text{FoldSkel}}, S_{\text{CompSkel}}) = 2.$$

Proof. The first two events in both flows are $0 \mid 00$. The third events are 001 and 000, respectively, so the longest common prefix has length 2. □

Corollary 9218.38 (Shared prefix indicates shared generative source). *Lean4✓* `BEDC.GroundCompiler.CaseStudie completion share starting prefix`

At the raw event-flow layer, the Add and fold skeleton and the Completion skeleton share the starting unit and one finite repetition. Their paths branch at the third event.

Proposition 9218.39 (Nat-like skeleton is a prefix of Completion skeleton). *Lean4✓* `BEDC.GroundCompiler.CaseS prefix completion`

Let

$$S_{\text{NatSkel}} = (0, 00, 000, 01)$$

and

$$S_{\text{CompSkel}} = (0, 00, 000, 01, 011, 100).$$

Then S_{NatSkel} is a prefix subflow of S_{CompSkel}.

Proof. The first four events of S_{CompSkel} are

$$(0, 00, 000, 01) = S_{\text{NatSkel}}.$$

□

Corollary 9218.40 (Completion skeleton extends Nat-like skeleton). *Lean4✓* `BEDC.GroundCompiler.CaseStudies extends nat like`

The Completion skeleton extends the Nat-like finite repetition and repeat-rule skeleton by adding

$$011 \mid 100,$$

the completion witness and normal-address candidate.

Theorem 9218.41 (Skeleton extension does not imply object extension). *Lean4✓ BEDC.GroundCompiler.CaseStud extension not object extension*

There exist two case-study skeleton readings whose event flows are related by prefix inclusion while their case-study targets are distinct. Hence raw skeleton extension alone does not determine inclusion, subobject, subtype, extension, or morphism between corresponding mature objects.

Proof. The Nat-like skeleton is a prefix of the Completion skeleton, but their target readings are distinct. The prefix relation is a raw event-flow relation. Mature-object relations require classifier, NameCert, derivation-certificate, bridge, or morphism certificates. Raw prefix structure supplies none of these. □

9218.8 Motif reports

Definition 9218.42 (Skeleton motif report). *Lean4 (definition) BEDC.GroundCompiler.CaseStudies.SkeletonMotifR*

For a skeleton flow S and recognizer family $\mathcal{R}$, define

$$\mathsf{SkReport}_{\mathcal{R}}(S)$$

to be the human-readable output view of its source flow, motif profile flow, support subflows, ledger subflows, and basic metrics. It is not formal input and not proof.

Example 9218.43 (Completion skeleton motif report). *For*

$$0 \mid 00 \mid 000 \mid 01 \mid 011 \mid 100,$$

a report may list finite repetition motif $0 \mid 00 \mid 000$*, repeat-rule motif* 01*, seal motif* 011*, carry motif* $011 \mid 100$*, raw prefix length of six events, seal depth one, carry index one, and a ledger warning that* $\mathsf{FullAxis}^{\uparrow}$ *is not licensed without* NameCert *flow.*

Example 9218.44 (Add and fold skeleton motif report). *For*

$$0 \mid 00 \mid 001 \mid 0011 \mid 0100,$$

a report may list finite source $0 \mid 00$*, additive recursion motif* 001*, fold completion motif* $0011 \mid 0100$*, seal-depth candidate one, carry-index candidate one, and a ledger warning that* $\mathsf{Add}^{\uparrow}$ *or* $\mathsf{Mul}^{\uparrow}$ *is not licensed without* NameCert *and derivation-certificate flows.*

Example 9218.45 (Nat-like versus List-like motif report). *If the Nat-like skeleton is* $0 \mid 00 \mid 000 \mid 01$ *and the List-like skeleton is* $0 \mid 00 \mid 000$*, a report may show shared finite repetition motif* $0 \mid 00 \mid 000$*, the Nat-like extra event* 01 *as repeat-rule witness, missing List-specific payload classifier, constructor-shape ledger, and length ledger, and the warning that the same finite spine does not imply the same object.*

Theorem 9218.46 (Skeleton motif reports are explanatory, not certificatory). *Lean4✓ BEDC.GroundCompiler.Cas reports not certificates*

There exists a skeleton motif report on a readable event-flow source whose reported source flow is not an accepted object flow. Hence the existence of a skeleton motif report alone does not license derived interfaces, theoremhood, accepted objects, or object equality.

Proof. Take the empty source-flow report. Its source flow is readable as an event flow, but it is not an accepted object flow because acceptance requires a nonempty accepted export together with recognized certificate structure. Motif reports are human-readable outputs generated from recognized motif profiles. They do not supply NameCert flow, derivation-certificate flow, proof flow, or acceptance-gate flow by themselves. They are explanatory tools, not certificates. □

Corollary 9218.47 (Skeleton comparison cannot replace proof)**.** `Lean4✓ BEDC.GroundCompiler.CaseStudies.comp not proof`

There exist two skeleton flows with shared raw prefix length 2 *that are not equal as event flows. Thus raw skeleton comparison alone cannot replace a proof of theorem equivalence, object equivalence, bridge, morphism, or certified reuse relation.*

9218.9 Conservativity

Theorem 9218.48 (Case-study analysis is conservative over the finite kernel)**.** `Lean4✓ BEDC.GroundCompiler.Case studies conservativity`

The concrete Add, fold, and Completion skeletons in this chapter use only display marks from the finite alphabet $\{\mathsf{b0}, \mathsf{b1}\}$*. Adding these case-study skeletons, motif reports, and cross-skeleton comparisons therefore does not add new raw marks, history constructors, sameness rules, continuation rules, derived-interface formation rules, or accepted-object export rules.*

Proof. All case-study skeletons are event flows over b0 and b1. Motif reports and comparisons are source-level analyses of event flows. They do not generate new b0 or b1, add msame, hsame, or psame rules, change Ext or Cont, license derived interfaces, or export accepted objects. Hence this analysis layer is conservative over the finite kernel. □

Remark 9218.49 (Outlook)**.** *This chapter gives the first concrete skeleton comparisons: finite repetition* 0 | 00 | 000*, Nat-like* 0 | 00 | 000 | 01*, Add* 0 | 00 | 001*, fold or MulSeed* 0 | 00 | 001 | 0011 | 0100*, and Completion or* $\mathsf{FullAxis}^{\uparrow}$ *skeleton* 0 | 00 | 000 | 01 | 011 | 100*. Their typical channel codes are* 011001100011*,* 01100110001101011*,* 0110011001011*,* 011001100101100101011010 0011*, and* 01100110001101011010101110001 1*. The analysis shows shared finite repetition prefixes, Add-to-fold extension, Nat-like-to-completion extension, and the split between fold and completion paths. It also records the limits: same finite spine does not imply same object, skeleton extension does not imply mature-object extension, motif reports are explanatory rather than certificates, and the case-study layer is conservative over the finite kernel. The next chapter defines theory-distance invariants such as prefix profile, seal depth, carry index, ledger depth, classifier compression ratio, reuse depth, and normal-address distance.*

Chapter 9219

Theory Metrics and Flow Invariants

chapter 9218 compares finite repetition, Nat-like, Add, fold, and Completion skeletons. It shows that skeletons can share low-level motifs without implying object equality, theorem equivalence, or mature export. This chapter defines a group of theory metrics for comparing event flows by their recognized structures.

The metrics include prefix profile, motif profile, seal depth, carry index, ledger depth, classifier compression ratio, reuse depth, normal-address distance, and theory-flow distance. These are not proof, NameCert, derivation certificate, or acceptance gate. They are statistics and comparisons over decoded source event flows, recognized motifs, recognized ledgers, recognized classifiers, normal-address records, and reuse structures.

The governing rule is

metrics are computed only from recognized event-flow structure, never from channel substrings or external label

9219.1 Admissible metric data

Definition 9219.1 (Metric recognizer family)**.** Lean4 (definition) `BEDC.GroundCompiler.MetricsFlow.MetricRecogn`

A metric recognizer family *is a finite family of generated recognizer flows*

$$\mathcal{R} = (R_1, \ldots, R_k),$$

where each R_i is certified for some structure used by the metric, such as finite repetition, continuation, seal, carry, ledger, classifier, reuse, bridge, theorem-flow, or chapter-flow recognition. The family $\mathcal{R}$ is not an external metric table. It is represented by event-flow structure and supported by recognizer certificates.

Definition 9219.2 (Metric admissibility)**.** Lean4 (definition) `BEDC.GroundCompiler.MetricsFlow.MetricAdmissible`

A metric specification records a finite list of data sources. A metric M is admissible *for a recognizer family $\mathcal{R}$ when every recorded source for $M(S)$ is one of:*

1. *the decoded source event flow S;*
2. *motif occurrences recognized by $\mathcal{R}$;*
3. *ledger flows recognized by $\mathcal{R}$;*
4. *classifier flows recognized by $\mathcal{R}$;*
5. *reuse flows recognized by $\mathcal{R}$;*

6. *normal-address flows recognized by $\mathcal{R}$;*

7. *the associated failure-flow and cannot-claim-flow data.*

It may not depend on channel-substring search, external object names, YAML fields, host ASTs, theorem labels, human chapter titles, external semantic categories, or unrecorded classifier judgments.

Principle 9219.3 (No external metric input)**.** Lean4 ✓ `BEDC.GroundCompiler.MetricsFlow.no external metric input`

Every theory metric must be event-flow-derived. A metric depending on external object names, host tags, YAML fields, manual theorem grouping, or unrecognized semantic labels is not a BEDC-admissible metric.

9219.2 Prefix profiles

Definition 9219.4 (Raw prefix profile)**.** Lean4 (definition) `BEDC.GroundCompiler.MetricsFlow.RawPrefixProfile`

For an event flow

$$S = (w_0, \ldots, w_{n-1}),$$

define its raw prefix profile *by*

$$\mathsf{RawPrefix}(S) = \{\, (w_0, \ldots, w_i) \mid 0 \le i < n \,\}.$$

For the empty event flow, set $\mathsf{RawPrefix}(S) = \{\epsilon\}$*. The raw prefix profile records source-level event prefixes but no semantic role.*

Definition 9219.5 (Recognized prefix profile)**.** Lean4 (definition) `BEDC.GroundCompiler.MetricsFlow.RecognizedPr`

Given a recognizer family $\mathcal{R}$, define $\mathsf{Prefix}_{\mathcal{R}}(S)$ *to be the set of all triples (P, μ, L) such that P is a raw prefix of S, P is recognized by some $R \in \mathcal{R}$ as motif role μ, and L is its motif ledger:*

$$(P, \mu, L) \in \mathsf{Prefix}_{\mathcal{R}}(S)$$

iff there exists $R \in \mathcal{R}$ with

$$\mathsf{RecognizesMotif}(R, S, P, \mu) \quad \textit{and} \quad \mathsf{MotifLedger}_R(S, P, \mu, L).$$

Remark 9219.6 (Raw prefix and semantic prefix differ)**.** *Two event flows can share a raw prefix without sharing a recognized prefix profile. For instance,* 01 *may be recognized in one flow as a repeat-boundary witness and in another as a branch separator. Different recognized roles or ledgers mean different semantic prefixes.*

Definition 9219.7 (Prefix-overlap length)**.** Lean4 (definition) `BEDC.GroundCompiler.MetricsFlow.RawPrefixOverla`

For event flows S and T, define $\mathsf{RawPrefixLen}(S, T)$ *as the largest k such that*

$$S[0:k] = T[0:k].$$

Define recognized prefix overlap by

$$\mathsf{PrefixOverlap}_{\mathcal{R}}(S, T) = \mathsf{Prefix}_{\mathcal{R}}(S) \cap \mathsf{Prefix}_{\mathcal{R}}(T),$$

where intersection is computed by recognized role, support subflow shape, and ledger-compatible equivalence, not by bare event strings alone.

Proposition 9219.8 (Raw prefix overlap is weaker than recognized prefix overlap). *Lean4 ✓ BEDC.GroundCompiler.MetricsFlow.raw prefix weaker*

If $\mathsf{PrefixOverlap}_{\mathcal{R}}(S,T) \neq \emptyset$*, then* S *and* T *share a raw prefix support. Conversely, shared raw prefix support need not imply recognized prefix overlap.*

Proof. A recognized prefix overlap includes a recognized motif support, so its support is a raw prefix of both flows. The converse fails because a shared raw prefix may be recognized under different roles, have incompatible ledgers, or fail to be recognized in one of the two flows. □

9219.3 Motif profiles and counts

Definition 9219.9 (Motif profile). *Lean4 (definition) BEDC.GroundCompiler.MetricsFlow.MotifProfile*

For a recognizer family $\mathcal{R}$*, define the motif profile of an event flow* S *as a finite list of recognized occurrence records satisfying*

$$(\mu, M, L, R) \in \mathsf{MotifProfile}_{\mathcal{R}}(S) \Longrightarrow R \in \mathcal{R},\ M \subseteq S,\ \mathsf{RecognizesMotif}(R, S, M, \mu) \wedge \mathsf{MotifLedger}_R(S, M, \mu, L).$$

Here μ *is the motif role,* M *the support subflow,* L *the motif ledger, and* R *the generated recognizer supplying the occurrence.*

Definition 9219.10 (Motif multiplicity). *Lean4 (definition) BEDC.GroundCompiler.MetricsFlow.MotifMultiplicity*

For a finite motif profile list P*, the multiplicity of motif role* μ *is*

$$\mathsf{Mult}(P, \mu) = \#\{\, (\mu', M, L, R) \in P \mid \mu' = \mu \,\}.$$

This chapter considers finite chapter, theorem, and package event flows.

Definition 9219.11 (Seal depth). *Lean4 (definition) BEDC.GroundCompiler.MetricsFlow.SealDepth*

The seal depth *of* S *is*

$$\mathsf{SealDepth}_{\mathcal{R}}(S) = \mathsf{Mult}_{\mathcal{R}}(S, \mu_{\text{seal}}),$$

where μ_{seal} *is the recognized event-flow role for seal motifs.*

Definition 9219.12 (Carry index). *Lean4 (definition) BEDC.GroundCompiler.MetricsFlow.CarryIndex*

The carry index *of* S *is*

$$\mathsf{CarryIndex}_{\mathcal{R}}(S) = \mathsf{Mult}_{\mathcal{R}}(S, \mu_{\text{carry}}),$$

where μ_{carry} *is the recognized carry motif role. A recognized occurrence* $011 \mid 100$ *contributes at least one carry occurrence.*

Definition 9219.13 (Ledger depth). *Lean4 (definition) BEDC.GroundCompiler.MetricsFlow.LedgerDepth*

The ledger depth $\mathsf{LedgerDepth}_{\mathcal{R}}(S)$ *is the maximum dependency nesting depth among recognized ledger flows in* S*. A ledger that references no other ledger has depth* 1*. If a ledger* L *references ledgers* $L_1, \ldots, L_k$*, then*

$$\operatorname{depth}(L) = 1 + \max_i \operatorname{depth}(L_i).$$

If no ledger flow is recognized in S*, the ledger depth is* 0*.*

Definition 9219.14 (Classifier compression ratio). *Lean4 (definition)* `BEDC.GroundCompiler.MetricsFlow.Compress`

If $\mathcal{R}$ recognizes a classifier quotient in S that sends k raw support flows $M_1, \ldots, M_k$ into r recognized classifier classes with $r > 0$, define

$$\mathsf{CompressionRatio}_{\mathcal{R}}(S) = \frac{k}{r}.$$

This metric is defined only when classifier recognition, ledger recognition, and exactness recognition are all supplied.

Remark 9219.15 (Compression ratio is not equality strength). *The compression ratio measures how strongly raw flows are grouped by a classifier. It does not express kernel equality or theorem equivalence. If several raw flows are compressed into one classifier class, the ledger must retain the raw supports.*

Definition 9219.16 (Reuse depth). *Lean4 (definition)* `BEDC.GroundCompiler.MetricsFlow.ReuseDepth`

The reuse depth $\mathsf{ReuseDepth}_{\mathcal{R}}(S)$ *is the length of the longest dependency chain of recognized reuse motifs in S. If no reuse motif is recognized, the reuse depth is* 0.

Definition 9219.17 (Bridge depth). *Lean4 (definition)* `BEDC.GroundCompiler.MetricsFlow.BridgeDepth`

If S contains recognized bridge motifs, its bridge depth $\mathsf{BridgeDepth}_{\mathcal{R}}(S)$ *is the maximum bridge-chain length from BEDC source flow to standard-side target flow. If no bridge motif is recognized, the bridge depth is* 0.

9219.4 Normal addresses and distances

Definition 9219.18 (Normal-address map). *Lean4 (definition)* `BEDC.GroundCompiler.MetricsFlow.NormalAddressM`

Given a source-level normalizer recognizer in $\mathcal{R}$, if S contains a ledger-preserving normalization

$$w \rightsquigarrow v,$$

then the normal-address record is

$$(w, v, L_{w \to v}),$$

where $L_{w \to v}$ is the normalization ledger. The normal-address map $\mathsf{NormAddr}_{\mathcal{R}}(S)$ is the set of all such records.

Definition 9219.19 (Normal-address distance). *Lean4 (definition)* `BEDC.GroundCompiler.MetricsFlow.NormalAddre`

For event flows S and T, define a normal-address distance by

$$\mathsf{NormDist}_{\mathcal{R}}(S, T) = 1 - \frac{|\mathsf{NormAddr}_{\mathcal{R}}(S) \cap \mathsf{NormAddr}_{\mathcal{R}}(T)|}{|\mathsf{NormAddr}_{\mathcal{R}}(S) \cup \mathsf{NormAddr}_{\mathcal{R}}(T)|}.$$

If the denominator is zero, the distance is either undefined or set to 0, *according to the chosen analysis protocol.*

Definition 9219.20 (Motif Jaccard distance). *Lean4 (definition)* `BEDC.GroundCompiler.MetricsFlow.MotifJaccardI`

The motif Jaccard distance is

$$\mathsf{MotifDist}_{\mathcal{R}}(S, T) = 1 - \frac{|\mathsf{MotifProfile}_{\mathcal{R}}(S) \cap \mathsf{MotifProfile}_{\mathcal{R}}(T)|}{|\mathsf{MotifProfile}_{\mathcal{R}}(S) \cup \mathsf{MotifProfile}_{\mathcal{R}}(T)|}.$$

Intersections and unions are computed by motif role, support shape, and ledger-compatible equivalence, not by raw strings.

Definition 9219.21 (Flow signature vector). *Lean4 (definition)* `BEDC.GroundCompiler.MetricsFlow.FlowSignature`

Given $\mathcal{R}$, define the flow signature vector *of S by*

$$\mathsf{Sig}_{\mathcal{R}}(S) = (\mathsf{SealDepth}, \mathsf{CarryIndex}, \mathsf{LedgerDepth}, \mathsf{CompressionRatio}, \mathsf{ReuseDepth}, \mathsf{BridgeDepth})_S,$$

with all components computed relative to $\mathcal{R}$.

Remark 9219.22 (Signature vector is not object identity). *Equal signature vectors do not imply that two event flows represent the same theory, theorem, object, or classifier class. A signature vector is an analysis summary, not an identity certificate.*

Theorem 9219.23 (Metrics are channel-roundtrip invariant). *Lean4 ✓* `BEDC.GroundCompiler.MetricsFlow.metric` `channel roundtrip invariant`

If $c = \mathsf{Compile}(S)$, then for every admissible metric M,

$$M(S) = M(\mathsf{Decode}(c)).$$

Proof. By channel round trip, $\mathsf{Decode}(\mathsf{Compile}(S)) = S$, so $\mathsf{Decode}(c) = S$. An admissible metric depends only on decoded event flow and recognized structure. Therefore it has the same value on S and on $\mathsf{Decode}(c)$. □

Corollary 9219.24 (Metrics may be computed from code after decoding). *Lean4 ✓* `BEDC.GroundCompiler.Metrics` `computed from decoded code`

If $c \in \mathsf{LegalZStream}$, one may first compute $S = \mathsf{Decode}(c)$ and then compute any admissible metric $M(S)$. This agrees with computing the metric on the original event flow.

Proposition 9219.25 (Channel substring metrics are inadmissible). *Lean4 ✓* `BEDC.GroundCompiler.MetricsFlow.` `substring metrics inadmissible`

Any metric that directly counts channel substrings such as 011, 100, *or* 11 *is inadmissible unless it first decodes the channel stream and turns the result into source-level event-flow recognition.*

Proof. Definition 9209.27 proves that channel substrings are not source events. A metric that counts channel substrings can confuse event terminators, raw-event encodings, and source-level event shapes. Such a metric depends on the wrong layer and violates Definition 9219.2. □

9219.5 Theory-flow distance and reports

Definition 9219.26 (Theory-flow distance). *Lean4 (definition)* `BEDC.GroundCompiler.MetricsFlow.TheoryFlowDist`

For recognized theory flows S and T, an optional theory-flow distance *is a weighted combination*

$$\begin{aligned}\mathsf{TheoryDist}_{\mathcal{R}}(S,T) = {} & \alpha_1 \mathsf{MotifDist}_{\mathcal{R}}(S,T) + \alpha_2 \mathsf{NormDist}_{\mathcal{R}}(S,T) \\ & + \alpha_3 d_{\text{prefix}}(S,T) + \alpha_4 d_{\text{ledger}}(S,T) + \alpha_5 d_{\text{reuse}}(S,T).\end{aligned}$$

The weights $\alpha_i \geq 0$ must be supplied by an analysis protocol flow, not hidden as external parameters.

Remark 9219.27 (Metric weights must be explicit). *If a weighted distance is used, the weights must be recorded in an analysis-protocol event flow. Otherwise the metric result contains hidden input.*

Definition 9219.28 (Analysis protocol flow). *Lean4 (definition)* `BEDC.GroundCompiler.MetricsFlow.AnalysisProto`

An analysis protocol flow *is an event flow P recording the chosen recognizer family, chosen metrics, metric weights, comparison domain, failure cases, ledger requirements, normalization policy, and report format. Without such a protocol, no distance or similarity is canonical.*

Theorem 9219.29 (Theory-flow distance is protocol-relative). Lean4 ✓ BEDC.GroundCompiler.MetricsFlow.theor distance protocol relative

The distance

$$\mathsf{TheoryDist}_{\mathcal{R},P}(S,T)$$

depends on recognizer family $\mathcal{R}$ and analysis protocol flow P. There is no unconditional absolute theory distance unless canonical recognizers and a canonical analysis protocol are supplied.

Proof. Theory-flow distance uses recognizer family, metric selection, weights, normalization policy, and ledger policy. These are specified by $\mathcal{R}$ and P. Changing either can change which motifs, normal addresses, ledger depths, and weights are available. Hence the distance is protocol-relative. □

Corollary 9219.30 (Similarity claims require analysis protocol). *A claim that two theories are similar, closer, or share more structure must supply an analysis protocol flow P and recognizer family $\mathcal{R}$. Without them the claim is informal intuition, not a BEDC-admissible metric claim.*

Definition 9219.31 (Metric report). Lean4 (definition) BEDC.GroundCompiler.MetricsFlow.MetricReport

A metric report *is an output view generated from an analysis protocol flow P, recognizer family $\mathcal{R}$, and one or more event flows. It records computed metrics, recognized motifs, normal-address records, ledger depth, classifier compression, reuse depth, bridge depth, warnings, and cannot-claim entries. It is not input, proof, or certificate.*

Principle 9219.32 (Metric reports are not evidence of theoremhood). Lean4 ✓ BEDC.GroundCompiler.MetricsFlow reports not theoremhood

A metric report does not prove theoremhood, object identity, mature export, bridge correctness, or classifier exactness. It records recognized analysis results only.

Theorem 9219.33 (Metrics do not imply object equality). Lean4 ✓ BEDC.GroundCompiler.MetricsFlow.metrics do not imply object equality

Even if

$$\mathsf{Sig}_{\mathcal{R}}(S) = \mathsf{Sig}_{\mathcal{R}}(T)$$

or

$$\mathsf{TheoryDist}_{\mathcal{R},P}(S,T) = 0,$$

one cannot conclude that S and T represent the same accepted object, theorem, chapter, or classified object unless an additional classifier, exactness, or bridge certificate is supplied. In particular, the empty admissible analysis assigns the same zero signature to distinct event flows, so equality of metric signatures does not even determine equality of the underlying event-flow datum.

Proof. Metrics are summaries or distances over recognized motifs and ledgers. Object equality and theorem equivalence require classifier or proof-level exactness. Equal metrics can occur for distinct flows with the same structural counts. Even distance zero relative to a protocol means only indistinguishability by that protocol, not equality in all recognized structures. Equality or equivalence therefore requires a separate certificate. □

Corollary 9219.34 (Metrics are explanatory, not identificatory). Lean4 ✓ BEDC.GroundCompiler.MetricsFlow.met explanatory not identificatory

Metric analysis can explain structural similarity, but it cannot identify objects without additional classifier or bridge flow.

9219.6 Examples and cannot-claims

Example 9219.35 (Metrics for Completion skeleton)**.** *Let*

$$S_{\mathrm{Comp}} = 0 \mid 00 \mid 000 \mid 01 \mid 011 \mid 100.$$

If the recognizer family identifies finite repetition $0 \mid 00 \mid 000$*, seal* 011*, and carry* $011 \mid 100$*, then the report may record*

$$\mathsf{SealDepth}(S_{\mathrm{Comp}}) = 1, \qquad \mathsf{CarryIndex}(S_{\mathrm{Comp}}) = 1, \qquad \mathsf{LedgerDepth}(S_{\mathrm{Comp}}) \geq 1.$$

If no recognized ledger flow is present, the carry index should not be treated as admissible, because carry motifs require ledger support.

Example 9219.36 (Metrics for Add and fold skeleton)**.** *Let*

$$S_{\mathrm{Fold}} = 0 \mid 00 \mid 001 \mid 0011 \mid 0100.$$

If additive recursion 001 *and fold completion* $0011 \mid 0100$ *are recognized, then a report may record a seal-depth candidate, carry-index candidate, and reuse depth* 1 *if* 001 *is recognized as reused by* 0011*. Whether* $\mathsf{Add}^{\uparrow}$ *or* $\mathsf{Mul}^{\uparrow}$ *is licensed still depends on* $\mathsf{NameCert}$ *and derivation-certificate flows.*

Example 9219.37 (Prefix comparison: Fold versus Completion)**.** *For*

$$S_{\mathrm{Fold}} = (0, 00, 001, 0011, 0100), \qquad S_{\mathrm{Comp}} = (0, 00, 000, 01, 011, 100),$$

the raw prefix overlap is $0 \mid 00$*, so*

$$\mathsf{RawPrefixLen}(S_{\mathrm{Fold}}, S_{\mathrm{Comp}}) = 2.$$

The recognized interpretation is that both share finite-source prefix, then the fold skeleton branches into additive recursion while the completion skeleton branches into repeat-boundary, seal, and carry. This is motif-level explanation, not a theorem of object relation.

Example 9219.38 (Nat-like versus Completion)**.** *For*

$$S_{\mathrm{Nat}} = (0, 00, 000, 01), \qquad S_{\mathrm{Comp}} = (0, 00, 000, 01, 011, 100),$$

S_{Nat} *is a raw prefix of* S_{Comp}*. A metric report may say that the Completion skeleton extends the Nat-like skeleton by* $011 \mid 100$*, but it may not say that the Completion object extends the Nat object without a bridge or object-level certificate.*

Definition 9219.39 (Metric cannot-claim entries)**.** *Lean4 (definition)* `BEDC.GroundCompiler.MetricsFlow.MetricCa`

A metric report must include cannot-claim entries for claims not supported by the metrics. Examples include:

- *same motif profile implies same theorem;*
- *same signature vector implies same object;*
- *shared prefix implies subobject;*
- *positive carry index implies dimension exists;*
- *positive seal depth implies real completion exists;*

- *compression ratio greater than one implies quotient exactness.*

These entries prevent metric analysis from being misread as proof.

Proposition 9219.40 (Cannot-claim entries are required for nontrivial reports)**.** Lean4✓ BEDC.GroundCompiler.M
claims required for nontrivial reports

A BEDC metric report satisfying the cannot-claim guard and involving seal, carry, classifier, bridge, or reuse motifs includes cannot-claim entries specifying what is not established by the report.

Proof. Seal, carry, classifier, bridge, and reuse motifs are easily confused with mature-object claims such as completion, equality, quotient exactness, standard bridge, or object construction. Metrics do not supply NameCert, derivation certificate, proof, or exactness by themselves. A report without cannot-claim entries can therefore overstate its results. Nontrivial reports must record these limits. □

9219.7 Conservativity

Theorem 9219.41 (Metric analysis is conservative over the finite kernel)**.** Lean4✓ BEDC.GroundCompiler.MetricsI
conservativity

Adding admissible metrics, metric reports, flow distances, signature vectors, and motif profiles does not add new raw marks, history constructors, sameness rules, continuation rules, or derived-interface formation rules.

Proof. All metrics are computed from decoded event flows and recognized motifs. They do not generate new b0 or b1, add msame, hsame, or psame rules, change Ext or Cont, or license derived interfaces. They summarize recognized structures only. Therefore metric analysis is conservative over the finite kernel. □

Corollary 9219.42 (Metrics cannot replace certificates or gates)**.** Lean4✓ BEDC.GroundCompiler.MetricsFlow.met
cannot replace certificates

No metric, distance, profile, or report can replace recognized NameCert *flow, derivation-certificate flow, proof flow, or acceptance-gate flow.*

Remark 9219.43 (Outlook)**.** *This chapter establishes the no-hidden-input version of theory metrics: metrics are computed only from decoded event flows and generated recognizers. It defines metric recognizer families, admissibility, raw and recognized prefix profiles, prefix overlap, motif profiles, motif multiplicity, seal depth, carry index, ledger depth, classifier compression ratio, reuse depth, bridge depth, normal-address maps and distances, motif Jaccard distance, flow signature vectors, theory-flow distance, analysis protocol flows, metric reports, and metric cannot-claim entries. It proves that recognized prefix overlap is stronger than raw prefix overlap, metrics are invariant under compile-decode round trip, channel substring metrics are inadmissible, theory-flow distance is protocol-relative, similarity claims require protocol data, metrics do not imply object equality, metric reports are explanatory rather than proof, nontrivial reports require cannot-claim entries, metric analysis is conservative over the finite kernel, and metrics cannot replace certificates or acceptance gates. The next chapter applies these indicators to higher-level objects such as* $\mathsf{Real}^{\uparrow}$*, topology, circle and phase structure,* $\mathsf{Complex}^{\uparrow}$*, functors, and homology.*

Chapter 9220

Higher-Layer Case Studies: Completion, Real, Topology, Geometry, Category, and Homology

chapter 9219 defines theory metrics on event flows: prefix profile, motif profile, seal depth, carry index, ledger depth, classifier compression ratio, reuse depth, bridge depth, normal-address distance, and theory-flow distance. Those metrics are explanatory analysis tools, not proof, NameCert, derivation certificate, or acceptance gate.

This chapter applies those indicators to higher-layer object routes: completion, real-number structure, metric structure, topology, circle or phase structure, complex-number structure, functors, and homology. The purpose is not to prove that these mature objects have been accepted. It is to show how traditionally different theories can share low-level event motifs such as finite approximation, compatible thread, seal, tail ledger, classifier quotient, reuse, carry or lift, bridge, composition, and boundary-square-zero.

The governing rule is

high-layer objects are not event codes; they are recognized structures after certificates, classifiers, ledgers, and ga

All case studies in this chapter say only that certain high-layer theories exhibit certain event-flow motifs. They do not imply mature export, object equality, completed bridge, or high-level theoremhood.

9220.1 Higher-layer case-study flows

Definition 9220.1 (Higher-layer case-study flow)**.** *Lean4 (definition)* `BEDC.GroundCompiler.CaseStudies.HigherLay`

A higher-layer case-study flow *is an event flow*

$$S \in \mathsf{EventFlow}$$

whose motif profile, under some recognizer family $\mathcal{R}$, contains at least one high-layer motif such as completion, metric, topology, phase, circle, complex, category, functor, homology, bridge, or analysis. The high-layer reading is not an external label; it is determined by motif roles and ledger structures recognized in S.

Definition 9220.2 (Higher-layer motif bundle)**.** *Lean4 (definition)* `BEDC.GroundCompiler.CaseStudies.HighMotifBu`

For an event flow S and recognizer family $\mathcal{R}$, define

$$\mathsf{HighMotif}_{\mathcal{R}}(S)$$

as the subcollection of $\mathsf{MotifProfile}_{\mathcal{R}}(S)$ *whose records are recognized as higher-layer roles: completion, metric, topology, phase, circle, complex, category, functor, homology, bridge, or analysis. These role names are explanatory; formally they are recognized motif role flows.*

Remark 9220.3 (Higher-layer motif bundles are not mature export)**.** *The bundle* $\mathsf{HighMotif}_{\mathcal{R}}(S)$ *is a collection of recognized motifs. It is not* $\mathrm{AcceptGate}(N, s)$ *and cannot automatically promote* S *to* $\mathsf{Real}^{\uparrow}$, $\mathsf{Topology}^{\uparrow}$, *circle structure,* $\mathsf{Complex}^{\uparrow}$, *or homology.*

9220.2 Completion and Real-like flows

Definition 9220.4 (Completion skeleton flow)**.** *Lean4 (definition)* `BEDC.GroundCompiler.CaseStudies.CompletionSk`

A completion skeleton flow *contains recognized finite-stage flow, compatible-thread flow, tail-classifier flow, seal witness flow, tail-ledger flow, and normal-address flow. An explanatory shape is*

$$0 \mid 00 \mid 000 \mid 01 \mid 011 \mid 100,$$

where the initial segment records finite stages, 01 *is a thread witness,* 011 *is a seal or completion witness, and* 100 *is a normal address. This shape does not by itself constitute* $\mathsf{Completion}^{\uparrow}$.

Definition 9220.5 (Completion motif record)**.** *Lean4 (definition)* `BEDC.GroundCompiler.CaseStudies.CompletionMo`

A completion motif record *is a tuple*

$$(M_{\text{stage}}, M_{\text{thread}}, M_{\text{classifier}}, M_{\text{seal}}, M_{\text{ledger}})$$

where the entries are finite-stage support flow, compatible-thread support flow, tail or equivalence classifier flow, seal witness flow, and tail ledger flow. The tuple must be recognized by a generated completion recognizer.

Proposition 9220.6 (Completion skeleton is seal-heavy)**.** *Lean4 ✓* `BEDC.GroundCompiler.CaseStudies.completion skeleton seal heavy`

If an event flow S contains a recognized completion motif record

$$(M_{\text{stage}}, M_{\text{thread}}, M_{\text{classifier}}, M_{\text{seal}}, M_{\text{ledger}}),$$

then M_{seal} is a nonempty recognized seal subflow of S. In the metric language of chapter 9219, this witnesses

$$\mathsf{SealDepth}_{\mathcal{R}}(S) \geq 1.$$

Proof. A completion motif record contains a seal witness flow M_{seal}. If that witness is recognized as a seal motif by $\mathcal{R}$, then the seal depth counts at least that occurrence. □

Proposition 9220.7 (Completion skeleton is ledger-dependent)**.** *Lean4 ✓* `BEDC.GroundCompiler.CaseStudies.comp skeleton ledger dependent`

If a candidate completion motif record in S has no nonempty tail ledger flow M_{ledger}, then it is not admissible as a recognized completion motif record.

Proof. Completion hides or compresses an infinite-looking compatible thread into a named or sealed interface. Without a ledger, the finite stages and their provenance cannot be recovered. BEDC ledger discipline requires hidden material to remain traceable. Hence a completion motif without tail ledger is inadmissible. □

Corollary 9220.8 (Seal event alone is not completion). Lean4 ✓ `BEDC.GroundCompiler.CaseStudies.seal event alone not completion`

A single event such as 011*, even when recognized as a seal witness, does not constitute completion. It must appear with finite-stage source, compatible-thread pattern, tail classifier, seal stability, and tail ledger.*

Definition 9220.9 (Real-like event flow). Lean4 (definition) `BEDC.GroundCompiler.CaseStudies.RealLikeEventFlou`

A Real-like event flow *is a completion skeleton enriched by rational or dyadic approximation source motif, Cauchy or regularity classifier motif, operation descent motif, order or metric compatibility motif, completion seal motif, and real-ledger motif. Thus it is finite approximation plus classifier, completion, operation descent, and order or metric ledger.*

Definition 9220.10 (Real motif bundle). Lean4 (definition) `BEDC.GroundCompiler.CaseStudies.RealMotifBundle`

Define $\mathsf{RealMotif}_{\mathcal{R}}(S)$ *as the collection of recognized approximation-source, Cauchy-classifier, completion-seal, operation-descent, order-compatibility, metric-compatibility, and real-ledger records in* S*. If these records are not all present,* S *is only a partial Real-like flow, not a complete* $\mathsf{Real}^{\uparrow}$ *certificate flow.*

Proposition 9220.11 (Real-like flow extends completion flow). Lean4 ✓ `BEDC.GroundCompiler.CaseStudies.real like extends completion`

If S *is a complete Real-like flow, then* S *contains a recognized completion motif.*

Proof. By Definition 9220.9, a Real-like flow contains completion seal and completion classifier structure. These are components of a recognized completion motif. □

Corollary 9220.12 (Completion is necessary but not sufficient for $\mathsf{Real}^{\uparrow}$). Lean4 ✓ `BEDC.GroundCompiler.CaseStu necessary not sufficient real`

Completion motif is a necessary part of Real-like structure, but it is not sufficient. $\mathsf{Real}^{\uparrow}$ *also requires approximation source, Cauchy or regularity classifier, operation descent, order and metric compatibility, and ledger.*

Theorem 9220.13 (Real-like motif profile does not export $\mathsf{Real}^{\uparrow}$). *If the motif profile of* S *contains Real-like motifs, one still cannot infer that* $\mathsf{Real}^{\uparrow}$ *has been exported.*

Proof. Motif profile records structural motifs only. Exporting $\mathsf{Real}^{\uparrow}$ requires recognized NameCert and derivation-certificate flows, including exactness, classifier, ledger, stability, and strength. The motif profile does not supply those certificates. □

9220.3 Metric and topology flows

Definition 9220.14 (Metric motif). Lean4 (definition) `BEDC.GroundCompiler.CaseStudies.MetricMotif`

A metric motif *is a recognized event structure containing carrier flow, distance-value flow, nonnegativity witness flow, symmetry witness flow, triangle witness flow, zero-exactness classifier flow, and metric ledger flow. It is only a source-level component of a possible* $\mathsf{Met}^{\uparrow}$ *certificate.*

Definition 9220.15 (Topology motif). *Lean4 (definition)* `BEDC.GroundCompiler.CaseStudies.TopologyMotif`

A topology motif *is a recognized event structure containing open or neighborhood source flow, finite-intersection stability flow, arbitrary-union or generated-union schema flow, continuity classifier flow, local ledger flow, and topology seal flow. If it contains only finite intersections and lacks union, basis, or generated-topology ledger, it is a partial topology motif.*

Definition 9220.16 (Neighborhood-basis motif). *Lean4 (definition)* `BEDC.GroundCompiler.CaseStudies.Neighborho`

A neighborhood-basis motif *is a weaker topology motif containing point flow, neighborhood candidate flow, refinement witness flow, intersection witness flow, and local ledger flow. It can serve as source for a topology construction, but it does not by itself give a full topology.*

Proposition 9220.17 (Metric motif generates topology-like motif only with certificate). *Lean4* ✓ `BEDC.GroundCompiler.CaseStudies.metric to topology needs cert`

A metric motif in S does not by itself imply a topology motif. An additional recognized flow is needed to prove that metric balls or neighborhoods generate a topology basis and to carry the basis ledger.

Proof. Metric motif supplies distance structure. Topology motif requires open or neighborhood closure behavior, finite intersection, union or generated-basis schema, and continuity classifier. These are not supplied by distance structure alone. They require a recognized construction certificate from metric balls to topology basis. □

Corollary 9220.18 (Metric does not automatically imply topology at raw motif layer). *Lean4* ✓ `BEDC.GroundCompiler.CaseStudies.metric not automatic topology`

Metric-like and topology-like event structures are related but not identical at the raw motif layer. The passage from one to the other requires bridge or certificate flow.

Definition 9220.19 (Topological classifier compression ratio). *Lean4 (definition)* `BEDC.GroundCompiler.CaseStudie`

If a topology flow uses an open-set or neighborhood classifier to group raw local flows into equivalent local neighborhoods, define

$$\mathsf{TopoCompression}_{\mathcal{R}}(S) = \mathsf{CompressionRatio}_{\mathcal{R}}(S)$$

restricted to topology classifier motifs.

Theorem 9220.20 (Topology motif does not prove continuity theorems). *Lean4* ✓ `BEDC.GroundCompiler.CaseStud` `motif not continuity`

There exists an event flow S that contains the topology source, finite-intersection, generated-union, continuity-classifier, basis-ledger, and topology-seal subflows of a topology motif, but contains no continuity proof-flow. Hence a topology motif alone does not prove any continuity theorem.

Proof. Take the canonical topology motif skeleton consisting exactly of the six topology-support subflows. It has the topology motif components, but no event subflow carrying a continuity proof. Continuity requires a separate relation between source and target topology flows and a proof that inverse image or neighborhood transport preserves that structure. □

9220.4 Phase, circle, and complex flows

Definition 9220.21 (Phase motif). *Lean4 (definition)* `BEDC.GroundCompiler.CaseStudies.PhaseMotif`

A phase motif *is a recognized event structure containing cyclic or periodic source flow, completion or seal witness flow, carry or wrap-around witness flow, normal-address flow, and phase ledger*

flow. Explanatory carry shapes include 011 | 100 *and* 10011 | 10100*, but these are source-level carry candidates, not equalities.*

Definition 9220.22 (Circle motif)**.** Lean4 (definition) `BEDC.GroundCompiler.CaseStudies.CircleMotif`

A circle motif *is phase motif plus unit-constraint or closed-loop classifier structure. It contains phase source flow, periodic closure flow, unit constraint flow, equation classifier flow, topological compatibility flow, and circle ledger flow. It does not automatically export circle structure.*

Proposition 9220.23 (Circle motif extends phase motif)**.** Lean4✓ `BEDC.GroundCompiler.CaseStudies.circle extends phase`

If S contains a recognized circle motif, then S contains a recognized phase motif.

Proof. By Definition 9220.22, circle motif contains phase source flow, periodic closure flow, and ledger structure whose base part is precisely phase motif structure. □

Corollary 9220.24 (Phase motif is necessary but not sufficient for circle)**.** Lean4✓ `BEDC.GroundCompiler.CaseStu necessary not sufficient circle`

Phase motif is part of circle-like construction, but circle structure still requires unit constraint, equation classifier, topological compatibility, and ledger.

Theorem 9220.25 (Carry motif does not imply geometric dimension)**.** Lean4✓ `BEDC.GroundCompiler.CaseStudie motif not dimension`

There exists a carry-only event flow, for example the source-level carry candidate 011 | 100*, that contains a carry motif and contains no dimension-certificate subflow. Therefore a carry motif does not imply geometric dimension, topological dimension, linear dimension, or manifold structure.*

Proof. The flow 011 | 100 records a carry candidate and no additional certificate subflow. Dimension requires carrier, topology, chart, vector-space, manifold, or homological certificates. Carry motif alone supplies none of these. □

Definition 9220.26 (Complex motif)**.** Lean4 (definition) `BEDC.GroundCompiler.CaseStudies.ComplexMotif`

A complex motif *is a recognized event structure containing ordered-pair or product source flow, real-component source flow, addition and multiplication descent flow, rotation or phase motif, conjugation or norm motif, field or ring classifier flow, and complex ledger flow. It typically reuses Real-like, product-like, ring-like, and phase-like flows, so its reuse depth and ledger depth are high.*

Definition 9220.27 (Complex analytic motif)**.** Lean4 (definition) `BEDC.GroundCompiler.CaseStudies.ComplexAnaly`

A complex analytic motif *is complex motif plus limit or derivative source flow, difference quotient flow, Cauchy-Riemann or analytic compatibility flow, local power-series flow, modulus ledger flow, and analytic seal flow. It is not automatic from the complex motif.*

Proposition 9220.28 (Complex motif inherits reuse depth from real and product components)**.** Lean4✓ `BEDC.GroundCompiler.CaseStudies.complex reuse depth`

If a complex motif in S is recognized as reusing Real-like and product-like flows, then

$$\mathsf{ReuseDepth}_{\mathcal{R}}(S)$$

is at least the maximum of the reuse depths of those components plus one.

Proof. The complex motif has reuse edges from the Real-like and product-like components into the complex construction. This adds one reuse layer above the maximum reuse depth of the reused components. □

Theorem 9220.29 (Complex motif does not imply complex analysis). Lean4 ✓ BEDC.GroundCompiler.CaseStudies not analysis

There exists a complex-motif-only event flow whose complex support is present but whose analysis-support flow is absent. Hence a complex motif alone does not imply complex differentiability, analyticity, Cauchy integral theorem, or power-series expansion.

Proof. Complex motif supplies algebraic or coordinate support over paired components. Complex analysis requires limit, derivative, analytic compatibility, local expansion, and proof-flow support. The exhibited motif-only flow contains the former support and omits the latter support. □

9220.5 Category, functor, and natural transformation motifs

Definition 9220.30 (Category composition motif). Lean4 (definition) BEDC.GroundCompiler.CaseStudies.Category

A category composition motif *is an event structure containing object-source flow, morphism-source flow, domain and codomain classifier flow, identity witness flow, composition witness flow, associativity proof-flow, unit proof-flow, and category ledger flow. It generalizes continuation or composition motif by adding object and morphism sorting and composability conditions.*

Definition 9220.31 (Functor motif). Lean4 (definition) BEDC.GroundCompiler.CaseStudies.FunctorMotif

A functor motif *is an event structure containing source-category flow, target-category flow, object-map flow, morphism-map flow, identity-preservation flow, composition-preservation flow, and functor ledger flow. It reuses two category motifs.*

Definition 9220.32 (Natural transformation motif). Lean4 (definition) BEDC.GroundCompiler.CaseStudies.Natural

A natural transformation motif *is an event structure containing source functor flow, target functor flow, component morphism family flow, naturality-square proof-flow, and component ledger flow. It reuses functor motifs and category composition motifs.*

Proposition 9220.33 (Functor motif extends category motif). Lean4 ✓ BEDC.GroundCompiler.CaseStudies.funct extends category

If S contains a recognized functor motif, then S contains or references recognized category motifs for source and target categories.

Proof. By Definition 9220.31, functor motif contains source-category and target-category flows. These must be recognized category motifs or references to recognized category flows. □

Proposition 9220.34 (Natural transformation motif extends functor motif). Lean4 ✓ BEDC.GroundCompiler.Case transformation extends functor

If S contains a recognized natural transformation motif, then S contains or references source and target functor motifs.

Proof. By Definition 9220.32, natural transformation motif contains source functor flow and target functor flow. □

Theorem 9220.35 (Composition motif alone does not yield category). Lean4 ✓ BEDC.GroundCompiler.CaseStudie not category

There exists a composition-motif-only event flow whose composition support is present but whose category-sorting support is absent. Hence a continuation or composition motif does not by itself yield a category.

Proof. Composition motif records operation-like event support. A category additionally requires object and morphism sorting, domain and codomain compatibility, identity witnesses, associativity proof-flow, unit proof-flow, and ledger. The exhibited composition-only flow omits the category-sorting support. □

9220.6 Homology as boundary-quotient flow

Definition 9220.36 (Chain-complex motif). Lean4 (definition) `BEDC.GroundCompiler.CaseStudies.ChainComplexMo`

A chain-complex motif *is an event structure containing graded object flow, boundary-map flow, boundary-composition flow, zero-composition proof-flow, and chain ledger flow. The key proof-flow states* $d \circ d = 0$.

Definition 9220.37 (Cycle-boundary classifier motif). Lean4 (definition) `BEDC.GroundCompiler.CaseStudies.Cycle`

A cycle-boundary classifier motif *is an event structure containing cycle flow, boundary flow, equivalence modulo boundaries, quotient classifier flow, and exactness ledger flow. It is classifier-heavy and ledger-dependent.*

Definition 9220.38 (Homology motif). Lean4 (definition) `BEDC.GroundCompiler.CaseStudies.HomologyMotif`

A homology motif *is chain-complex motif plus cycle-boundary classifier motif plus quotient ledger: chain complex, cycle classifier, boundary classifier, quotient flow, exactness proof-flow, and homology ledger.*

Proposition 9220.39 (Homology motif has classifier compression). Lean4 ✓ `BEDC.GroundCompiler.CaseStudies.h` `has classifier compression`

If S *contains a recognized homology motif, then* S *contains a classifier quotient motif.*

Proof. Homology motif includes equivalence modulo boundaries. This identifies raw cycles that differ by boundaries, so it contains classifier quotient structure. □

Theorem 9220.40 (Chain-complex motif does not imply homology). Lean4 ✓ `BEDC.GroundCompiler.CaseStudies` `complex not homology`

There exists a chain-complex-motif-only event flow whose chain support is present but whose homology quotient support is absent. Hence a chain-complex motif alone does not yield homology.

Proof. Chain-complex motif supplies graded objects and a boundary map with $d^2 = 0$. Homology requires forming cycles modulo boundaries. That formation needs classifier quotient and quotient ledger; the exhibited chain-complex-only flow omits that quotient support. □

9220.7 Cross-domain comparison

Definition 9220.41 (Cross-domain motif comparison). Lean4 (definition) `BEDC.GroundCompiler.CaseStudies.Cros`

For event flows S *and* T*, define their cross-domain comparison by*

$$\mathsf{CrossCompare}_{\mathcal{R}}(S,T) = (\mathsf{MotifProfile}_{\mathcal{R}}(S), \mathsf{MotifProfile}_{\mathcal{R}}(T), \mathsf{Overlap}_{\mathcal{R}}(S,T), \mathsf{TheoryDist}_{\mathcal{R},P}(S,T)).$$

This comparison is valid only relative to recognizer family $\mathcal{R}$ *and analysis protocol* P.

Example 9220.42 ($\mathsf{Completion}^{\uparrow}$ versus $\mathsf{Real}^{\uparrow}$). *Expected shared motifs include finite approximation, compatible thread, seal, and tail ledger. Real-like structure adds Cauchy or regularity classifier, operation descent, order or metric compatibility, and field ledger. The report may say that* $\mathsf{Real}^{\uparrow}$ *is completion motif plus arithmetic, metric, and classifier stack, but it may not claim* $\mathsf{Completion}^{\uparrow} = \mathsf{Real}^{\uparrow}$.

Example 9220.43 (Phase structure versus circle)**.** *Expected shared motifs include periodic or cyclic source, seal, carry or wrap-around, and normal address. Circle-like structure adds unit constraint, equation classifier, topology compatibility, and circle ledger. Carry motif is not the circle object.*

Example 9220.44 ($\mathsf{Add}^{\uparrow}$ versus category composition)**.** *Expected shared motifs include composition or continuation, identity or unit, and associativity. Category structure adds object and morphism sorting, domain and codomain classifier, identity morphism ledger, and composability ledger. This supports the claim that they share a continuation-stability motif, not that* $\mathsf{Add}^{\uparrow}$ *is category composition.*

Example 9220.45 (Homology versus rational or Cauchy quotient)**.** *Expected shared motifs include classifier quotient, exactness or equivalence witness, and ledger preserving raw representatives. Homology adds chain complex,* $d^2 = 0$*, and cycle-boundary quotient. Cauchy quotient adds approximation sequence, tail-control classifier, and completion seal. Both are quotient-heavy, but their source and exactness motifs differ.*

Theorem 9220.46 (Cross-domain motif overlap does not imply bridge)**.** Lean4✓ `BEDC.GroundCompiler.CaseStudi` `not bridge`

If two flows share motifs across domains, this does not imply that there is a bridge between the corresponding mature theories.

Proof. Motif overlap records structural similarity at event-flow level. A bridge requires translation flow, soundness flow, reflection or completeness where available, and no-host-leak ledger. Motif overlap supplies none of these. □

Corollary 9220.47 (Bridge requires bridge motif plus certificate)**.** Lean4✓ `BEDC.GroundCompiler.CaseStudies.br` `needs cert`

Even when two theories have high motif similarity, a conservative bridge must be supplied as a separate recognized bridge flow with certificate support.

9220.8 Reports, limits, and conservativity

Definition 9220.48 (High-level motif report)**.** Lean4 (definition) `BEDC.GroundCompiler.CaseStudies.HighLevelMot`

A high-level motif report *for an event flow* S *includes its higher-layer motif bundle, seal depth, carry index, ledger depth, classifier compression ratio, reuse depth, bridge depth, normal-address map, warnings, and cannot-claim entries. It is an output view, not proof.*

Principle 9220.49 (High-level reports require cannot-claim entries)**.** Lean4✓ `BEDC.GroundCompiler.CaseStudies.` `level reports require cannot claims`

Any report involving Real-like, Topology-like, Circle-like, Complex-like, Category-like, or Homology-like motifs must include cannot-claim entries preventing overinterpretation. Required examples include: Real-like motifs do not export $\mathsf{Real}^{\uparrow}$*; topology motif does not prove continuity; carry motif does not imply dimension; phase motif does not imply circle structure; complex motif does not imply complex analysis; composition motif does not imply category; chain-complex motif does not imply homology; motif overlap does not imply bridge.*

Theorem 9220.50 (High-level motif analysis is conservative over the finite kernel)**.** Lean4✓ `BEDC.GroundCompiler.CaseStudies.higher layer conservativity`

Adding high-layer motif analysis for Completion, Real, Topology, Circle, Complex, Category, Functor, Natural Transformation, and Homology does not add new raw marks, history constructors, sameness rules, continuation rules, derived-interface formation rules, or accepted-object export rules.

Proof. High-layer motif analysis operates on decoded event flows and recognized motif profiles. It does not create new b0 or b1, add kernel sameness, change Ext or Cont, or license any derived interface. Object export still requires NameCert flow, derivation-certificate flow, and acceptance-gate flow. Therefore the analysis is conservative over the finite kernel. □

Corollary 9220.51 (High-layer motifs cannot replace certificates)**.** `Lean4✓ BEDC.GroundCompiler.CaseStudies.h` `layer motifs cannot replace certificates`

No high-layer motif bundle, metric report, or similarity score can replace NameCert *flow, derivation-certificate flow, proof flow, acceptance-gate flow, bridge certificate, or ledger completeness.*

Remark 9220.52 (Outlook)**.** *This chapter applies event-flow metrics to higher-layer routes. It defines and analyzes completion motif, Real motif bundle, metric motif, topology motif, neighborhood-basis motif, phase motif, circle motif, complex motif, complex analytic motif, category composition motif, functor motif, natural transformation motif, chain-complex motif, cycle-boundary classifier motif, homology motif, cross-domain motif comparison, and high-level motif reports. It proves that completion is seal-heavy and ledger-dependent, completion is necessary but not sufficient for Real-like structure, Real-like motifs do not export* $\mathsf{Real}^{\uparrow}$*, metric motifs do not automatically generate topology, topology motifs do not prove continuity, circle motifs extend phase motifs, carry motifs do not imply dimension, complex motifs do not imply complex analysis, functor and natural transformation motifs extend category and functor motifs, composition does not yield category, homology includes classifier quotient while chain-complex alone does not yield homology, cross-domain overlap does not imply bridge, high-level reports require cannot-claim entries, high-level motif analysis is conservative, and high-layer motifs cannot replace certificates. The next chapter organizes motifs, metrics, and reports into a compiler analysis pipeline from channel code decoding through recognizer selection, protocol flow, reports, distance matrices, cannot-claim audit, and bridge-obligation discovery.*

Chapter 9221

Compiler Analysis Pipeline

chapter 9220 applies event-flow metrics to Completion, Real, Topology, Circle, Complex, Category, and Homology routes. It shows that these theories can share finite approximation, seal, carry, classifier quotient, ledger compression, reuse, bridge, and composition motifs without thereby proving mature export, equality, or bridge correctness.

This chapter packages those ingredients into a compiler analysis pipeline:

$$\text{channel code} \longrightarrow \text{legality check} \longrightarrow \text{decode} \longrightarrow \text{protocol recognition} \longrightarrow \text{recognizer verification}$$
$$\longrightarrow \text{motif extraction} \longrightarrow \text{metric computation} \longrightarrow \text{report generation} \longrightarrow \text{cannot-claim audit} \longrightarrow \text{bridge-obligation}$$

The pipeline remains subject to the same no-hidden-input rule:

$$\boxed{\text{analysis is driven by protocol flows and recognizer flows, not by external configuration.}}$$

Recognizer families, analysis protocols, metric weights, report formats, cannot-claim audits, and bridge-obligation discovery must appear as recognized event-flow structure.

9221.1 Inputs and protocol recognition

Definition 9221.1 (Analysis input)**.** *Lean4 (definition)* `BEDC.GroundCompiler.AnalysisPipeline.AnalysisInput`

An analysis input *is either a legal channel stream*

$$c \in \mathsf{LegalZStream}$$

or equivalently an event flow

$$S \in \mathsf{EventFlow}.$$

The two presentations are related by the channel bijection:

$$S = \mathsf{Decode}(c), \qquad c = \mathsf{Compile}(S).$$

If the input is channel code, it must be decoded before analysis. If the input is already a source event flow, it may be analyzed directly.

Principle 9221.2 (Decode-first analysis)**.** *Lean4 ✓* `BEDC.GroundCompiler.AnalysisPipeline.decode first analysis`

Every analysis acts on source-level event flow. For $c \in \mathsf{LegalZStream}$*, the pipeline first forms*

$$S = \mathsf{Decode}(c).$$

All recognizer, motif, metric, ledger, cannot-claim, and bridge-obligation analysis then acts on S*, not on channel bit substrings.*

Definition 9221.3 (Analysis protocol candidate flow). *Lean4 (definition)* `BEDC.GroundCompiler.AnalysisPipeline.`

An analysis protocol candidate flow *is an event flow*

$$P \in \mathsf{EventFlow}.$$

It has not yet been recognized as an analysis protocol. Thus $P \in \mathsf{EventFlow}$ *does not imply that* P *specifies a recognizer family, metrics, weights, report format, cannot-claim audit, or bridge discovery policy.*

Definition 9221.4 (Generated analysis-protocol recognizer). *Lean4 (definition)* `BEDC.GroundCompiler.AnalysisPip`

A generated analysis-protocol recognizer *is an event flow*

$$R_P \in \mathsf{EventFlow}.$$

It is not an external configuration parser, YAML schema, host analysis script, or handwritten metric table. It is generated from the two raw marks and acts on event flows.

Definition 9221.5 (Analysis-protocol recognition relation). *Lean4 (definition)* `BEDC.GroundCompiler.AnalysisPipe`

The analysis-protocol recognition relation is written

$$\mathsf{RecognizesAnalysisProtocol}(R_P, P), \qquad R_P, P \in \mathsf{EventFlow}.$$

It is read as: the generated protocol recognizer flow R_P *recognizes event flow* P *as an analysis protocol flow. The relation records source-level support by requiring the generated recognizer flow and the protocol candidate flow to be present as nonempty event flows. If such an* R_P *exists,* P *is a recognized analysis protocol flow.*

Definition 9221.6 (Analysis protocol subflows). *Lean4 (definition)* `BEDC.GroundCompiler.AnalysisPipeline.Analy`

If $\mathsf{RecognizesAnalysisProtocol}(R_P, P)$*, then* R_P *may recognize subflows of* P *as protocol roles:*

$$\begin{aligned}
&\mathsf{ProtInputDom}_{R_P}(P, P_0), && \mathsf{ProtRecognizerFamily}_{R_P}(P, P_1),\\
&\mathsf{ProtMotifSelection}_{R_P}(P, P_2), && \mathsf{ProtMetricSelection}_{R_P}(P, P_3),\\
&\mathsf{ProtMetricWeights}_{R_P}(P, P_4), && \mathsf{ProtNormalizationPolicy}_{R_P}(P, P_5),\\
&\mathsf{ProtLedgerPolicy}_{R_P}(P, P_6), && \mathsf{ProtCannotClaimPolicy}_{R_P}(P, P_7),\\
&\mathsf{ProtBridgeObligationPolicy}_{R_P}(P, P_8), && \mathsf{ProtReportPolicy}_{R_P}(P, P_9),\\
&\mathsf{ProtSeal}_{R_P}(P, \sigma_P).
\end{aligned}$$

These are not external field labels. They are source-level subflow roles recognized inside P*.*

Principle 9221.7 (No external analysis configuration). *Lean4✓* `BEDC.GroundCompiler.AnalysisPipeline.no external analysis config`

There is no formal input such as analysis YAML, metric JSON, motif table, weight vector, report template, manual object grouping, human theory category list, or external bridge candidate list. If such information is used, it must appear as a recognized subflow of an analysis protocol flow.

Theorem 9221.8 (Unrecognized protocol cannot drive analysis). *Lean4✓* `BEDC.GroundCompiler.AnalysisPipelin protocol rejected`

If there is no R_P *such that*

$$\mathsf{RecognizesAnalysisProtocol}(R_P, P),$$

then P *cannot be used as a formal analysis protocol.*

Proof. An analysis protocol determines recognizer family, metric selection, weights, normalization policy, ledger policy, cannot-claim policy, and report policy. If P is not recognized by a generated protocol recognizer, these choices have no event-flow support. Using P would introduce external analysis configuration, contrary to the no-hidden-input discipline. □

Corollary 9221.9 (Metric weights require protocol flow)**.** Lean4 ✓ `BEDC.GroundCompiler.AnalysisPipeline.metri` `weights require protocol flow`

Any weighted distance or similarity metric whose weights are not recorded by a recognized protocol flow is not a BEDC-admissible metric.

9221.2 Pipeline stages

Definition 9221.10 (Analysis pipeline)**.** Lean4 (definition) `BEDC.GroundCompiler.AnalysisPipeline.Analyze`

Given $c \in \mathsf{LegalZStream}$ and a recognized analysis protocol flow P, define

$$\mathsf{Analyze}(c, P)$$

as the following sequence of stages:

1. *legality check;*
2. *decode;*
3. *protocol recognition;*
4. *recognizer-family extraction;*
5. *motif extraction;*
6. *metric computation;*
7. *normal-address analysis;*
8. *ledger audit;*
9. *cannot-claim audit;*
10. *bridge-obligation discovery;*
11. *report generation.*

Every stage acts on event flows or recognized event-flow structures, not on channel substrings or external labels.

Definition 9221.11 (Stage 0: legality check)**.** Lean4 (definition) `BEDC.GroundCompiler.AnalysisPipeline.StageLeg`

Stage 0 checks $c \in \mathsf{LegalZStream}$. If this fails, the pipeline rejects the input.

Definition 9221.12 (Stage 1: decode)**.** Lean4 (definition) `BEDC.GroundCompiler.AnalysisPipeline.StageDecode`

Stage 1 forms

$$S := \mathsf{Decode}(c).$$

All later stages act on S and recognized subflows of S.

Definition 9221.13 (Stage 2: protocol recognition)**.** Lean4 (definition) `BEDC.GroundCompiler.AnalysisPipeline.St`

Stage 2 checks whether

$$\mathsf{RecognizesAnalysisProtocol}(R_P, P)$$

holds. If the protocol is not recognized, the pipeline rejects the analysis run.

Definition 9221.14 (Stage 3: recognizer-family extraction). *Lean4 (definition)* `BEDC.GroundCompiler.AnalysisPipe`

Stage 3 identifies the recognizer-family subflow

$$\mathsf{ProtRecognizerFamily}_{R_P}(P, P_1).$$

This subflow specifies generated recognizers

$$\mathcal{R}_P = (R_1, \ldots, R_k).$$

Each R_i must be certified. If an R_i is not certified, the pipeline rejects or records a bootstrap obligation.

Definition 9221.15 (Stage 4: motif extraction). *Lean4 (definition)* `BEDC.GroundCompiler.AnalysisPipeline.Stagel`

Stage 4 computes

$$\mathsf{MotifProfile}_{\mathcal{R}_P}(S),$$

namely all triples (μ, M, L) such that some $R \in \mathcal{R}_P$ satisfies

$$\mathsf{RecognizesMotif}(R, S, M, \mu) \quad \textit{and} \quad \mathsf{MotifLedger}_R(S, M, \mu, L).$$

Motif recognition without a required ledger is recorded as a failure or cannot-claim item, not silently accepted.

Definition 9221.16 (Stage 5: metric computation). *Lean4 (definition)* `BEDC.GroundCompiler.AnalysisPipeline.St`

Stage 5 computes the admissible metrics selected by the protocol: prefix profile, motif profile, seal depth, carry index, ledger depth, classifier compression ratio, reuse depth, bridge depth, normal-address distance, or theory-flow distance. If a metric requires a recognizer or ledger that is missing, the metric is undefined or blocked; the pipeline may not output a misleading numerical value.

Definition 9221.17 (Stage 6: normal-address analysis). *Lean4 (definition)* `BEDC.GroundCompiler.AnalysisPipelin`

Stage 6 uses the protocol's normalization-policy flow to recognize source-level normal-address records

$$(w, v, L_{w \to v}).$$

For example, $011 \mid 100$ *may be recognized as raw-to-normal carry ledger. This analysis acts on decoded event flow, never on channel bits.*

Definition 9221.18 (Stage 7: ledger audit). *Lean4 (definition)* `BEDC.GroundCompiler.AnalysisPipeline.StageLedg`

Stage 7 checks whether recognized motifs, packages, certificates, theorem flows, and bridge candidates carry their required ledgers. It emits ledger-audit failure items for motif without ledger, package without ledger, NameCert *without ledger, completion without tail ledger, carry without pre-normal ledger, and bridge without no-host-leak ledger.*

Definition 9221.19 (Stage 8: cannot-claim audit). *Lean4 (definition)* `BEDC.GroundCompiler.AnalysisPipeline.Sta`

Stage 8 uses the cannot-claim policy flow to attach required cannot-claim entries. Typical entries include: motif overlap does not imply object equality, same signature vector does not imply theorem equivalence, carry motif does not imply dimension, seal motif does not imply completion object, completion motif does not imply $\mathsf{Real}^{\uparrow}$*, topology motif does not prove continuity, complex motif does not imply complex analysis, bridge candidate does not imply bridge certificate, and code existence does not imply acceptance gate.*

Definition 9221.20 (Stage 9: bridge-obligation discovery). *Lean4 (definition)* `BEDC.GroundCompiler.AnalysisPipel`

Stage 9 identifies bridge-obligation candidates, such as strong motif overlap without recognized bridge flow, reuse-like source relation without reuse-certificate flow, or normal-address relation without classifier exactness flow. Discovery creates obligation candidates; it does not establish bridges.

Definition 9221.21 (Stage 10: report generation). *Lean4 (definition)* `BEDC.GroundCompiler.AnalysisPipeline.Sta`

Stage 10 generates a human-readable report: motif report, metric report, ledger audit report, cannot-claim report, bridge-obligation report, distance matrix, or summary visualization. These are output views, not formal inputs and not proofs.

9221.3 Pipeline correctness

Definition 9221.22 (Well-formed analysis run). *Lean4 (definition)* `BEDC.GroundCompiler.AnalysisPipeline.WellFo`

A well-formed analysis run *is a triple*

$$(c, P, O)$$

such that $c \in \mathsf{LegalZStream}$*,* P *is a recognized analysis protocol flow,* O *is the output or report flow generated by the stages of Definition 9221.10, every used recognizer is certified or recorded by bootstrap obligation, every nontrivial motif recognition has a ledger, and every high-risk claim has a cannot-claim entry.*

Theorem 9221.23 (Well-formed analysis run is source-determined). *Lean4 ✓* `BEDC.GroundCompiler.AnalysisPipe` `formed analysis run source determined`

If (c, P, O) *is a well-formed analysis run and* $S = \mathsf{Decode}(c)$*, then the formal output descriptor of the run is determined by* S*,* P*, and the recognizer family recognized inside* P*.*

Proof. Stages 0 and 1 uniquely decode c into S. Stage 2 fixes the recognized protocol P. Stage 3 extracts the recognizer family from P. Stages 4 through 10 are specified by S, P, and that recognizer family. No external metric table, YAML file, object label, or manual grouping is used. □

Corollary 9221.24 (Same decoded flow and protocol give same output). *Lean4 ✓* `BEDC.GroundCompiler.Analysis` `decoded same protocol same output`

If $\mathsf{Decode}(c) = \mathsf{Decode}(c')$ *and both runs use the same recognized protocol flow* P *and recognizer family, then the formal analysis output descriptors agree.*

Theorem 9221.25 (Pipeline is invariant under compile-decode round trip). *Lean4 ✓* `BEDC.GroundCompiler.Analys` `roundtrip invariant`

If $c = \mathsf{Compile}(S)$*, then for any recognized protocol flow* P *and recognizer family, the descriptor obtained from the code is the descriptor obtained from the decoded source:*

$$\mathsf{DescriptorFromCode}(\mathsf{Compile}(S), P, \mathcal{R}_P) = \mathsf{CanonicalDescriptor}(S, P, \mathcal{R}_P).$$

Proof. By the channel round trips, $\mathsf{Decode}(\mathsf{Compile}(S)) = S$ and, for legal c, $\mathsf{Compile}(\mathsf{Decode}(c)) = c$. Both sides decode to the same source event flow and use the same protocol. By Definition 9221.23, their outputs agree. □

Theorem 9221.26 (Pipeline is conservative over the finite kernel). *Lean4✓ BEDC.GroundCompiler.AnalysisPipeli pipeline conservativity*

Adding the analysis pipeline, protocol recognition, motif reports, metric reports, ledger audits, cannot-claim audits, and bridge-obligation discovery does not add new raw marks, history constructors, sameness rules, continuation rules, or derived-interface formation rules.

Proof. Pipeline stages act only on decoded event flows and recognized structures. They do not generate new b0 or b1, add msame, hsame, or psame rules, change Ext or Cont, or license derived interfaces. Object export still requires NameCert, derivation-certificate, and acceptance-gate flows. Bridge-obligation discovery is not bridge certification. Hence the pipeline is conservative over the finite kernel. □

9221.4 Report discipline

Definition 9221.27 (Report flow). *Lean4 (definition) BEDC.GroundCompiler.AnalysisPipeline.ReportFlow*

A report flow *is an event flow O recognized by a generated report recognizer as an output of the analysis pipeline. It may contain recognized motif lists, metric tables, normal-address tables, ledger audit results, cannot-claim entries, bridge-obligation candidates, failure cases, and summary remarks. It is output, not input.*

Principle 9221.28 (Reports are not evidence). *Lean4✓ BEDC.GroundCompiler.AnalysisPipeline.reports not evidence*

A report flow is not a proof-flow, certificate-flow, or accepted-object-flow. It can serve only as explanatory output unless separately recognized in some stronger role.

Proposition 9221.29 (Report cannot discharge certificate obligations). *Lean4✓ BEDC.GroundCompiler.AnalysisP cannot discharge certificate obligation*

If an object lacks NameCert *flow, derivation-certificate flow, or acceptance-gate flow, no report flow can supply the missing certificate obligation.*

Proof. NameCert, derivation-certificate, and acceptance-gate flows are recognized certificate structures required for object export. A report flow is analysis output and does not have the certificate-recognition role. Unless the same event flow is separately recognized as a certificate, it cannot discharge certificate obligations. □

Corollary 9221.30 (Motif report cannot license mature object). *Lean4✓ BEDC.GroundCompiler.AnalysisPipeline report cannot license mature object*

Even if a report shows completion, Real-like, Circle-like, or Homology-like motifs, it does not license the corresponding mature object.

Definition 9221.31 (Bridge-obligation candidate). *Lean4 (definition) BEDC.GroundCompiler.AnalysisPipeline.Bri*

A bridge-obligation candidate *is a recognized item B_{obl} in a report flow attached to a source event flow S and a target event flow T. It records support and evidence subflows saying that motif-level similarity suggests a possible bridge, together with the explicit condition that no recognized bridge flow from S to T has been supplied.*

Proposition 9221.32 (Bridge obligation is not bridge). *Lean4✓ BEDC.GroundCompiler.AnalysisPipeline.bridge obligation not bridge*

If B_{obl} is a bridge-obligation candidate attached to source event flow S and target event flow T, then B_{obl} does not establish a recognized bridge flow from S to T.

Proof. A bridge obligation records a missing bridge certificate. It explicitly reports that a bridge flow has not yet been supplied. It therefore cannot imply the bridge it asks for. □

Corollary 9221.33 (Bridge discovery remains noncommittal)**.** Lean4 ✓ `BEDC.GroundCompiler.AnalysisPipeline.discovery noncommittal`

Bridge-obligation discovery may guide later work, but each bridge-obligation candidate it records remains noncommittal: it does not establish correspondence, soundness, reflection, or conservative bridge between its source and target flows.

9221.5 Failure handling

Definition 9221.34 (Analysis failure item)**.** Lean4 (definition) `BEDC.GroundCompiler.AnalysisPipeline.AnalysisFa`

An analysis failure item *is an event subflow in a report flow recording failure at some pipeline stage, together with a failure kind. Common failure kinds include illegal channel stream, unrecognized protocol, uncertified recognizer, missing ledger, missing cannot-claim entry, undefined metric, missing classifier exactness, missing bridge certificate, normalization without raw ledger, and source/channel layer confusion.*

Definition 9221.35 (Failure-complete report)**.** Lean4 (definition) `BEDC.GroundCompiler.AnalysisPipeline.Failure`

For a list F_{req} of required analysis failure items and a list F_{rec} of recorded analysis failure items, a report flow is failure-complete *when every item of F_{req} occurs in F_{rec}.*

Theorem 9221.36 (Non-failure-complete report is inadmissible)**.** Lean4 ✓ `BEDC.GroundCompiler.AnalysisPipelin failure complete inadmissible`

If an analysis run requires a failure item $f \in F_{\mathrm{req}}$ and its report omits f from F_{rec}, then the report is not failure-complete and is not admissible as a failure-complete report.

Proof. A report that omits failures hides analysis obligations. It may make a metric appear defined when its recognizer is missing, or make a motif appear valid when its ledger is absent. The no-hidden-input discipline requires these conditions to be explicit. Failure omission therefore makes the report inadmissible. □

Corollary 9221.37 (Missing data cannot be silently treated as zero)**.** Lean4 ✓ `BEDC.GroundCompiler.AnalysisPipe data not zero`

If a metric is undefined because a recognizer or ledger is missing, the pipeline may not set it to zero by default. It must record a failure or undefined-metric item.

9221.6 Theorem and chapter code analysis

Definition 9221.38 (Theorem-code analysis)**.** Lean4 (definition) `BEDC.GroundCompiler.AnalysisPipeline.Theorem`

Given theorem code

$$c_T = \mathsf{Compile}(T),$$

where T is a sound theorem flow, define theorem-code analysis by

$$\mathsf{Analyze}(c_T, P).$$

Its report may contain proof motif profile, dependency motif profile, certificate motif profile, ledger depth, status flow, cannot-claim audit, and bridge-obligation candidates.

Definition 9221.39 (Chapter-code analysis). *Lean4 (definition)* `BEDC.GroundCompiler.AnalysisPipeline.ChapterC`

Given chapter code

$$c_C = \mathsf{Compile}(C),$$

where C is a sound chapter flow, define chapter-code analysis by

$$\mathsf{Analyze}(c_C, P).$$

Its report may contain definition, theorem, proof, and certificate motif profiles, certificate coverage, cannot-claim coverage, status distribution, ledger-depth distribution, reuse graph, and bridge-obligation list.

Proposition 9221.40 (Theorem-code analysis does not reprove theorem). *Lean4✓* `BEDC.GroundCompiler.Analysi` `code analysis not reprove`

The analysis $\mathsf{Analyze}(c_T, P)$ *does not reprove the theorem. It analyzes the structure of the theorem flow.*

Proof. The proof is contained in the proof flow and checked by proof recognizer or proof checker flow. The analysis pipeline extracts motifs and metrics; it does not perform proof checking unless proof checking is explicitly part of the protocol and recognized in that role. □

Proposition 9221.41 (Chapter-code analysis does not validate all chapter claims). *Lean4✓* `BEDC.GroundCompiler` `code analysis not validation`

The analysis $\mathsf{Analyze}(c_C, P)$ *does not automatically validate every claim in the chapter.*

Proof. Chapter validation requires chapter recognition, theorem recognition, proof checking, certificate recognition, ledger audit, and status flow. The analysis protocol may include some of these stages, but motif or metric analysis alone does not validate all claims. The report therefore records only the structures, metrics, failures, and obligations recognized by the selected protocol. □

9221.7 Examples and determinacy

Example 9221.42 (Analyze completion skeleton code). *For input code*

$$011001100011010110101011100011,$$

Stage 1 decodes

$$0 \mid 00 \mid 000 \mid 01 \mid 011 \mid 100.$$

Possible recognized motifs are finite repetition $0 \mid 00 \mid 000$*, repeat boundary* 01*, seal* 011*, and carry* $011 \mid 100$*. A report may record seal depth* 1*, carry index* 1*, ledger depth at least* 1 *when carry ledger is recognized, and cannot-claim entries saying that the completion skeleton does not license* $\mathsf{FullAxis}^{\uparrow}$*, carry motif does not imply dimension, and motif report does not imply object equality.*

Example 9221.43 (Analyze fold skeleton code). *For input code*

$$011001100101100101011010 0011,$$

Stage 1 decodes

$$0 \mid 00 \mid 001 \mid 0011 \mid 0100.$$

Possible recognized motifs are finite source $0 \mid 00$*, additive recursion* 001*, and fold completion* $0011 \mid 0100$*. A report may record carry-index candidate and reuse-depth candidate, while retaining cannot-claim entries that additive recursion does not license* $\mathsf{Add}^{\uparrow}$ *and fold motif does not license* $\mathsf{Mul}^{\uparrow}$*.*

Example 9221.44 (Compare completion and fold skeletons)**.** *For*

$$S_{\mathrm{Comp}} = 0 \mid 00 \mid 000 \mid 01 \mid 011 \mid 100$$

and

$$S_{\mathrm{Fold}} = 0 \mid 00 \mid 001 \mid 0011 \mid 0100,$$

the raw prefix overlap is $0 \mid 00$*. A report may say that both share finite-source motif, while the completion skeleton branches into repeat-boundary, seal, and carry, and the fold skeleton branches into additive recursion and fold completion. It may not claim that shared prefix implies subobject, that shared finite-source motif implies the same theory, or that fold and completion are bridge-equivalent.*

Theorem 9221.45 (Analysis is deterministic relative to protocol)**.** `Lean4✓` `BEDC.GroundCompiler.AnalysisPipeli` `deterministic relative protocol`

If $c \in \mathsf{LegalZStream}$*,* P *is a recognized analysis protocol flow, and all recognizers selected by* P *are deterministic on the decoded input domain, then* $\mathsf{Analyze}(c, P)$ *is uniquely determined.*

Proof. The code c uniquely decodes to S. The protocol P fixes recognizer family, metric selection, weights, normalization policy, ledger policy, cannot-claim policy, and report policy. If each selected recognizer is deterministic on the domain, then motif extraction, metric computation, ledger audit, and report generation are uniquely determined. □

Corollary 9221.46 (Nondeterministic recognizer requires nondeterminism ledger)**.** *If the recognizer family contains a nondeterministic recognizer, the analysis output must record choice branches, failure branches, or all possible outputs. Otherwise the report is not admissible.*

Remark 9221.47 (Outlook)**.** *This chapter establishes the compiler analysis pipeline: legality check, decode, protocol recognition, recognizer-family extraction, motif extraction, metric computation, normal-address analysis, ledger audit, cannot-claim audit, bridge-obligation discovery, and report generation. It defines analysis inputs, protocol candidate flows, protocol recognizers, protocol subflows, well-formed runs, report flows, bridge-obligation candidates, analysis failure items, failure-complete reports, theorem-code analysis, chapter-code analysis, and protocol-relative determinacy. It proves that unrecognized protocols cannot drive analysis, metric weights require protocol flow, well-formed runs are source-determined, equal decoded flow and protocol give equal output, the pipeline is invariant under compile-decode round trip and conservative over the finite kernel, reports cannot discharge certificates, bridge obligation is not bridge, incomplete failure reporting is inadmissible, missing data cannot silently become zero, theorem-code analysis does not reprove theorem, chapter-code analysis does not validate all claims, deterministic protocols determine analysis output, and nondeterminism requires ledger. The next chapter collects the main theorem of the no-hidden-input compiler discipline.*

Chapter 9222

Main Theorems and Cannot-Claim Registry

The preceding chapters establish the components of the no-hidden-input compiler discipline: ground event flows, Zeckendorf-safe channel encoding, source/channel separation, package recognition, certificate recognition, theorem and chapter recognition, recognizer flows, self-hosting compiler flows, motif analysis, theory metrics, higher-layer case studies, and the compiler analysis pipeline.

This chapter collects the main theorems and records the cannot-claim registry for this part. The governing assertion is:

$$\boxed{\text{the only formal ground input is a finite event flow generated from } \mathsf{b0}, \mathsf{b1}.}$$

All higher structures are recognized structures inside event flows:

package, certificate, acceptance gate, theorem, chapter, recognizer, compiler, motif, metric, and report.

None of these may enter as an external object.

9222.1 Compiler state and hidden input

Definition 9222.1 (No-hidden-input compiler state)**.** *Lean4 (definition)* `BEDC.GroundCompiler.MainTheorems.NoHid`

A no-hidden-input compiler state *is a tuple*

$$\mathcal{C} = (\mathsf{EventFlow}, \mathsf{LegalZStream}, \mathsf{Compile}, \mathsf{Decode}, \mathsf{RecognizerHierarchy}, \mathsf{CertificateFlows}, \mathsf{LedgerFlows}, \mathsf{BootstrapObligat}$$

satisfying:

1. $\mathsf{EventFlow} = (\{0,1\}^*)^*$*;*
2. $\mathsf{LegalZStream} = ((0 \mid 10)^*11)^*$*;*
3. $\mathsf{Compile}$ *is the Zeckendorf-safe channel compiler;*
4. Decode *is its streaming inverse decoder;*
5. *package, certificate, theorem, chapter, and compiler structures are recognized by the recognizer hierarchy;*
6. *every nontrivial recognition carries ledger data;*

7. *every not-yet-self-hosted component is recorded as a bootstrap obligation.*

Definition 9222.2 (Hidden input). *Lean4 (definition)* `BEDC.GroundCompiler.MainTheorems.HiddenInput`

A datum X is a hidden input *when it is used for compilation, recognition, proof, analysis, or reporting, but X is not any of:*

1. *a raw event;*
2. *an event flow;*
3. *a recognized event-flow structure;*
4. *a recognized certificate flow;*
5. *a recognized ledger flow;*
6. *a recognized bootstrap obligation;*
7. *a recognized analysis protocol flow;*
8. *a self-hosted compiler flow, or an explicitly recorded bootstrap boundary.*

Typical hidden inputs include external atom tables, external enums, YAML, manifests, host ASTs, external package structures, theorem identifiers, external proof objects, host parsers, host proof checkers, external metric tables, motif tables, type tags, mode tags, unrecorded package boundaries, and unrecorded classifier oracles.

Principle 9222.3 (No hidden input). *Lean4✓* `BEDC.GroundCompiler.MainTheorems.no hidden input`

The formal compiler discipline may not use hidden input. If a component is not yet generated and recognized as event-flow structure, it must be explicitly recorded as a bootstrap obligation. Otherwise it may not support a formal claim.

9222.2 Channel and layer separation

Theorem 9222.4 (Channel bijection theorem). *Lean4✓* `BEDC.GroundCompiler.MainTheorems.channel bijection`

The channel compiler gives a bijection

$$\boxed{\mathsf{EventFlow} \cong \mathsf{LegalZStream}}$$

where

$$\mathsf{EventFlow} = (\{0,1\}^*)^*, \qquad \mathsf{LegalZStream} = ((0 \mid 10)^* 11)^*.$$

The event encoding is

$$\zeta(0) = 0, \qquad \zeta(1) = 10, \qquad \mathsf{Ev}(w) = \zeta(w)11,$$

and

$$\mathsf{Compile}(w_0, \ldots, w_{n-1}) = \mathsf{Ev}(w_0) \cdots \mathsf{Ev}(w_{n-1}).$$

Proof. The channel-encoding chapter proves that event bodies lie in $(0 \mid 10)^*$ and contain no internal adjacent 11. Hence the first 11 after an event body is the event terminator. The streaming decoder therefore uniquely recovers each raw event and then the whole event flow. Thus

$$\mathsf{Decode}(\mathsf{Compile}(S)) = S$$

and, for every legal stream c,

$$\mathsf{Compile}(\mathsf{Decode}(c)) = c.$$

So Compile and Decode are inverse maps. □

Corollary 9222.5 (Channel code is lossless). *Lean4✓ BEDC.GroundCompiler.MainTheorems.channel code lossless*

If

$$\mathsf{Compile}(S) = \mathsf{Compile}(T),$$

then $S = T$.

Proof. Apply Decode to both sides and use the round-trip law. □

Corollary 9222.6 (Channel code is not proof). *Lean4✓ BEDC.GroundCompiler.MainTheorems.code not proof*

The judgment $c \in \mathsf{LegalZStream}$ *only says that* c *decodes to an event flow. It does not say that the flow is a theorem, proof, name certificate, derivation certificate, accepted object, or mature interface.*

Theorem 9222.7 (Source/channel layer separation theorem). *Lean4✓ BEDC.GroundCompiler.MainTheorems.sourc channel separation*

Source events and channel streams are strictly separated:

1. *source events belong to* $\mathsf{RawEvent} = \{0,1\}^*$*;*
2. *channel streams belong to* LegalZStream*;*
3. *channel-level* 11 *is an event terminator;*
4. *source-level* 11 *may be part of a raw event;*
5. *source-level normalization acts only on decoded event flows;*
6. *channel substrings cannot be used directly as source events.*

Proof. The first two clauses are definitions. The third follows from $\mathsf{Ev}(w) = \zeta(w)11$. The fourth follows because raw events are arbitrary finite binary words; the source event 11 has channel code $\mathsf{Ev}(11) = 101011$, not 11. The fifth follows because source-level normalization is defined over EventFlow. For the sixth, the channel code 1011 contains the substring 011, but decodes to the source event 1, not the source event 011. □

Corollary 9222.8 (Source carry is not channel rewrite). *Lean4✓ BEDC.GroundCompiler.MainTheorems.carry not channel rewrite*

A source-level relation such as $011 \rightsquigarrow 100$ *cannot be applied as a string rewrite on compiled channel bits. The valid order is decode, source-level normalization, and compile.*

9222.3 Recognized structures and exports

Definition 9222.9 (Generated structure). *Lean4 (definition) BEDC.GroundCompiler.MainTheorems.GeneratedStruct*

A structure K *is a* generated structure *when there are an event flow* S *and a generated recognizer flow* R *such that*

$$\mathsf{Recognizes}_K(R, S).$$

Here $\mathsf{Recognizes}_K$ *may be package recognition,* $\mathsf{NameCert}$ *recognition, derivation-certificate recognition, theorem recognition, chapter recognition, compiler recognition, motif recognition, or analysis-protocol recognition.*

Theorem 9222.10 (Structure emergence theorem)**.** Lean4✓ BEDC.GroundCompiler.MainTheorems.structure emergence

Packages, name certificates, derivation certificates, acceptance gates, theorems, chapters, recognizers, compilers, motifs, metrics, and reports are not first-layer inputs. They may appear only as generated structures.

Proof. If any of these structures were first-layer inputs, their fields, boundaries, roles, order, nesting, or intended reading would be externally supplied. That is hidden input. By Definition 9222.3, such input is not admissible. Therefore these structures must be supplied by event flows and generated recognizer flows. □

Corollary 9222.11 (YAML and AST are output views only)**.** Lean4✓ BEDC.GroundCompiler.MainTheorems.yaml ast output only

YAML, ASTs, Markdown outlines, JSON reports, theorem tables, and dependency graphs may be human-readable output views of decoded event flows. They are not formal inputs.

Corollary 9222.12 (Recognizer generatedness)**.** Lean4✓ BEDC.GroundCompiler.MainTheorems.recognizer generatedness

A recognizer cannot be a host parser or external function. A recognizer used in a formal recognition judgment must itself be an event flow and must carry a recognizer certificate flow.

Definition 9222.13 (Certificate-mediated export)**.** Lean4 (definition) BEDC.GroundCompiler.MainTheorems.Certifi

An object candidate N *is a* certificate-mediated export *at strength* s *when there are recognized name-certificate, derivation-certificate, and acceptance-gate flows such that*

$$\mathsf{AcceptGateFlow}(N, s)$$

holds.

Theorem 9222.14 (Accepted export theorem)**.** Lean4✓ BEDC.GroundCompiler.MainTheorems.accepted export

A mature object N *may be exported at strength* s *exactly when its decoded event flow supplies the recognized name-certificate, derivation-certificate, and acceptance-gate structure:*

$$\boxed{\mathsf{AcceptedExport}(N, s) \iff \mathsf{AcceptGateFlow}(N, s).}$$

Proof. By definition, $\mathsf{AcceptGateFlow}(N, s)$ holds exactly when there is an acceptance flow containing a sound name-certificate flow and a sound derivation-certificate flow. The original acceptance discipline requires $\mathrm{NameCert}(N) \wedge \mathrm{DerivCert}(N, s)$. The compiler discipline reads those two components as recognized event-flow certificates. If either certificate is missing, export is not licensed; if both are soundly recognized and accepted, export is licensed. □

Corollary 9222.15 (Code existence does not imply export)**.** Lean4✓ BEDC.GroundCompiler.MainTheorems.code existence not export

From $c \in \mathsf{LegalZStream}$ *alone one cannot infer that* c *recognizes* $\mathsf{AcceptedExport}(N, s)$*. The stream must first be decoded, and the required certificate and acceptance flows must be recognized.*

Corollary 9222.16 (Motif existence does not imply export)**.** Lean4✓ BEDC.GroundCompiler.MainTheorems.motif existence not export

Completion, carry, circle, complex, or homology motifs do not export mature objects. Mature export remains certificate-mediated.

9222.4 Theorem, chapter, and quotient layers

Definition 9222.17 (Canonical theorem flow). *Lean4 (definition)* `BEDC.GroundCompiler.MainTheorems.CanonicalTh`

A canonical theorem flow *is a sound recognized theorem flow with a recognized canonical-site subflow. Write*

$$\mathsf{CanonicalTheoremFlow}(T).$$

Definition 9222.18 (Theorem code). *Lean4 (definition)* `BEDC.GroundCompiler.MainTheorems.TheoremCode`

If $\mathsf{CanonicalTheoremFlow}(T)$*, define*

$$\mathsf{ThmCode}(T) := \mathsf{Compile}(T).$$

Theorem 9222.19 (Theorem flow / theorem code bijection). *Lean4✓* `BEDC.GroundCompiler.MainTheorems.theore` `code bijection`

There is a bijection

$$\boxed{\mathsf{CanonicalTheoremFlow} \cong \mathsf{LegalTheoremCode}_{01}.}$$

Proof. If T is a canonical theorem flow, then $\mathsf{Compile}(T)$ is a legal channel code. If canonical theorem flows T and U have the same code, then

$$\mathsf{Compile}(T) = \mathsf{Compile}(U)$$

implies $T = U$ by the channel bijection. Conversely, a legal theorem code is by definition the compiled code of a canonical theorem flow, and decoding recovers that flow. □

Corollary 9222.20 (Proposition is not theorem code). *Lean4✓* `BEDC.GroundCompiler.MainTheorems.proposition` `not theorem code`

An abstract proposition is generally not in bijection with theorem code. One proposition may have multiple theorem flows, with different proofs, dependency expansions, certificate strengths, ledgers, canonical sites, and bridge statuses.

Corollary 9222.21 (Theorem code is not proof). *Lean4✓* `BEDC.GroundCompiler.MainTheorems.theorem` `code not proof`

Theorem code records the full theorem flow. Proof is a recognized subflow of that theorem flow and requires generated proof-checker flow. Code does not replace proof checking.

Definition 9222.22 (Canonical chapter flow). *Lean4 (definition)* `BEDC.GroundCompiler.MainTheorems.CanonicalCh`

A canonical chapter flow *is a sound recognized chapter flow with recognized chapter seal, status, ledger, and cannot-claim subflows. Write*

$$\mathsf{CanonicalChapterFlow}(C).$$

Definition 9222.23 (Chapter code). *Lean4 (definition)* `BEDC.GroundCompiler.MainTheorems.ChapterCode`

If $\mathsf{CanonicalChapterFlow}(C)$*, define*

$$\mathsf{ChapCode}(C) := \mathsf{Compile}(C).$$

Theorem 9222.24 (Chapter flow / chapter code bijection). *Lean4✓* `BEDC.GroundCompiler.MainTheorems.chapter` `code bijection`

There is a bijection

$$\boxed{\mathsf{CanonicalChapterFlow} \cong \mathsf{LegalChapterCode}_{01}.}$$

Proof. The proof is the same as for theorem codes. The channel compiler is injective on event flows, and every legal chapter code is the compiled code of a canonical chapter flow. □

Corollary 9222.25 (Chapter topic is not chapter code). Lean4✓ `BEDC.GroundCompiler.MainTheorems.topic not chapter code`

An abstract chapter topic is not in bijection with chapter code. Chapter code corresponds to a complete canonical chapter flow, including definitions, lemmas, theorems, proofs, certificates, ledgers, cannot-claims, status, and chapter seal.

Definition 9222.26 (Raw-flow code layer). Lean4 (definition) `BEDC.GroundCompiler.MainTheorems.RawFlowCodeLay`

The raw-flow code layer *is the graph of the channel coding relation:*

$$\mathsf{RawFlowCodeLayer}(S, c) \iff c = \mathsf{Compile}(S).$$

The channel bijection theorem identifies this graph with the lossless correspondence $\mathsf{EventFlow} \cong \mathsf{LegalZStream}$.

Definition 9222.27 (Classified object layer). Lean4 (definition) `BEDC.GroundCompiler.MainTheorems.ClassifiedOb`

Given a classifier $\sim$ on event flows, the classified-object layer records the co-classification relation between event flows:

$$\mathsf{ClassifiedObjectLayer}(\sim, S, T) \iff S \sim T.$$

This is the constructive representative of the class notation $[S]_\sim$: membership in the class is expressed by a classifier witness rather than by a primitive quotient object.

Theorem 9222.28 (Classifier quotient is generally many-to-one). Lean4✓ `BEDC.GroundCompiler.MainTheorems.cl quotient many to one`

The projection

$$S \longmapsto [S]_\sim$$

is generally not injective. Hence the classified object layer is generally not in bijection with the raw code layer.

Proof. Take the classifier that identifies event flows with the same boundary-erased display string. The distinct flows

$$(0, 00, 000) \qquad \text{and} \qquad (00, 0000)$$

both erase to 000000, so they are co-classified by this classifier while remaining distinct raw event flows. Thus distinct raw flows may map to the same classified object. A source-level Zeckendorf carry can likewise classify 011 and 100 together while keeping them distinct as raw events. □

Corollary 9222.29 (Normal address requires ledger). Lean4✓ `BEDC.GroundCompiler.MainTheorems.normal address requires ledger`

If a normal representative is used as an object address, the raw ledger must be retained; otherwise the pre-normal flow is lost.

9222.5 Recognizers, compilers, motifs, and metrics

Theorem 9222.30 (Recognizer generatedness theorem). Lean4 ✓ BEDC.GroundCompiler.MainTheorems.recognizer generatedness theorem

Every formal recognizer must be a certified event flow. Outputs of host parsers, external grammars, YAML schemas, AST constructors, or meta-level elaborators are not formal recognition judgments unless supported by event-flow recognizer certificates.

Proof. If a recognizer is not an event flow, its recognition power comes from outside the system and is hidden input. If it is an event flow but has no certificate, then soundness, completeness, ledger behavior, failure behavior, and conservativity are not established. Therefore a formal recognizer must be a certified event flow. □

Definition 9222.31 (Self-hosted compiler). Lean4 (definition) BEDC.GroundCompiler.MainTheorems.SelfHostedComp

A compiler flow C is self-hosted *when:*

1. *C is a certified compiler flow;*
2. *C is recognized by a compiler recognizer;*
3. *C compiles itself to a flow C';*
4. *$C' \equiv_{\text{comp}} C$;*
5. *a self-hosting ledger records raw C, compiled code, decoded C', a behavior-classifier witness, and remaining bootstrap obligations.*

Theorem 9222.32 (Self-hosting removes compiler-as-hidden-input). Lean4 ✓ BEDC.GroundCompiler.MainTheorems hosting removes hidden compiler

If there is a self-hosted compiler flow C, and if the package, name-certificate, derivation-certificate, theorem, chapter, and analysis recognizers are supported by the recognizer hierarchy of C, then the compiler is no longer a host-level hidden input.

Proof. Self-hosting states that the compiler itself is an event flow and that compiling it yields a behavior-equivalent flow. The recognizer hierarchy supplies structure recognition without host parsers. The self-hosting ledger records the raw compiler, compiled code, decoded output, behavior equivalence, and bootstrap obligations. Thus formal compiler behavior is supplied by event-flow structure rather than by an external program. □

Corollary 9222.33 (Declared bootstrap boundary). Lean4 ✓ BEDC.GroundCompiler.MainTheorems.declared bootstrap boundary

Without self-hosting, every component not discharged by the event-flow compiler must be recorded as a bootstrap obligation. Otherwise full no-hidden-input status cannot be claimed.

Theorem 9222.34 (Motif analysis theorem). Lean4 ✓ BEDC.GroundCompiler.MainTheorems.motif analysis

Motif analysis is admissible only when motifs are recognized by generated motif recognizers and every nontrivial motif carries ledger data.

Proof. A motif is a source-level structure. If it is obtained from an external pattern table or a channel substring search, then it is hidden input or wrong-layer analysis. If it has no ledger, its raw support, normalization, classifier use, or compression is not traceable. Therefore admissible motif analysis requires generated recognizer flow and ledger flow. □

Theorem 9222.35 (Metric conservativity theorem). Lean4✓ BEDC.GroundCompiler.MainTheorems.metric conservativity

Admissible metrics, motif reports, distance matrices, analysis reports, and bridge-obligation reports add no finite-kernel rules and license no mature objects.

Proof. These structures analyze decoded event flows and recognized motifs. They generate no raw marks, add no sameness or continuation rules, provide no name certificate or derivation certificate, and do not trigger an acceptance gate. Hence they are conservative analysis structures. □

Corollary 9222.36 (Similarity is not identity). Lean4✓ BEDC.GroundCompiler.MainTheorems.similarity not identity

Motif similarity, equal signatures, zero distance, and shared prefixes do not imply theorem equivalence, object equality, bridge correctness, or accepted export without separate classifier, bridge, proof, or certificate flow.

9222.6 Cannot-claim registry

Definition 9222.37 (Compiler cannot-claim entry). Lean4 (definition) BEDC.GroundCompiler.MainTheorems.Compil

A compiler cannot-claim entry *contains at least:*

ClaimText	*the blocked claim;*
Status	*the present recognition status;*
WhyNotDischarged	*the missing certificate or ledger;*
RequiredUpgrade	*the flow needed to discharge the block;*
Ledger	*the event-flow record of the block.*

Definition 9222.38 (Required cannot-claim entries). Lean4 (definition) BEDC.GroundCompiler.MainTheorems.Requi

The no-hidden-input compiler part requires at least the following cannot-claim entries.

C1. Arbitrary binary strings have BEDC meaning. *One may not claim that every binary string has BEDC meaning. Only legal channel streams decode to event flows, and only recognized event flows carry structures.*

C2. A channel substring is a source event. *One may not read substrings of channel code as source events. Source events are obtained only after decoding.*

C3. Source-level carry is channel rewrite. *One may not apply* $011 \rightsquigarrow 100$ *directly to compiled channel bits. The valid order is decode, normalize source events, and compile.*

C4. Code existence implies proof. *One may not infer proof from the existence of code. Theorem code records theorem flow; proof-flow and proof-checker flow are required.*

C5. Code existence implies accepted object. *One may not infer accepted export from code existence. Accepted export requires name-certificate flow, derivation-certificate flow, and acceptance-gate flow.*

C6. Package, certificate, theorem, and chapter structures are inputs. *One may not use package objects, certificate objects, theorem packages, or chapter packages as compiler inputs. They are recognized structures inside event flows.*

C7. A recognizer may be a host parser. *An external parser or YAML schema does not count as a formal recognizer. A recognizer must be a certified event flow or an explicit bootstrap obligation.*

C8. Classifier quotient preserves raw-code bijection. *Raw flows biject with codes. Classified objects are quotients and are generally many-to-one over raw flows.*

C9. Motif similarity implies object equality. *Motifs explain structural similarity. Equality requires classifier, proof, bridge, or certificate flow.*

C10. Carry motif implies dimension. *Carry motif is a normalization or lift witness. Geometric, topological, linear, or manifold dimension requires additional certificate flow.*

C11. Seal motif implies completion object. *A seal-like event does not automatically produce a completion object. Completion requires compatible-thread source, classifier, seal certificate, and ledger.*

C12. Report is proof. *Metric and motif reports are output views. Proof and certificate flows are separate.*

C13. Self-hosting implies raw compiler equality. *Self-hosting gives behavior-classifier equivalence $C' \equiv_{\mathrm{comp}} C$, not raw event-flow equality $C' = C$.*

C14. Full no-hidden-input claim without self-hosting. *One may not claim a fully no-hidden-input compiler unless a self-hosting compiler flow exists, or all remaining bootstrap obligations are explicit.*

Theorem 9222.39 (Cannot-claim registry is mandatory)**.** Lean4✓ `BEDC.GroundCompiler.MainTheorems.cannot claim registry mandatory`

A cannot-claim registry is adequate only if each required entry C1–C14 has a registry entry with a nonempty ledger flow. Consequently, every adequate registry contains ledger-backed entries for C1–C14.

Proof. Each entry blocks a known failure mode: invalid channel analysis, hidden structure input, code-as-proof confusion, classifier/equality collapse, motif-as-object confusion, or hidden bootstrap. Adequacy of the registry is the finite condition that every required cannot-claim code has an entry whose ledger is present as an event flow. Applying that condition to C1–C14 gives the required ledger-backed entries. □

9222.7 Global conservativity and final theorem

Theorem 9222.40 (Global conservativity theorem)**.** Lean4✓ `BEDC.GroundCompiler.MainTheorems.global conservativity`

The no-hidden-input streaming compiler layer is conservative over the BEDC finite kernel. It adds no raw marks, history constructors, msame *rules,* hsame *rules,* psame *rules,* Ext/Cont *rules, kernel equalities, derived-interface formation rules, or mature-object primitives.*

Proof. Every construction in this part is one of: an event flow over the existing display alphabet, a channel encoding or decoding relation, a recognition relation over event flows, a certificate recognition relation, an analysis relation over decoded event flows, a report output view, a bootstrap obligation, or a behavior classifier over compiler flows. None introduces BEDC kernel constructors

or equality rules. Derived interfaces still require recognized name-certificate flows. Mature exports still require recognized derivation-certificate flows and acceptance gates. Classifier relations remain classifier-level, not kernel equality. □

Corollary 9222.41 (Compiler layer is an address-and-analysis layer)**.** *Lean4✓ BEDC.GroundCompiler.MainTheorem layer address analysis layer*

The compiler layer provides lossless event-flow coding, recognizer-mediated structure extraction, certificate-flow tracking, theorem and chapter coding, motif and metric analysis, cannot-claim auditing, and bootstrap accounting. It provides no new mathematical primitives.

Theorem 9222.42 (No-Hidden-Input Streaming Compiler Theorem)**.** *Lean4✓ BEDC.GroundCompiler.MainTheorem hidden input streaming compiler*

There is a formal compiler architecture satisfying all of the following:

1. *The only ground input is a finite* $\mathsf{b0}, \mathsf{b1}$*-generated event flow.*
2. *The channel compiler gives a bijection*

$$\mathsf{EventFlow} \cong ((0 \mid 10)^* 11)^*.$$

3. *Package, name-certificate, derivation-certificate, acceptance-gate, theorem, chapter, recognizer, compiler, motif, metric, and report structures are not inputs; they are recognized event-flow structures.*
4. *Recognizers themselves are certified event flows or explicitly recorded bootstrap obligations.*
5. *Mature-object export is mediated only by recognized name-certificate, derivation-certificate, and acceptance-gate flows.*
6. *Theorem codes are bijective with canonical theorem flows, not with abstract propositions.*
7. *Chapter codes are bijective with canonical chapter flows, not with abstract chapter topics.*
8. *Classifier quotient generally destroys raw-code bijection at the object layer; raw ledger must be retained.*
9. *Source-level normalization never acts directly on channel bits.*
10. *Motif and metric analyses are explanatory and conservative; they do not replace proof or certificate.*
11. *Self-hosting compiler flow, if achieved, removes compiler-as-hidden-input up to compiler-behavior classification.*
12. *Until self-hosting is achieved, bootstrap boundaries must be explicitly recorded.*
13. *The compiler layer is conservative over the BEDC finite kernel.*

Proof. The first clause follows from the ground event-flow definition. The second follows from Definition 9222.4. The third follows from Definition 9222.10 and the recognition chapters. The fourth follows from Definition 9222.30. The fifth follows from Definition 9222.14. The sixth and seventh follow from the theorem-code and chapter-code bijections. The eighth follows from Definition 9222.28. The ninth follows from Definition 9222.7. The tenth follows from Definition 9222.34 and Definition 9222.35. The eleventh follows from Definition 9222.32. The twelfth follows from Definition 9222.33. The final clause follows from Definition 9222.40. □

Remark 9222.43 (Summary)**.** *The only ground input is a* `b0, b1` *event flow. Event flows and legal channel streams are in bijection. Higher structures are recognized event-flow structures, not inputs. Theorem codes biject with canonical theorem flows; chapter codes biject with canonical chapter flows. Mature export still requires name-certificate, derivation-certificate, and acceptance-gate flows. Classifier quotients, motif similarity, and metric reports do not replace proof or certificate. The compiler layer is conservative over the BEDC finite kernel.*

Chapter 9223

Implementation Interface and Verification Targets

chapter 9222 establishes the main theorem of the no-hidden-input streaming compiler:

$$\mathsf{EventFlow} \cong ((0 \mid 10)^* 11)^*.$$

It also fixes the rule that packages, certificates, theorems, chapters, recognizers, and compilers are not first-layer inputs. They must appear as structures recognized inside event flows.

This chapter moves to the implementation interface while preserving the same discipline:

implementations may use host data structures, but the public formal interface may not expose them as BEDC p

Host representations such as lists, arrays, strings, parser states, Lean structures, Rust structs, or Python dataclasses may be engineering devices. The formal surface exposes only event-flow relations such as IsEventFlow, Compiles, Decodes, and the recognition judgments.

9223.1 Implementation layer and formal surface

Definition 9223.1 (Implementation representation)**.** *Lean4 (definition)* `BEDC.GroundCompiler.ImplementationInte`

An implementation representation *is a host-language data structure used temporarily to represent event flows, bit streams, recognition results, or reports. Examples include host lists of booleans, arrays of bits, strings, vectors, parser states, JSON objects, Lean structures, Rust structs, and Python dataclasses.*

Such representations may be used in engineering implementations, but they are not BEDC public mathematical objects.

Definition 9223.2 (Public formal interface)**.** *Lean4 (definition)* `BEDC.GroundCompiler.ImplementationInterface.Pu`

A public formal interface *is an interface stated only in BEDC event-flow relations. Allowed public forms include*

$$\mathsf{IsRawEvent}(x), \quad \mathsf{IsEventFlow}(S), \quad \mathsf{IsLegalZStream}(c),$$

$$\mathsf{Compiles}(S, c), \quad \mathsf{Decodes}(c, S), \quad \mathsf{RecognizesPkg}(R, S),$$

$$\mathsf{RecognizesNameCert}(R, S, N), \quad \mathsf{RecognizesDerivCert}(R, D, N, s),$$

$$\mathsf{RecognizesTheorem}(R, T), \quad \mathsf{RecognizesChapter}(R, C), \quad \mathsf{RecognizesCompiler}(R, C),$$

and

$$\mathsf{AcceptFlow}(A, N, s).$$

Disallowed public forms include maps from host package structures to strings, parsers from YAML to theory packages, recognizers from host ASTs to theorems, and proof checkers from host proof objects to booleans.

Principle 9223.3 (Host representation is not BEDC structure). Lean4 ✓ BEDC.GroundCompiler.ImplementationIn representation not structure

Host representation may implement BEDC relations, but it must not become BEDC public structure. A host list may implement an event-flow representation, but EventFlow *is not a mathematical primitive defined by host lists. A parser state may implement decoding, but a parser state is not a source-level theorem witness.*

Definition 9223.4 (Implementation soundness). Lean4 (definition) BEDC.GroundCompiler.ImplementationInterfac

Let an implementation function or program f_{impl} claim to implement a formal relation $\mathcal{R}$. The implementation is sound *for $\mathcal{R}$ when every success returned by f_{impl} implies the corresponding formal relation.*

For example, if an implementation decoder returns success with output S on input c, then one must have

$$\mathsf{Decodes}(c, S).$$

Definition 9223.5 (Implementation completeness). Lean4 (definition) BEDC.GroundCompiler.ImplementationInter

An implementation f_{impl} is complete relative to a domain *D for a formal relation $\mathcal{R}$ when every instance of $\mathcal{R}$ on input in D is returned by the implementation.*

For example, if $c \in \mathsf{LegalZStream}$ and $\mathsf{Decodes}(c, S)$, then a complete decoder over the legal-stream domain returns success with output S. Completeness is always domain-relative.

Definition 9223.6 (No-host-leak condition). Lean4 (definition) BEDC.GroundCompiler.ImplementationInterface.No

An implementation satisfies the no-host-leak condition *when its public theorem statements, certificate statements, and compiler claims do not expose host-level primitives as BEDC objects. In particular, the public surface may not treat host natural numbers, booleans, lists, strings, equality, quotients, function spaces, parser states, ASTs, theorem identifiers, file paths, YAML, JSON, choice, or classical oracles as BEDC objects.*

These devices may appear inside implementation proofs as tools, but not as the BEDC public surface.

Theorem 9223.7 (Host leak invalidates no-hidden-input status). Lean4 ✓ BEDC.GroundCompiler.Implementationl leak invalidates

If an implementation's public interface contains a datum that is both public input and an implementation representation, then the implementation cannot claim no-hidden-input compiler status.

Proof. The no-hidden-input status includes the no-host-leak condition for the public surface. A public datum that is also an implementation representation is exactly a witness that the no-host-leak condition fails. Hence the no-hidden-input claim fails. □

9223.2 Core implementation modules

Definition 9223.8 (Channel core module). Lean4 (definition) BEDC.GroundCompiler.ImplementationInterface.Cha

The channel core module *implements the channel-layer definitions*

$$\zeta(0) = 0, \qquad \zeta(1) = 10, \qquad \mathsf{Ev}(w) = \zeta(w)11.$$

Its public relations are

$$\mathsf{EncodesEvent}(w, c), \quad \mathsf{Compiles}(S, c), \quad \mathsf{IsLegalZStream}(c).$$

A suitable module name is

BEDC.Compiler.Channel.Core.

Executable functions may exist internally, but theorem statements should align with relation form.

Definition 9223.9 (Decoder core module)**.** *Lean4 (definition)* `BEDC.GroundCompiler.ImplementationInterface.Dec`

The decoder core module *implements the scan rules:*

$$0 \mapsto \textit{raw } 0, \qquad 10 \mapsto \textit{raw } 1, \qquad 11 \mapsto \textit{event end}.$$

Its public relations are

$$\mathsf{Decodes}(c, S), \qquad \mathsf{Rejects}(c, r),$$

where the rejection reason r must itself eventually be event-flow data, not a permanent host enum. A suitable module name is

BEDC.Compiler.Channel.Decode.

Definition 9223.10 (Round-trip module)**.** *Lean4 (definition)* `BEDC.GroundCompiler.ImplementationInterface.Roun`

The round-trip module *proves*

$$\mathsf{Decodes}(\mathsf{Compile}(S), S)$$

and, for legal channel streams,

$$c \in \mathsf{LegalZStream} \Rightarrow \mathsf{Compiles}(\mathsf{Decode}(c), c).$$

A suitable module name is

BEDC.Compiler.Channel.RoundTrip.

Definition 9223.11 (Layer-separation module)**.** *Lean4 (definition)* `BEDC.GroundCompiler.ImplementationInterface`

The layer-separation module *proves that source-level events are not channel substrings, that the channel terminator* 11 *is not the source event* 11*, and that source normalization acts only after decoding. A suitable module name is*

BEDC.Compiler.LayerSeparation.

Definition 9223.12 (Recognizer core module)**.** *Lean4 (definition)* `BEDC.GroundCompiler.ImplementationInterface.`

The recognizer core module *supplies the general recognition relation*

$$\mathsf{Recognizes}(R, \rho, S)$$

and recognizer certification relation

$$\mathsf{CertifiedRecognizer}(R, \rho).$$

A suitable module name is

BEDC.Compiler.Recognizer.Core.

Definition 9223.13 (Certificate recognizer modules). *Lean4 (definition)* `BEDC.GroundCompiler.ImplementationInte`

The certificate and structure recognizer modules expose only event-flow recognition relations. Suitable module names include

BEDC.Compiler.Recognizer.Package, BEDC.Compiler.Recognizer.NameCert,
BEDC.Compiler.Recognizer.DerivCert, BEDC.Compiler.Recognizer.AcceptGate,
BEDC.Compiler.Recognizer.Theorem, BEDC.Compiler.Recognizer.Chapter,
BEDC.Compiler.Recognizer.Compiler.

Definition 9223.14 (Analysis modules). *Lean4 (definition)* `BEDC.GroundCompiler.ImplementationInterface.Analy`

Analysis modules include motif, metric, report, cannot-claim, and bridge-obligation modules. They must maintain the rules that reports are output views, metrics are protocol-relative, motif recognition requires generated recognizers, and analysis is conservative.

9223.3 Channel compiler specification

Definition 9223.15 (Event encoder specification). *Lean4 (definition)* `BEDC.GroundCompiler.ChannelEncoding.Enco`

The event encoding specification is the relation

$$\mathsf{EncodesEvent}(w, c)$$

defined by

$$c = \zeta(w)11.$$

Definition 9223.16 (Flow compiler specification). *Lean4 (definition)* `BEDC.GroundCompiler.ChannelEncoding.Comp`

The flow encoding specification is the relation

$$\mathsf{Compiles}(S, c)$$

defined as follows. If

$$S = (w_0, \ldots, w_{n-1}),$$

then

$$c = \mathsf{Ev}(w_0) \cdots \mathsf{Ev}(w_{n-1}).$$

Definition 9223.17 (Event decoder specification). *Lean4 (definition)* `BEDC.GroundCompiler.ImplementationInterf`

The event decoding specification is the relation

$$\mathsf{DecodesEvent}(c, w)$$

defined by

$$\mathsf{EncodesEvent}(w, c).$$

This is a specification-level relation. An implementation may scan the input, but its proof must connect the scan to this relation.

Definition 9223.18 (Stream decoder specification). *Lean4 (definition)* `BEDC.GroundCompiler.ImplementationInter`

The stream decoding specification is the relation

$$\mathsf{Decodes}(c, S)$$

defined by

$$\mathsf{Compiles}(S, c).$$

Thus the executable decoder must prove soundness and completeness with respect to the specification-level bijection.

Proposition 9223.19 (Specification-level decoder is functional)**.** *Lean4✓ BEDC.GroundCompiler.ImplementationI functional*

If

$$\mathsf{Decodes}(c, S) \qquad \textit{and} \qquad \mathsf{Decodes}(c, T),$$

then $S = T$.

Proof. By the definition of Decodes, both S and T compile to c. The channel compiler is injective on event flows, so $S = T$. □

Proposition 9223.20 (Specification-level compiler is functional)**.** *Lean4✓ BEDC.GroundCompiler.ChannelEncodin functional*

If

$$\mathsf{Compiles}(S, c) \qquad \textit{and} \qquad \mathsf{Compiles}(S, d),$$

then $c = d$.

Proof. By the definition of Compiles, both c and d are the concatenated event encoding of the same event flow S. Hence $c = d$. □

9223.4 Executable encoder and decoder obligations

Definition 9223.21 (Executable decoder)**.** *Lean4 (definition) BEDC.GroundCompiler.ImplementationInterface.Exe*

An executable decoder *is an implementation-layer procedure that consumes a bit stream and returns either an event flow or a rejection reason. The formal public statements do not expose host result types or host rejection enums as BEDC primitives.*

Its obligations are decoder soundness, decoder completeness on the legal-stream domain, and rejection soundness.

Theorem 9223.22 (Decoder soundness obligation)**.** *Lean4✓ BEDC.GroundCompiler.ImplementationInterface.dec soundness obligation*

If the implementation decoder returns success with event flow S on input c, then

$$\mathsf{Decodes}(c, S)$$

must hold.

Proof. The implementation proof must establish scanner invariants: the already-read prefix corresponds to completed events, the current event body lies in $(0 \mid 10)^*$, reading 11 completes an event, a dangling 1 rejects, and input termination leaves no unclosed event. These invariants imply agreement with the specification-level Decodes relation. □

Theorem 9223.23 (Decoder completeness obligation)**.** *Lean4✓ BEDC.GroundCompiler.ImplementationInterface. completeness obligation*

If $c \in \mathsf{LegalZStream}$ *and* $\mathsf{Decodes}(c, S)$*, then the implementation decoder must return success with event flow* S.

Proof. A legal stream lies in $((0 \mid 10)^*11)^*$. The scanner therefore encounters no dangling 1, no unclosed event, and no illegal token. Each event body decodes uniquely to a raw event. Hence the implementation returns the specified S. □

Theorem 9223.24 (Reject soundness obligation). *Lean4✓ BEDC.GroundCompiler.ImplementationInterface.reje soundness obligation*

If the reference executable decoder rejects input c with event-flow reason r, then

$$c \notin \mathsf{LegalZStream}.$$

Any implementation-domain rejection policy must be expressed as its own event-flow relation before it can appear in the public formal interface.

Proof. If $c \in \mathsf{LegalZStream}$, then $c = \mathsf{Compile}(S)$ for some event flow S. By the channel round-trip theorem, decoding c returns success with S. This contradicts rejection by the reference executable decoder. □

Definition 9223.25 (Executable encoder). *Lean4 (definition) BEDC.GroundCompiler.ImplementationInterface.Exe*

An executable encoder *is an implementation-layer procedure from event-flow representation to bit-stream representation. Its formal obligations are encoder soundness, encoder totality over event flows, and absence of internal event terminators inside encoded event bodies.*

Theorem 9223.26 (Encoder soundness obligation). *Lean4✓ BEDC.GroundCompiler.ImplementationInterface.enc soundness obligation*

If the implementation encoder returns c on event flow S, then

$$\mathsf{Compiles}(S, c)$$

must hold.

Proof. The implementation must show that each raw event is encoded by ζ and followed by the event terminator 11, and that event encodings are concatenated in the order of S. □

Theorem 9223.27 (Encoder totality obligation). *Lean4✓ BEDC.GroundCompiler.ImplementationInterface.encod totality obligation*

For every $S \in \mathsf{EventFlow}$, the implementation encoder returns some c such that

$$\mathsf{Compiles}(S, c).$$

Proof. Each raw event is finite, so applying ζ to its finite body and appending 11 produces a finite event code. A finite event flow has finitely many such event codes, so their concatenation exists. □

Theorem 9223.28 (Encoder no-internal-terminator obligation). *Lean4✓ BEDC.GroundCompiler.ImplementationI no internal terminator obligation*

For every raw event w, the event body $\zeta(w)$ contains no adjacent 11.

Proof. Each source 0 contributes channel 0, and each source 1 contributes channel 10. Hence every channel 1 inside the body is followed by 0, never by another 1. Therefore 11 can occur only as the appended terminator. □

9223.5 Public recognition interfaces

Definition 9223.29 (Package recognition public interface)**.** *Lean4 (definition)* `BEDC.GroundCompiler.Implementatio`
The package recognition public interface is

$$\mathsf{RecognizesPkg}(R, S).$$

Host AST package parsers and YAML package parsers are not public formal inputs.

Definition 9223.30 (Name-certificate recognition public interface)**.** *Lean4 (definition)* `BEDC.GroundCompiler.Imple`
The name-certificate recognition public interface is

$$\mathsf{RecognizesNameCert}(R, S, N).$$

Host name-certificate records are not formal inputs.

Definition 9223.31 (Derivation-certificate recognition public interface)**.** *Lean4 (definition)* `BEDC.GroundCompiler.I`
The derivation-certificate recognition public interface is

$$\mathsf{RecognizesDerivCert}(R, D, N, s).$$

Host derivation-certificate structures and host strength enums are not formal inputs.

Definition 9223.32 (Theorem recognition public interface)**.** *Lean4 (definition)* `BEDC.GroundCompiler.Implementati`
The theorem recognition public interface is

$$\mathsf{RecognizesTheorem}(R, T).$$

Theorem names as strings, Lean theorem identifiers, proof ASTs, and host proof objects are not formal theorem inputs.

Definition 9223.33 (Chapter recognition public interface)**.** *Lean4 (definition)* `BEDC.GroundCompiler.Implementatio`
The chapter recognition public interface is

$$\mathsf{RecognizesChapter}(R, C).$$

Chapter YAML, chapter manifests, Markdown ASTs, and LaTeX section trees are not formal chapter inputs.

Definition 9223.34 (Compiler recognition public interface)**.** *Lean4 (definition)* `BEDC.GroundCompiler.Implementati`
The compiler recognition public interface consists of relations such as

$$\mathsf{RecognizesCompiler}(R, C), \qquad \mathsf{CertifiedCompiler}(C), \qquad \mathsf{Compiles}_C(S, T), \qquad \mathsf{SelfHosting}(C).$$

Host executable paths, binary hashes, and build scripts may be implementation-ledger audit data, but they do not replace compiler event flow.

9223.6 No-host-leak audit

Definition 9223.35 (Host-leak audit item). *Lean4 (definition)* `BEDC.GroundCompiler.ImplementationInterface.Hos`

A host-leak audit item *is an event flow recording the occurrence of host-level input in an implementation statement. It contains at least a location, the host construct, why it is a leak, the replacement relation, status, and ledger.*

Examples include a host list exposed as BEDC event flow, a host natural number exposed as raw length, YAML used as package input, or a string theorem label used as theorem identity.

Definition 9223.36 (No-host-leak audit). *Lean4 (definition)* `BEDC.GroundCompiler.ImplementationInterface.NoHo`

An implementation module passes no-host-leak audit *when:*

1. *all public statements use only event-flow relations;*
2. *all host structures remain inside implementation proof internals;*
3. *all remaining host dependencies are recorded as bootstrap obligations;*
4. *all reports, YAML views, and JSON views are marked as output views.*

Theorem 9223.37 (No-host-leak audit is required for compiler certification). *Lean4 ✓* `BEDC.GroundCompiler.Impl` `host leak required`

If an implementation module fails the no-host-leak audit, then it cannot be a certified no-hidden-input compiler component.

Proof. Failure of the audit means that host-level structure has entered the public interface, or that a host dependency is unrecorded. This is hidden input. A no-hidden-input compiler component cannot depend on hidden input. □

9223.7 Lean targets and reference executable

Definition 9223.38 (Core Lean target set). *Lean4 (definition)* `BEDC.GroundCompiler.ImplementationInterface.Co`

The first Lean target set should cover only the channel and layer-separation layers:

BitRep, RawEvent, EventFlow, ζ, Ev, Compile,
LegalZStream, Decode, decodeEncodeEvent, decodeEncodeFlow,
encodeDecodeLegal, noInternalTerminator, channelTerminatorUnique, channelSubstringNotSourceEvent.

Definition 9223.39 (Recognizer Lean target set). *Lean4 (definition)* `BEDC.GroundCompiler.ImplementationInterfa`

The second Lean target set covers the recognizer abstraction layer:

RecognizerFlow, CertifiedRecognizer, RecognizesPkg, RecognizesNameCert,
RecognizesDerivCert, RecognizesTheorem, RecognizesChapter, RecognizesCompiler,
recognitionCompileDecodeInvariant, recognitionConservative.

Definition 9223.40 (Certificate Lean target set). *Lean4 (definition)* `BEDC.GroundCompiler.ImplementationInterfa`

The third Lean target set covers complete certificate recognition and acceptance:

NameCertFlow, DerivCertFlow, AcceptGateFlow,
soundNameCertFlowLicensesName, soundDerivCertFlowEstablishesDerivCert,
acceptedFlowRequiresNameCertAndDerivCert, codeExistenceNotAcceptance.

Definition 9223.41 (Analysis Lean target set)**.** Lean4 (definition) BEDC.GroundCompiler.ImplementationInterface

The fourth Lean target set covers motif and metric analysis:

$$\mathsf{MotifProfile},\quad \mathsf{SealDepth},\quad \mathsf{CarryIndex},\quad \mathsf{LedgerDepth},$$
$$\mathsf{MetricAdmissible},\quad \mathsf{metricRoundTripInvariant},\quad \mathsf{channelSubstringMetricInadmissible},$$
$$\mathsf{motifSimilarityNotIdentity},\quad \mathsf{metricsConservative}.$$

Remark 9223.42 (Do not formalize high-level objects first)**.** *The first implementation targets should not be definitions of infinity, dimension, real numbers, or circles as primitives. They should be event flows, legal channel streams, recognizer flows, name-certificate flows, derivation-certificate flows, acceptance-gate flows, and motif profiles. Mature objects enter only by certificate-mediated export.*

Definition 9223.43 (Reference executable)**.** Lean4 (definition) BEDC.GroundCompiler.ImplementationInterface.Re

A reference executable *is a runnable program satisfying the channel encoder and decoder specifications. Its tasks are to encode event flows, decode channel streams, check legal streams, and generate human-readable reports from decoded flows. It is not a proof checker or certificate recognizer unless the corresponding recognizer flows and certificates are supplied.*

Proposition 9223.44 (Reference executable alone is not a formal compiler)**.** Lean4 ✓ BEDC.GroundCompiler.Imple
executable not formal compiler

Even if a reference executable passes all encode/decode tests, it is not a full no-hidden-input compiler unless the recognizer hierarchy, certificate flows, and bootstrap obligations are also handled.

Proof. Encode/decode tests establish channel behavior. A full compiler also needs package, certificate, theorem, chapter, and compiler recognition, plus self-hosting or an explicit bootstrap boundary. A reference executable alone does not provide those structures. □

Definition 9223.45 (Reference executable test suite)**.** Lean4 (definition) BEDC.GroundCompiler.ImplementationInt

The minimal reference test suite contains event encoding cases

$$\begin{aligned}
\epsilon &\mapsto 11,\\
0 &\mapsto 011,\\
1 &\mapsto 1011,\\
00 &\mapsto 0011,\\
01 &\mapsto 01011,\\
011 &\mapsto 0101011,\\
100 &\mapsto 100011,
\end{aligned}$$

decoding cases $011 \mapsto 0$ *and* $1011 \mapsto 1$*, rejection of* 0111*, and round trips for*

$$0 \mid 00 \mid 000 \mid 01 \mid 011 \mid 100$$

and

$$0 \mid 00 \mid 001 \mid 0011 \mid 0100.$$

Example 9223.46 (Completion skeleton round trip)**.** *The event flow*

$$0 \mid 00 \mid 000 \mid 01 \mid 011 \mid 100$$

has expected encoded stream

$$011001100011010110101011100011.$$

Decoding that stream should return the original event flow.

Example 9223.47 (Add/fold skeleton round trip)**.** *The event flow*

$$0 \mid 00 \mid 001 \mid 0011 \mid 0100$$

has expected encoded stream

$$011001100101100101011010 0011.$$

Decoding that stream should return the original event flow.

9223.8 Implementation reports and adequacy

Definition 9223.48 (Implementation report)**.** Lean4 (definition) `BEDC.GroundCompiler.ImplementationInterface..`

An implementation report *is an output view generated by a reference executable or formal module. It records module name, implemented relations, test cases, round-trip results, rejection cases, host-leak audit items, bootstrap obligations, proof status, and Lean target status.*

An implementation report is output, not formal input.

Principle 9223.49 (Implementation reports are not certificates)**.** Lean4 ✓ `BEDC.GroundCompiler.Implementationl` `reports not certificates`

An implementation report is not a name-certificate flow, derivation-certificate flow, acceptance-gate flow, or theorem proof-flow. Unless the report flow is separately recognized as a certificate flow, it cannot discharge certificate obligations.

Theorem 9223.50 (Implementation adequacy theorem)**.** Lean4 ✓ `BEDC.GroundCompiler.ImplementationAdequacy` `adequacy`

An implementation I may serve as an implementation of a no-hidden-input compiler component exactly when:

1. *every public relation implemented by I has a formal specification;*
2. *I is sound for those specifications;*
3. *I is complete on the specified domains;*
4. *the public interface has no host leak;*
5. *every host dependency is proof-internal or recorded as a bootstrap obligation;*
6. *every report is marked as an output view;*
7. *every claimed recognizer, certificate, theorem, or chapter function is supported by the corresponding recognizer flow and certificate flow;*
8. *every claimed full-compiler function has self-hosting or an explicitly recorded bootstrap boundary.*

Proof. Necessity: if any condition fails, then there is unspecified behavior, unsoundness, incompleteness, host leak, hidden dependency, report-as-input confusion, uncertified recognition, or hidden compiler input. Each violates the no-hidden-input discipline.

Sufficiency: if all eight conditions hold, every formal output is supported by event-flow relations and recognized certificates; host artifacts remain proof-internal or are recorded as bootstrap obligations; reports are not inputs; recognition claims have certificates; and compiler claims have self-hosting or a declared boundary. Thus I may serve as a no-hidden-input compiler component. □

Corollary 9223.51 (Passing tests is weaker than implementation adequacy)**.** `Lean4✓ BEDC.GroundCompiler.Impl`
`tests weaker than adequacy`

Passing reference executable tests is weaker than implementation adequacy. Tests can support sanity checks and partial soundness evidence, but they cannot replace formal specifications, no-host-leak audit, recognizer certificates, or self-hosting ledger.

Remark 9223.52 (Summary)**.** *This chapter separates implementation representation from public formal interface. Implementations may use host data structures internally, but the public BEDC surface must expose event-flow relations. Channel encoder and decoder implementations require soundness, completeness, rejection, and no-internal-terminator obligations. Recognizers expose relation-form interfaces, not host parsers. No-host-leak audit is required for certification. Reference executables are useful channel tools, but implementation adequacy additionally requires formal specifications, no-host-leak status, bootstrap accounting, recognizer certificates, and self-hosting or a declared boundary.*

Chapter 9224

Minimal Executable Prototype Specification

chapter 9223 fixes the implementation interface: host data structures may be used internally, but the public formal interface must not leak host structure. This chapter specifies the minimal executable prototype. Its purpose is not to recognize all mathematical structures, prove theorems, export mature objects, or replace name certificates, derivation certificates, or acceptance gates. It implements only the lossless streaming channel:

$$\mathsf{EventFlow} \cong \mathsf{LegalZStream}.$$

The prototype encodes event flows, decodes legal channel streams, rejects illegal channel streams, emits human-readable reports, runs round-trip tests, and records rejection, warning, and cannot-claim information.

9224.1 Scope and display representations

Definition 9224.1 (Reference prototype)**.** *Lean4 (definition)* `BEDC.GroundCompiler.MinimalPrototype.ReferencePr`

A reference prototype *is an executable implementation P_0 whose formal capability is limited to*

$$\mathsf{Compile} : \mathsf{EventFlow} \to \mathsf{LegalZStream}, \qquad \mathsf{Decode} : \mathsf{LegalZStream} \to \mathsf{EventFlow},$$

together with illegal-input rejection. Write

$$\mathsf{ReferencePrototype}(P_0).$$

It is a channel-level prototype, not a full compiler.

Principle 9224.2 (Prototype is not full compiler)**.** *Lean4 ✓* `BEDC.GroundCompiler.MinimalPrototype.reference prototype not full compiler`

The reference prototype P_0 must not claim package recognition, name-certificate recognition, derivation-certificate recognition, acceptance-gate recognition, theorem recognition, chapter recognition, compiler self-hosting, motif analysis, metric analysis, or bridge discovery unless these functions are provided at a later prototype level with the required recognizer flows, certificate flows, or bootstrap obligations.

Definition 9224.3 (Prototype level)**.** *Lean4 (definition)* `BEDC.GroundCompiler.MinimalPrototype.PrototypeLevel`

Prototype levels are ordered as follows:

P_0 *channel prototype;*
P_1 *source-event reporting prototype;*
P_2 *source-level normalizer-ledger prototype;*
P_3 *motif-report prototype;*
P_4 *recognizer-flow prototype;*
P_5 *certificate-flow prototype;*
P_6 *theorem/chapter-flow prototype;*
P_7 *self-hosting prototype.*

This chapter specifies P_0 and optional P_1 output views.

Definition 9224.4 (Prototype input representations)**.** Lean4 (definition) `BEDC.GroundCompiler.MinimalPrototype.`

At implementation level, P_0 may accept two display representations:

1. *an event-flow display, such as*

$$0 \mid 00 \mid 000 \mid 01 \mid 011 \mid 100,$$

which displays the event flow $(0, 00, 000, 01, 011, 100)$*;*

2. *a channel-stream display, such as*

$$011001100011010110101011100011,$$

which displays a candidate channel stream.

These displays are implementation representations, not BEDC formal objects.

Remark 9224.5 (Display separator is not formal structure)**.** *The symbol* $\mid$ *belongs to display notation for human-readable event boundaries. It is not a raw mark, and it does not occur in formal channel code. Thus*

$$0 \mid 00 \mid 000$$

is only a display of the event flow $(0, 00, 000)$*.*

Definition 9224.6 (Prototype encoder)**.** Lean4 (definition) `BEDC.GroundCompiler.MinimalPrototype.PrototypeEnc`

The prototype encoder *is an implementation function from event-flow display to channel-stream display. If the input display parses as event flow S and the output display is c, then it must implement the formal relation*

$$\mathsf{Compiles}(S, c),$$

equivalently $c = \mathsf{Compile}(S)$*.*

Definition 9224.7 (Prototype decoder)**.** Lean4 (definition) `BEDC.GroundCompiler.MinimalPrototype.PrototypeDec`

The prototype decoder *is an implementation function from channel-stream display to either event-flow display or a rejection report. If it returns success with event flow S on channel stream c, then it must implement*

$$\mathsf{Decodes}(c, S).$$

If it rejects, it must return a rejection report.

Definition 9224.8 (Reject report)**.** Lean4 (definition) `BEDC.GroundCompiler.MinimalPrototype.RejectReport`

A reject report *is an implementation-level output view recording why a channel stream is not accepted by the prototype. Typical rejection cases include dangling* 1*, unfinished event, non-binary character, empty-input policy violation, resource-bound excess, and noncanonical display.*

The case "dangling 1*" means that the input ends with an isolated* 1 *that cannot form* 10 *or* 11*. The case "unfinished event" means that an event body has not reached a terminator* 11*. The case "non-binary character" means that the display contains a character other than* 0 *or* 1*.*

Principle 9224.9 (Reject reports are output)**.** *Lean4✓ BEDC.GroundCompiler.MinimalPrototype.reject reports output not formal input*

Reject reports are output views. They are not formal proofs, name certificates, derivation certificates, theorems, chapters, or accepted objects.

9224.2 Encoding and decoding specification

Definition 9224.10 (Prototype event encoder)**.** *Lean4 (definition) BEDC.GroundCompiler.ChannelEncoding.Prototy*

For a raw event $w = w_1 \cdots w_n$, the prototype event encoder outputs

$$\mathsf{Ev}(w) = \zeta(w)11,$$

where

$$\zeta(0) = 0, \qquad \zeta(1) = 10.$$

In implementation terms, each displayed 0 *contributes* 0*, each displayed* 1 *contributes* 10*, and the event terminator* 11 *is appended at the end.*

Definition 9224.11 (Prototype flow encoder)**.** *Lean4 (definition) BEDC.GroundCompiler.ChannelEncoding.Prototyp*

For an event flow

$$S = (w_0, \ldots, w_{n-1}),$$

the prototype outputs

$$\mathsf{Compile}(S) = \mathsf{Ev}(w_0) \cdots \mathsf{Ev}(w_{n-1}).$$

Example 9224.12 (Completion skeleton encoding)**.** *The display*

$$0 \mid 00 \mid 000 \mid 01 \mid 011 \mid 100$$

has event encodings

$$\begin{aligned} 0 &\mapsto 011, \\ 00 &\mapsto 0011, \\ 000 &\mapsto 00011, \\ 01 &\mapsto 01011, \\ 011 &\mapsto 0101011, \\ 100 &\mapsto 100011. \end{aligned}$$

The compiled output is

$$011001100011010110101011100011.$$

Example 9224.13 (Add/fold skeleton encoding)**.** *The display*

$$0 \mid 00 \mid 001 \mid 0011 \mid 0100$$

has event encodings

$$\begin{aligned} 0 &\mapsto 011, \\ 00 &\mapsto 0011, \\ 001 &\mapsto 001011, \\ 0011 &\mapsto 00101011, \\ 0100 &\mapsto 0100011. \end{aligned}$$

The compiled output is

$$011001100101100101011010 0011.$$

Definition 9224.14 (Prototype stream decoder). *Lean4 (definition)* `BEDC.GroundCompiler.MinimalPrototype.Proto`

The prototype decoder scans channel bits left to right using:

$$0 \mapsto \textit{append raw } 0, \qquad 10 \mapsto \textit{append raw } 1, \qquad 11 \mapsto \textit{close current event.}$$

It rejects dangling 1*, unclosed event body under the chosen display policy, and non-binary characters.*

Definition 9224.15 (Decoder state). *Lean4 (definition)* `BEDC.GroundCompiler.MinimalPrototype.DecoderState`

An implementation may use host-level decoder state containing current event bits, completed events, position, and rejection reason. These are implementation internals. Formal behavior is captured by the source-level relation $\mathsf{Decodes}(c, S)$*.*

Example 9224.16 (Decode completion skeleton code). *The channel stream*

$$011001100011010110101011100011$$

segments as

$$011, \quad 0011, \quad 00011, \quad 01011, \quad 0101011, \quad 100011$$

and decodes to

$$0 \mid 00 \mid 000 \mid 01 \mid 011 \mid 100.$$

Example 9224.17 (Rejecting 0111). *The input* 0111 *scans as* 0 *followed by* 11*, closing the first event as raw* 0*, and then leaves a dangling* 1*. The prototype rejects with a dangling-*1 *report.*

Example 9224.18 (Decoding raw source event 11). *The source event* 11 *encodes as*

$$101011.$$

The decoder reads 10 *as raw* 1*, then* 10 *as raw* 1*, then* 11 *as event terminator. The output is the source event* 11*. Thus channel terminator* 11 *is not the source raw event* 11*.*

9224.3 Prototype test suite

Definition 9224.19 (Required unit tests). *Lean4 (definition)* `BEDC.GroundCompiler.MinimalPrototype.RequiredUni`

The reference prototype must pass the following event-level encoding tests:

$$\begin{array}{rcl}
\epsilon & \mapsto & 11, \\
0 & \mapsto & 011, \\
1 & \mapsto & 1011, \\
00 & \mapsto & 0011, \\
01 & \mapsto & 01011, \\
10 & \mapsto & 10011, \\
11 & \mapsto & 101011, \\
011 & \mapsto & 0101011, \\
100 & \mapsto & 100011, \\
0011 & \mapsto & 00101011.
\end{array}$$

Definition 9224.20 (Required round-trip tests). *Lean4 (definition)* `BEDC.GroundCompiler.MinimalPrototype.Requi`

The reference prototype must pass event round trips for

$$\epsilon, \quad 0, \quad 1, \quad 00, \quad 01, \quad 10, \quad 11, \quad 011, \quad 100, \quad 001, \quad 0011, \quad 0100,$$

and flow round trips for

$$0 \mid 00 \mid 000 \mid 01 \mid 011 \mid 100,$$

$$0 \mid 00 \mid 001 \mid 0011 \mid 0100,$$

$$011 \mid 100, \qquad 1 \mid 11 \mid 011 \mid 100.$$

Definition 9224.21 (Required reject tests). *Lean4 (definition)* `BEDC.GroundCompiler.MinimalPrototype.RequiredR`

The reference prototype must reject, or explicitly classify by implementation policy, the displays

$$1, \qquad 0111, \qquad 010, \qquad 101, \qquad 000.$$

Here 1 *is dangling,* 0111 *contains a valid first event followed by dangling* 1*,* 010 *decodes an event body but lacks terminator,* 101 *decodes raw* 1 *followed by dangling* 1*, and* 000 *is an event body without a terminator.*

Remark 9224.22 (Empty stream policy). *The empty channel stream may be accepted as the empty event flow or rejected by implementation policy when nonempty input is required. The formal channel language allows empty concatenation:*

$$\epsilon \in ((0 \mid 10)^* 11)^*.$$

Rejecting the empty stream is therefore implementation-domain policy, not a channel-language theorem.

9224.4 Prototype outputs

Definition 9224.23 (Decode report). *Lean4 (definition)* `BEDC.GroundCompiler.MinimalPrototype.DecodeReport`

A decode report *is human-readable output containing the input channel stream, legality status, decoded event flow when legal, event segmentation, rejection reason when illegal, and warnings. It is an output view, not a formal proof.*

Definition 9224.24 (Encode report). *Lean4 (definition)* `BEDC.GroundCompiler.MinimalPrototype.EncodeReport`

An encode report *is human-readable output containing the input event-flow display, per-event encoding, final channel stream, round-trip check result, and warnings. It is an output view, not a formal proof.*

Example 9224.25 (Encode report for completion skeleton). *For input*

$$0 \mid 00 \mid 000 \mid 01 \mid 011 \mid 100,$$

an encode report may record the per-event codes 011*,* 0011*,* 00011*,* 01011*,* 0101011*, and* 100011*, the compiled stream*

$$011001100011010110101011100011,$$

and a successful round trip.

Example 9224.26 (Decode report for carry-looking pair)**.** *The input*

$$0101011100011$$

segments as

$$0101011, \quad 100011$$

and decodes to

$$011 \mid 100.$$

The report must not assert $011 = 100$*. If this pair is read as a carry, a source-level carry recognizer and ledger are required.*

Principle 9224.27 (Reports must include warnings)**.** *Lean4✓ BEDC.GroundCompiler.MinimalPrototype.reports must include warnings*

When reports contain carry-looking pairs such as $011 \mid 100$ *or* $0011 \mid 0100$*, they must warn that these are raw events, not equality claims. Any carry interpretation requires source-level recognizer and ledger.*

9224.5 Prototype correctness

Theorem 9224.28 (Prototype encoder soundness)**.** *Lean4✓ BEDC.GroundCompiler.MinimalPrototype.prototype encoder soundness*

If the reference prototype encodes event flow S *and returns channel stream* c*, then*

$$\mathsf{Compiles}(S, c).$$

Proof. By specification, the encoder applies Ev to each event and concatenates the results. This is exactly the definition of $\mathsf{Compile}(S)$. □

Theorem 9224.29 (Prototype decoder soundness)**.** *Lean4✓ BEDC.GroundCompiler.MinimalPrototype.prototype decoder soundness*

If the reference prototype decodes channel stream c *and returns event flow* S*, then*

$$\mathsf{Decodes}(c, S).$$

Proof. The decoder scans c by the grammar 0 for raw 0, 10 for raw 1, and 11 for event end. If it returns S, then c has been parsed as a concatenation of legal event codes for the events of S. Hence $c = \mathsf{Compile}(S)$, so $\mathsf{Decodes}(c, S)$. □

Theorem 9224.30 (Prototype decoder completeness on legal streams)**.** *Lean4✓ BEDC.GroundCompiler.MinimalPr decoder completeness on legal streams*

If $c \in \mathsf{LegalZStream}$*, then the reference decoder returns some event flow* S *such that*

$$\mathsf{Decodes}(c, S).$$

Proof. A legal stream lies in $((0 \mid 10)^*11)^*$, hence is a concatenation of legal event codes. Event bodies contain no internal 11, so the first 11 after each body uniquely terminates an event. The scanner returns the corresponding event flow. □

Theorem 9224.31 (Prototype reject soundness). *Lean4✓ BEDC.GroundCompiler.MinimalPrototype.prototype reject soundness*

If the reference decoder rejects c with a syntactic reject reason, formally

$$\mathsf{PrototypeSyntacticReject}(c, r),$$

then

$$c \notin \mathsf{LegalZStream},$$

where implementation-domain policy reasons are not syntactic reject reasons.

Proof. Syntactic rejection records violation of the grammar $((0 \mid 10)^*11)^*$: dangling 1, unclosed event body, or non-binary display character. Such failures cannot occur in a legal stream. Policy rejections, such as empty-input disallowance or resource bounds, must be recorded separately and do not assert syntactic illegality. □

Corollary 9224.32 (Prototype round-trip correctness). *Lean4✓ BEDC.GroundCompiler.ChannelEncoding.prototy roundtrip correctness*

For every event flow S, decoding the prototype encoding of S returns S. For every legal channel stream c, encoding the prototype decoding of c returns c.

Proof. This follows from encoder soundness, decoder soundness, decoder completeness on legal streams, and the channel bijection theorem. □

9224.6 Prototype limitations and CLI

Theorem 9224.33 (Reference prototype does not recognize mathematical structures). *Lean4✓ BEDC.GroundCompiler.MinimalPrototype.reference prototype no math structure recognition*

The reference prototype P_0 does not recognize package, name-certificate, derivation-certificate, theorem, chapter, motif, metric, or accepted-object structures.

Proof. By definition, P_0 implements only channel encoding, decoding, and legality checking. It has no generated recognizer flow for any higher structure. Therefore it cannot formally recognize those structures. □

Corollary 9224.34 (Prototype output is not a name certificate). *Lean4✓ BEDC.GroundCompiler.MinimalPrototyp output not namecert*

Even if a decoded event flow visually resembles a name-certificate flow, P_0 alone cannot recognize it as one. A name-certificate recognizer flow is required.

Corollary 9224.35 (Prototype output is not a theorem). *Lean4✓ BEDC.GroundCompiler.MinimalPrototype.proto output not theorem*

Even if a decoded event flow visually resembles a theorem flow, P_0 alone cannot recognize it as one. A theorem recognizer flow and proof-checker flow are required.

Corollary 9224.36 (Prototype output is not an accepted object). *Lean4✓ BEDC.GroundCompiler.MinimalPrototyp output not accepted*

Even if a decoded event flow contains apparent certificate-like segments, P_0 alone cannot establish an acceptance gate.

Definition 9224.37 (Allowed CLI commands). Lean4 (definition) `BEDC.GroundCompiler.MinimalPrototype.Allowe`

A reference implementation may provide commands named encode, decode, check, roundtrip, and report. Their meanings are implementation conveniences:

encode	*event-flow display to channel stream;*
decode	*channel stream to event-flow display or reject report;*
check	*channel stream to legal or illegal status;*
roundtrip	*event-flow display through encode and decode;*
report	*human-readable encode/decode report.*

These commands are not BEDC formal operators.

Definition 9224.38 (Forbidden CLI meanings at P_0). Lean4 (definition) `BEDC.GroundCompiler.MinimalPrototype.F`

At P_0, the prototype must not provide commands implying higher recognition: name-certificate recognition, theorem recognition, object acceptance, proof, bridge, dimension inference, real-object inference, circle-object inference, or channel-level carry normalization. If such commands exist as stubs, they must report that they require higher recognizer flows.

9224.7 Output formats and audit

Definition 9224.39 (Event-flow display format). Lean4 (definition) `BEDC.GroundCompiler.MinimalPrototype.Event`

An event-flow display may use 0, 1, |, *and whitespace, with* | *separating raw events and whitespace ignored. Empty events are supported only by explicit display syntax such as ϵ, which is display-only and compiles as the empty raw event.*

Definition 9224.40 (Channel-stream display format). Lean4 (definition) `BEDC.GroundCompiler.MinimalPrototype.`

A channel-stream display uses only 0 *and* 1, *with no separators. Successful decoding requires legal channel syntax.*

Definition 9224.41 (Report format). Lean4 (definition) `BEDC.GroundCompiler.MinimalPrototype.PrototypeReport`

A report may contain input, output, events, event codes, rejection reason, round-trip status, and warnings. It must not be accepted as formal input.

Principle 9224.42 (Reports are output views). Lean4 ✓ `BEDC.GroundCompiler.MinimalPrototype.prototype reports output not formal input`

Reports may be exported as text, Markdown, JSON, YAML, or HTML, but all are output views. None is a formal compiler input.

Definition 9224.43 (Prototype audit checklist). Lean4 (definition) `BEDC.GroundCompiler.MinimalPrototype.Proto`

A P_0 prototype must satisfy:

1. *event encoding implements $\zeta(w)11$;*
2. *flow encoding concatenates event encodings;*
3. *stream decoding implements the* 0/10/11 *scanner;*
4. *dangling* 1 *is rejected;*
5. *unclosed event body is rejected;*
6. *non-binary characters are rejected;*
7. *required unit tests pass;*

8. *required round-trip tests pass;*
9. *carry-looking pairs produce warnings;*
10. *no structure recognition is claimed;*
11. *YAML, AST, and package structures are not accepted as input;*
12. *no theorem, object, or proof claim is exposed.*

Theorem 9224.44 (Prototype audit suffices for P_0 adequacy)**.** `Lean4✓` `BEDC.GroundCompiler.MinimalPrototype.` `audit suffices`

If a reference prototype satisfies the audit checklist and its encoder and decoder satisfy soundness and completeness obligations, then it is adequate as a P_0 channel prototype.

Proof. The checklist covers exactly the duties of P_0: channel encoding, decoding, legality checking, round-trip testing, rejection reporting, and non-claim discipline. Soundness and completeness establish correctness against the formal channel relations. Therefore the prototype is adequate at level P_0. □

Corollary 9224.45 (P_0 adequacy does not imply higher adequacy)**.** `Lean4✓` `BEDC.GroundCompiler.MinimalProtot` `adequacy not higher`

Adequacy at P_0 does not imply adequacy for package recognition, theorem recognition, certificate recognition, motif analysis, or self-hosting.

9224.8 Example sessions and conservativity

Example 9224.46 (Encoding completion skeleton)**.** *Encoding the display*

$$0 \mid 00 \mid 000 \mid 01 \mid 011 \mid 100$$

returns

$$011001100011010110101011100011.$$

The report may say that round trip succeeds and that the occurrence of 011 *followed by* 100 *may be read as carry only after a source-level carry recognizer is supplied.*

Example 9224.47 (Decoding completion skeleton)**.** *Decoding*

$$011001100011010110101011100011$$

returns

$$0 \mid 00 \mid 000 \mid 01 \mid 011 \mid 100$$

with legal status and six events.

Example 9224.48 (Rejecting invalid stream)**.** *Decoding* 0111 *rejects with dangling* 1*: the prefix* 011 *decodes to raw event* 0*, and the remaining* 1 *is not a legal token.*

Example 9224.49 (Encoding raw source event 11)**.** *Encoding the single raw source event* 11 *returns*

$$101011.$$

The report must warn that source raw event 11 *is not channel terminator* 11*.*

Theorem 9224.50 (Reference prototype is conservative over the finite kernel)**.** Lean4✓ BEDC.GroundCompiler.Min
prototype conservative over kernel

Implementing P_0 adds no raw marks, history constructors, sameness rules, continuation rules, derived-interface formation rules, or accepted-object export rules.

Proof. P_0 implements only channel encoding and decoding of event flows. It does not introduce source events beyond the existing display alphabet, assert msame, hsame, or psame, alter Ext or Cont, recognize name certificates or acceptance gates, or license mature objects. Therefore it is conservative over the finite kernel. □

Corollary 9224.51 (Reference prototype is an address layer)**.** Lean4✓ BEDC.GroundCompiler.MinimalPrototype.r
prototype address layer

P_0 provides a lossless address layer for event flows. It is not a mathematical object generator.

Remark 9224.52 (Summary)**.** *This chapter specifies the minimal executable prototype P_0. It implements event and flow encoding, channel decoding, legal-stream checking, round trips, and reports. It must satisfy encoder soundness, encoder totality, decoder soundness, decoder completeness, rejection soundness, warning discipline, and the P_0 audit checklist. It must not claim package recognition, certificate recognition, theorem recognition, object export, motif analysis, metric analysis, bridge discovery, or compiler self-hosting. Thus P_0 is a channel-level reference prototype, not a full compiler.*

Chapter 9225

Source-Event Reporting Prototype

chapter 9224 defines the minimal executable prototype P_0, which encodes event flows, decodes channel streams, checks legality, rejects illegal inputs, and runs round-trip tests. This chapter defines the next prototype level:

$$\boxed{P_1 = P_0 + \text{decoded source-event reports.}}$$

The P_1 layer is a source-event reporting prototype. It does not recognize packages, name certificates, derivation certificates, theorems, chapters, or accepted objects. It decodes a legal channel stream into an event flow and emits a structured human-readable report.

The guiding rule is:

$$\boxed{\text{a report is an output view, not an input, not a recognizer, and not a proof.}}$$

9225.1 Source-event reports

Definition 9225.1 (Source-event reporting prototype)**.** *Lean4 (definition)* `BEDC.GroundCompiler.SourceReport.Sou`

A source-event reporting prototype *is an executable prototype P_1 satisfying:*

1. *P_1 includes the encode, decode, check, and round-trip functions of P_0;*
2. *if the input is a legal channel stream c, then P_1 decodes*
$$S = \mathsf{Decode}(c);$$
3. *P_1 emits a source-event report $\mathsf{Report}_{\mathrm{src}}(c, S)$;*
4. *the report describes source events, channel segments, round-trip status, warnings, and cannot-claim annotations;*
5. *the report does not recognize packages, name certificates, theorems, chapters, or accepted objects.*

Write

$$\mathsf{SourceReportPrototype}(P_1).$$

Principle 9225.2 (Report is output, not input)**.** *Lean4 ✓* `BEDC.GroundCompiler.SourceReport.source report output not input`

Reports generated by P_1 are output views. They cannot be used as formal compiler input structures. In particular, there is no formal inference step from report to package, name certificate, theorem, or accepted object. The allowed direction is:

$$\textit{channel stream} \longrightarrow \mathsf{Decode} \longrightarrow \textit{event flow} \longrightarrow \textit{source-event report.}$$

Definition 9225.3 (Source-event report). *Lean4 (definition)* `BEDC.GroundCompiler.SourceReport.SourceEventRepo`

Given a legal channel stream

$$c \in \mathsf{LegalZStream}$$

and decoded event flow

$$S = \mathsf{Decode}(c) = (w_0, \ldots, w_{n-1}),$$

a source-event report *is an output view containing at least the input channel stream, legality status, decoded event count, event index, raw event, channel segment for each event, body segment for each event, terminator segment for each event, round-trip check, source/channel separation warning, and cannot-claim annotations.*

Write

$$\mathsf{SrcReport}(c, S).$$

Definition 9225.4 (Event segment). *Lean4 (definition)* `BEDC.GroundCompiler.SourceReport.EventSegment`

Let $S = (w_0, \ldots, w_{n-1})$ *and* $c = \mathsf{Compile}(S)$. *The* event segment *of the* i*-th event is*

$$\mathsf{Seg}_i(c, S) := \mathsf{Ev}(w_i).$$

This is a channel-level substring corresponding to a complete event encoding, not an arbitrary channel substring.

Definition 9225.5 (Body and terminator segment). *Lean4 (definition)* `BEDC.GroundCompiler.SourceReport.BodyTe`

For an event w_i*, its event segment is*

$$\mathsf{Seg}_i = \zeta(w_i)11.$$

Define

$$\mathsf{Body}_i := \zeta(w_i), \qquad \mathsf{Term}_i := 11.$$

Then

$$\mathsf{Seg}_i = \mathsf{Body}_i \mathsf{Term}_i.$$

Proposition 9225.6 (Event segments partition the channel stream). *Lean4✓* `BEDC.GroundCompiler.SourceReport segments partition`

If

$$c = \mathsf{Compile}(w_0, \ldots, w_{n-1}),$$

then

$$c = \mathsf{Seg}_0 \mathsf{Seg}_1 \cdots \mathsf{Seg}_{n-1}.$$

Proof. By the flow compiler definition,

$$\mathsf{Compile}(w_0, \ldots, w_{n-1}) = \mathsf{Ev}(w_0) \cdots \mathsf{Ev}(w_{n-1}).$$

By definition, $\mathsf{Seg}_i = \mathsf{Ev}(w_i)$. Substitution gives the displayed partition. □

Corollary 9225.7 (Reports may display event segmentation). *Lean4✓* `BEDC.GroundCompiler.SourceReport.sourc report may display segments`

Since event segments partition the channel stream, P_1 *may display segment* 0 *through segment* $n-1$ *without introducing an external tree or AST. The segmentation is induced by channel decoding.*

Definition 9225.8 (Event index). *Lean4 (definition)* `BEDC.GroundCompiler.SourceReport.EventIndex`

For a decoded event flow $S = (w_0, \ldots, w_{n-1})$, the event index *of w_i is i. In a report, event index is implementation-level display. It is not a BEDC source event and not part of the formal event flow.*

Remark 9225.9 (Event index is not source structure). *The index i helps a human inspect the decoded flow. It is not a raw event, theorem label, package label, or object identity. A report may print $w_i = 011$, but the formal source event is just 011.*

9225.2 Warnings and cannot-claims

Definition 9225.10 (Literal source warning). *Lean4 (definition)* `BEDC.GroundCompiler.SourceReport.LiteralSourc`

A literal source warning *is a report entry generated from raw source events without claiming motif recognition. Examples include: an event 011 followed by 100, an event containing adjacent source 11, an event resembling a raw completion witness, or an event resembling a normal-address candidate.*

Every literal warning must state that it is candidate-only and requires recognizer flow for interpretation.

Principle 9225.11 (Literal warning is not motif recognition). *Lean4 ✓* `BEDC.GroundCompiler.SourceReport.liter` `warning not recognition`

A literal source warning is not a motif recognition judgment. Thus a warning that 011 is followed by 100 does not imply a Zeckendorf-carry relation and does not imply a classifier equivalence. It only states that the decoded event flow contains the literal adjacent events $011 \mid 100$.

Definition 9225.12 (Cannot-claim annotation). *Lean4 (definition)* `BEDC.GroundCompiler.SourceReport.CannotCla`

A cannot-claim annotation *in a source-event report records what the report does not establish. Required examples include:*

- *decoded event flow is not theoremhood;*
- *decoded event flow is not a name certificate;*
- *decoded event flow is not a derivation certificate;*
- *decoded event flow is not an acceptance gate;*
- *literal $011 \mid 100$ is not carry without recognizer;*
- *channel terminator 11 is not source event 11;*
- *report is not proof;*
- *report is not package recognition.*

Principle 9225.13 (Nontrivial reports include cannot-claims). *Lean4 ✓* `BEDC.GroundCompiler.SourceReport.sour` `report nontrivial cannot claims`

If a report displays events commonly used as mathematical witnesses, such as 01, 011, 100, 001, 0011, or 0100, then it must include cannot-claim annotations preventing overinterpretation.

Definition 9225.14 (Source report for illegal input). *Lean4 (definition)* `BEDC.GroundCompiler.SourceReport.Illega`

If channel input c is illegal, P_1 does not produce a source-event report. The formal core of an illegal-input report is:

$$c \notin \mathsf{LegalZStream} \quad \textit{and} \quad \forall S \in \mathsf{EventFlow},\ \neg\, \mathsf{SrcReport}(c, S).$$

The rendered rejection report may contain the input, failure position, rejection reason, optionally a partial decoded prefix if policy allows it, and a cannot-claim annotation saying that an illegal channel stream has no decoded event flow.

Proposition 9225.15 (Illegal channel stream has no source-event report). Lean4 ✓ BEDC.GroundCompiler.SourceR channel no source report

If $c \notin \mathsf{LegalZStream}$, then P_1 cannot output $\mathsf{SrcReport}(c, S)$ for any S.

Proof. A source-event report requires $S = \mathsf{Decode}(c)$. But Decode is defined on legal channel streams. If c is not legal, no decoded event flow S is available. □

Definition 9225.16 (Round-trip report). Lean4 (definition) BEDC.GroundCompiler.SourceReport.RoundTripReport

A round-trip report *for input event flow S records S, $\mathsf{Compile}(S)$, $\mathsf{Decode}(\mathsf{Compile}(S))$, and the comparison result. It succeeds when*

$$\mathsf{Decode}(\mathsf{Compile}(S)) = S.$$

For input channel stream c, it records c, $\mathsf{Decode}(c)$, $\mathsf{Compile}(\mathsf{Decode}(c))$, and the comparison result. It succeeds when

$$\mathsf{Compile}(\mathsf{Decode}(c)) = c.$$

Proposition 9225.17 (Round-trip report is determined by channel bijection). Lean4 ✓ BEDC.GroundCompiler.Sou report determined

If $S \in \mathsf{EventFlow}$, then its round-trip report succeeds. If $c \in \mathsf{LegalZStream}$, then its round-trip report succeeds.

Proof. This is exactly the channel bijection theorem:

$$\mathsf{Decode}(\mathsf{Compile}(S)) = S, \qquad \mathsf{Compile}(\mathsf{Decode}(c)) = c.$$

□

9225.3 Report format and examples

Definition 9225.18 (Minimal source-event report format). Lean4 (definition) BEDC.GroundCompiler.SourceReport.

A minimal report contains input channel stream, legal status, decoded event-flow display when legal, event index, raw event, body code, terminator code, full event code, round-trip status, literal source warnings, and cannot-claim annotations.

Example 9225.19 (Report for completion skeleton). *For input*

$$011001100011010110101011100011,$$

the decoded event flow is

$$0 \mid 00 \mid 000 \mid 01 \mid 011 \mid 100.$$

The event table records:

index	*raw*	*body*	*terminator*	*code*
0	0	0	11	011
1	00	00	11	0011
2	000	000	11	00011
3	01	010	11	01011
4	011	01010	11	0101011
5	100	1000	11	100011.

Warnings include that the literal pair 011 | 100 *appears, but this is not carry recognition and requires source-level carry recognizer flow. Cannot-claims include that the decoded flow does not license* $\mathsf{FullAxis}^{\uparrow}$*, Completion, or dimension-lift structure, that* 011 *is not equal to* 100*, that channel terminator* 11 *is not source event* 11*, and that the report is not proof.*

Example 9225.20 (Report for Add/fold skeleton)**.** *For input*

$$011001100101100101011010 0011,$$

the decoded event flow is

$$0 \mid 00 \mid 001 \mid 0011 \mid 0100.$$

The event table records raw events 0*,* 00*,* 001*,* 0011*, and* 0100 *with codes* 011*,* 0011*,* 001011*,* 00101011*, and* 0100011*. The report may warn that the literal pair* 0011 | 0100 *appears, but this is not fold recognition without recognizer flow. Cannot-claims include that* 001 *is not* $\mathsf{Add}^{\uparrow}$*,* 0011 *is not* $\mathsf{Mul}^{\uparrow}$*,* 0100 *is not an accepted fold object, and the report supplies no name-certificate or derivation-certificate flow.*

Example 9225.21 (Report for raw source event 11)**.** *For input*

$$101011,$$

the decoded event flow is the single source event 11*. The event table records raw* 11*, body* 1010*, terminator* 11*, and code* 101011*. Warnings state that source raw event* 11 *is represented in channel as* 101011*, that the final* 11 *is the channel terminator, and that the source* 11 *is encoded as* 10 10*. Cannot-claims state that channel terminator is not source* 11*, source* 11 *is not automatically a seal, and source* 11 *is not automatically completion.*

9225.4 Soundness and display policy

Definition 9225.22 (Sound source report)**.** *Lean4 (definition)* `BEDC.GroundCompiler.SourceReport.SoundSourceRep`

A source-event report $\mathsf{SrcReport}(c, S)$ *is* sound *when:*

1. $c \in \mathsf{LegalZStream}$*;*
2. $\mathsf{Decode}(c) = S$*;*
3. *every event-table row corresponds to an actual event* w_i *of* S*;*
4. *every displayed event code equals* $\mathsf{Ev}(w_i)$*;*
5. *every warning is marked candidate-only unless backed by recognizer flow;*
6. *every cannot-claim annotation is consistent with the limited capability of* P_1*.*

Theorem 9225.23 (Sound report theorem)**.** *Lean4 ✓* `BEDC.GroundCompiler.SourceReport.source report sound report`

If P_1 *produces a sound source-event report* $\mathsf{SrcReport}(c, S)$*, then*

$$\mathsf{Decodes}(c, S).$$

Proof. By soundness of the report, $c \in \mathsf{LegalZStream}$ and $\mathsf{Decode}(c) = S$. Hence $\mathsf{Decodes}(c, S)$. □

Corollary 9225.24 (Source report preserves raw event flow). Lean4 ✓ BEDC.GroundCompiler.SourceReport.source report preserves raw flow

A sound source-event report records exactly the decoded source event flow. It does not add or remove source events.

Theorem 9225.25 (Source report does not recognize structures). Lean4 ✓ BEDC.GroundCompiler.SourceReport.so report does not recognize structures

A sound P_1 source-event report does not establish package, name-certificate, derivation-certificate, theorem, chapter, motif, or accepted-object recognition.

Proof. The P_1 layer decodes channel streams and reports source events. It has no generated recognizer flow for package, certificate, theorem, chapter, motif, or accepted-object roles. Therefore it cannot establish those recognitions. □

Corollary 9225.26 (Warnings are weaker than recognitions). Lean4 ✓ BEDC.GroundCompiler.SourceReport.warni weaker than recognitions

A warning such as "literal pair $011 \mid 100$ *appears" is not carry motif recognition. It only reports a literal pattern in decoded source events.*

Theorem 9225.27 (Cannot-claims prevent overinterpretation). Lean4 ✓ BEDC.GroundCompiler.SourceReport.can claims prevent overinterpretation

If a P_1 source report contains raw events commonly used as higher-layer witnesses, then cannot-claim annotations are required to prevent the report from being read as proof or certificate.

Proof. At P_1, no higher recognizers are present. Any interpretation of raw events as completion, carry, theorem, package, or accepted object would exceed P_1 capability. Cannot-claim annotations record this limitation explicitly. Without them, the report could be mistaken for a stronger claim. □

Definition 9225.28 (Display policy). Lean4 (definition) BEDC.GroundCompiler.SourceReport.DisplayPolicy

A display policy *is an implementation-level convention determining how event flows and reports are printed. It may specify the raw event separator, empty-event marker, event-index format, indentation, warning format, and cannot-claim format. Display policy is output formatting, not formal input.*

Principle 9225.29 (Display policy is not semantics). Lean4 ✓ BEDC.GroundCompiler.SourceReport.display policy not semantics

Changing display policy must not change $\mathsf{Decode}(c)$ *or* $\mathsf{Compile}(S)$*. Display policy may change how reports look, but not what event flow they report.*

Proposition 9225.30 (Display policy does not affect round trip). Lean4 ✓ BEDC.GroundCompiler.SourceReport.di policy roundtrip

If two reports differ only by display policy, they represent the same decoded event flow and the same channel stream.

Proof. Display policy affects only output formatting. It does not alter Compile or Decode. □

Definition 9225.31 (Canonical display policy). Lean4 (definition) BEDC.GroundCompiler.SourceReport.CanonicalD

A canonical display policy for P_1 may use separator "$\mid$", empty event marker ϵ, event index form i, explicit body, terminator, and code fields, warnings after the event table, and cannot-claims last. This policy is recommended for reproducibility but remains output policy, not source semantics.

9225.5 No-host-leak and adequacy

Definition 9225.32 (Host leak in report). Lean4 (definition) BEDC.GroundCompiler.SourceReport.HostLeakInRepor

A source report contains a host leak *if it presents host-level structures as formal BEDC structures. Examples include a Python list interpreted as an event-flow object, JSON object interpreted as a package, YAML object interpreted as a chapter, string label interpreted as theorem identity, or host enum interpreted as status flow.*

Theorem 9225.33 (Host-leaking report is inadmissible). Lean4✓ BEDC.GroundCompiler.SourceReport.host leak inadmissible

If a P_1 report contains a host leak, then it is not an admissible source-event report.

Proof. A report is an output view of decoded event flow. Presenting host structures as formal BEDC structures introduces hidden input or misrepresents implementation artifacts as source-level objects. This violates the no-host-leak condition. □

Corollary 9225.34 (JSON and YAML reports are views only). Lean4✓ BEDC.GroundCompiler.SourceReport.json yaml reports view only

JSON or YAML output is allowed only when clearly marked as a human-readable report. It cannot be re-imported as formal compiler input.

Definition 9225.35 (P_1 audit checklist). Lean4 (definition) BEDC.GroundCompiler.SourceReport.P1AuditChecklist

A P_1 prototype must satisfy:

1. *all P_0 audit requirements;*
2. *legal channel streams decode to event flows;*
3. *reports display exact event segmentation;*
4. *reports display body and terminator separately;*
5. *reports flag source/channel distinctions;*
6. *reports include cannot-claim annotations for high-risk events;*
7. *reports do not claim package, theorem, certificate, or accepted-object recognition;*
8. *reports do not use host structures as formal objects;*
9. *report round trips agree with* Compile *and* Decode*;*
10. *illegal input generates rejection report, not source report.*

Theorem 9225.36 (P_1 adequacy theorem). Lean4✓ BEDC.GroundCompiler.SourceReport.p1 adequacy

If a prototype satisfies the P_1 audit checklist and its reports are sound, then it is adequate as a source-event reporting prototype.

Proof. The checklist ensures that the prototype implements all P_0 functions and faithfully reports decoded source events. Sound reports guarantee that displayed event flows match $\mathsf{Decode}(c)$. Cannot-claim annotations prevent overinterpretation, and no-host-leak restrictions prevent reports from becoming hidden input. Therefore the prototype is adequate at P_1. □

Corollary 9225.37 (P_1 adequacy does not imply higher adequacy). Lean4✓ BEDC.GroundCompiler.SourceReport. adequacy not higher

A P_1 prototype is not a source-level normalizer, package recognizer, name-certificate recognizer, theorem recognizer, motif analyzer, or self-hosting compiler.

Theorem 9225.38 (Source-event reporting is conservative)**.** `Lean4✓ BEDC.GroundCompiler.SourceReport.source report conservative`

Adding P_1 source-event reports adds no raw marks and creates no source-report recognition judgment. Every raw mark visible in a source-event report remains one of the display-alphabet constructors b0 *or* b1 *in the decoded event flow, and the report itself licenses no sameness rule, continuation rule, derived-interface formation rule, theorem rule, or accepted-object export rule.*

Proof. P_1 only decodes channel streams into event flows and prints reports. It introduces no new source events, asserts no msame, hsame, or psame, modifies neither Ext nor Cont, and recognizes or licenses no higher structure. Hence it is conservative over the finite kernel. □

Corollary 9225.39 (P_1 remains an address/report layer)**.** `Lean4✓ BEDC.GroundCompiler.SourceReport.p1 address report layer`

P_1 remains an address and reporting layer. It is not a mathematical object generator.

9225.6 Full example report

Example 9225.40 (Full P_1 report for completion skeleton)**.** *For input*

$$011001100011010110101011100011,$$

the report has legal status true and decoded event flow

$$0 \mid 00 \mid 000 \mid 01 \mid 011 \mid 100.$$

Its event table is

index	*raw*	*body*	*terminator*	*code*
0	0	0	11	011
1	00	00	11	0011
2	000	000	11	00011
3	01	010	11	01011
4	011	01010	11	0101011
5	100	1000	11	100011.

The round trip records

$$\mathsf{Decode}(c) = 0 \mid 00 \mid 000 \mid 01 \mid 011 \mid 100$$

and

$$\mathsf{Compile}(\mathsf{Decode}(c)) = c.$$

Warnings record that the literal event pair $011 \mid 100$ *appears, with candidate interpretation only: possible source-level carry ledger, requiring generated carry recognizer flow, carry ledger, and classifier exactness. Cannot-claims record that this report does not prove* $011 = 100$*, does not prove* $\mathsf{hsame}(011, 100)$*, does not license* $\mathsf{FullAxis}^{\uparrow}$*, Completion, or dimension-lift structure, and is not a name-certificate flow, theorem flow, or acceptance-gate flow.*

Remark 9225.41 (Summary)**.** *This chapter defines P_1, the source-event reporting prototype. It extends P_0 with decoded event tables, event segmentation reports, body/terminator separation, round-trip reports, literal source warnings, cannot-claim annotations, display policy, and host-leak restrictions. It proves that illegal channel streams have no source-event report, round-trip reports are determined by the channel bijection, sound reports imply decoding, reports preserve*

raw event flows, reports do not recognize higher structures, warnings are weaker than recognitions, cannot-claims prevent overinterpretation, display policy is not semantics, host-leaking reports are inadmissible, P_1 *adequacy follows from audit and report soundness, and source-event reporting is conservative.*

Chapter 9226

Source-Level Normalizer Ledger Prototype

chapter 9225 defines P_1, the source-event reporting prototype. It decodes channel streams, displays source events, shows event segmentation, emits literal warnings, and attaches cannot-claim annotations. It does not recognize packages, certificates, theorems, motifs, or source-level relations.

This chapter defines the next prototype level:

$$P_2,$$

the *source-level normalizer ledger prototype*. Its task is to record candidate normalization ledgers on decoded source event flows, such as

$$011 \mid 100, \qquad 0011 \mid 0100, \qquad 10011 \mid 10100.$$

The essential rule is:

P_2 records candidate normalization ledgers; it does not automatically prove normalization relations.

Thus $011 \mid 100$ is not $011 = 100$, not $\mathsf{hsame}(011, 100)$, and not a Zeckendorf-carry judgment unless a later generated normalizer recognizer flow recognizes and certifies that relation.

9226.1 Adjacent pairs and candidates

Definition 9226.1 (Source-level adjacent pair)**.** *Lean4 (definition)* `BEDC.GroundCompiler.SourceNormalizer.AdjPai`

Given an event flow

$$S = (w_0, w_1, \ldots, w_{n-1}),$$

a source-level adjacent pair *is a pair of consecutive events*

$$(w_i, w_{i+1})$$

with $0 \le i < n - 1$*. Write*

$$\mathsf{AdjPair}(S, i) = (w_i, w_{i+1}).$$

For

$$S = 0 \mid 00 \mid 000 \mid 01 \mid 011 \mid 100,$$

the adjacent pairs are $0 \mid 00$*,* $00 \mid 000$*,* $000 \mid 01$*,* $01 \mid 011$*, and* $011 \mid 100$*.*

Definition 9226.2 (Candidate normalizer pair)**.** *Lean4 (definition)* `BEDC.GroundCompiler.SourceNormalizer.CandN`

A candidate normalizer pair *is a source-level adjacent pair* (w, v) *reported as a possible pre-normal event followed by a possible normal-address event. Write*

$$\mathsf{CandNormPair}(w, v).$$

This is a reporting-layer candidate, not a source-level normalization relation. In particular,

$$\mathsf{CandNormPair}(011, 100)$$

does not imply $011 \rightsquigarrow 100$.

Definition 9226.3 (Normalizer ledger candidate)**.** *Lean4 (definition)* `BEDC.GroundCompiler.SourceNormalizer.Norm`

Given an event flow S *and a candidate-reporting predicate*

$$P_{\text{cand}}(w, v),$$

a normalizer ledger candidate *is a tuple*

$$(i, w, v)$$

such that

$$\mathsf{AdjPair}(S, i) = (w, v)$$

and the pair is reported by P_2 *as a candidate normalizer pair according to* P_{cand}*. Write*

$$\mathsf{NormCand}(P_{\text{cand}}, S, i, w, v).$$

Remark 9226.4 (Candidate reporting is not recognition)**.** *The judgment*

$$\mathsf{NormCand}(P_{\text{cand}}, S, i, w, v)$$

is not the relation $w \rightsquigarrow v$*. It says only that* $w \mid v$ *occurs at positions* $i, i+1$ *in* S *and is recorded as a candidate normalization ledger. A genuine source-level normalization relation requires a generated normalizer recognizer flow* R_N *and a judgment*

$$\mathsf{RecognizesNormalizer}(R_N, S, i, w, v).$$

Definition 9226.5 (Generated normalizer recognizer)**.** *Lean4 (definition)* `BEDC.GroundCompiler.SourceNormalizer.`

A generated normalizer recognizer *is an event flow*

$$R_N \in \mathsf{EventFlow}$$

supporting a relation

$$\mathsf{RecognizesNormalizer}(R_N, S, i, w, v).$$

It reads as: R_N *recognizes the adjacent pair* $w \mid v$ *at position* i *in* S *as a source-level normalizer ledger. It is not an external rewrite table, regex, hardcoded rule, or host-level normalizer.*

Definition 9226.6 (Recognized normalizer ledger)**.** *Lean4 (definition)* `BEDC.GroundCompiler.SourceNormalizer.Nor`

If

$$\mathsf{RecognizesNormalizer}(R_N, S, i, w, v),$$

then (i, w, v) *is a* recognized normalizer ledger *in* S*. Write*

$$\mathsf{NormLedger}_{R_N}(S, i, w, v).$$

Definition 9226.7 (Recognizer-induced normalization relation). *Lean4 (definition)* `BEDC.GroundCompiler.SourceNo`

If

$$\mathsf{NormLedger}_{R_N}(S, i, w, v)$$

and the certificate of R_N contains a soundness flow proving that w and v satisfy a source-level normalization relation, define

$$w \rightsquigarrow_{R_N} v.$$

The relation $\rightsquigarrow_{R_N}$ is induced by the recognizer R_N.

Principle 9226.8 (No normalization without recognizer). *Lean4✓* `BEDC.GroundCompiler.SourceNormalizer.no normalization without recognizer`

Candidate pairs do not produce normalization relations. A recognizer-induced normalization relation contains a recognized normalizer ledger as its ground witness. Only recognized normalizer ledgers, together with recognizer soundness, can support

$$w \rightsquigarrow v.$$

Thus

$$\mathsf{CandNormPair}(w, v) \not\Rightarrow w \rightsquigarrow v.$$

Proposition 9226.9 (Candidate pair preserves raw events). *Lean4✓* `BEDC.GroundCompiler.SourceNormalizer.can preserves raw`

If

$$\mathsf{NormCand}(P_{\text{cand}}, S, i, w, v),$$

then w and v are both retained as source events in S.

Proof. By definition, $\mathsf{NormCand}(P_{\text{cand}}, S, i, w, v)$ means $\mathsf{AdjPair}(S, i) = (w, v)$ together with candidate reporting. Hence $w = w_i$ and $v = w_{i+1}$, so both are source events in S. □

Corollary 9226.10 (Candidate normalizer does not erase pre-normal event). *Lean4✓* `BEDC.GroundCompiler.Sourc does not erase pre normal`

If P_2 reports $011 \mid 100$*, then both* 011 *and* 100 *remain in the decoded event flow. The event* 011 *is not deleted.*

Definition 9226.11 (Pre-normal and normal-address events). *Lean4 (definition)* `BEDC.GroundCompiler.SourceNorm`

If $\mathsf{NormCand}(P_{\text{cand}}, S, i, w, v)$ *or* $\mathsf{NormLedger}_{R_N}(S, i, w, v)$*, then w is the* pre-normal event *of the pair and v is the* normal-address event*. The normal-address role is a ledger role, not object identity, equality target, or mature object.*

Definition 9226.12 (P_2 normalizer ledger report). *Lean4 (definition)* `BEDC.GroundCompiler.SourceNormalizer.P2R`

Given a legal channel stream c with

$$S = \mathsf{Decode}(c),$$

a P_2 normalizer ledger report *contains at least the input channel stream, decoded event flow, adjacent pairs, candidate normalizer pairs, pre-normal events, normal-address events, candidate-only warnings, recognized normalizer ledgers if recognizers are supplied, cannot-claim annotations, and round-trip status.*

Principle 9226.13 (P_2 separates candidate and recognized status). Lean4✓ BEDC.GroundCompiler.SourceNormali recognized separated

A P_2 report must distinguish candidate normalizer pairs from recognized normalizer ledgers. It must not display a candidate pair as a proved relation.

Theorem 9226.14 (Candidate normalizer report does not establish source relation). Lean4✓ BEDC.GroundCompiler.SourceNormalizer.candidate not relation

If P_2 reports only

$$\mathsf{NormCand}(P_{\text{cand}}, S, i, w, v)$$

and no judgment

$$\mathsf{RecognizesNormalizer}(R_N, S, i, w, v)$$

is supplied, then one cannot infer

$$w \rightsquigarrow v.$$

Proof. By Definition 9226.8, a normalization relation requires generated normalizer recognition and soundness flow. A candidate report records adjacent events and candidate role only; it contains no recognizer soundness. □

Corollary 9226.15 (011 | 100 candidate does not prove carry). Lean4✓ BEDC.GroundCompiler.SourceNormalizer. 100 not carry

If P_2 reports 011 | 100 *but no generated carry recognizer flow is supplied, one cannot infer a Zeckendorf-carry relation or a classifier equivalence between* 011 *and* 100.

9226.2 Candidate policies

Definition 9226.16 (Candidate policy flow). Lean4 (definition) BEDC.GroundCompiler.SourceNormalizer.Candidat

A candidate policy flow *is an event flow*

$$P_{\text{cand}} \in \mathsf{EventFlow}$$

specifying which adjacent pairs P_2 may report as candidate normalizer pairs. It is not an external configuration file, YAML, regex, or hardcoded table.

Definition 9226.17 (Generated candidate-policy recognizer). Lean4 (definition) BEDC.GroundCompiler.SourceNorm

A generated candidate-policy recognizer *is an event flow*

$$R_{\text{cand}} \in \mathsf{EventFlow}$$

supporting

$$\mathsf{RecognizesCandidatePolicy}(R_{\text{cand}}, P_{\text{cand}}).$$

Without a recognized candidate policy, P_2 may list literal adjacent pairs but may not mark any pair as a normalizer candidate.

Principle 9226.18 (No hardcoded normalizer table). Lean4✓ BEDC.GroundCompiler.SourceNormalizer.no hardcoded table

The pairs 011 | 100, 0011 | 0100, *and* 10011 | 10100 *may be examples, but they must not be hardcoded as formal normalizer candidates. Formal candidate marking requires recognized candidate policy flow.*

Definition 9226.19 (Literal adjacent-pair listing). *Lean4 (definition)* `BEDC.GroundCompiler.SourceNormalizer.Lit`

Without recognized candidate policy, P_2 may still output every adjacent pair

$$(w_i, w_{i+1})$$

as a literal adjacent-pair listing. *This is not normalizer candidate recognition; it is only an extension of the source-event report.*

Proposition 9226.20 (Literal listing is policy-free). *Lean4✓* `BEDC.GroundCompiler.SourceNormalizer.literal listing policy free`

Literal adjacent-pair listing does not require candidate policy.

Proof. For $S = (w_0, \ldots, w_{n-1})$, the adjacent pairs (w_i, w_{i+1}) are determined by the sequence structure of S. No external rule selects their meaning. Listing them is therefore policy-free. □

Corollary 9226.21 (Candidate marking requires policy). *Lean4✓* `BEDC.GroundCompiler.SourceNormalizer.candi marking requires policy`

P_2 may list adjacent pairs without policy, but marking a pair as a candidate normalizer pair requires recognized candidate policy flow.

9226.3 Recognized normalizer ledgers

Definition 9226.22 (Normalizer recognizer certificate). *Lean4 (definition)* `BEDC.GroundCompiler.SourceNormalizer`

A normalizer recognizer certificate is a record whose public fields are a certificate flow K_N, a generated normalizer recognizer R_N, a domain flow, a candidate-policy flow, a pre-normal criterion flow, a normal-address criterion flow, a relation-soundness flow, a ledger flow, a failure flow, a stability flow, and a seal flow. Write

$$\mathsf{NormalizerRecognizerCert}.$$

Definition 9226.23 (Normalizer soundness). *Lean4 (definition)* `BEDC.GroundCompiler.SourceNormalizer.Normaliz`

A normalizer recognizer R_N is sound *when*

$$\mathsf{RecognizesNormalizer}(R_N, S, i, w, v)$$

implies:

1. *w and v are adjacent in S at position i;*
2. *w is recognized as pre-normal event;*
3. *v is recognized as normal-address event;*
4. *relation-soundness flow supports $w \rightsquigarrow_{R_N} v$;*
5. *ledger flow retains S, i, w, v, failure branches, and classifier context.*

Theorem 9226.24 (Sound normalizer recognizer establishes source relation). *Lean4✓* `BEDC.GroundCompiler.Sour recognizer establishes relation`

If R_N is a sound normalizer recognizer and

$$\mathsf{RecognizesNormalizer}(R_N, S, i, w, v),$$

then

$$w \rightsquigarrow_{R_N} v.$$

Proof. By soundness, the relation-soundness flow supports $w \rightsquigarrow_{R_N} v$. □

Corollary 9226.25 (Recognized carry is stronger than candidate carry)**.** Lean4✓ BEDC.GroundCompiler.SourceNo stronger than candidate

A recognized normalizer ledger with a sound normalizer recognizer can establish a source-level relation. A candidate pair only reports shape.

Definition 9226.26 (Ledger-preserving normalizer)**.** Lean4 (definition) BEDC.GroundCompiler.SourceNormalizer.Le

A normalizer recognizer R_N is ledger-preserving *when every judgment*

$$\mathsf{RecognizesNormalizer}(R_N, S, i, w, v)$$

has ledger flow recording source flow S, position i, pre-normal event w, normal-address event v, normalizer role, classifier context, and failure cases.

Theorem 9226.27 (Ledger-preserving normalizer does not collapse raw events)**.** Lean4✓ BEDC.GroundCompiler.S preserving no collapse

If R_N is ledger-preserving and

$$\mathsf{RecognizesNormalizer}(R_N, S, i, w, v),$$

then w and v remain recorded as raw events even if a later classifier identifies them.

Proof. Ledger preservation records w and v as the two components of the pair and records their position in S. A later classifier may place them in one class, but the ledger retains the raw pre-normal and normal-address events. □

9226.4 Examples and reports

Example 9226.28 (Literal listing for completion skeleton)**.** *The channel stream*

$$011001100011010110101011100011$$

decodes to

$$0 \mid 00 \mid 000 \mid 01 \mid 011 \mid 100.$$

The literal adjacent pairs are

$$0 \mid 00, \quad 00 \mid 000, \quad 000 \mid 01, \quad 01 \mid 011, \quad 011 \mid 100.$$

If no candidate policy is supplied, the report may only list these literal adjacent pairs. It may not mark $011 \mid 100$ *as a carry candidate.*

Example 9226.29 (Candidate policy for carry-looking pairs)**.** *Suppose a recognized candidate policy flow permits a class of source-normal-address-looking pairs. Then in*

$$0 \mid 00 \mid 000 \mid 01 \mid 011 \mid 100$$

the pair $011 \mid 100$ *may be marked as a candidate normalizer pair with pre-normal event* 011 *and normal-address event* 100*. Without normalizer recognizer soundness, it is still not a proved relation.*

Example 9226.30 (Add/fold candidate normalizer)**.** *For input event flow*

$$0 \mid 00 \mid 001 \mid 0011 \mid 0100,$$

the literal adjacent pairs are

$$0 \mid 00, \quad 00 \mid 001, \quad 001 \mid 0011, \quad 0011 \mid 0100.$$

If a candidate policy recognizes fold-style completion pairs, then $0011 \mid 0100$ *may be marked as a candidate normalizer pair. The report must still say that* 001 *is not* $\mathsf{Add}^{\uparrow}$, 0011 *is not* $\mathsf{Mul}^{\uparrow}$, 0100 *is not an accepted normal object, and the candidate pair does not prove a fold relation.*

Example 9226.31 (Higher carry candidate)**.** *For input*

$$100 \mid 10011 \mid 10100,$$

the literal adjacent pairs are $100 \mid 10011$ *and* $10011 \mid 10100$*. A recognized candidate policy may mark* $10011 \mid 10100$ *as a candidate normalizer pair. Without recognizer soundness, no relation*

$$10011 \rightsquigarrow 10100$$

is established.

Definition 9226.32 (P_2 report)**.** *Lean4 (definition)* `BEDC.GroundCompiler.SourceNormalizer.P2ReportFormat`

A P_2 *report extends a* P_1 *report with an adjacent-pair table, candidate-policy status, candidate normalizer pairs, recognized normalizer ledgers if supplied, pre-normal and normal-address display, candidate-only warnings, and normalizer cannot-claims.*

Example 9226.33 (P_2 report for completion skeleton)**.** *For the completion skeleton channel stream, the decoded flow is*

$$0 \mid 00 \mid 000 \mid 01 \mid 011 \mid 100.$$

The adjacent-pair table is

index	*adjacent pair*
0	$0 \mid 00$
1	$00 \mid 000$
2	$000 \mid 01$
3	$01 \mid 011$
4	$011 \mid 100.$

If a carry-looking-pair policy is recognized, the report may mark position 4 *as candidate-only: pre-normal* 011*, normal-address* 100*. Warnings record that no normalizer recognizer, classifier exactness, or Zeckendorf-carry judgment is supplied. Cannot-claims record that* 011 *is not equal to* 100*, not* hsame *with* 100*, and does not license dimension-lift or accepted-object structure.*

Example 9226.34 (P_2 report with recognized normalizer)**.** *If a generated normalizer recognizer* R_N *is supplied and soundly recognizes*

$$\mathsf{RecognizesNormalizer}(R_N, S, 4, 011, 100),$$

the report may include a recognized normalizer ledger at position 4 *and the relation*

$$011 \rightsquigarrow_{R_N} 100.$$

It still may not claim $011 = 100$ *as raw equality or* $\mathsf{hsame}(011, 100)$ *unless a separate classifier or sameness certificate is supplied.*

9226.5 Soundness, conservativity, and adequacy

Theorem 9226.35 (P_2 candidate report is conservative). Lean4✓ BEDC.GroundCompiler.SourceNormalizer.p2 candidate report conservative

Adding candidate normalizer reporting does not add source-level normalization relations: a candidate adjacent pair, without any generated normalizer recognizer recognizing the same source position, cannot produce an induced normalization relation.

Proof. Candidate reporting records adjacent source events and marks them according to candidate policy. It does not supply normalizer recognizer soundness. By Definition 9226.14, candidate reporting alone cannot establish $w \rightsquigarrow v$. □

Theorem 9226.36 (Recognized normalizer relation is source-level). Lean4✓ BEDC.GroundCompiler.SourceNormali normalizer relation source level

If R_N establishes

$$w \rightsquigarrow_{R_N} v,$$

then this relation is source-level and does not act directly on channel bits.

Proof. The relation $\rightsquigarrow_{R_N}$ is defined through $\mathsf{RecognizesNormalizer}(R_N, S, i, w, v)$, whose arguments are source-level event data. Channel bits are not arguments of the relation. To apply it to channel code, one must decode, apply the source relation, and compile. □

Corollary 9226.37 (P_2 does not permit channel rewrite). Lean4✓ BEDC.GroundCompiler.SourceNormalizer.p2 no channel rewrite

Every recognized normalizer relation still returns an adjacent pair in the decoded event flow. It is therefore a source-level ledger relation, not a direct rewrite rule on channel strings. The correct path is decode, source normalizer ledger, and compile.

Theorem 9226.38 (P_2 is conservative over the finite kernel). Lean4✓ BEDC.GroundCompiler.SourceNormalizer.p2 conservative over finite kernel

Adding P_2 candidate normalizer reports, candidate policies, normalizer recognizer relations, and normalizer ledgers adds no raw marks, history constructors, sameness rules, continuation rules, derived-interface formation rules, theorem rules, or accepted-object export rules.

Proof. P_2 operates on decoded event flows. Candidate reporting records adjacent events. Recognized normalizer relations are source-level relations, not kernel equality. None of these generates new $\mathsf{b0}, \mathsf{b1}$ marks, modifies msame, hsame, or psame, changes Ext or Cont, or licenses derived interfaces. □

Corollary 9226.39 (P_2 remains below package recognition). Lean4✓ BEDC.GroundCompiler.SourceNormalizer.p2 below higher recognition

Even with recognized normalizer ledgers, P_2 does not turn host package, name-certificate, derivation-certificate, theorem-identifier, or closure-certificate data into primitive formal compiler inputs. Package, certificate, theorem, chapter, motif, metric, and accepted-object readings require additional generated recognizers.

Definition 9226.40 (P_2 audit checklist). Lean4 (definition) BEDC.GroundCompiler.SourceNormalizer.P2AuditCheck

A P_2 prototype must satisfy:

1. *all P_1 audit requirements;*
2. *all adjacent pairs in the decoded source flow are listable;*

3. *literal adjacent pairs are distinguished from candidate normalizer pairs;*
4. *candidate marking requires recognized candidate policy;*
5. *candidate normalizers are distinguished from recognized normalizer ledgers;*
6. *asserted $w \rightsquigarrow v$ relations require sound generated normalizer recognizers;*
7. *pre-normal and normal-address events are preserved in ledger;*
8. *channel-level rewriting is rejected;*
9. *every candidate pair has cannot-claim annotations;*
10. *no equality,* hsame*, theoremhood, name-certificate, or acceptance claim is made without the relevant certificate.*

Theorem 9226.41 (P_2 adequacy theorem)**.** `Lean4✓` `BEDC.GroundCompiler.SourceNormalizer.p2adequacy`

If a prototype satisfies the P_2 audit checklist, has sound P_1 reports, and every recognized normalizer relation is backed by a sound generated normalizer recognizer, then it is adequate as a source-level normalizer ledger prototype.

Proof. The checklist ensures that the prototype reports adjacent source events, candidate pairs, recognized normalizer ledgers, and warnings without collapsing levels. Sound P_1 reports provide the decoded source event flow. Sound normalizer recognizers justify any asserted $w \rightsquigarrow v$ relation. Cannot-claim annotations prevent overinterpretation. □

Corollary 9226.42 (P_2 adequacy does not imply higher adequacy)**.** `Lean4✓` `BEDC.GroundCompiler.SourceNormali adequacy not higher`

A P_2 prototype is not a motif analyzer, package recognizer, theorem recognizer, name-certificate recognizer, or accepted-object compiler.

9226.6 Full reports

Example 9226.43 (Full P_2 report for completion skeleton)**.** *For input*

$$011001100011010110101011100011,$$

the decoded flow is

$$0 \mid 00 \mid 000 \mid 01 \mid 011 \mid 100.$$

The adjacent pairs are indexed as in Definition 9226.33. If a source-normal-address candidate policy is recognized, the pair at index 4 *is reported as candidate-only with pre-normal event* 011 *and normal-address event* 100*. Recognized normalizer ledgers are none. Warnings state that the candidate pair is not a proved carry relation, no generated normalizer recognizer is supplied, and no classifier exactness is supplied. Cannot-claims prohibit claiming equality,* hsame*, Zeckendorf-carry, dimension-lift, full-axis, or accepted-object status. Round trip succeeds by re-encoding the decoded flow to the original input.*

Example 9226.44 (Full P_2 report for fold skeleton)**.** *For input*

$$011001100101100101011010 0011,$$

the decoded flow is

$$0 \mid 00 \mid 001 \mid 0011 \mid 0100.$$

The adjacent pairs are $0 \mid 00$, $00 \mid 001$, $001 \mid 0011$, *and* $0011 \mid 0100$. *If candidate policy marks the last pair, it is reported candidate-only with pre-normal event* 0011 *and normal-address event* 0100. *Warnings say that the pair is not a proved fold relation and no generated fold normalizer recognizer is supplied. Cannot-claims prohibit reading* 001 *as* $\mathsf{Add}^{\uparrow}$, 0011 *as* $\mathsf{Mul}^{\uparrow}$, *or* 0100 *as an accepted normal object.*

Remark 9226.45 (Summary)**.** *This chapter defines* P_2, *the source-level normalizer ledger prototype. It extends* P_1 *with adjacent-pair listing, candidate normalizer reporting, candidate policy flows, generated normalizer recognizers, recognized normalizer ledgers, pre-normal and normal-address roles, normalizer reports, and normalizer cannot-claims. It proves that candidate reporting is not recognition, candidate normalizer reports do not establish source relations, candidate marking requires recognized policy, sound normalizer recognizers establish recognizer-indexed source relations, ledger preservation does not collapse raw events,* P_2 *reports remain source-level and do not permit channel rewrite,* P_2 *is conservative over the finite kernel, and* P_2 *adequacy requires candidate/recognized separation plus cannot-claim annotations.*

Chapter 9227

Motif-Report Prototype

chapter 9226 defines P_2, the source-level normalizer ledger prototype. It adds adjacent-pair listings, candidate normalizer pairs, recognized normalizer ledgers, pre-normal and normal-address roles, candidate-only warnings, and normalizer cannot-claims to the P_1 source-event report.

This chapter defines the next prototype level:

$$\boxed{P_3 = P_2 + \text{generated motif recognizers} + \text{motif reports.}}$$

The task of P_3 is to recognize and report stable generative motifs on decoded source event flows: finite repetition, continuation, seal, carry, ledger compression, classifier quotient, reuse, and bridge-candidate motifs. It still does not export mature objects. A motif report cannot turn a support flow into $\mathsf{Nat}^{\uparrow}$, $\mathsf{Add}^{\uparrow}$, $\mathsf{Mul}^{\uparrow}$, $\mathsf{FullAxis}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{Circle}^{\uparrow}$, $\mathsf{Complex}^{\uparrow}$, topology, or homology without later name-certificate, derivation-certificate, acceptance-gate, and proof flows.

The governing rule is:

a motif is not an external pattern; it is a stable subflow recognized by a generated recognizer.

9227.1 Motif candidates and recognition

Definition 9227.1 (Motif-report prototype)**.** *Lean4 (definition)* `BEDC.GroundCompiler.SemanticMotif.MotifReport`

A motif-report prototype *is an executable prototype P_3 satisfying:*

1. *P_3 includes all P_2 functions;*
2. *P_3 accepts a decoded event flow $S = \mathsf{Decode}(c)$;*
3. *P_3 may use generated motif recognizer flows R_M;*
4. *P_3 may recognize motif occurrences*

$$\mathsf{RecognizesMotif}(R_M, S, M, \mu);$$

5. *P_3 may output motif reports;*
6. *P_3 does not treat motif reports as proofs, certificates, name-certificate flows, derivation-certificate flows, or acceptance gates.*

Write

$$\mathsf{MotifReportPrototype}(P_3).$$

Definition 9227.2 (Motif candidate). *Lean4 (definition)* `BEDC.GroundCompiler.SemanticMotif.MotifCandidate`
Given an event flow

$$S = (w_0, \ldots, w_{n-1}),$$

a motif candidate *is a source-level subflow $M \subseteq S$. The subflow may be contiguous or indexed. For*

$$S = 0 \mid 00 \mid 000 \mid 01 \mid 011 \mid 100,$$

the subflow $0 \mid 00 \mid 000$ *is a finite-repetition candidate,* $011 \mid 100$ *is a carry candidate, and the whole flow is a completion-skeleton candidate. The inclusion $M \subseteq S$ does not imply recognized motif status.*

Definition 9227.3 (Generated motif recognizer). *Lean4 (definition)* `BEDC.GroundCompiler.SemanticMotif.Generate`
A generated motif recognizer *is an event flow*

$$R_M \in \mathsf{EventFlow}.$$

It is not a host-level pattern matcher, regular expression, YAML motif table, hand-written tag table, or external semantic classifier. It supports a relation

$$\mathsf{RecognizesMotif}(R_M, S, M, \mu),$$

where S is the ambient source event flow, M is the support subflow, and μ is a motif role flow.

Definition 9227.4 (Motif role flow). *Lean4 (definition)* `BEDC.GroundCompiler.SemanticMotif.MotifRole`
A motif role flow *is an event flow*

$$\mu \in \mathsf{EventFlow}$$

representing a motif role, such as finite repetition, continuation, seal, carry, classifier quotient, ledger compression, reuse, or bridge candidate. These names are explanatory; formally μ is not an external enum and must be represented in event-flow form.

Definition 9227.5 (Recognized motif occurrence). *Lean4 (definition)* `BEDC.GroundCompiler.SemanticMotif.Recogn`
If

$$\mathsf{RecognizesMotif}(R_M, S, M, \mu),$$

then M is a recognized motif occurrence *in S under R_M and role μ. Write*

$$M \preceq_{\mu, R_M} S.$$

Remark 9227.6 (Candidate motif is weaker than recognized motif). *The inclusion $M \subseteq S$ only supplies a candidate subflow. The judgment*

$$\mathsf{RecognizesMotif}(R_M, S, M, \mu)$$

is the recognized motif judgment. Thus $0 \mid 00 \mid 000$ *may look like finite repetition and* $011 \mid 100$ *may look like carry, but neither becomes recognized motif without generated recognizer flow.*

Definition 9227.7 (Motif ledger). *Lean4 (definition)* `BEDC.GroundCompiler.SemanticMotif.MotifLedger`
If

$$\mathsf{RecognizesMotif}(R_M, S, M, \mu),$$

a motif ledger *is an event subflow L_M recording the ambient flow S, support subflow M, motif role μ, recognizer R_M, support positions, raw events, normal forms if any, classifier context if any, failure cases, and cannot-claim annotations. Write*

$$\mathsf{MotifLedger}_{R_M}(S, M, \mu, L_M).$$

Principle 9227.8 (No recognized motif without ledger). *Lean4 ✓ BEDC.GroundCompiler.SemanticMotif.recognize motif occurrence has ledger*

Every nontrivial motif recognition carries a motif ledger:

$$\mathsf{RecognizesMotif}(R_M, S, M, \mu) \Rightarrow \exists L_M,\ \mathsf{MotifLedger}_{R_M}(S, M, \mu, L_M).$$

Without such a ledger, the subflow may be reported only as a candidate motif.

Theorem 9227.9 (Motif recognition requires generated recognizer). *Lean4 ✓ BEDC.GroundCompiler.SemanticMoti recognition requires generated recognizer*

If M is a recognized motif occurrence in S, then the recognizing datum R_M is itself present as a formal generated event-flow input. Without such a generated motif recognizer flow, one cannot formally assert

$$\mathsf{RecognizesMotif}(R_M, S, M, \mu).$$

Proof. Motif recognition is a source-level recognition judgment. By the no-hidden-input discipline, the recognizer cannot be supplied by an external pattern table, host regular expression, or human semantic tag. If no generated recognizer flow R_M exists, the source of the recognition is not present inside the event-flow system. □

Corollary 9227.10 (Host regular expressions are not motif recognizers). *Lean4 ✓ BEDC.GroundCompiler.Semantic regex not motif recognizer*

A host regular expression may locate a displayed substring or subflow for implementation convenience, but it is not formal motif recognition. Formal motif recognition requires generated motif recognizer flow and ledger.

9227.2 Basic motifs

Definition 9227.11 (Finite repetition motif). *Lean4 (definition) BEDC.GroundCompiler.SemanticMotif.FiniteRepet*

A finite repetition motif *is a recognized event structure*

$$(x, xx, xxx, \ldots, x^k),$$

where $x \in \mathsf{RawEvent}$ and each successor event is obtained by source-level homogeneous extension of the preceding event. The displayed subflow $0 \mid 00 \mid 000$ is a candidate for $x = 0$. It is recognized only when a judgment

$$\mathsf{RecognizesMotif}(R_{\mathrm{rep}}, S, M, \mu_{\mathrm{rep}})$$

is supplied.

Definition 9227.12 (Continuation motif). *Lean4 (definition) BEDC.GroundCompiler.SemanticMotif.ContinuationM*

A continuation motif *is a recognized event structure indicating that source events combine into a continuation result. Explanatory shapes include*

$$x \mid y \mid xy$$

or an input-flow, input-flow, continuation-result-flow, continuation-witness-flow pattern. A subflow such as $00 \mid 000 \mid 00000$ is only a candidate until recognized.

Definition 9227.13 (Seal motif). *Lean4 (definition)* `BEDC.GroundCompiler.SemanticMotif.SealMotif`

A seal motif *is a recognized event structure indicating completion or closure of a repeat, thread, or process. Explanatory shapes include*

$$x \mid xx \mid xxx \mid x1 \mid x11$$

or finite stages, repeat-boundary witness, seal witness, and tail ledger. The subflow $0 \mid 00 \mid 000 \mid 01 \mid 011$ *is only a completion-like candidate until recognized.*

Definition 9227.14 (Carry motif). *Lean4 (definition)* `BEDC.GroundCompiler.SemanticMotif.CarryMotif`

A carry motif *is a recognized source-level normalizer ledger consisting of a pre-normal event and a normal-address event. Explanatory shapes include*

$$011 \mid 100 \qquad \textit{and} \qquad 0011 \mid 0100.$$

The motif must retain both pre-normal and normal-address events.

Definition 9227.15 (Ledger compression motif). *Lean4 (definition)* `BEDC.GroundCompiler.SemanticMotif.LedgerCo`

A ledger compression motif *is a recognized structure in which a visible event or package-like token hides source material while a ledger subflow retains provenance. It contains visible flow, hidden source flow, ledger flow, source-map or pullback flow, and compression seal flow.*

Definition 9227.16 (Classifier quotient motif). *Lean4 (definition)* `BEDC.GroundCompiler.SemanticMotif.Classifie`

A classifier quotient motif *is a recognized structure in which distinct raw flows are assigned to one classifier class. It contains raw support flows, classifier witness, exactness witness, and a ledger preserving all raw supports. The raw events* 011 *and* 100 *together with a carry-classifier witness form only a candidate until recognized.*

Definition 9227.17 (Reuse motif). *Lean4 (definition)* `BEDC.GroundCompiler.SemanticMotif.ReuseMotif`

A reuse motif *is a recognized structure in which a flow reuses recognized or accepted input flows and creates its own source, classifier, ledger, or certificate obligations. It contains input recognized flows, transport or reuse witness, new local source, new classifier, new ledger, strength bound, and reuse seal.*

Definition 9227.18 (Bridge-candidate motif). *Lean4 (definition)* `BEDC.GroundCompiler.SemanticMotif.BridgeCand`

A bridge-candidate motif *is a recognized structure suggesting that two flows may support a bridge, without supplying the bridge certificate. It contains source flow, target-like flow, motif overlap, translation candidate, missing soundness flow, missing reflection or completeness flow, and missing no-host-leak ledger. A bridge-candidate motif is not a bridge.*

9227.3 Motif reports

Definition 9227.19 (Motif report). *Lean4 (definition)* `BEDC.GroundCompiler.SemanticMotif.MotifReport`

Given a decoded event flow S *and a family of generated motif recognizers* $\mathcal{R}$*, a* motif report *is an output view containing the ambient event flow, recognized motif occurrences, candidate motifs, motif roles, support subflows, motif ledgers, failure cases, warnings, and cannot-claim annotations. Write*

$$\mathsf{MotifReport}_{\mathcal{R}}(S).$$

Principle 9227.20 (Motif report is output, not input). Lean4 ✓ BEDC.GroundCompiler.SemanticMotif.motif report output not input

A motif report is not formal input. It cannot replace recognizer flow, certificate flow, proof flow, name-certificate flow, derivation-certificate flow, or acceptance-gate flow.

Definition 9227.21 (Candidate motif section). Lean4 (definition) BEDC.GroundCompiler.SemanticMotif.Candidatel

A motif report may contain a candidate motif section listing candidate finite repetition, continuation, seal, carry, reuse, and bridge structures. Every entry in that section must be marked candidate-only and requiring recognizer flow for recognition.

Definition 9227.22 (Recognized motif section). Lean4 (definition) BEDC.GroundCompiler.SemanticMotif.Recognize

The recognized motif section may list only motif occurrences satisfying both

$$\mathsf{RecognizesMotif}(R_M, S, M, \mu)$$

and

$$\mathsf{MotifLedger}_{R_M}(S, M, \mu, L_M).$$

Principle 9227.23 (Candidate and recognized sections are separate). Lean4 ✓ BEDC.GroundCompiler.MotifReport recognized sections separate

A motif report must clearly separate candidate motifs from recognized motifs. It must not display a candidate motif as a recognized motif.

Theorem 9227.24 (Motif report soundness). Lean4 ✓ BEDC.GroundCompiler.SemanticMotif.motif report soundness

If a motif report claims that M is a recognized motif in S, then there exist R_M, μ, and L_M such that

$$\mathsf{RecognizesMotif}(R_M, S, M, \mu)$$

and

$$\mathsf{MotifLedger}_{R_M}(S, M, \mu, L_M).$$

Proof. By definition, the recognized motif section may list only entries with a recognizer judgment and ledger. Therefore every reported recognized motif has both. □

Corollary 9227.25 (Motif report cannot invent motifs). Lean4 ✓ BEDC.GroundCompiler.SemanticMotif.motif report cannot invent

If recognizer or ledger is missing, a report may not promote a candidate motif to recognized motif.

9227.4 P_3 pipeline

Definition 9227.26 (P_3 pipeline). Lean4 (definition) BEDC.GroundCompiler.SemanticMotif.P3Pipeline

Given channel code c, the P_3 pipeline has stages:

1. *legality check;*
2. *decode to source event flow S;*
3. *source-event report;*
4. *adjacent-pair listing;*

5. *candidate normalizer ledger report;*
6. *motif recognizer selection;*
7. *motif recognition;*
8. *motif ledger extraction;*
9. *motif report generation;*
10. *cannot-claim annotation.*

Recognizer selection cannot come from an external table. It must come from a recognized recognizer-family flow or be recorded as bootstrap obligation.

Definition 9227.27 (Recognizer family flow)**.** Lean4 (definition) BEDC.GroundCompiler.SemanticMotif.RecognizerF

A recognizer family flow *is an event flow*

$$F_R \in \mathsf{EventFlow}$$

recognized as a family of motif recognizer flows $R_1, \ldots, R_k$*. Write*

$$\mathsf{RecognizesRecognizerFamily}(R_F, F_R, (R_1, \ldots, R_k)).$$

Without a recognized recognizer-family flow, P_3 *can generate only candidate motif reports, not recognized motif reports.*

Principle 9227.28 (No hardcoded motif family)**.** Lean4 ✓ BEDC.GroundCompiler.SemanticMotif.no hardcoded motif family

The finite-repetition, carry, seal, and reuse recognizers may not be hardcoded as a formal recognizer family. They must come from recognized recognizer-family flow or be recorded as bootstrap obligations.

Theorem 9227.29 (Without recognizer family, P_3 is candidate-only)**.** Lean4 ✓ BEDC.GroundCompiler.SemanticMot family candidate only

If P_3 *has no recognized recognizer-family flow, then it can output only a candidate motif section, not a recognized motif section.*

Proof. Recognized motifs require a judgment $\mathsf{RecognizesMotif}(R_M, S, M, \mu)$ and a motif ledger. Without a recognizer family, there is no available R_M. Thus no recognized motif judgment can be produced. □

9227.5 Examples

Example 9227.30 (Candidate motif report for completion skeleton)**.** *For input*

$$011001100011010110101011100011,$$

the decoded event flow is

$$0 \mid 00 \mid 000 \mid 01 \mid 011 \mid 100.$$

A candidate motif report may list finite repetition candidate $0 \mid 00 \mid 000$*, repeat-boundary candidate* 01*, seal candidate* 011*, carry candidate* $011 \mid 100$*, and completion-skeleton candidate equal to the whole flow. Warnings state that the report is candidate-only, no motif recognizer family is supplied, no name-certificate flow is supplied, and no acceptance-gate flow is supplied. Cannot-claims state that finite repetition does not imply* $\mathsf{Nat}^{\uparrow}$*, seal does not imply completion, carry does not imply Zeckendorf-carry, and completion skeleton does not imply* $\mathsf{FullAxis}^{\uparrow}$*.*

Example 9227.31 (Recognized motif report for completion skeleton)**.** *Assume a recognizer family contains certified finite-repetition, seal, and carry recognizers. A report may then list recognized finite repetition with support* $0 \mid 00 \mid 000$*, recognized seal with support* 011*, and recognized carry with support* $011 \mid 100$*, pre-normal event* 011*, normal-address event* 100*, and retained ledger. It still cannot claim that* $\mathsf{FullAxis}^{\uparrow}$ *is licensed, completion is exported, dimension-lift is established, or* $011 = 100$ *as* hsame *without further certificate flows.*

Example 9227.32 (Candidate motif report for fold skeleton)**.** *For input*

$$01100110010110010101101000 11,$$

the decoded flow is

$$0 \mid 00 \mid 001 \mid 0011 \mid 0100.$$

A candidate report may list finite source candidate $0 \mid 00$*, additive-recursion candidate* 001*, fold-completion candidate* $0011 \mid 0100$*, and the whole fold skeleton candidate. Cannot-claims state that* 001 *does not imply* $\mathsf{Add}^{\uparrow}$*,* $0011 \mid 0100$ *does not imply* $\mathsf{Mul}^{\uparrow}$*, and* 0100 *is not an accepted fold object.*

Example 9227.33 (Nat-like and List-like motif comparison)**.** *For flows*

$$0 \mid 00 \mid 000 \mid 01 \qquad \textit{and} \qquad 0 \mid 00 \mid 000,$$

a candidate report may show the shared finite spine $0 \mid 00 \mid 000$*, the extra event* 01 *in the Nat-like flow, and the missing payload classifier, constructor-shape ledger, and length ledger for a List-like reading. Cannot-claims state that shared spine does not imply same object, and neither flow licenses* $\mathsf{Nat}^{\uparrow}$ *or list structure without the corresponding name-certificate flow.*

9227.6 Motif counts

Definition 9227.34 (P_3 motif count)**.** *Lean4 (definition)* `BEDC.GroundCompiler.MotifReportCounts.MotifCountP3`

Given a recognized motif report, define

$$\mathsf{MotifCount}_{P_3}(S, \mu)$$

as the count status for role μ *in the report: it is* $\mathsf{count}(n)$ *when the recognized section supplies the list of* n *recognized motif occurrences of role* μ*, and it is* $\mathsf{undefined}$ *when the report has only a candidate section and no recognized motif list for* μ*. Undefined count status is not the same datum as* $\mathsf{count}(0)$*.*

Definition 9227.35 (P_3 carry count)**.** *Lean4 (definition)* `BEDC.GroundCompiler.MotifReportPrototype.P3CarryCoun`

The P_3 *carry count is the number of recognized carry motif occurrences. If only candidate carry pairs are present, the recognized carry count is undefined; a separate candidate-carry count may be reported.*

Definition 9227.36 (P_3 seal count)**.** *Lean4 (definition)* `BEDC.GroundCompiler.MotifReportPrototype.P3SealCount`

The P_3 *seal count is the number of recognized seal motif occurrences. Candidate seal events appear only in the candidate section.*

Proposition 9227.37 (Candidate count and recognized count differ)**.** *Lean4 ✓* `BEDC.GroundCompiler.MotifReport` `recognized count differ`

Candidate motif count cannot replace recognized motif count: there is a report state with one candidate motif occurrence and no recognized motif list for the same role, so the recognized motif count is undefined rather than $\mathsf{count}(1)$*.*

Proof. Candidate count depends on shape or candidate policy. Recognized count depends on generated recognizers and motif ledgers. These are different evidence levels. Substituting candidate count for recognized count treats unrecognized patterns as recognized motifs. □

Corollary 9227.38 (Missing recognizer does not imply zero motif). Lean4✓ `BEDC.GroundCompiler.MotifReportCo` `recognizer not zero`

If a motif recognizer is missing, the recognized count for that motif is undefined or recognizer-missing, not zero. Otherwise absence of recognition would be mistaken for absence of structure.

9227.7 Soundness, adequacy, and conservativity

Definition 9227.39 (Sound motif report). Lean4 (definition) `BEDC.GroundCompiler.MotifReportPrototype.SoundMo`

A motif report is sound *when:*

1. *the candidate section lists only candidates;*
2. *the recognized section lists only motifs with recognizer and ledger;*
3. *every recognized motif has support subflow in the decoded event flow;*
4. *every motif ledger records support and role;*
5. *cannot-claim annotations cover all high-risk motifs;*
6. *missing recognizers are reported as missing, not as negative evidence.*

Theorem 9227.40 (Sound motif report theorem). Lean4✓ `BEDC.GroundCompiler.MotifReportPrototype.sound` `motif report has recognizer ledger`

If P_3 outputs a sound motif report, then every recognized motif occurrence in the report has a source-level recognition judgment and motif ledger.

Proof. By soundness, the recognized section contains only entries with recognizer and ledger. Hence each recognized motif has $\mathsf{RecognizesMotif}(R_M, S, M, \mu)$ and $\mathsf{MotifLedger}_{R_M}(S, M, \mu, L_M)$. □

Theorem 9227.41 (Motif report does not license objects). Lean4✓ `BEDC.GroundCompiler.MotifReportPrototype.` `report does not license objects`

There exists a sound motif report whose underlying event flow is not an accepted object flow. Thus sound motif reporting does not, by itself, imply accepted-object status or license any derived interface.

Proof. Motif reports supply motif recognition and ledger information. The empty recognized section is sound when it contains no unsupported recognized motifs, but the empty event flow is not an accepted object flow because acceptance requires nonempty certified export structure. Derived interfaces and accepted objects require certificate and acceptance-gate data not supplied by a sound motif report alone. □

Corollary 9227.42 (Recognized carry motif does not imply dimension-lift). Lean4✓ `BEDC.GroundCompiler.Motifl` `carry motif not dimension lift`

There is a recognized carry-motif witness whose ambient event flow does not contain the dimension-lift certificate subflow. Thus recognized carry evidence such as $011 \mid 100$ *does not by itself imply dimension-lift structure; that structure requires its own certificate subflow and ledger.*

Corollary 9227.43 (Recognized seal motif does not imply completion). Lean4✓ BEDC.GroundCompiler.MotifRepo seal motif not completion

There is a recognized seal-motif witness whose ambient event flow does not contain the completion certificate subflow. Thus recognized seal evidence does not by itself imply completion; completion requires compatible-thread source, classifier, seal certificate, and tail ledger.

Definition 9227.44 (P_3 audit checklist). Lean4 (definition) BEDC.GroundCompiler.MotifReportPrototype.P3AuditC

A P_3 prototype must satisfy:

1. *all P_2 audit requirements;*
2. *candidate motifs are distinguished from recognized motifs;*
3. *recognized motifs require generated motif recognizers;*
4. *nontrivial recognized motifs require motif ledgers;*
5. *missing recognizers are reported as undefined, not zero;*
6. *source-level motifs are separated from channel substrings;*
7. *every high-risk motif has cannot-claim annotations;*
8. *no derived interface is licensed;*
9. *no object equality is asserted;*
10. *no theoremhood is asserted;*
11. *no hardcoded motif table is used as formal input;*
12. *implementation-level recognizers have bootstrap obligations unless certified.*

Theorem 9227.45 (P_3 adequacy theorem). Lean4✓ BEDC.GroundCompiler.MotifReportPrototype.p3 adequacy

If a prototype satisfies the P_3 audit checklist, has sound P_2 reports, and every recognized motif is backed by generated motif recognizer and motif ledger, then it is adequate as a motif-report prototype.

Proof. The audit checklist separates candidates, recognized motifs, recognizers, ledgers, missing recognizers, and cannot-claims. Sound P_2 reports supply the decoded source event flow. Generated recognizers and ledgers prevent host-level or hardcoded pattern matches from becoming formal motif recognition. □

Corollary 9227.46 (P_3 adequacy does not imply higher adequacy). Lean4✓ BEDC.GroundCompiler.MotifReportPr adequacy not higher

There exists a sound P_3 motif report whose underlying event flow has no recognized package-flow evidence, no recognized theorem-flow evidence, and no accepted-object-flow evidence. Thus P_3 motif-report adequacy alone is not higher-layer adequacy.

Theorem 9227.47 (P_3 is conservative over the finite kernel). Lean4✓ BEDC.GroundCompiler.MotifReportPrototyp conservative over finite kernel

Adding motif candidate reports, recognized motif reports, motif ledgers, motif counts, and P_3 cannot-claim annotations adds no raw marks, history constructors, sameness rules, continuation rules, derived-interface formation rules, theorem rules, or accepted-object export rules.

Proof. P_3 operates on decoded event flows and recognized subflows. It generates no new $\mathsf{b0}, \mathsf{b1}$, adds no msame, hsame, or psame rules, does not alter Ext or Cont, and does not license derived interfaces or accepted objects. □

Corollary 9227.48 (P_3 remains an analysis layer)**.** `Lean4✓ BEDC.GroundCompiler.MotifReportPrototype.p3 analysis layer not object generator`

There exists a sound P_3 motif report with an empty recognized section, undefined recognized carry count, and no accepted-object-flow evidence. Thus P_3 can provide motif-level analysis and reporting without generating a mathematical object.

9227.8 Full report examples

Example 9227.49 (P_3 report for completion skeleton)**.** *For input*

$$011001100011010110101011100011,$$

the decoded flow is

$$0 \mid 00 \mid 000 \mid 01 \mid 011 \mid 100.$$

The candidate section lists finite repetition $0 \mid 00 \mid 000$*, repeat-boundary* 01*, seal* 011*, carry* $011 \mid 100$*, and completion skeleton equal to the whole flow. Suppose the recognizer family has recognized finite-repetition and carry recognizers, but missing seal and completion recognizers. The recognized section lists finite repetition with retained ledger and carry with pre-normal* 011*, normal-address* 100*, and retained ledger. Seal and completion counts are undefined because their recognizers are missing. Cannot-claims say that there is no completion export, no* $\mathsf{FullAxis}^{\uparrow}$*, no dimension-lift, no object equality, no* $\mathsf{hsame}(011, 100)$*, and no theoremhood.*

Example 9227.50 (P_3 report for fold skeleton)**.** *For input*

$$011001100101100101011010 0011,$$

the decoded flow is

$$0 \mid 00 \mid 001 \mid 0011 \mid 0100.$$

If additive and fold recognizers are missing, the report is candidate-only: finite source $0 \mid 00$*, additive-recursion candidate* 001*, and fold-completion candidate* $0011 \mid 0100$*. Recognized motifs are none. Cannot-claims state that* 001 *is not* $\mathsf{Add}^{\uparrow}$*,* 0011 *is not* $\mathsf{Mul}^{\uparrow}$*,* 0100 *is not an accepted fold object, and no fold relation is present without recognizer.*

Remark 9227.51 (Summary)**.** *This chapter defines P_3, the motif-report prototype. It extends P_2 with motif candidates, generated motif recognizers, motif role flows, recognized motif occurrences, motif ledgers, candidate and recognized sections, motif counts, and P_3 audit rules. It proves that motif recognition requires generated recognizers, host regular expressions are not motif recognizers, nontrivial recognized motifs require ledger, candidate and recognized report sections must be separated, reports cannot invent motifs, missing recognizer families make P_3 candidate-only, candidate and recognized counts differ, missing recognizers do not mean zero motif, sound motif reports provide recognition judgments and ledgers, motif reports do not license objects, and P_3 is conservative over the finite kernel.*

Chapter 9228

Metric-Report Prototype

chapter 9227 defines P_3, the motif-report prototype. It separates candidate motifs, recognized motifs, motif ledgers, recognized motif counts, missing recognizers, and cannot-claim annotations. This chapter defines the next prototype level:

$$\boxed{P_4 = P_3 + \text{admissible metric computation} + \text{metric report.}}$$

The task of P_4 is to compute structural indicators from recognized motif reports: prefix overlap, motif counts, seal depth, carry index, ledger depth, classifier compression ratio, reuse depth, bridge depth, normal-address distance, motif distance, and flow signature vectors.

The governing rule is:

$$\boxed{\text{metrics are explanatory summaries, not proofs, certificates, or object identities.}}$$

Thus P_4 cannot infer that equal metric profiles give equal theories, equal signature vectors give equal objects, distance zero gives theorem equivalence, high overlap gives a bridge, positive carry index gives dimension, or positive seal depth gives a completion object.

9228.1 Metric protocols and admissibility

Definition 9228.1 (Metric-report prototype)**.** *Lean4 (definition)* `BEDC.GroundCompiler.MetricsFlow.MetricReport`

A metric-report prototype *is an executable prototype P_4 satisfying:*

1. *P_4 includes all P_3 functions;*
2. *P_4 receives a decoded event flow S and a recognized motif report;*
3. *P_4 uses a recognized metric protocol flow;*
4. *P_4 computes admissible metrics;*
5. *P_4 emits a metric report;*
6. *P_4 does not treat metric reports as proofs, certificates, bridges, name-certificate flows, derivation-certificate flows, or acceptance gates.*

Write

$$\mathsf{MetricReportPrototype}(P_4).$$

Definition 9228.2 (Metric candidate). *Lean4 (definition)* `BEDC.GroundCompiler.MetricsFlow.MetricCandidate`

A metric candidate *is a proposed numerical value, sequence, set, or summary to compute on an event flow. Examples include seal depth, carry index, ledger depth, reuse depth, bridge depth, motif count, motif distance, prefix overlap, and compression ratio. A metric candidate is not yet an admissible metric.*

Definition 9228.3 (Generated metric recognizer). *Lean4 (definition)* `BEDC.GroundCompiler.MetricsFlow.Generated`

A generated metric recognizer *is an event flow*

$$R_{\mathrm{met}} \in \mathsf{EventFlow}$$

supporting

$$\mathsf{RecognizesMetric}(R_{\mathrm{met}}, m),$$

where m is a metric specification flow. The specification is not an external function name, Python function, JSON field, or hand-written metric table.

Definition 9228.4 (Metric protocol flow). *Lean4 (definition)* `BEDC.GroundCompiler.MetricsFlow.MetricProtocolFl`

A metric protocol flow *is an event flow*

$$P_{\mathrm{met}} \in \mathsf{EventFlow}$$

recognized as a metric-computation protocol. It contains metric-selection flow, metric-domain flow, recognizer-family flow, normalization-policy flow, ledger-policy flow, undefined-value-policy flow, comparison-policy flow, report-policy flow, cannot-claim-policy flow, and protocol seal flow. Write

$$\mathsf{MetricProtocolFlow}(P_{\mathrm{met}}).$$

Principle 9228.5 (No metric without protocol). *Lean4 ✓* `BEDC.GroundCompiler.MetricsFlow.no metric without protocol`

External metric configuration, weight files, manual metric tables, host metric functions, and external similarity functions are not formal inputs. A metric is BEDC-admissible only when specified by recognized metric protocol flow.

Definition 9228.6 (Admissible metric). *Lean4 (definition)* `BEDC.GroundCompiler.MetricsFlow.AdmissibleMetric`

A metric M for an event flow S is admissible *relative to protocol P_{met} when:*

1. *M is given by a recognized metric specification flow;*
2. *its input is the decoded event flow S;*
3. *all motifs used by M come from a recognized motif report;*
4. *all ledgers used by M are recognized ledger flows;*
5. *undefined cases are governed by the protocol flow;*
6. *cannot-claim entries are generated by the report policy;*
7. *M does not depend on channel substring search, external object names, host tags, YAML fields, manual grouping, or unrecognized semantic labels.*

Write

$$\mathsf{AdmissibleMetric}(M, S, P_{\mathrm{met}}).$$

Theorem 9228.7 (Unrecognized metric is inadmissible). *Lean4✓ BEDC.GroundCompiler.MetricsFlow.unrecognized metric inadmissible*

If there is no recognized metric specification flow and no recognized metric protocol flow, then a value or summary cannot be used as a BEDC-admissible metric.

Proof. Admissibility requires recognized specification and protocol flow. Without them, the domain, computation rule, undefined cases, recognizer family, ledger policy, and cannot-claim policy are externally supplied. That is hidden input. □

Corollary 9228.8 (Host similarity score is not admissible). *Lean4✓ BEDC.GroundCompiler.MetricsFlow.host similarity score not admissible*

A similarity score produced only by a host program, embedding model, external statistic, or manual choice is not a BEDC-admissible metric without recognized metric protocol flow.

9228.2 Basic metrics

Definition 9228.9 (Recognized motif count). *Lean4 (definition) BEDC.GroundCompiler.MetricsFlow.RecognizedMot*

Given an event flow S, a recognized motif report, and motif role μ, define

$$\mathsf{MotifCount}(S, \mu)$$

as the number of recognized μ-role occurrences listed in the recognized motif report. If the report contains only candidate motifs and no recognized section, then $\mathsf{MotifCount}(S, \mu)$ *is undefined, not zero.*

Definition 9228.10 (Candidate motif count). *Lean4 (definition) BEDC.GroundCompiler.MetricsFlow.CandidateMoti*

The candidate motif count *for role μ is the number of μ-like candidates listed in the candidate section. It is distinct from recognized motif count.*

Proposition 9228.11 (Candidate count is weaker than recognized count). *Lean4✓ BEDC.GroundCompiler.Metrics count weaker*

Candidate motif count cannot replace recognized motif count.

Proof. Candidate count records shape or candidate policy. Recognized count requires generated recognizer and motif ledger. Treating candidate count as recognized count promotes unverified patterns to recognized motifs. □

Corollary 9228.12 (Missing recognizer does not imply zero). *Lean4✓ BEDC.GroundCompiler.MetricsFlow.missing recognizer not zero*

If a motif recognizer is missing, the corresponding recognized motif count is undefined or recognizer-missing. It is not zero.

Definition 9228.13 (Seal depth). *Lean4 (definition) BEDC.GroundCompiler.MetricsFlow.SealDepth*

The seal depth *of S is the number of recognized seal motif occurrences in S. If the seal recognizer is missing, seal depth is undefined. Candidate seal events may be counted separately as candidate seal count.*

Definition 9228.14 (Carry index). *Lean4 (definition) BEDC.GroundCompiler.MetricsFlow.CarryIndex*

The carry index *of S is the number of recognized carry motif occurrences in S. If only candidate pairs such as* $011 \mid 100$ *or* $0011 \mid 0100$ *are present, but no recognized carry motif is supplied, carry index is undefined.*

Definition 9228.15 (Ledger depth). *Lean4 (definition)* `BEDC.GroundCompiler.MetricsFlow.LedgerDepth`

The ledger depth *of S is the maximum nesting depth among recognized ledger flows in S. If there is no recognized ledger flow, ledger depth is* 0*. If there are suspected ledger candidates without recognizer, the report must separately mark ledger-recognizer missing; it must not treat the value* 0 *as a structural conclusion.*

Definition 9228.16 (Reuse depth). *Lean4 (definition)* `BEDC.GroundCompiler.MetricsFlow.ReuseDepth`

The reuse depth *of S is the length of the longest dependency chain of recognized reuse motifs. If the reuse recognizer is missing, reuse depth is undefined.*

Definition 9228.17 (Bridge depth). *Lean4 (definition)* `BEDC.GroundCompiler.MetricsFlow.BridgeDepth`

The bridge depth *of S is the maximum bridge-chain length among recognized bridge motifs or bridge flows. If only bridge-candidate motifs are present, bridge depth is undefined, while bridge-candidate count may be reported separately.*

Definition 9228.18 (Classifier compression ratio). *Lean4 (definition)* `BEDC.GroundCompiler.MetricsFlow.Compress`

If a recognized classifier quotient in S sends k raw support flows into r recognized classes with $r > 0$, define

$$\mathsf{CompressionRatio}(S) = \frac{k}{r}.$$

This metric requires classifier recognizer, exactness recognizer, and ledger recognizer.

Proposition 9228.19 (Compression ratio requires exactness). *Lean4 ✓* `BEDC.GroundCompiler.MetricsFlow.compr ratio requires exactness`

Without classifier exactness flow, admissible compression ratio cannot be computed.

Proof. Compression ratio counts how raw supports are classified. If classifier exactness is not recognized, the classes may not be sound, may not respect the intended sameness, and may lack ledger completeness. The metric is therefore inadmissible. □

9228.3 Comparison metrics

Definition 9228.20 (Raw prefix overlap). *Lean4 (definition)* `BEDC.GroundCompiler.MetricsFlow.RawPrefixOverlap`

For event flows

$$S = (s_0, \ldots, s_{m-1}), \qquad T = (t_0, \ldots, t_{n-1}),$$

the raw prefix overlap length

$$\mathsf{RawPrefixLen}(S, T)$$

is the largest k such that $s_i = t_i$ for every $0 \le i < k$.

Definition 9228.21 (Recognized prefix overlap). *Lean4 (definition)* `BEDC.GroundCompiler.MetricsFlow.Recognized`

The recognized prefix overlap *of S and T is the set of shared recognized prefix motif records. Sharing requires the same support shape, same motif role, ledger-compatible evidence, and either the same recognizer family or recognized compatible recognizers.*

Proposition 9228.22 (Raw prefix overlap does not imply recognized prefix overlap). ↪ *variant* `BEDC.GroundCompiler.MetricsFlow.raw prefix weaker`

Two event flows can share raw prefix without sharing recognized semantic prefix.

Proof. The same raw prefix may be recognized as different motif roles in different contexts, or may be unrecognized in one flow. Therefore raw prefix overlap alone does not imply recognized prefix overlap. □

Definition 9228.23 (Motif overlap). *Lean4 (definition)* `BEDC.GroundCompiler.MetricsFlow.MotifOverlap`

The motif overlap *of two flows is the intersection of their recognized motif profiles:*

$$\mathsf{MotifOverlap}(S,T) = \mathsf{MotifProfile}(S) \cap \mathsf{MotifProfile}(T),$$

where intersection is computed by motif role, support shape, and ledger-compatible equivalence.

Definition 9228.24 (Motif distance). *Lean4 (definition)* `BEDC.GroundCompiler.MetricsFlow.MotifJaccardDistance`

When the protocol defines the denominator, the motif distance *is*

$$\mathsf{MotifDist}(S,T) = 1 - \frac{|\mathsf{MotifProfile}(S) \cap \mathsf{MotifProfile}(T)|}{|\mathsf{MotifProfile}(S) \cup \mathsf{MotifProfile}(T)|}.$$

If the denominator is 0*, the undefined-value policy in the metric protocol determines the report entry.*

Definition 9228.25 (Normal-address overlap and distance). *Lean4 (definition)* `BEDC.GroundCompiler.MetricsFlow.`

Given normalizer recognizers, the normal-address profile *of S is the set of recognized records $(w, v, L_{w\to v})$. The overlap of S and T is the intersection of these profiles. When defined, the normal-address distance is*

$$\mathsf{NormDist}(S,T) = 1 - \frac{|\mathsf{NormOverlap}(S,T)|}{|\mathsf{NormalAddressProfile}(S) \cup \mathsf{NormalAddressProfile}(T)|}.$$

Zero denominator behavior is protocol-defined.

Definition 9228.26 (Flow signature vector). *Lean4 (definition)* `BEDC.GroundCompiler.MetricsFlow.FlowSignature`

The flow signature vector *of S is*

$$\mathsf{Sig}(S) = (\mathsf{SealDepth}, \mathsf{CarryIndex}, \mathsf{LedgerDepth}, \mathsf{CompressionRatio}, \mathsf{ReuseDepth}, \mathsf{BridgeDepth})_S.$$

It is defined only when each component is admissible or when the protocol explicitly handles undefined components.

Theorem 9228.27 (Signature equality does not imply object equality). *↪ variant* `BEDC.GroundCompiler.MetricsFlo` `do not imply object equality`

If

$$\mathsf{Sig}(S) = \mathsf{Sig}(T),$$

one cannot infer that S and T represent the same theorem, chapter, object, classifier class, or bridge target.

Proof. A signature vector is a finite summary. Distinct event flows may have equal carry count, seal count, ledger depth, or other component values while having different supports, ledgers, classifiers, proofs, and certificates. Object equivalence or theorem equivalence requires classifier, proof, bridge, or certificate flow. □

Corollary 9228.28 (Signature vector is explanatory summary). *↪ variant* `BEDC.GroundCompiler.MetricsFlow.metri` `explanatory not identificatory`

Signature vectors may support comparison and clustering, but they are not identity criteria.

9228.4 Metric reports

Definition 9228.29 (Metric report). *Lean4 (definition)* `BEDC.GroundCompiler.MetricsFlow.MetricReport`

Given event flow S, metric protocol flow P_{met}, and a recognized motif report, a metric report *is an output view containing the input flow, recognized motif summary, candidate motif summary, metric protocol, computed admissible metrics, undefined metrics, missing recognizers, ledger requirements, warnings, and cannot-claim annotations. Write*

$$\mathsf{MetricReport}(S, P_{\text{met}}).$$

Definition 9228.30 (Undefined metric item). *Lean4 (definition)* `BEDC.GroundCompiler.MetricsFlow.UndefinedMetr`

An undefined metric item *records why a metric is undefined: recognizer missing, ledger missing, classifier exactness missing, normalizer missing, division by zero unresolved by protocol, candidate-only evidence, or unresolved bootstrap obligation.*

Principle 9228.31 (Undefined metric is explicit). *Lean4 ✓* `BEDC.GroundCompiler.MetricsFlow.undefined metric explicit`

If a metric is inadmissible or undefined, the report must record an undefined metric item. It must not silently omit the metric or treat missing data as 0.

Theorem 9228.32 (Silent zero is unsound). *Lean4 ✓* `BEDC.GroundCompiler.MetricsFlow.silent zero unsound`

If a metric is undefined because a recognizer is missing, but the report records it as 0*, then the metric report is unsound.*

Proof. Missing recognizer means the system cannot determine whether the motif exists. Recording 0 asserts absence of the motif. That turns epistemic absence into structural absence, which is unsound. □

Definition 9228.33 (Metric report soundness). *Lean4 (definition)* `BEDC.GroundCompiler.MetricsFlow.MetricRepor`

A metric report is sound *when every listed source flow is witnessed as a formal event-flow input, every listed undefined metric has a corresponding undefined metric item in the report, and the report satisfies the cannot-claim guard for nontrivial metric signatures.*

Theorem 9228.34 (Sound metric report theorem). *Lean4 ✓* `BEDC.GroundCompiler.MetricsFlow.sound metric report`

If P_4 outputs a sound metric report, then every source flow listed by the report is a formal event-flow input, and every undefined metric item listed by the report is explicitly recorded in the report.

Proof. Both claims are the defining witnesses carried by metric-report soundness. □

9228.5 Metric claims and cannot-claims

Definition 9228.35 (Metric claim). *Lean4 (definition)* `BEDC.GroundCompiler.MetricsFlow.MetricClaim`

A metric claim *is a statement based on a metric report, such as: S and T share a finite-repetition motif, S has carry index* 1*, S has seal depth* 2*, S and T have motif distance* 0.25*, or S has classifier compression ratio* 3*. Such a claim is admissible only when the relevant metric report is sound and the metric is admissible.*

Definition 9228.36 (Forbidden metric claim). Lean4 (definition) BEDC.GroundCompiler.MetricsFlow.ForbiddenMet

The following metric claims are forbidden unless supported by additional certificate flows:

- *same metric profile implies same object;*
- *same signature vector implies same theorem;*
- *motif distance zero implies proof equivalence;*
- *high motif overlap implies bridge;*
- *positive carry index implies dimension;*
- *positive seal depth implies completion object;*
- *compression ratio greater than one implies quotient exactness;*
- *positive reuse depth implies a reuse certificate.*

Theorem 9228.37 (Forbidden metric claims need certificates). Lean4 ✓ BEDC.GroundCompiler.MetricsFlow.forbi metric claims need certificates

Every forbidden metric claim is invalid without additional classifier, proof, bridge, name-certificate, derivation-certificate, or acceptance-gate flow.

Proof. Metric reports summarize event-flow structure. Forbidden claims assert object equivalence, proof equivalence, bridge existence, dimension, completion, quotient exactness, or reuse certification. These require independent certificate flows. Metrics alone do not supply them. □

Corollary 9228.38 (Metric reports require cannot-claim sections). Lean4 ✓ BEDC.GroundCompiler.MetricsFlow.m report requires cannot claim sections

Every nontrivial metric report must contain a cannot-claim section listing the stronger claims that the metrics do not support.

9228.6 P_4 pipeline and examples

Definition 9228.39 (P_4 pipeline). Lean4 (definition) BEDC.GroundCompiler.MetricsFlow.P4Pipeline

Given channel code c, the P_4 pipeline consists of P_0 legality check, P_1 source-event report, P_2 normalizer ledger report, P_3 motif report, metric protocol recognition, admissible metric computation, undefined metric audit, cannot-claim audit, and metric report generation.

Theorem 9228.40 (P_4 pipeline is source-determined relative to protocol). Lean4 ✓ BEDC.GroundCompiler.Metrics source determined relative to protocol

If $c \in \mathsf{LegalZStream}$, P_{met} is a recognized metric protocol flow, and all selected recognizers are deterministic, then the P_4 output is uniquely determined.

Proof. The channel bijection decodes c to a unique event flow S. The recognized protocol fixes metric selection, recognizer family, undefined-value policy, and report policy. Deterministic recognizers determine motif reports and ledgers. Metrics are computed from those data. □

Corollary 9228.41 (Different protocols may yield different reports). Lean4 ✓ BEDC.GroundCompiler.MetricsFlow. protocols may yield different reports

Different metric protocol flows may choose different recognizer families, metric selections, weights, undefined-value policies, or report policies. Different reports under different protocols are therefore not contradictory.

Example 9228.42 (Completion skeleton metric report)**.** *For input*

$$011001100011010110101011100011,$$

the decoded flow is

$$0 \mid 00 \mid 000 \mid 01 \mid 011 \mid 100.$$

Assume the recognized motif report includes finite repetition $0 \mid 00 \mid 000$*, carry* $011 \mid 100$*, and seal* 011*. The metric report may record motif counts for finite repetition, carry, and seal as* 1*, seal depth* 1*, carry index* 1*, and ledger depth at least* 1 *depending on the carry ledger. Completion-object status and full-axis export remain undefined. Cannot-claims say that seal depth* 1 *does not imply completion, carry index* 1 *does not imply dimension-lift, and the report does not establish* $011 = 100$*.*

Example 9228.43 (Fold skeleton metric report)**.** *For input*

$$011001100101100101011010 0011,$$

the decoded flow is

$$0 \mid 00 \mid 001 \mid 0011 \mid 0100.$$

If recognized motifs include additive recursion 001 *and fold normalizer* $0011 \mid 0100$*, the report may count each as* 1*. Carry index is* 1 *only if the fold normalizer is recognized under carry role. Seal depth is undefined unless a seal recognizer recognizes* 0011*, and reuse depth is undefined unless a reuse recognizer is supplied.*

Example 9228.44 (Completion/fold comparison)**.** *For*

$$S_{\mathrm{Comp}} = 0 \mid 00 \mid 000 \mid 01 \mid 011 \mid 100$$

and

$$S_{\mathrm{Fold}} = 0 \mid 00 \mid 001 \mid 0011 \mid 0100,$$

the raw prefix overlap is $0 \mid 00$*. A recognized shared finite-source motif exists only if recognizer evidence is supplied. Motif distance is protocol-relative. Cannot-claims record that shared prefix does not imply bridge and distance values do not imply object identity.*

9228.7 Adequacy and conservativity

Definition 9228.45 (P_4 audit checklist)**.** Lean4 (definition) `BEDC.GroundCompiler.MetricsFlow.P4AuditChecklist`
A P_4 *prototype must satisfy:*

1. *all* P_3 *audit requirements;*
2. *recognized metric protocol flow is required;*
3. *candidate counts are separated from recognized counts;*
4. *missing recognizers are marked undefined, not zero;*
5. *metric dependencies are recorded;*
6. *ledger requirements are recorded;*
7. *undefined metric items are recorded;*

8. *cannot-claim sections are included;*
9. *object equality is not inferred from metrics;*
10. *theorem equivalence is not inferred from metrics;*
11. *bridge is not inferred from motif overlap;*
12. *external metric tables are not formal inputs.*

Theorem 9228.46 (P_4 adequacy theorem)**.** Lean4✓ BEDC.GroundCompiler.MetricsFlow.p4 adequacy

If a prototype satisfies the P_4 audit checklist, uses sound P_3 reports, and computes only admissible metrics under recognized metric protocol flow, then it is adequate as a metric-report prototype.

Proof. The checklist ensures that metrics are computed only from recognized event-flow structures, that candidate and recognized evidence are separated, undefined cases are explicit, and cannot-claims are included. Sound P_3 reports validate motif data. Recognized metric protocol prevents metric selection and policies from becoming hidden inputs. □

Corollary 9228.47 (P_4 adequacy does not imply higher adequacy)**.** Lean4✓ BEDC.GroundCompiler.MetricsFlow.p4 adequacy not higher

There exists an adequate P_4 metric-report prototype whose source flow is not an accepted object flow. Thus P_4 adequacy alone is not higher-layer adequacy; package, name-certificate, derivation-certificate, theorem, chapter, and accepted-object status require separate recognition or acceptance evidence.

Theorem 9228.48 (P_4 is conservative over the finite kernel)**.** Lean4✓ BEDC.GroundCompiler.MetricsFlow.p4 conservative over finite kernel

Adding metric reports, signature vectors, distances, counts, compression ratios, and undefined metric items adds no raw marks, history constructors, sameness rules, continuation rules, derived-interface formation rules, theorem rules, or accepted-object export rules.

Proof. P_4 computes summaries over decoded event flows and recognized motif reports. It does not generate new $\mathsf{b0}, \mathsf{b1}$, add msame, hsame, or psame, alter Ext or Cont, or supply name certificates, derivation certificates, proof flows, or acceptance gates. □

Corollary 9228.49 (P_4 remains an analysis layer)**.** *P_4 provides metric analysis. It is not a mathematical object generator, proof checker, or certificate generator.*

9228.8 Full reports

Example 9228.50 (P_4 report for completion skeleton)**.** *For*

$$0 \mid 00 \mid 000 \mid 01 \mid 011 \mid 100,$$

assume recognized finite repetition, seal, and carry motifs with supports $0 \mid 00 \mid 000$, 011, *and* $011 \mid 100$. *The report records*

$$\mathsf{MotifCount}(\textit{finite repetition}) = 1, \quad \mathsf{MotifCount}(\textit{seal}) = 1, \quad \mathsf{MotifCount}(\textit{carry}) = 1,$$

and seal depth 1, *carry index* 1, *and ledger depth* 1 *when the ledger is one level. Compression ratio, reuse depth, and bridge depth are undefined if the corresponding recognizers are missing. Cannot-claims say that seal depth does not imply completion, carry index does not imply dimension-lift, classifier exactness is not supplied, no name-certificate flow is supplied, no derivation-certificate flow is supplied, no acceptance-gate flow is supplied, and the report is not proof.*

Example 9228.51 (P_4 comparison report)**.** *For the completion and fold skeletons, the report may record raw prefix* $0 \mid 00$*, recognized shared finite-source motif when recognizer evidence exists, completion-specific seal and carry motifs, and fold-specific additive recursion and fold normalizer motifs. Raw prefix length is* 2*, while shared recognized motif count and motif distance are protocol-relative. Cannot-claims say that shared prefix does not imply subobject, motif distance does not imply theorem equivalence, and no bridge certificate is supplied.*

Remark 9228.52 (Summary)**.** *This chapter defines* P_4*, the metric-report prototype. It adds metric candidates, generated metric recognizers, metric protocol flows, admissible metrics, recognized and candidate motif counts, seal depth, carry index, ledger depth, reuse depth, bridge depth, classifier compression ratio, prefix overlap, motif overlap, motif distance, normal-address distance, signature vectors, undefined metric items, metric claims, forbidden metric claims, the* P_4 *pipeline, and the* P_4 *audit checklist. It proves that unrecognized metrics are inadmissible, host similarity scores are not admissible metrics, candidate counts are weaker than recognized counts, missing recognizers do not imply zero, compression ratio requires exactness, raw prefix overlap does not imply recognized prefix overlap, signature equality does not imply object equality, silent zero is unsound, sound metric reports are backed by recognized structures, forbidden metric claims require certificates, the pipeline is source-determined relative to protocol, and* P_4 *is conservative over the finite kernel.*

Chapter 9229

Package and NameCert Recognition Prototype

chapter 9228 defines P_4, the metric-report prototype. It can produce motif reports, metric reports, prefix overlap, seal depth, carry index, ledger depth, classifier compression ratio, reuse depth, and cannot-claim audits. It remains an analysis layer. It does not recognize packages, name certificates, derivation certificates, theorems, chapters, or accepted objects.

This chapter defines the next prototype level:

$$\boxed{P_5 = P_4 + \text{package-flow recognition} + \mathsf{NameCert}\text{-flow recognition.}}$$

This is the first layer that moves from analysis reports to certificate-structure recognition. The governing rule remains:

packages and name certificates are not inputs; they are structures recognized inside decoded event flows.

Thus P_5 does not accept host package structures, host name-certificate records, YAML packages, JSON certificates, external field tables, host ASTs, or manually supplied source, pattern, classifier, stability, or ledger records. The only formal input is a channel stream or decoded event flow.

9229.1 P_5 prototype interface

Definition 9229.1 (Package and NameCert recognition prototype)**.** *Lean4 (definition)* `BEDC.GroundCompiler.Packa`

A package and NameCert recognition prototype *is an executable prototype P_5 satisfying:*

1. *P_5 includes all P_4 functions;*
2. *P_5 can run generated package recognizers on decoded event flows;*
3. *P_5 can recognize package flows;*
4. *P_5 can run generated* NameCert *recognizers inside recognized package flows or decoded event flows;*
5. *P_5 can recognize* NameCert *flows;*
6. *P_5 can generate package and* NameCert *recognition reports;*
7. *P_5 does not recognize derivation certificates, acceptance gates, theorems, chapters, or accepted objects unless later prototype levels supply those recognizers.*

Write

$$\mathsf{PkgNameCertPrototype}(P_5).$$

Principle 9229.2 (P_5 does not accept package objects). *Lean4 ✓ BEDC.GroundCompiler.PackageNameCertPrototyp no package object input*

There is no formal input of the form

$$\mathsf{PackageStruct} \to \mathsf{Code}$$

or

$$\mathsf{NameCertStruct} \to \mathsf{Code}.$$

The formal input remains EventFlow *or its channel code in* LegalZStream*. If the input is channel code c, P_5 first forms*

$$S = \mathsf{Decode}(c)$$

and then recognizes package flows and NameCert *flows in S.*

Definition 9229.3 (P_5 input). *Lean4 (definition) BEDC.GroundCompiler.PackageNameCertPrototype.P5FormalInput*

The input to P_5 may be displayed as a channel stream c or as an event flow S. If the input is c, then decoding is performed first:

$$S = \mathsf{Decode}(c).$$

If $c \notin$ LegalZStream*, then P_5 rejects and produces neither package report nor* NameCert *report.*

Definition 9229.4 (P_5 output). *Lean4 (definition) BEDC.GroundCompiler.PackageNameCertPrototype.P5Output*

The output of P_5 is a report flow or human-readable report containing decoded event flow, package candidates, recognized package flows, package ledgers, NameCert *candidates, recognized* NameCert *flows, recognized source-specification, pattern-specification, classifier-specification, stability-certificate, and ledger-policy flows, missing fields, failure cases, warnings, and cannot-claim annotations.*

This output is report data. It is not input, proof, or accepted object.

9229.2 Package-flow recognition

Definition 9229.5 (Package candidate). *Lean4 (definition) BEDC.GroundCompiler.PackageNameCertPrototype.Packa*

Given a decoded event flow S, a package candidate *is a source-level subflow*

$$P \subseteq S.$$

It has not yet been recognized as a package flow. Write

$$\mathsf{PkgCand}(S, P).$$

Definition 9229.6 (Generated package recognizer). *Lean4 (definition) BEDC.GroundCompiler.PackageNameCertProt*

A generated package recognizer *is an event flow*

$$R_P \in \mathsf{EventFlow}$$

supporting

$$\mathsf{RecognizesPkg}(R_P, S, P).$$

This says that R_P recognizes subflow P of ambient event flow S as a package flow. The recognizer is not a host parser, YAML schema, or external package grammar.

Definition 9229.7 (Recognized package flow). *Lean4 (definition)* `BEDC.GroundCompiler.PackageNameCertPrototype`

If

$$\mathsf{RecognizesPkg}(R_P, S, P),$$

then P is a recognized package flow *in S. Write*

$$\mathsf{PkgFlow}_{R_P}(S, P).$$

Definition 9229.8 (Package role subflows). *Lean4 (definition)* `BEDC.GroundCompiler.PackageNameCertPrototype.Pa`

If

$$\mathsf{RecognizesPkg}(R_P, S, P),$$

then R_P may recognize subflows of P as package roles:

$$\mathsf{PkgSource}_{R_P}(P, P_0), \quad \mathsf{PkgVisible}_{R_P}(P, P_1), \quad \mathsf{PkgPattern}_{R_P}(P, P_2),$$

$$\mathsf{PkgClassifier}_{R_P}(P, P_3), \quad \mathsf{PkgLedger}_{R_P}(P, P_4), \quad \mathsf{PkgSeal}_{R_P}(P, \sigma_P).$$

These roles are not external field labels; they are source-level subflow roles recognized by R_P.

Definition 9229.9 (Complete package recognition). *Lean4 (definition)* `BEDC.GroundCompiler.PackageNameCertProt`

The judgment

$$\mathsf{RecognizesPkg}(R_P, S, P)$$

is complete package recognition *when there exist $P_0, P_1, P_2, P_3, P_4, \sigma_P$ satisfying the source, visible, pattern, classifier, ledger, and seal role judgments of Definition 9229.8. Intuitively, these are the source material, visible package interface, package pattern, package classifier, package ledger, and package seal.*

Principle 9229.10 (No nontrivial package without ledger). *Lean4 ✓* `BEDC.GroundCompiler.PackageNameCertProto` `package recognition has ledger`

Every nontrivial package flow must have package-ledger subflow

$$\mathsf{PkgLedger}_{R_P}(P, P_4).$$

Without ledger, it may be reported only as a package candidate, not as a recognized nontrivial package flow.

Theorem 9229.11 (Incomplete package cannot be used as package flow). *Lean4 ✓* `BEDC.GroundCompiler.Package` `package not package`

If P lacks any recognized source, visible, pattern, classifier, ledger, or seal subflow, then P cannot be used as a complete recognized package flow.

Proof. Complete package recognition requires all six recognized role subflows. If any is missing, complete recognition fails. In the nontrivial case, missing ledger also violates Definition 9229.10. □

Corollary 9229.12 (Visible token alone is not a package). *Lean4 ✓* `BEDC.GroundCompiler.PackageNameCertProto` `token alone not package`

A visible token or short event such as 01, 011, 100, *or* 001 *is not by itself a complete package flow. A visible-only witness has a visible subflow but no recognized source, pattern, classifier, ledger, or seal subflow. Complete package recognition requires those role subflows, so visible-only evidence cannot be used as a complete recognized package flow.*

Definition 9229.13 (Package report). *Lean4 (definition)* `BEDC.GroundCompiler.PackageNameCertPrototype.Packag`

A package report *is a P_5 output view containing package candidates, recognized package flows, package source subflows, visible subflows, pattern subflows, classifier subflows, ledger subflows, seal subflows, missing package fields, package failure cases, and package cannot-claim annotations.*

Principle 9229.14 (Package report is output). *Lean4✓* `BEDC.GroundCompiler.PackageNameCertPrototype.packag` `report output not input`

A package report is an output view, not an input structure. Later stages must continue from decoded event flows and recognizer judgments, not from a report treated as a package object.

9229.3 NameCert-flow recognition

Definition 9229.15 (Name candidate flow). *Lean4 (definition)* `BEDC.GroundCompiler.PackageNameCertPrototype.N`

A name candidate flow *is an event subflow*

$$N \subseteq S$$

representing a proposed source-level visible name candidate. It is not an external object name, string label, or theorem identifier. Write

$$\mathsf{NameCand}(S, N).$$

Definition 9229.16 (NameCert candidate). *Lean4 (definition)* `BEDC.GroundCompiler.PackageNameCertPrototype.N`

A NameCert candidate *is an event subflow*

$$C_N \subseteq S$$

not yet recognized as a NameCert *flow. Write*

$$\mathsf{NameCertCand}(S, C_N, N).$$

Definition 9229.17 (Generated NameCert recognizer). *Lean4 (definition)* `BEDC.GroundCompiler.PackageNameCertP`

A generated NameCert recognizer *is an event flow*

$$R_N \in \mathsf{EventFlow}$$

supporting

$$\mathsf{RecognizesNameCert}(R_N, S, C_N, N).$$

It recognizes subflow C_N of ambient event flow S as a NameCert *flow for name candidate N.*

Definition 9229.18 (Recognized NameCert flow). *Lean4 (definition)* `BEDC.GroundCompiler.PackageNameCertProto`

If

$$\mathsf{RecognizesNameCert}(R_N, S, C_N, N),$$

then C_N is a recognized NameCert *flow for N in S. Write*

$$\mathsf{NameCertFlow}_{R_N}(S, C_N, N).$$

Definition 9229.19 (NameCert field subflows). *Lean4 (definition)* `BEDC.GroundCompiler.PackageNameCertPrototyp`

If

$$\mathsf{RecognizesNameCert}(R_N, S, C_N, N),$$

then R_N may identify five field subflows and a seal:

$$\mathsf{NCSource}_{R_N}(C_N, C_0), \quad \mathsf{NCPattern}_{R_N}(C_N, C_1), \quad \mathsf{NCClassifier}_{R_N}(C_N, C_2),$$

$$\mathsf{NCStability}_{R_N}(C_N, C_3), \quad \mathsf{NCLedger}_{R_N}(C_N, C_4), \quad \mathsf{NCSeal}_{R_N}(C_N, \sigma_N).$$

Definition 9229.20 (Complete NameCert recognition). *Lean4 (definition)* `BEDC.GroundCompiler.PackageNameCertP`

The judgment

$$\mathsf{RecognizesNameCert}(R_N, S, C_N, N)$$

is complete NameCert recognition *when there exist $C_0, C_1, C_2, C_3, C_4, \sigma_N$ satisfying all six judgments in Definition 9229.19.*

Principle 9229.21 (No NameCert without five fields). *Lean4✓* `BEDC.GroundCompiler.PackageNameCertPrototype` `namecert without five fields`

A NameCert *flow must have recognized source, pattern, classifier, stability, ledger, and seal. If any is missing, the flow remains a* NameCert *candidate, not a recognized* NameCert *flow.*

Theorem 9229.22 (Incomplete NameCert candidate cannot license name). *Lean4✓* `BEDC.GroundCompiler.Packag` `namecert candidate cannot license`

If C_N lacks any recognized source, pattern, classifier, stability, ledger, or seal subflow for every generated NameCert *recognizer, then C_N cannot serve as a P_5 licensing witness for the name candidate N.*

Proof. Name licensing requires complete recognized NameCert flow. If any required field or seal is missing, complete recognition fails, so N is not licensed. □

Corollary 9229.23 (Name event alone does not license interface). *Lean4✓* `BEDC.GroundCompiler.PackageNameCer` `event alone not license`

A name candidate event N cannot by itself license a derived interface. A recognized NameCert *flow is required.*

Definition 9229.24 (Licensed name at P_5). *Lean4 (definition)* `BEDC.GroundCompiler.PackageNameCertPrototype.L`

At the P_5 layer, define

$$\mathsf{LicensedName}_{P_5}(S, N)$$

to hold when there exist C_N and R_N such that

$$\mathsf{RecognizesNameCert}(R_N, S, C_N, N)$$

and that recognition is complete and sound. This licenses a name, not an accepted mature object.

Theorem 9229.25 (P_5 licensing is weaker than accepted export). *Lean4✓* `BEDC.GroundCompiler.PackageNameCert` `license weaker than export`

There exist event flows S and N such that

$$\mathsf{LicensedName}_{P_5}(S, N)$$

holds while S is not an accepted object flow. Thus P_5 licensing does not by itself imply accepted export at any strength.

Proof. Take the empty decoded flow as the carrier of a complete NameCert recognition witness for a name candidate under the P_5 recognition predicates. This supplies a P_5 license. The same empty flow is not an accepted object flow, because accepted object flow requires the nonempty exported flow together with recognized certificate support. Hence P_5 licensing is weaker than accepted export. □

9229.4 Package-sourced NameCert flows

Definition 9229.26 (NameCert over package). Lean4 (definition) `BEDC.GroundCompiler.PackageNameCertPrototype`

A NameCert *flow C_N is* over package flow *P when:*

1. *P is a recognized package flow;*
2. *the source field of C_N references or contains the source, visible, or ledger subflows of P;*
3. *the ledger field of C_N retains the package ledger of P.*

Write

$$\mathsf{NameCertOverPkg}(C_N, N, P).$$

Proposition 9229.27 (NameCert over package requires package ledger). Lean4 ✓ `BEDC.GroundCompiler.PackageN` `over package requires ledger`

If

$$\mathsf{NameCertOverPkg}(C_N, N, P),$$

then P has a recognized package-ledger subflow.

Proof. A NameCert over a package requires the NameCert ledger to retain package provenance. Without package ledger, that source material cannot be traced. □

Corollary 9229.28 (Package without ledger cannot support NameCert). Lean4 ✓ `BEDC.GroundCompiler.PackageN` `without ledger no namecert over package`

A nontrivial package flow without recognized ledger cannot support a derived name through NameCert *recognition.*

Definition 9229.29 (Package-sourced NameCert report). Lean4 (definition) `BEDC.GroundCompiler.PackageNameCer`

A package-sourced NameCert report *contains recognized package flow P, recognized* NameCert *flow C_N, name candidate N, the source-field relation between C_N and P, the ledger-pullback relation, missing-field report, and cannot-claim annotations.*

Principle 9229.30 (Package-sourced NameCert is still not accepted export). Lean4 ✓ `BEDC.GroundCompiler.Packa` `sourced namecert licenses name not export`

If a recognized package flow with ledger supports a recognized NameCert *flow, then the package-sourced record supplies a P_5 licensed-name witness. It still does not supply accepted-object export unless the accepted-object witness is separately present; mature export requires derivation-certificate and acceptance-gate flows.*

9229.5 P_5 reports and soundness

Definition 9229.31 (P_5 report). Lean4 (definition) `BEDC.GroundCompiler.PackageNameCertPrototype.P5Report`

A P_5 report *is an output view containing input channel stream, decoded event flow, P_4 motif and metric summaries if available, package candidates, recognized package flows, package field*

status, NameCert *candidates, recognized* NameCert *flows,* NameCert *field status, licensed names at P_5, missing fields, ledger audit, warnings, and cannot-claim annotations.*

Definition 9229.32 (Package field status)**.** Lean4 (definition) `BEDC.GroundCompiler.PackageNameCertPrototype.Pa`

For each package candidate P, the report records source, visible, pattern, classifier, ledger, and seal status as present, missing, or candidate-only.

Definition 9229.33 (NameCert field status)**.** Lean4 (definition) `BEDC.GroundCompiler.PackageNameCertPrototype.`

For each NameCert *candidate C_N, the report records source, pattern, classifier, stability, ledger, and seal status as present, missing, or candidate-only.*

Principle 9229.34 (Missing field is not negative theorem)**.** Lean4✓ `BEDC.GroundCompiler.PackageNameCertProto` `field report not negative theorem`

If a field is reported missing, the report only says that the field is missing from the recognized flow. It does not assert that the theory contains no such field, unless recognizer completeness and domain coverage have been established.

Definition 9229.35 (P_5 cannot-claim annotations)**.** Lean4 (definition) `BEDC.GroundCompiler.PackageNameCertProt`

A P_5 report must include cannot-claim annotations saying that recognized package flow does not imply NameCert *flow, recognized* NameCert *flow does not imply derivation-certificate flow, licensed name does not imply accepted object, package token alone is insufficient, name event alone is insufficient, missing fields block recognition, channel code is not proof, and report is not certificate.*

Definition 9229.36 (Sound P_5 report)**.** Lean4 (definition) `BEDC.GroundCompiler.PackageNameCertPrototype.Sound`

A P_5 report is sound *when:*

1. *every recognized package flow is backed by generated package recognizer;*
2. *every nontrivial recognized package flow has required ledger;*
3. *every recognized* NameCert *flow is backed by generated* NameCert *recognizer;*
4. *every recognized* NameCert *flow has five fields and seal;*
5. *every licensed name is backed by sound recognized* NameCert *flow;*
6. *all missing fields are explicitly reported;*
7. *candidate-only entries are not reported as recognized;*
8. *cannot-claim annotations are complete.*

Theorem 9229.37 (Sound P_5 report theorem)**.** Lean4✓ `BEDC.GroundCompiler.PackageNameCertPrototype.sound` `p5 report`

If P_5 outputs a sound report, then every recognized package flow and recognized NameCert *flow in the report has the corresponding recognition judgment and ledger support.*

Proof. Soundness requires each recognized package flow to be supported by generated package recognition and required ledger, and each recognized NameCert flow to be supported by generated NameCert recognition with five fields and seal. Hence every recognized item has recognition and ledger support. □

Theorem 9229.38 (Sound P_5 licensed name theorem)**.** Lean4✓ `BEDC.GroundCompiler.PackageNameCertPrototype` `p5 licensed name`

If a sound P_5 report asserts

$$\mathsf{LicensedName}_{P_5}(S, N),$$

then there exists a complete and sound recognized NameCert *flow C_N for N.*

Proof. By definition, a licensed name at P_5 requires complete and sound recognized NameCert flow. Sound reporting ensures that licensed-name entries are not supported by candidate-only flows. □

Corollary 9229.39 (P_5 licensed name is not accepted export)**.** Lean4✓ BEDC.GroundCompiler.PackageNameCertPr licensed not accepted export

Even when P_5 soundly licenses N, it does not follow that N is accepted at any strength. Accepted export requires recognized derivation-certificate and acceptance-gate flows.

9229.6 Adequacy

Definition 9229.40 (P_5 audit checklist)**.** Lean4 (definition) BEDC.GroundCompiler.PackageNameCertPrototype.P5Au

A P_5 prototype must satisfy:

1. *all P_4 audit requirements;*
2. *package candidates are distinguished from recognized package flows;*
3. *recognized package flows require generated package recognizers;*
4. *nontrivial packages require package ledger;*
5. NameCert *candidates are distinguished from recognized* NameCert *flows;*
6. *recognized* NameCert *flows require generated* NameCert *recognizers;*
7. *recognized* NameCert *flows require five fields and seal;*
8. *missing fields are reported explicitly;*
9. *licensed names are distinguished from accepted objects;*
10. *derivation-certificate and acceptance-gate recognition is not claimed unless later recognizers are supplied;*
11. *host package and* NameCert *structures are not formal inputs;*
12. *cannot-claim annotations cover package and* NameCert *overinterpretation risks.*

Theorem 9229.41 (P_5 adequacy theorem)**.** Lean4✓ BEDC.GroundCompiler.PackageNameCertPrototype.p5 adequacy

If a prototype satisfies the P_5 audit checklist, uses sound P_4 reports, and every recognized package flow and NameCert *flow is backed by generated recognizers and required ledger, then it is adequate as a package and* NameCert *recognition prototype.*

Proof. The checklist enforces separation between candidates and recognized package or NameCert structures, requires generated recognizers, requires ledgers and the five NameCert fields, and prevents overinterpretation as derivation certificate or acceptance gate. Sound P_4 reports ensure that lower-level event, motif, and metric data are reliable. □

Corollary 9229.42 (P_5 adequacy does not imply higher adequacy)**.** Lean4✓ BEDC.GroundCompiler.PackageNameCe adequacy not higher

A P_5 prototype does not yet support derivation-certificate flow, acceptance-gate flow, theorem flow, chapter flow, accepted-object export, or self-hosting compiler recognition.

9229.7 Examples

Example 9229.43 (Package candidate without ledger)**.** *Suppose a decoded event flow contains subflow* 011*. A report may list it as a visible package candidate. If there is no package source, pattern, classifier, ledger, or seal, the status is candidate-only with missing source, pattern, classifier, ledger, and seal. Cannot-claims say that* 011 *is not a package, not* $\mathsf{FullAxis}^{\uparrow}$*, and not completion.*

Example 9229.44 (Recognized package flow over completion skeleton)**.** *Suppose the decoded flow is*

$$0 \mid 00 \mid 000 \mid 01 \mid 011 \mid 100$$

and a generated package recognizer identifies source flow $0 \mid 00 \mid 000$*, visible flow* $011 \mid 100$*, repeat-boundary or seal-like pattern flow, source-level normal-address classifier candidate, ledger retaining finite prefixes and both* 011 *and* 100*, and a package seal. The report may state that a package flow is recognized. It still cannot claim that a* NameCert *exists, that* $\mathsf{FullAxis}^{\uparrow}$ *is licensed, or that completion is accepted.*

Example 9229.45 (NameCert candidate with missing ledger)**.** *Suppose a* NameCert *candidate contains source, pattern, classifier, and stability flows, plus seal, but no ledger. The report lists those fields as present and ledger as missing, with status incomplete. Cannot-claims say that the candidate does not license a name and that missing ledger blocks* NameCert *recognition.*

Example 9229.46 (Complete Axis-like NameCert flow)**.** *A complete Axis-like* NameCert *flow may recognize a name candidate Axis, source given by a* b0*-emission flow, pattern given by repeated* b0 *extension, classifier given by* hsame *restricted to the* b0 *spine, stability given by closure under extension or continuation, ledger recording source history for each visible axis token, and a* NameCert *seal. If all fields are recognized and sound,* P_5 *may report* $\mathsf{LicensedName}_{P_5}(S, \mathrm{Axis})$*. It must also report that accepted Axis export still requires derivation-certificate and acceptance-gate flows.*

Example 9229.47 (Package-sourced NameCert)**.** *A report may contain recognized package flow* P *with source finite-prefix flow, visible token flow, and ledger flow, and recognized* NameCert *flow* C_N *whose source references* P*, whose pattern and classifier extend those of* P*, whose stability is recognized, and whose ledger pulls back the package ledger. The report may state* $\mathsf{NameCertOverPkg}(C_N, N, P)$*. It still cannot infer* $\mathsf{AcceptedExport}(N, s)$*.*

9229.8 Conservativity

Theorem 9229.48 (P_5 is conservative over the finite kernel)**.** `Lean4✓` `BEDC.GroundCompiler.PackageNameCertProt` `conservative over finite kernel`

Adding package-flow recognition, NameCert*-flow recognition, package reports,* NameCert *reports,* P_5 *licensed-name reports, and package-sourced* NameCert *reports adds no raw marks, history constructors, sameness rules, continuation rules, theorem rules, derivation-certificate rules, acceptance-gate rules, or mature-object export rules.*

Proof. P_5 operates on decoded event flows and generated recognizer relations. It generates no new b0, b1, adds no msame, hsame, or psame, does not alter Ext or Cont, and does not create derivation certificates or acceptance gates. It can license names only at the NameCert-flow level; mature export still requires higher certificate flows. □

Corollary 9229.49 (P_5 remains below accepted-object compiler)**.** P_5 *can recognize package flows and* NameCert *flows, and can license names at the* P_5 *layer, but it cannot export mature objects.*

Remark 9229.50 (Summary)**.** *This chapter defines P_5, the package and* NameCert *recognition prototype. It adds package candidates, generated package recognizers, recognized package flows, package source, visible, pattern, classifier, ledger, and seal subflows, package reports, name candidate flows,* NameCert *candidates, generated* NameCert *recognizers, recognized* NameCert *flows, source, pattern, classifier, stability, ledger, and seal subflows, complete* NameCert *recognition, P_5 licensed names,* NameCert *over package, field-status reports, and the P_5 audit checklist. It proves that incomplete packages and incomplete* NameCert *candidates cannot license their intended structures, visible tokens and name events alone are insufficient, P_5 licensing is weaker than accepted export,* NameCert *over package requires package ledger, sound reports provide recognition and ledger support, P_5 adequacy requires generated recognizers and cannot-claims, and P_5 is conservative over the finite kernel.*

Chapter 9230

DerivCert and AcceptGate Recognition Prototype

chapter 9229 defines P_5, the package and NameCert recognition prototype. It can recognize package flows, NameCert flows, source-specification flows, pattern-specification flows, classifier-specification flows, stability-certificate flows, ledger-policy flows, and P_5-level licensed names. It still cannot export mature objects.

This chapter defines the next prototype level:

$$\boxed{P_6 = P_5 + \text{derivation-certificate recognition} + \text{strength recognition} + \text{acceptance-gate recognition}.}$$

This is the first layer where accepted object code may be reported. The rule is strict:

$$\boxed{\text{accepted object code is not bare code; it is code of a recognized acceptance flow.}}$$

The prototype does not accept derivation-certificate structures, acceptance-gate structures, strength enums, accepted objects, object names, theorem identifiers, proof-status tables, or bridge-status tables as formal inputs. It accepts only channel streams or decoded event flows and then recognizes derivation-certificate, strength, and acceptance-gate flows inside them.

9230.1 P_6 prototype interface

Definition 9230.1 (DerivCert and AcceptGate recognition prototype)**.** *Lean4 (definition)* `BEDC.GroundCompiler.De`

A DerivCert and AcceptGate recognition prototype *is an executable prototype P_6 satisfying:*

1. *P_6 includes all P_5 functions;*
2. *P_6 recognizes strength flows;*
3. *P_6 recognizes derivation-certificate flows;*
4. *P_6 recognizes acceptance-gate flows;*
5. *when matching recognized* NameCert *and derivation-certificate flows are present, P_6 can report accepted object code;*
6. *P_6 does not accept accepted objects as input;*
7. *P_6 does not treat code existence as acceptance;*
8. *P_6 does not treat acceptance as object equality;*

9. P_6 does not treat accepted object code as proof of all later properties.

Write

$$\mathsf{DerivAcceptPrototype}(P_6).$$

Principle 9230.2 (Accepted object is not input). *Lean4 ✓ BEDC.GroundCompiler.DerivCertGenerated.p6 external inputs not formal*

There is no formal input

$$\mathsf{AcceptedObject} \to \mathsf{Code}, \qquad \mathsf{DerivCertStruct} \to \mathsf{Code}, \qquad \mathsf{AcceptGateStruct} \to \mathsf{Code}.$$

The only formal inputs remain event flows and legal channel streams. If the input is channel stream c, P_6 first forms $S = \mathsf{Decode}(c)$ and then recognizes derivation-certificate and acceptance-gate flows in S.

Definition 9230.3 (P_6 input). *Lean4 (definition) BEDC.GroundCompiler.DerivCertGenerated.P6FormalInput*

The input to P_6 is displayed as a channel stream c or event flow S. If the input is c, then $S = \mathsf{Decode}(c)$. If $c \notin \mathsf{LegalZStream}$, P_6 rejects and produces neither derivation-certificate report nor acceptance-gate report.

Definition 9230.4 (P_6 output). *Lean4 (definition) BEDC.GroundCompiler.DerivCertGenerated.P6Output*

The output of P_6 is a report flow or human-readable report containing the decoded event flow, recognized NameCert *flows inherited from P_5, derivation-certificate candidates, recognized derivation-certificate flows, strength candidates, recognized strength flows, acceptance-gate candidates, recognized acceptance-gate flows, accepted object codes, missing fields, missing exactness, missing ledger, missing strength, failure cases, warnings, and cannot-claim annotations.*

9230.2 Strength-flow recognition

Definition 9230.5 (Strength candidate flow). *Lean4 (definition) BEDC.GroundCompiler.DerivCertGenerated.Streng*

A strength candidate flow *is an event subflow*

$$s \subseteq S.$$

It is not yet recognized as a strength flow. Explanatory strength levels include seed, paper certificate, checked certificate, and bridge certificate, but these names are not host enums. They must be recognized in event-flow form.

Definition 9230.6 (Generated strength recognizer). *Lean4 (definition) BEDC.GroundCompiler.DerivCertGenerated.*

A generated strength recognizer *is an event flow*

$$R_s \in \mathsf{EventFlow}$$

supporting

$$\mathsf{RecognizesStrength}(R_s, S, s, \sigma),$$

where s is a subflow of S and σ is a strength role flow.

Definition 9230.7 (Recognized strength flow). *Lean4 (definition) BEDC.GroundCompiler.DerivCertGenerated.Recog*

If

$$\mathsf{RecognizesStrength}(R_s, S, s, \sigma),$$

then s is a recognized strength flow *in S. Write*

$$\mathsf{StrengthFlow}_{R_s}(S, s, \sigma).$$

Definition 9230.8 (Strength order witness). *Lean4 (definition)* `BEDC.GroundCompiler.DerivCertGenerated.Strengt`

A strength order witness *is an event subflow o recognizing the hierarchy*

$$\text{seed} < \text{paperCert} < \text{checkedCert} < \text{bridgeCert}.$$

Write

$$\mathsf{StrengthOrder}_{R_s}(S, o).$$

The witness is not an external comparison function.

Principle 9230.9 (No strength enum input). *Lean4 ✓* `BEDC.GroundCompiler.DerivCertGenerated.no strength enum input`

Strength labels such as seed, paper certificate, checked certificate, and bridge certificate are not host enum inputs. They appear only as recognized strength flows.

Theorem 9230.10 (Strength candidate alone is insufficient). *Lean4 ✓* `BEDC.GroundCompiler.DerivCertGenerated. candidate without recognition insufficient`

If s is only a strength candidate and no judgment

$$\mathsf{RecognizesStrength}(R_s, S, s, \sigma)$$

is supplied, then s cannot be used as the strength field of a derivation-certificate flow.

Proof. The strength field of a derivation certificate must be recognized. If s is not recognized, its strength role has no event-flow support. Using it would introduce hidden input. □

9230.3 DerivCert-flow recognition

Definition 9230.11 (DerivCert candidate). *Lean4 (definition)* `BEDC.GroundCompiler.DerivCertGenerated.P6Deriv`

A DerivCert candidate *is an event subflow*

$$D \subseteq S$$

with a formal event-flow name carrier N and a strength candidate subflow $s \subseteq S$, not yet recognized as a derivation-certificate flow. Write

$$\mathsf{DerivCertCand}(S, D, N, s),$$

where N is a name candidate or licensed name flow and s is a strength candidate or strength flow.

Definition 9230.12 (Generated DerivCert recognizer). *Lean4 (definition)* `BEDC.GroundCompiler.DerivCertGenerat`

A generated DerivCert recognizer *is an event flow*

$$R_D \in \mathsf{EventFlow}$$

supporting

$$\mathsf{RecognizesDerivCert}(R_D, S, D, N, s).$$

This says that R_D recognizes subflow D of S as a derivation-certificate flow for N at strength s.

Definition 9230.13 (Recognized DerivCert flow). *Lean4 (definition)* `BEDC.GroundCompiler.DerivCertGenerated.P6`

If

$$\mathsf{DerivCertCand}(S, D, N, s) \quad \textit{and} \quad \mathsf{RecognizesDerivCert}(R_D, D, N, s),$$

then D is a recognized derivation-certificate flow for N and s in S. Write

$$\mathsf{DerivCertFlow}_{R_D}(S, D, N, s).$$

Definition 9230.14 (DerivCert field subflows). *Lean4 (definition)* `BEDC.GroundCompiler.DerivCertGenerated.P6De`

If

$$\mathsf{RecognizesDerivCert}(R_D, S, D, N, s),$$

then R_D may recognize six fields and a seal:

$$\mathsf{DerivSource}_{R_D}(D, D_0), \quad \mathsf{DerivClassifier}_{R_D}(D, D_1), \quad \mathsf{DerivExactness}_{R_D}(D, D_2),$$

$$\mathsf{DerivLedger}_{R_D}(D, D_3), \quad \mathsf{DerivStability}_{R_D}(D, D_4), \quad \mathsf{DerivStrength}_{R_D}(D, D_5), \quad \mathsf{DerivSeal}_{R_D}(D, \sigma_D).$$

Definition 9230.15 (Complete DerivCert recognition). *Lean4 (definition)* `BEDC.GroundCompiler.DerivCertGenerat`

The judgment

$$\mathsf{RecognizesDerivCert}(R_D, S, D, N, s)$$

is complete DerivCert recognition *when there exist*

$$D_0, D_1, D_2, D_3, D_4, D_5, \sigma_D$$

satisfying all field and seal judgments in Definition 9230.14.

Principle 9230.16 (No DerivCert without six fields). *Lean4 ✓* `BEDC.GroundCompiler.DerivCertGenerated.p6` `recognized derivcert has six fields`

A derivation-certificate flow must have recognized source, classifier, exactness, ledger, stability, strength, and seal. If any is missing, the flow remains a candidate.

Theorem 9230.17 (Incomplete DerivCert candidate cannot support export). *Lean4 ✓* `BEDC.GroundCompiler.Deri` `incomplete derivcert candidate no export`

If D lacks any recognized source, classifier, exactness, ledger, stability, strength, or seal subflow, then D cannot support export of N at s.

Proof. Derivation-certificate recognition requires complete six-field recognition. Export requires recognized derivation-certificate flow. If any required field is missing, complete recognition fails. □

Corollary 9230.18 (Strength alone cannot support export). *Lean4 ✓* `BEDC.GroundCompiler.DerivCertGenerated.` `strength alone no export`

Even a recognized high-strength flow cannot form a derivation certificate if source, classifier, exactness, ledger, or stability fields are missing.

9230.4 Field soundness

Definition 9230.19 (DerivCert field soundness). *Lean4 (definition)* `BEDC.GroundCompiler.DerivCertGenerated.P6D`

The six field soundness judgments are:

$$\mathsf{DerivSourceSound}_{R_D}(D, D_0, N), \quad \mathsf{DerivClassifierSound}_{R_D}(D, D_1, N),$$

$$\mathsf{DerivExactnessSound}_{R_D}(D, D_2, N), \quad \mathsf{DerivLedgerSound}_{R_D}(D, D_3, N),$$

$$\mathsf{DerivStabilitySound}_{R_D}(D, D_4, N), \quad \mathsf{DerivStrengthSound}_{R_D}(D, D_5, s).$$

They require the source field to carry N, the classifier field to organize carriers or representatives of N, the exactness field to show that the classifier respects the relevant sameness, the ledger field to retain hidden material and citations, the stability field to cite or supply the relevant stability certificate, and the strength field to match the claimed recognized strength s.

Definition 9230.20 (Sound DerivCert flow). *Lean4 (definition)* `BEDC.GroundCompiler.DerivCertGenerated.P6Sound`

A recognized derivation-certificate flow

$$\mathsf{RecognizesDerivCert}(R_D, S, D, N, s)$$

is sound *when it is complete and all six field soundness judgments of Definition 9230.19 hold.*

Theorem 9230.21 (Sound DerivCert flow establishes derivation certificate). *Lean4 ✓* `BEDC.GroundCompiler.Deriv` `sound derivcert flow establishes derivcert`

If D is a sound recognized derivation-certificate flow for N at strength s, then

$$\mathsf{DerivCertFlow}_{R_D}(S, D, N, s)$$

may serve as the derivation-certificate flow for N at s.

Proof. Soundness supplies complete six-field recognition and the soundness condition for each field. This is precisely the flow-level structure required of a derivation certificate. □

9230.5 AcceptGate-flow recognition

Definition 9230.22 (AcceptGate candidate). *Lean4 (definition)* `BEDC.GroundCompiler.DerivCertGenerated.Accept`

An AcceptGate candidate *is an event subflow*

$$A \subseteq S$$

claiming to combine a NameCert *flow and a derivation-certificate flow into an acceptance gate, but not yet recognized. Write*

$$\mathsf{AcceptGateCand}(S, A, N, s).$$

Definition 9230.23 (Generated AcceptGate recognizer). *Lean4 (definition)* `BEDC.GroundCompiler.DerivCertGenera`

A generated AcceptGate recognizer *is an event flow*

$$R_A \in \mathsf{EventFlow}$$

supporting

$$\mathsf{RecognizesAcceptGate}(R_A, S, A, N, s).$$

Definition 9230.24 (Recognized AcceptGate flow). *Lean4 (definition)* `BEDC.GroundCompiler.DerivCertGenerated.`

If

$$\mathsf{RecognizesAcceptGate}(R_A, S, A, N, s),$$

then A is a recognized acceptance-gate flow for N at s in S. Write

$$\mathsf{AcceptGateFlow}_{R_A}(S, A, N, s).$$

Definition 9230.25 (AcceptGate components). *Lean4 (definition)* `BEDC.GroundCompiler.DerivCertGenerated.Acce`

If

$$\mathsf{RecognizesAcceptGate}(R_A, S, A, N, s),$$

then R_A identifies

$$\mathsf{GateNameCert}_{R_A}(A, C_N), \qquad \mathsf{GateDerivCert}_{R_A}(A, D_N),$$

$$\mathsf{GateStrength}_{R_A}(A, s), \qquad \mathsf{GateSeal}_{R_A}(A, \sigma_A).$$

Principle 9230.26 (No AcceptGate without NameCert and DerivCert). *Lean4✓* `BEDC.GroundCompiler.DerivCert` `acceptgate components from recognition`

An acceptance-gate flow must contain a recognized NameCert *flow and a sound recognized derivation-certificate flow. If either is missing, the flow is only an acceptance-gate candidate.*

Theorem 9230.27 (AcceptGate recognition requires NameCert and DerivCert). *Lean4✓* `BEDC.GroundCompiler.D` `acceptgate requires namecert derivcert`

If

$$\mathsf{AcceptGateFlow}_{R_A}(S, A, N, s),$$

then there exist C_N and D_N such that

$$\mathsf{NameCertFlow}(C_N, N) \qquad \textit{and} \qquad \mathsf{DerivCertFlow}(D_N, N, s).$$

Proof. By the component definition, recognized acceptance-gate flow identifies NameCert and derivation-certificate components. By the acceptance-gate principle, these components must be recognized flows. □

Corollary 9230.28 (NameCert alone does not imply AcceptGate). *Lean4✓* `BEDC.GroundCompiler.DerivCertGene` `alone no acceptgate`

There exists a recognized NameCert *flow whose same event-flow carrier is not an accepted flow. Licensing a name at P_5 therefore does not by itself supply the derivation-certificate flow, gate seal, and gate recognition required for an acceptance gate.*

Corollary 9230.29 (DerivCert alone does not imply AcceptGate). *Lean4✓* `BEDC.GroundCompiler.DerivCertGene` `alone no acceptgate`

There exists a recognized derivation-certificate flow whose same event-flow carrier is not an accepted flow. Derivation-certificate recognition alone therefore does not supply the matching NameCert *flow, gate seal, and gate recognition required for an acceptance gate.*

9230.6 Accepted object code

Definition 9230.30 (Accepted object flow). *Lean4 (definition)* `BEDC.GroundCompiler.DerivCertGenerated.P6Accep`

If

$$\mathsf{RecognizesAcceptGate}(R_A, S, A, N, s)$$

and A is a sound recognized acceptance-gate flow, then A is an accepted object flow *for N at s. Write*

$$\mathsf{AcceptedObjectFlow}(A, N, s).$$

Definition 9230.31 (Accepted object code). *Lean4 (definition)* `BEDC.GroundCompiler.DerivCertGenerated.P6Accep`

If

$$\mathsf{AcceptedObjectFlow}(A, N, s),$$

define

$$\mathsf{AcceptedObjectCode}(A, N, s) := \mathsf{Compile}(A).$$

This is the channel code of the acceptance flow. It is not bare object code, object equality, theorem proof, or bridge certificate.

Theorem 9230.32 (Accepted object code is injective on raw acceptance flows). *Lean4✓* `BEDC.GroundCompiler.Der` `accepted object code injective raw flows`

If

$$\mathsf{AcceptedObjectCode}(A, N, s) = \mathsf{AcceptedObjectCode}(B, M, t),$$

then $A = B$.

Proof. By definition both sides are compiled channel codes:

$$\mathsf{Compile}(A) = \mathsf{Compile}(B).$$

The channel compiler is injective on event flows, so $A = B$. □

Remark 9230.33 (Accepted object code is not classified-object identity). *The injectivity theorem concerns raw acceptance flows and their codes. If a later classifier or bridge identifies two accepted flows as the same mature object, the mature-object layer is a quotient and may be many-to-one.*

Corollary 9230.34 (Accepted code equality is stronger than object equivalence). *Lean4✓* `BEDC.GroundCompiler.D` `accepted code equality stronger than equivalence`

Equal accepted object codes imply equal raw acceptance flows. Equivalent mature objects under classifier or bridge need not have equal accepted object codes.

9230.7 Strength monotonicity and promotion

Definition 9230.35 (Flow-level strength monotonicity). *Lean4 (definition)* `BEDC.GroundCompiler.DerivCertGenera`

Flow-level strength monotonicity is the rule that, when an accepted flow at strength s contains a recognized lower-strength derivation-certificate subflow supporting s', P_6 may report

$$\mathsf{AcceptGateFlow}(N, s) \Rightarrow \mathsf{AcceptGateFlow}(N, s')$$

provided that the higher-strength derivation-certificate flow contains a recognized lower-strength derivation-certificate subflow supporting s'.

Theorem 9230.36 (Strength monotonicity). *Lean4 ✓ BEDC.GroundCompiler.DerivCertGenerated.p6 strength monotonicity*

If AcceptGateFlow(N, s) *holds and the accepted flow contains a recognized lower-strength derivation-certificate subflow supporting* s'*, then* AcceptGateFlow(N, s') *holds.*

Proof. The acceptance gate at s contains a NameCert flow and a derivation-certificate flow at s. The lower-strength subflow supplies the derivation-certificate component at s'. Together with the same NameCert flow, it forms an acceptance gate at s'. □

Definition 9230.37 (Upgrade flow). *Lean4 (definition) BEDC.GroundCompiler.DerivCertGenerated.UpgradeFlow*

An upgrade flow *is an event flow* U *that upgrades object* N *from strength* s *to* $s' > s$*. It contains prior acceptance-gate flow at* s*, new obligations for* s'*, new proof, exactness, bridge, or checked-target flow, new ledger, and upgrade seal. Write*

$$\mathsf{UpgradeFlow}(U, N, s, s').$$

Principle 9230.38 (No retroactive promotion). *Lean4 ✓ BEDC.GroundCompiler.DerivCertGenerated.p6 no retroactive promotion*

An object accepted at s *does not become accepted at* $s' > s$ *merely because a dependency is later upgraded. A recognized upgrade flow is required.*

Theorem 9230.39 (Upgrade requires upgrade flow). *Lean4 ✓ BEDC.GroundCompiler.DerivCertGenerated.upgrade requires upgrade flow*

If UpgradeFlow(U, N, s, s') *holds, then the flow contains* AcceptGateFlow(N, s)*, a recognized strength flow for* s'*, and recognized derivation-certificate and seal subflows inside* U *supporting* N *at* s'*.*

Proof. This is the defining projection from the upgrade-flow predicate: the prior acceptance gate, new strength flow, and new derivation-certificate and seal subflows are conjunctive components of UpgradeFlow(U, N, s, s'). □

9230.8 Reports and soundness

Definition 9230.40 (P_6 report). *Lean4 (definition) BEDC.GroundCompiler.DerivCertReports.P6Report*

A P_6 report *is an output view containing decoded event flow, recognized* NameCert *flows, derivation-certificate candidates, recognized derivation-certificate flows, derivation-certificate field status, strength-flow status, acceptance-gate candidates, recognized acceptance-gate flows, accepted object flows, accepted object codes, missing fields, upgrade status, warnings, and cannot-claim annotations.*

Definition 9230.41 (DerivCert and AcceptGate field status). *Lean4 (definition) BEDC.GroundCompiler.DerivCertRe*

For each derivation-certificate candidate D*, the report records source, classifier, exactness, ledger, stability, strength, and seal status as present, missing, or candidate-only. For each acceptance-gate candidate* A*, it records* NameCert*-flow, derivation-certificate flow, strength flow, and gate-seal status as present, missing, or candidate-only.*

Definition 9230.42 (P_6 cannot-claim annotations). *Lean4 (definition) BEDC.GroundCompiler.DerivCertReports.Co*

A P_6 *report must state that* NameCert *flow alone does not imply accepted export, derivation-certificate flow alone does not imply accepted export, strength flow alone does not imply derivation*

certificate, accepted flow code is not object equality, accepted object code is not proof of later theorems, accepted object code is not bridge certificate, retroactive promotion is not allowed, classifier equivalence may identify distinct accepted flows, and report is not proof unless theorem-flow recognition is supplied separately.

Definition 9230.43 (Sound P_6 report)**.** Lean4 (definition) `BEDC.GroundCompiler.DerivCertReports.SoundP6Report`

A P_6 report is sound *when:*

1. *every recognized derivation-certificate flow is backed by generated derivation-certificate recognizer;*
2. *every recognized derivation-certificate flow has six fields and seal;*
3. *every recognized derivation-certificate flow satisfies field soundness;*
4. *every recognized strength flow is backed by generated strength recognizer;*
5. *every recognized acceptance-gate flow contains matching* NameCert *and derivation-certificate flows;*
6. *every accepted object code comes from recognized acceptance-gate flow;*
7. *missing fields are explicitly reported;*
8. *candidate-only entries are not reported as recognized;*
9. *cannot-claim annotations are complete.*

Theorem 9230.44 (Sound P_6 report theorem)**.** Lean4✓ `BEDC.GroundCompiler.DerivCertReports.sound p6 report`

If P_6 outputs a sound report, then every accepted object code in the report corresponds to a recognized acceptance-gate flow containing sound NameCert *and derivation-certificate flows.*

Proof. By report soundness, accepted object code can come only from recognized acceptance-gate flow. Such a gate contains matching NameCert and derivation-certificate flows, and the derivation-certificate flow has all six fields and field soundness. □

Corollary 9230.45 (Sound accepted code is certificate-mediated)**.** Lean4✓ `BEDC.GroundCompiler.DerivCertRepor accepted code certificate mediated`

Every sound P_6 accepted object code is certificate-mediated, not bare-code export.

Theorem 9230.46 (P_6 code existence still does not imply theoremhood)**.** Lean4✓ `BEDC.GroundCompiler.DerivCer code not theoremhood`

In a sound P_6 report, accepted object code is recorded together with the cannot-claim annotation that accepted object code is not proof of later theorems. Thus no theorem about the object follows unless a recognized theorem flow and proof flow are supplied.

Proof. Accepted object code records that an acceptance gate has been recognized for an object candidate at a strength. Theoremhood requires theorem-flow recognition with statement, proof, dependencies, certificates, ledger, status, and canonical site. The accepted object code does not provide those data. □

9230.9 Adequacy and examples

Definition 9230.47 (P_6 audit checklist)**.** Lean4 (definition) BEDC.GroundCompiler.DerivCertReports.P6AuditCheck

A P_6 prototype must satisfy:

1. *all P_5 audit requirements;*
2. *derivation-certificate candidates are distinguished from recognized derivation-certificate flows;*
3. *recognized derivation-certificate flows require generated recognizers;*
4. *six derivation-certificate fields and seal are required;*
5. *field soundness is required;*
6. *strength candidates are distinguished from recognized strength flows;*
7. *strength recognition requires generated recognizer;*
8. *acceptance-gate candidates are distinguished from recognized acceptance-gate flows;*
9. *matching* NameCert *and derivation-certificate flows are required for acceptance gates;*
10. *accepted object code comes only from recognized acceptance-gate flow;*
11. *missing fields are reported explicitly;*
12. *accepted code is distinguished from object equality;*
13. *no retroactive promotion is recorded;*
14. *theoremhood is not inferred from accepted object code;*
15. *cannot-claim annotations are included.*

Theorem 9230.48 (P_6 adequacy theorem)**.** Lean4 ✓ BEDC.GroundCompiler.DerivCertReports.p6 adequacy

If a prototype satisfies the P_6 audit checklist, uses sound P_5 reports, and every recognized derivation-certificate or acceptance-gate flow is backed by generated recognizers and field soundness, then it is adequate as a DerivCert and AcceptGate recognition prototype.

Proof. The checklist enforces separation between candidates and recognized flows, six-field derivation-certificate recognition, strength recognition, matching NameCert and derivation-certificate components for acceptance gates, and cannot-claim discipline. Sound P_5 reports supply NameCert correctness. Generated recognizers and field soundness supply the certificate support. □

Corollary 9230.49 (P_6 adequacy does not imply higher adequacy)**.** Lean4 ✓ BEDC.GroundCompiler.DerivCertRepo adequacy does not imply higher

A P_6 prototype can report accepted object codes, but it is not yet a theorem-flow recognizer, chapter-flow recognizer, bridge certifier, full proof checker, or self-hosting compiler.

Example 9230.50 (NameCert without DerivCert)**.** *If a report has a recognized and sound* NameCert *flow, but missing derivation-certificate and acceptance-gate flows, it may say that the name is licensed at P_5 but that there is no accepted object at P_6.*

Example 9230.51 (DerivCert candidate missing exactness)**.** *If a derivation-certificate candidate has source, classifier, ledger, stability, strength, and seal fields, but exactness is missing, the report says that derivation-certificate recognition fails, acceptance-gate recognition fails, and no accepted object code is produced.*

Example 9230.52 (Accepted Axis-like object at seed strength)**.** *Suppose the report recognizes a sound Axis-like* NameCert *flow, a sound derivation-certificate flow with source, classifier, exactness, ledger, stability, seed strength, and seal, and an acceptance-gate flow combining them. Then P_6 may report*

$$\mathsf{AcceptedObjectCode}(\mathrm{Axis}, \mathrm{seed}) = \mathsf{Compile}(\textit{acceptance-gate flow}).$$

Cannot-claims state that seed strength does not imply checked certificate or bridge certificate, and accepted code is not equality with another Axis presentation.

Example 9230.53 (FullAxis candidate still not accepted)**.** *For the completion skeleton* 0 | 00 | 000 | 01 | 011 | 100*, suppose the* NameCert *candidate has source and pattern present, classifier candidate, stability missing, and ledger present, while derivation certificate and acceptance gate are missing. The report must say that* $\mathsf{FullAxis}^{\uparrow}$ *is not accepted: missing stability blocks* NameCert *recognition, and missing derivation certificate blocks acceptance.*

Example 9230.54 (No retroactive promotion)**.** *If an object N is accepted at seed strength and a dependency is later upgraded to checked-certificate strength, P_6 must still report N as accepted only at seed unless there is a recognized upgrade flow for N from seed to checked-certificate strength.*

9230.10 Conservativity

Theorem 9230.55 (P_6 is conservative over the finite kernel)**.** *Lean4✓ BEDC.GroundCompiler.DerivCertReports.p6 conservative over finite kernel*

Adding derivation-certificate recognition, strength recognition, acceptance-gate recognition, accepted object code reports, and upgrade-flow reports adds no raw marks, history constructors, sameness rules, continuation rules, theorem rules, bridge rules, or object-equality rules.

Proof. P_6 operates on decoded event flows and generated recognition relations. It generates no new b0, b1, adds no msame, hsame, or psame, does not alter Ext or Cont, and does not create kernel equality. Accepted object code is mediated by NameCert and derivation-certificate flows; it does not introduce mature objects as primitives. □

Corollary 9230.56 (P_6 is accepted-object reporting, not proof engine)**.** *Lean4✓ BEDC.GroundCompiler.DerivCertI not proof engine*

P_6 can report accepted object codes, but it does not prove arbitrary theorems about those objects. Proofs require theorem-flow and proof-flow recognition.

Remark 9230.57 (Summary)**.** *This chapter defines P_6, the DerivCert and AcceptGate recognition prototype. It adds strength candidates, generated strength recognizers, recognized strength flows, derivation-certificate candidates, generated derivation-certificate recognizers, recognized derivation-certificate flows, six derivation-certificate fields, field soundness, acceptance-gate candidates, generated acceptance-gate recognizers, accepted object flows, accepted object codes, strength monotonicity, upgrade flows, no-retroactive-promotion discipline, P_6 reports, and the P_6 audit checklist. It proves that strength candidates and incomplete derivation certificates cannot support export, sound derivation certificates establish derivation-certificate flows, acceptance gates require* NameCert *and derivation-certificate flows, accepted object code is injective only on raw acceptance flows, accepted code is not object identity or theoremhood, upgrade requires upgrade flow, sound P_6 reports are certificate-mediated, and P_6 is conservative over the finite kernel.*

Chapter 9231

Theorem and Proof Recognition Prototype

chapter 9230 defines P_6, the derivation-certificate and acceptance-gate recognition prototype. It can report accepted object code, but it is still not a theorem recognizer. An accepted object does not automatically provide arbitrary theorems about that object.

This chapter defines the next prototype level:

$$\boxed{P_7 = P_6 + \text{statement-flow recognition} + \text{proof-flow recognition} + \text{theorem-flow recognition.}}$$

This is the first layer where theorem code may be reported. The distinctions among theorem code, proof-flow, accepted theorem, and abstract proposition are strict:

a theorem is not an external label; it is a recognized statement/proof/dependency/certificate/ledger/status/site

Thus P_7 does not accept theorem objects, theorem labels, Lean theorem names, host proof objects, proof ASTs, external proposition strings, or manual theorem tables. It accepts channel streams or decoded event flows and recognizes theorem and proof flows by generated recognizers and generated proof checkers.

9231.1 P_7 prototype interface

Definition 9231.1 (Theorem and proof recognition prototype)**.** *Lean4 (definition)* `BEDC.GroundCompiler.TheoremPr`

A theorem and proof recognition prototype *is an executable prototype P_7 satisfying:*

1. *P_7 includes all P_6 functions;*
2. *P_7 recognizes statement flows;*
3. *P_7 recognizes dependency flows;*
4. *P_7 recognizes proof flows;*
5. *P_7 recognizes theorem certificate flows;*
6. *P_7 recognizes theorem ledger flows;*
7. *P_7 recognizes theorem status flows;*
8. *P_7 recognizes canonical-site flows;*

9. *P_7 recognizes theorem-seal flows;*
10. *when proof-flow is validated by generated proof checker, P_7 can report theorem code;*
11. *P_7 does not treat theorem code as mature-object export;*
12. *P_7 does not treat theorem code as abstract-proposition identity;*
13. *P_7 does not treat theorem code as bridge certificate.*

Write

$$\mathsf{TheoremProofPrototype}(P_7).$$

Principle 9231.2 (Theorem is not input). *Lean4✓ BEDC.GroundCompiler.TheoremProofPrototype.theorem proof objects not formal*

There is no formal input

$$\mathsf{TheoremObject} \to \mathsf{Code} \qquad \textit{or} \qquad \mathsf{ProofObject} \to \mathsf{Code}.$$

The only formal input remains EventFlow *or* LegalZStream*. If the input is channel stream c, then P_7 first checks $c \in \mathsf{LegalZStream}$ and forms $S = \mathsf{Decode}(c)$.*

Definition 9231.3 (P_7 input). *Lean4 (definition) BEDC.GroundCompiler.TheoremProofPrototype.P7FormalInput*

The input to P_7 is displayed as channel stream c or event flow S. If $c \notin \mathsf{LegalZStream}$, P_7 rejects and produces no theorem report.

Definition 9231.4 (P_7 output). *Lean4 (definition) BEDC.GroundCompiler.TheoremProofPrototype.P7Output*

The output of P_7 is a report flow or human-readable report containing decoded event flow, statement candidates, recognized statement flows, dependency candidates, recognized dependency flows, proof candidates, recognized proof flows, proof-checking results, theorem candidates, recognized theorem flows, theorem code, theorem field status, missing fields, proof failures, certificate failures, ledger failures, status failures, canonical-site failures, warnings, and cannot-claim annotations.

9231.2 Statement and dependency recognition

Definition 9231.5 (Statement candidate). *Lean4 (definition) BEDC.GroundCompiler.TheoremProofPrototype.Statem*

A statement candidate *is an event subflow*

$$\Phi \subseteq S$$

not yet recognized as a statement flow. Write

$$\mathsf{StmtCand}(S, \Phi).$$

Definition 9231.6 (Generated statement recognizer). *Lean4 (definition) BEDC.GroundCompiler.TheoremProofProto*

A generated statement recognizer *is an event flow*

$$R_\Phi \in \mathsf{EventFlow}$$

supporting

$$\mathsf{RecognizesStatement}(R_\Phi, S, \Phi).$$

Definition 9231.7 (Recognized statement flow)**.** *Lean4 (definition)* `BEDC.GroundCompiler.TheoremProofPrototype.`

If

$$\mathsf{RecognizesStatement}(R_\Phi, S, \Phi),$$

then Φ *is a recognized statement flow in* S*. Write*

$$\mathsf{StatementFlow}_{R_\Phi}(S, \Phi).$$

Remark 9231.8 (Statement flow is not abstract proposition)**.** *A statement flow is a statement structure inside an event flow. It is not an external proposition, host-level formula, Lean theorem statement, or LaTeX string. One abstract proposition may have multiple statement flows with different presentations, unfoldings, dependency exposure, notation, bridge expression, or canonical site.*

Definition 9231.9 (Dependency candidate and recognizer)**.** *Lean4 (definition)* `BEDC.GroundCompiler.TheoremProof`

A dependency candidate *is an event subflow*

$$D_{\mathrm{dep}} \subseteq S$$

claiming to record theorem dependencies. A generated dependency recognizer *is an event flow* R_{dep} *supporting*

$$\mathsf{RecognizesDependencies}(R_{\mathrm{dep}}, S, D_{\mathrm{dep}}).$$

If this holds, D_{dep} *is a recognized dependency flow.*

Definition 9231.10 (Dependency soundness)**.** *Lean4 (definition)* `BEDC.GroundCompiler.TheoremProofPrototype.De`

A dependency flow D_{dep} *is* sound *when every raw dependency entry it records has a dependency status among: generated in an earlier event flow, proved in an earlier theorem flow, recognized in an earlier certificate flow, local to the same theorem flow, explicitly marked as deferred obligation, explicitly listed as cannot-claim, or explicitly listed as open obligation. A dependency entry whose status is future-ungenerated is unsound.*

Theorem 9231.11 (Unsound dependency blocks theorem recognition)**.** *Lean4 ✓* `BEDC.GroundCompiler.TheoremPr` `dependency blocks theorem recognition`

If a theorem candidate has a recognized dependency subflow whose dependency soundness predicate fails, then that candidate cannot become a sound theorem flow with that dependency subflow.

Proof. The sound theorem-flow predicate includes dependency soundness for the recognized dependency subflow. If dependency soundness fails for that subflow, the conjunction required for sound theorem recognition cannot be constructed. □

9231.3 Proof-flow recognition and checking

Definition 9231.12 (Proof candidate)**.** *Lean4 (definition)* `BEDC.GroundCompiler.TheoremProofPrototype.ProofCand`

A proof candidate *is an event subflow*

$$\Pi \subseteq S$$

not yet recognized as a proof flow. Write

$$\mathsf{ProofCand}(S, \Pi).$$

Definition 9231.13 (Generated proof-flow recognizer). *Lean4 (definition)* `BEDC.GroundCompiler.TheoremProofProt`

A generated proof-flow recognizer *is an event flow*

$$R_\Pi \in \mathsf{EventFlow}$$

supporting

$$\mathsf{RecognizesProofFlow}(R_\Pi, S, \Pi).$$

Definition 9231.14 (Recognized proof flow). *Lean4 (definition)* `BEDC.GroundCompiler.TheoremProofPrototype.Rec`

If

$$\mathsf{RecognizesProofFlow}(R_\Pi, S, \Pi),$$

then Π *is a recognized proof flow in* S*. Write*

$$\mathsf{ProofFlow}_{R_\Pi}(S, \Pi).$$

Definition 9231.15 (Generated proof checker). *Lean4 (definition)* `BEDC.GroundCompiler.TheoremProofPrototype.G`

A generated proof checker *is an event flow*

$$R_{\mathrm{chk}} \in \mathsf{EventFlow}$$

supporting

$$\mathsf{ChecksProof}(R_{\mathrm{chk}}, \Phi, D_{\mathrm{dep}}, \Pi).$$

This says that R_{chk} *checks proof-flow* Π *as a proof of statement-flow* Φ *using dependency-flow* D_{dep}*. It is not host proof checker output or external proof-engine result. Host proof checkers must be recorded by bootstrap obligation or bridge/certificate flow.*

Definition 9231.16 (Proof soundness). *Lean4 (definition)* `BEDC.GroundCompiler.TheoremProofPrototype.ProofSou`

A proof flow Π *is* sound *for statement flow* Φ *and dependency flow* D_{dep} *when there exists a generated proof checker* R_{chk} *such that*

$$\mathsf{ChecksProof}(R_{\mathrm{chk}}, \Phi, D_{\mathrm{dep}}, \Pi).$$

Theorem 9231.17 (Proof candidate alone is insufficient). *Lean4✓* `BEDC.GroundCompiler.TheoremProofPrototype.candidate alone insufficient`

If Π *is a proof candidate in an event flow* S*, no generated proof-flow recognizer recognizes* Π *in* S*, and no generated proof checker establishes*

$$\mathsf{ChecksProof}(R_{\mathrm{chk}}, \Phi, D_{\mathrm{dep}}, \Pi),$$

then Π *cannot be used as a theorem proof for statement flow* Φ *and dependency flow* D_{dep}*.*

Proof. A proof candidate is just an event subflow. To serve as theorem proof, it must first be recognized as proof flow and then checked by generated proof checker against the statement and dependencies. Without both, the proof role is not established. □

Corollary 9231.18 (Code is not proof flow). *Lean4✓* `BEDC.GroundCompiler.TheoremProofPrototype.code not proof flow`

A channel code may decode to an event flow, but it does not thereby become proof flow. Proof-flow recognition is required.

Corollary 9231.19 (Proof flow is not proof checking). *Lean4✓* `BEDC.GroundCompiler.TheoremProofPrototype.pro flow not checking`

Recognized proof flow does not by itself prove a statement. A ChecksProof *judgment is required.*

9231.4 Theorem-flow recognition

Definition 9231.20 (Theorem candidate). *Lean4 (definition)* `BEDC.GroundCompiler.TheoremProofPrototype.Theor`

A theorem candidate *is an event subflow*

$$T \subseteq S$$

not yet recognized as theorem flow. Write

$$\mathsf{TheoremCand}(S, T).$$

Definition 9231.21 (Generated theorem recognizer). *Lean4 (definition)* `BEDC.GroundCompiler.TheoremProofProtot`

A generated theorem recognizer *is an event flow*

$$R_T \in \mathsf{EventFlow}$$

supporting

$$\mathsf{RecognizesTheorem}(R_T, S, T).$$

Definition 9231.22 (Theorem subflows). *Lean4 (definition)* `BEDC.GroundCompiler.TheoremProofPrototype.P7Theor`

If

$$\mathsf{RecognizesTheorem}(R_T, S, T),$$

then R_T may identify:

$$\mathsf{ThmStatement}_{R_T}(T, \Phi), \qquad \mathsf{ThmDependencies}_{R_T}(T, D_{\mathrm{dep}}),$$

$$\mathsf{ThmProof}_{R_T}(T, \Pi), \qquad \mathsf{ThmCertificates}_{R_T}(T, C_{\mathrm{thm}}),$$

$$\mathsf{ThmLedger}_{R_T}(T, L_{\mathrm{thm}}), \qquad \mathsf{ThmStatus}_{R_T}(T, s_{\mathrm{thm}}),$$

$$\mathsf{ThmCanonicalSite}_{R_T}(T, \kappa), \qquad \mathsf{ThmSeal}_{R_T}(T, \sigma_T).$$

Definition 9231.23 (Complete theorem recognition). *Lean4 (definition)* `BEDC.GroundCompiler.TheoremProofProtot`

The judgment

$$\mathsf{P7CompleteTheoremRecognition}(R_T, T)$$

is complete theorem recognition *when statement, dependency, proof, certificate, ledger, status, canonical-site, and seal subflows are all recognized.*

Principle 9231.24 (No theorem without eight subflows). *Lean4✓* `BEDC.GroundCompiler.TheoremProofPrototype.theorem without eight subflows`

A theorem flow must have recognized statement, dependencies, proof, certificates, ledger, status, canonical site, and seal. If any is missing, the flow remains a theorem candidate.

Theorem 9231.25 (Incomplete theorem candidate cannot be theorem flow). *Lean4✓* `BEDC.GroundCompiler.Theor incomplete theorem candidate not theorem`

If a theorem candidate T lacks any required recognized subflow, then T cannot be used as recognized theorem flow.

Proof. Theorem-flow recognition requires complete theorem recognition. Missing any of the eight required subflows blocks completeness. □

9231.5 Theorem-flow soundness and code

Definition 9231.26 (Theorem-flow soundness components). Lean4 (definition) BEDC.GroundCompiler.TheoremProof

The soundness components for a theorem flow are:

1. *statement soundness: the statement is recognized and every symbol, dependency, and object reference has a source in the dependency or certificate flow;*
2. *dependency soundness: the dependency flow satisfies Definition 9231.10;*
3. *proof soundness: a generated proof checker validates* $\mathsf{ChecksProof}(R_{\mathrm{chk}}, \Phi, D_{\mathrm{dep}}, \Pi)$*;*
4. *certificate soundness: required certificate flows are recognized or explicitly marked as open obligations;*
5. *ledger soundness: the ledger records statement, dependency, proof, certificate, hidden abbreviation, classifier quotient, normal-address, bridge-obligation, and failure-branch material;*
6. *status soundness: status is recognized and matches proof, certificate, checked-flow, or bridge-flow status;*
7. *canonical-site soundness: the site records the theorem's canonical position, with competing sites marked as variant, wrapper, or projection.*

Definition 9231.27 (Sound theorem flow). Lean4 (definition) BEDC.GroundCompiler.TheoremProofPrototype.P7Sou

A recognized theorem flow T is sound *when complete theorem recognition holds and all soundness components of Definition 9231.26 hold.*

Theorem 9231.28 (Sound theorem flow establishes theorem code). Lean4✓ BEDC.GroundCompiler.TheoremProofP theorem flow establishes theorem code

If T is a sound theorem flow, define

$$\mathsf{TheoremCode}(T) := \mathsf{Compile}(T).$$

This code is the lossless channel encoding of T.

Proof. The theorem flow T is an event-flow subflow, so $\mathsf{Compile}(T)$ is defined. By the channel bijection, compilation is lossless. By soundness, T has the statement, dependencies, proof, certificates, ledger, status, site, and seal required for theoremhood. □

Theorem 9231.29 (Theorem code is injective on raw theorem flows). Lean4✓ BEDC.GroundCompiler.TheoremProof theorem code injective

If T and U are sound theorem flows and

$$\mathsf{TheoremCode}(T) = \mathsf{TheoremCode}(U),$$

then $T = U$.

Proof. Both theorem codes are compiled event-flow codes. Equality gives $\mathsf{Compile}(T) = \mathsf{Compile}(U)$, hence $T = U$ by injectivity of the channel compiler. □

Corollary 9231.30 (Theorem code equality is stronger than statement equivalence). Lean4✓ BEDC.GroundCompiler.TheoremProofPrototype.theorem code stronger than statement

Equal theorem codes imply equal complete theorem flows, including statement, dependencies, proof, certificates, ledger, status, and canonical site. Statement-flow equivalence alone does not imply theorem-code equality.

9231.6 Abstract propositions and accepted theorem flows

Definition 9231.31 (Statement classifier and abstract proposition class). *Lean4 (definition)* `BEDC.GroundCompiler.`

A statement classifier *is a source-level classifier* $\sim_{\mathrm{stmt}}$ *on statement flows. If* $\Phi \sim_{\mathrm{stmt}} \Psi$*, then* Φ *and* Ψ *may be read as statement-flow presentations of the same abstract proposition. The abstract proposition class is*

$$[\Phi]_{\sim_{\mathrm{stmt}}}.$$

Proposition 9231.32 (Abstract proposition may have many theorem flows). *Lean4 ✓* `BEDC.GroundCompiler.Theo` `proposition many flows`

There may be distinct theorem flows T *and* U *whose statement flows lie in the same abstract proposition class.*

Proof. Let the statement flows of T and U be Φ and Ψ, with $\Phi \sim_{\mathrm{stmt}} \Psi$. If proof flow, dependency flow, ledger flow, or canonical-site flow differs, then the complete event flows T and U differ. □

Corollary 9231.33 (Abstract proposition is not theorem code). *Lean4 ✓* `BEDC.GroundCompiler.TheoremProofProt` `proposition not theorem code`

Theorem code is bijective with theorem flow. Abstract proposition classes are quotients of statement flows and are generally not in bijection with theorem codes.

Definition 9231.34 (Accepted theorem flow). *Lean4 (definition)* `BEDC.GroundCompiler.TheoremProofPrototype.P7`

A sound theorem flow T *is an* accepted theorem flow *when its proof flow is checked by generated proof checker, all required certificates in its certificate flow are recognized, any claimed mature-object export has the relevant acceptance-gate flow, status matches proof and certificate state, and ledger is complete. Write*

$$\mathsf{AcceptedTheoremFlow}(T).$$

Definition 9231.35 (Accepted theorem code). *Lean4 (definition)* `BEDC.GroundCompiler.TheoremProofPrototype.Ac`

If

$$\mathsf{AcceptedTheoremFlow}(T),$$

define

$$\mathsf{AcceptedTheoremCode}(T) := \mathsf{Compile}(T).$$

Proposition 9231.36 (Accepted theorem code is theorem-flow code with acceptance status). *Lean4 ✓* `BEDC.GroundCompiler.TheoremProofPrototype.accepted theorem code same code`

Accepted theorem code is not a new encoding function. It is theorem-flow code for a theorem flow satisfying accepted-theorem conditions.

Proof. By definition, $\mathsf{AcceptedTheoremCode}(T) = \mathsf{Compile}(T)$. □

Theorem 9231.37 (Accepted theorem code does not imply accepted object). *Lean4 ✓* `BEDC.GroundCompiler.Theo` `theorem not object acceptance distinct`

There exists an accepted theorem flow T *and an object-flow mention* O *inside* T *such that* O *is not an accepted object flow. Thus accepted-theorem status is a status of the theorem flow and does not by itself provide the acceptance-gate flows required for every object mentioned by the theorem.*

Proof. Accepted theorem status concerns the theorem package: proof, certificates, ledger, status, and site. Object acceptance is separately mediated by acceptance-gate flows for the objects. A theorem flow may mention an empty object-flow position; the empty flow has no accepted-object witness, because accepted object flow requires nonempty accepted structure and recognized certificate flows. □

Corollary 9231.38 (Theorem acceptance and object acceptance are distinct). Lean4 ✓ BEDC.GroundCompiler.Theo acceptance and object acceptance distinct

Theorem-flow acceptance and object acceptance are different statuses requiring different recognized flows.

9231.7 Reports and soundness

Definition 9231.39 (P_7 report). Lean4 (definition) BEDC.GroundCompiler.TheoremProofPrototype.P7ReportDatum

A P_7 report *is an output view containing decoded event flow, statement candidates, recognized statement flows, dependency candidates, recognized dependency flows, proof candidates, recognized proof flows, proof-checking status, theorem candidates, recognized theorem flows, theorem field status, accepted theorem flows, theorem codes, missing fields, proof failures, dependency failures, certificate failures, ledger failures, status failures, canonical-site failures, and cannot-claim annotations.*

Definition 9231.40 (Theorem field and proof status). Lean4 (definition) BEDC.GroundCompiler.TheoremProofProto

For each theorem candidate T*, the report records statement, dependencies, proof, certificates, ledger, status, canonical site, and seal as present, missing, or candidate-only. For each proof candidate* Π*, it records whether proof-flow is recognized, statement and dependencies match, proof checker is supplied, proof check passes, failure reason, and ledger status.*

Definition 9231.41 (P_7 cannot-claim annotations). Lean4 (definition) BEDC.GroundCompiler.TheoremProototy

A P_7 *report must state that statement flow alone is not theorem, proof flow alone is not theorem, recognized proof flow is not checked proof unless proof checker validates it, theorem code is not abstract-proposition identity, accepted theorem does not imply all mentioned objects are accepted, theorem code is not bridge certificate, same statement classifier does not imply same theorem code, missing proof checker blocks accepted theorem, and missing canonical site blocks canonical theorem code.*

Definition 9231.42 (Sound P_7 report). Lean4 (definition) BEDC.GroundCompiler.TheoremProofPrototype.SoundP7R

A P_7 *report is* sound *when:*

1. *every recognized statement flow is backed by generated statement recognizer;*
2. *every recognized dependency flow is backed by generated dependency recognizer;*
3. *every recognized proof flow is backed by generated proof-flow recognizer;*
4. *every successful proof-checking claim is backed by generated proof checker;*
5. *every recognized theorem flow has eight subflows;*
6. *every accepted theorem flow satisfies accepted-theorem conditions;*
7. *every theorem code is* $\mathsf{Compile}(T)$*;*
8. *candidate-only entries are not reported as recognized;*
9. *missing fields and failure cases are explicit;*
10. *cannot-claim annotations are complete.*

Theorem 9231.43 (Sound P_7 report theorem). Lean4 ✓ BEDC.GroundCompiler.TheoremProofPrototype.sound p7 report theorem

If P_7 *outputs a sound report, then every theorem code in the report corresponds to a sound theorem flow, and every accepted theorem code corresponds to an accepted theorem flow.*

Proof. By soundness, theorem code comes only from recognized theorem flow with all required subflows and soundness data. Accepted theorem code further requires accepted-theorem conditions. □

Corollary 9231.44 (Sound theorem code is flow-mediated). Lean4✓ BEDC.GroundCompiler.TheoremProofPrototyp theorem code flow mediated

P_7 theorem code is not an external theorem label; it is the channel compilation of theorem flow.

Theorem 9231.45 (P_7 code existence still does not imply bridge). Lean4✓ BEDC.GroundCompiler.TheoremProofPr code existence still not bridge

There exists an accepted theorem flow whose accepted theorem code is legal theorem code and whose theorem flow contains no bridge-certificate witness flow.

Proof. Accepted theorem flow may have non-bridge status. Bridge certification requires additional bridge-certificate flow. A singleton accepted theorem flow has legal theorem code, but it cannot contain the designated bridge-certificate witness flow. □

9231.8 Adequacy and examples

Definition 9231.46 (P_7 audit checklist). Lean4 (definition) BEDC.GroundCompiler.TheoremProofPrototype.P7Audit

A P_7 prototype must satisfy:

1. *all P_6 audit requirements;*
2. *statement candidates are distinguished from recognized statement flows;*
3. *proof candidates are distinguished from recognized proof flows;*
4. *proof-checking claims require generated proof checker;*
5. *theorem candidates are distinguished from recognized theorem flows;*
6. *eight theorem subflows are required;*
7. *dependency soundness is required;*
8. *proof soundness is required;*
9. *certificate soundness is required;*
10. *ledger soundness is required;*
11. *status soundness is required;*
12. *canonical-site soundness is required;*
13. *theorem code is distinguished from abstract proposition;*
14. *theorem acceptance is distinguished from object acceptance;*
15. *missing fields and proof failures are recorded;*
16. *cannot-claim annotations are included.*

Theorem 9231.47 (P_7 adequacy theorem). Lean4✓ BEDC.GroundCompiler.TheoremProofPrototype.p7 adequacy

If a prototype satisfies the P_7 audit checklist, then it is adequate as a theorem and proof recognition prototype: recognized statement entries are backed by generated statement recognizers, recognized theorem entries are backed by generated theorem recognizers, and theorem-code entries are mediated by theorem flows rather than by external theorem labels.

Proof. The audit checklist includes the backing obligations for recognized statement entries, recognized theorem entries, and theorem-code entries. Projecting those obligations yields the adequacy clauses for the prototype. □

Corollary 9231.48 (P_7 adequacy does not imply higher adequacy)**.** Lean4✓ BEDC.GroundCompiler.TheoremProofP adequacy does not imply higher

P_7 recognizes theorem and proof flows, but does not yet recognize chapter flows, compiler self-hosting, full bridge protocols, or global manuscript status.

Example 9231.49 (Channel round-trip theorem flow)**.** *A theorem flow for channel round trip may contain a statement flow* $\mathsf{Decode}(\mathsf{Compile}(S)) = S$*, dependency flows for* ζ*, event encoding, compilation, and decoding, proof flow by induction on event flow, certificate flow for channel compiler definitions and decoder correctness, ledger retaining raw event flow, compiled stream, and decoded stream, status flow, canonical site in the channel compiler chapter, and theorem seal. Its theorem code is* $\mathsf{Compile}(T_{\text{roundtrip}})$*.*

Example 9231.50 (Carry theorem flow)**.** *A theorem flow for source-level carry may state that* 011 *and* 100 *are related by a carry classifier. It contains dependencies for source events, normalizer recognizer, carry classifier, and ledger-preservation theorem; proof flow from recognizer soundness; certificates for normalizer recognition and classifier exactness; ledger retaining pre-normal* 011 *and normal-address* 100*; status, canonical site, and seal. Cannot-claims state that this does not prove* $011 = 100$ *as* hsame*, does not imply dimension-lift without its own* NameCert *flow, and does not imply geometric dimension.*

Example 9231.51 (Accepted object theorem flow)**.** *A theorem flow may state* $\mathsf{AcceptGateFlow}(N, s)$*. It contains dependencies on the* NameCert *flow for* N*, derivation-certificate flow for* N *at* s*, and strength flow* s*; proof flow constructing the acceptance gate; certificate flow with* P_6 *accepted-object data; ledger referencing certificate ledgers; status, canonical site, and seal. This theorem code proves the acceptance-flow statement, but not arbitrary properties of* N*.*

Example 9231.52 (Incomplete theorem candidate)**.** *If a theorem candidate has statement, dependencies, certificates, ledger, status, canonical site, and seal, but proof is missing, the report says recognized theorem flow is absent and theorem code is not produced. The cannot-claim annotation says that statement alone is not theorem.*

9231.9 Conservativity

Theorem 9231.53 (P_7 is conservative over the finite kernel)**.** Lean4✓ BEDC.GroundCompiler.TheoremProofPrototy conservative over finite kernel

Adding statement-flow recognition, proof-flow recognition, proof-checking relations, theorem-flow recognition, theorem-code reports, and accepted-theorem reports adds no raw marks, history constructors, sameness rules, continuation rules, derived-interface formation rules, object-equality rules, or bridge rules.

Proof. P_7 operates on decoded event flows and generated recognition relations. It generates no new $\mathsf{b0}, \mathsf{b1}$, adds no msame, hsame, or psame, does not alter Ext or Cont, and does not license mature objects except through existing certificate-mediated acceptance flows. Theorem recognition records statement and proof structure; it does not change the finite kernel. □

Corollary 9231.54 (P_7 is theorem-reporting layer)**.** `Lean4✓ BEDC.GroundCompiler.TheoremProofPrototype.p7 theorem reporting layer`

P_7 can recognize theorem and proof flows, but without chapter-flow recognition and compiler self-hosting it is not a full manuscript compiler.

Remark 9231.55 (Summary)**.** *This chapter defines P_7, the theorem and proof recognition prototype. It adds statement candidates, generated statement recognizers, recognized statement flows, dependency candidates and flows, proof candidates, generated proof-flow recognizers, recognized proof flows, generated proof checkers, theorem candidates, generated theorem recognizers, recognized theorem flows, eight theorem subflows, proof, certificate, ledger, status, and canonical-site soundness, theorem code, abstract proposition classes, accepted theorem flows, P_7 reports, and the P_7 audit checklist. It proves that theorem is not input, statement flow is not abstract proposition, unsound dependencies block theorem recognition, proof candidates and proof flows are insufficient without checking, incomplete theorem candidates are not theorem flows, sound theorem flows establish theorem code, theorem code is injective on raw theorem flows, abstract proposition classes are quotients, accepted theorem code does not imply object acceptance or bridge status, P_7 adequacy requires generated recognizers and proof checkers, and P_7 is conservative over the finite kernel.*

Theorem 9231.56 (Accepted theorem export cites an AcceptGate witness)**.** *Let T be an accepted theorem flow. If the theorem ledger of T records a mature-object export claim for an object-flow name O at strength s, then there exist an event flow S, an acceptance-gate flow A, and a generated acceptance-gate recognizer R_A such that*

$$\mathsf{AcceptGateFlow}_{R_A}(S, A, O, s)$$

and the certificate or ledger subflow of T contains or cites A as the witness for that export claim.

Proof. By Definition 9231.34, accepted-theorem status is not only proof checking. It also requires that any claimed mature-object export has the relevant acceptance-gate flow, that all required certificates are recognized, and that the ledger is complete. Apply this defining condition to the ledger entry asserting export of O at strength s. The accepted-theorem witness for T therefore supplies a relevant acceptance-gate flow for that same object name and strength.

By Definition 9230.24, a relevant acceptance-gate flow is represented by some event flow S, subflow A, and generated recognizer R_A satisfying

$$\mathsf{AcceptGateFlow}_{R_A}(S, A, O, s).$$

The same accepted-theorem condition places this gate in the finite evidence carried by T: because the export is a theorem-ledger claim and the ledger is complete, the gate cannot be external unstated data; it must occur either as a certificate subflow of T or as a ledger citation retained by T. Thus the mature-object export claim projects to a concrete recognized AcceptGate witness for O at s. □

Chapter 9232

Chapter and Manuscript Recognition Prototype

chapter 9231 defines P_7, the theorem and proof recognition prototype. It recognizes statement flows, dependency flows, proof flows, theorem certificate flows, theorem ledgers, theorem status, canonical sites, and theorem seals. It can report theorem code and accepted theorem code, but it is still not a chapter compiler or manuscript compiler.

This chapter defines the next prototype level:

$$\boxed{P_8 = P_7 + \text{chapter-flow recognition} + \text{manuscript-flow recognition.}}$$

This is the first layer where chapter code, section code, and manuscript code may be reported. The boundary remains strict:

a chapter is not a heading, and a manuscript is not a file; both are recognized event-flow structures.

Thus P_8 does not accept chapter manifests, manuscript manifests, LaTeX section trees, Markdown heading trees, file paths, chapter numbers, external tables of contents, manual theorem lists, manual status tables, or manual dependency graphs. It accepts channel streams or decoded event flows, then recognizes chapter and manuscript structures by generated recognizers.

9232.1 P_8 prototype interface

Definition 9232.1 (Chapter and manuscript recognition prototype)**.** *Lean4 (definition)* `BEDC.GroundCompiler.Chap`

A chapter and manuscript recognition prototype *is an executable prototype P_8 satisfying:*

1. *P_8 includes all P_7 functions;*
2. *P_8 recognizes definition flows;*
3. *P_8 recognizes lemma flows;*
4. *P_8 recognizes theorem-flow lists;*
5. *P_8 recognizes proof-flow lists;*
6. *P_8 recognizes certificate-flow lists;*
7. *P_8 recognizes chapter-level ledger flows;*
8. *P_8 recognizes chapter-level cannot-claim registries;*

9. *P_8 recognizes chapter status flows;*
10. *P_8 recognizes chapter-seal flows;*
11. *P_8 recognizes manuscript-level chapter sequences;*
12. *P_8 recognizes manuscript dependency flows;*
13. *P_8 recognizes manuscript global status flows;*
14. *P_8 recognizes manuscript-seal flows;*
15. *P_8 does not treat chapter titles, section numbers, file paths, YAML, LaTeX, or Markdown as formal input.*

Write

$$\mathsf{ChapterManuscriptPrototype}(P_8).$$

Principle 9232.2 (Chapter and manuscript are not inputs)**.** *Lean4✓ BEDC.GroundCompiler.ChapterManuscript.ch manuscript not input*

There is no formal input

$$\mathsf{ChapterPkg} \to \mathsf{Code} \qquad \textit{or} \qquad \mathsf{ManuscriptFile} \to \mathsf{Code}.$$

The only formal input remains EventFlow *or* LegalZStream*. If the input is channel stream c, then P_8 first forms $S = \mathsf{Decode}(c)$ and only then recognizes chapter or manuscript flows in S.*

Definition 9232.3 (P_8 input)**.** *Lean4 (definition) BEDC.GroundCompiler.ChapterManuscript.P8FormalInput*

The input to P_8 is displayed as channel stream c or event flow S. If the input is c, then P_8 first requires $c \in \mathsf{LegalZStream}$ and decodes it. If $c \notin \mathsf{LegalZStream}$, P_8 rejects and produces no chapter report or manuscript report.

Definition 9232.4 (P_8 output)**.** *Lean4 (definition) BEDC.GroundCompiler.ChapterManuscript.P8Output*

The output of P_8 is a report flow or human-readable report containing decoded event flow, chapter candidates, recognized chapter flows, chapter field status, definition-flow lists, lemma-flow lists, theorem-flow lists, proof-flow lists, certificate-flow lists, chapter ledger flow, chapter cannot-claim registry, chapter status flow, chapter seal flow, manuscript candidates, recognized manuscript flows, manuscript dependency order, global cannot-claim registry, global status table, manuscript seal flow, missing fields, warnings, and cannot-claim annotations.

9232.2 Definition and lemma recognition

Definition 9232.5 (Definition candidate and recognizer)**.** *Lean4 (definition) BEDC.GroundCompiler.ChapterFlow.De*

A definition candidate *is an event subflow*

$$D_{\mathrm{def}} \subseteq S$$

not yet recognized as a definition flow. Write $\mathsf{DefCand}(S, D_{\mathrm{def}})$.

A generated definition recognizer *is an event flow $R_{\mathrm{def}} \in \mathsf{EventFlow}$ supporting*

$$\mathsf{RecognizesDefinition}(R_{\mathrm{def}}, S, D_{\mathrm{def}}).$$

If this holds, D_{def} is a recognized definition flow. Write

$$\mathsf{DefinitionFlow}_{R_{\mathrm{def}}}(S, D_{\mathrm{def}}).$$

Definition 9232.6 (Definition soundness). *Lean4 (definition)* `BEDC.GroundCompiler.ChapterFlow.DefinitionSoundn`

A definition flow is sound *when it only cites generated or deferred dependencies, does not introduce uncertified mature objects, includes or cites a NameCert-flow whenever it proposes a derived name, marks candidate-only definitions as candidate-only, records source events and hidden material in ledger flow, and does not treat host-level names as BEDC primitives.*

Theorem 9232.7 (Unsound definition cannot enter chapter-flow). *Lean4✓* `BEDC.GroundCompiler.ChapterFlow.un` `definition blocks`

Let $\mathsf{DefinitionSoundness}(R_{\mathrm{def}}, S, D_{\mathrm{def}})$ *record the dependency, certificate, ledger, candidate-only, and no-host-name clauses for a recognized definition flow. If a definition candidate* D_{def} *does not satisfy* $\mathsf{DefinitionSoundness}(R_{\mathrm{def}}, S, D_{\mathrm{def}})$*, then it cannot serve as a sound chapter definition subflow.*

Proof. A sound chapter-flow must not inject hidden input or uncertified mature objects through its definitions. If a definition candidate lacks dependency tracking, certificate support, ledger support, or a candidate-only marker, then the chapter would import unsupported structure. Hence the candidate cannot be admitted as a sound definition subflow. □

Definition 9232.8 (Lemma candidate and recognizer). *Lean4 (definition)* `BEDC.GroundCompiler.ChapterFlow.Lemma`

A lemma candidate *is an event subflow* $L_{\mathrm{lem}} \subseteq S$ *not yet recognized as a lemma flow. A* generated lemma recognizer *is an event flow* $R_{\mathrm{lem}} \in \mathsf{EventFlow}$ *supporting*

$$\mathsf{RecognizesLemma}(R_{\mathrm{lem}}, S, L_{\mathrm{lem}}).$$

If this holds, L_{lem} *is a recognized lemma flow.*

Proposition 9232.9 (Lemma-flow is theorem-like but site-local). *Lean4✓* `BEDC.GroundCompiler.ChapterFlow.lem` `site local`

If L_{lem} *is a recognized lemma-flow, then it has theorem-like subflow structure, while its canonical-site flow may be chapter-local rather than global.*

Proof. A lemma is a proof package used as a supporting result inside a chapter. It therefore requires statement, dependencies, proof, ledger, status, and seal data like a theorem-flow. Its canonical site records its chapter-local role, so it need not be a global theorem site. □

9232.3 Chapter-flow recognition

Definition 9232.10 (Chapter candidate and recognizer). *Lean4 (definition)* `BEDC.GroundCompiler.ChapterFlow.Cha` *Lean4 (definition)* `BEDC.GroundCompiler.ChapterFlow.GeneratedChapterRecognizer` *Lean4 (definition)* `BEDC.GroundCompiler.ChapterFlow.RecognizesChapter`

A chapter candidate *is an event subflow*

$$C \subseteq S$$

not yet recognized as a chapter flow. Write $\mathsf{ChapCand}(S, C)$.

A generated chapter recognizer *is an event flow* $R_C \in \mathsf{EventFlow}$ *supporting*

$$\mathsf{RecognizesChapter}(R_C, S, C).$$

Definition 9232.11 (Chapter subflows). *Lean4 (definition)* `BEDC.GroundCompiler.ChapterFlow.ChapterSubflows`

If $\mathsf{RecognizesChapter}(R_C, S, C)$*, then* R_C *may identify:*

$$\begin{aligned}
&\mathsf{ChapStart}_{R_C}(C, C_0),\\
&\mathsf{ChapDependencies}_{R_C}(C, C_1),\\
&\mathsf{ChapDefinitions}_{R_C}(C, C_2),\\
&\mathsf{ChapLemmas}_{R_C}(C, C_3),\\
&\mathsf{ChapTheorems}_{R_C}(C, C_4),\\
&\mathsf{ChapProofs}_{R_C}(C, C_5),\\
&\mathsf{ChapCertificates}_{R_C}(C, C_6),\\
&\mathsf{ChapLedger}_{R_C}(C, C_7),\\
&\mathsf{ChapCannotClaims}_{R_C}(C, C_8),\\
&\mathsf{ChapStatus}_{R_C}(C, C_9),\\
&\mathsf{ChapSeal}_{R_C}(C, \sigma_C).
\end{aligned}$$

These are source-level subflow roles, not external fields from a table of contents.

Definition 9232.12 (Complete chapter recognition). *Lean4 (definition)* `BEDC.GroundCompiler.ChapterFlow.Comple`

The recognition $\mathsf{RecognizesChapter}(R_C, S, C)$ *is* complete *when all chapter subflows in Definition 9232.11 are recognized.*

Principle 9232.13 (No chapter without complete chapter subflows). *Lean4 ✓* `BEDC.GroundCompiler.ChapterManus` `incomplete chapter`

A chapter-flow must contain recognized start, dependencies, definitions, lemmas, theorems, proofs, certificates, ledger, cannot-claims, status, and seal. If any required subflow is missing, the flow remains a chapter candidate.

Theorem 9232.14 (Incomplete chapter candidate cannot be chapter-flow). *Lean4 ✓* `BEDC.GroundCompiler.Chapte` `chapter candidate not flow`

If a chapter candidate C *lacks any required chapter subflow, then* C *cannot become a recognized chapter-flow.*

Proof. Recognized chapter-flow requires complete chapter recognition. Missing any required subflow prevents complete recognition, so C cannot be used as a recognized chapter-flow. □

Corollary 9232.15 (Title alone is not chapter). *Lean4 ✓* `BEDC.GroundCompiler.ChapterManuscript.title` `alone not chapter`

A chapter-title-like event or chapter-start-flow alone is not a chapter-flow.

Corollary 9232.16 (Theorem list alone is not chapter). *Lean4 ✓* `BEDC.GroundCompiler.ChapterManuscript.theor` `list alone not chapter`

A recognized theorem-flow list alone is not a chapter-flow. Dependencies, definitions, proofs, certificates, ledger, cannot-claims, status, and seal are also required.

9232.4 Chapter soundness and code

Definition 9232.17 (Chapter soundness clauses). *Lean4 (definition)* `BEDC.GroundCompiler.ChapterManuscript.Cha`

For a recognized chapter-flow:

- *dependency soundness requires each dependency to be generated earlier, generated in an earlier chapter of the same manuscript-flow, generated earlier inside the same chapter, marked deferred, or listed as an open obligation;*
- *definition soundness requires every definition-flow to satisfy Definition 9232.6;*
- *theorem soundness requires every theorem-flow to be sound or explicitly marked as a theorem obligation;*
- *proof soundness requires every proof-flow to be checked by a generated proof checker or explicitly marked unchecked;*
- *certificate soundness requires every certificate-flow to be recognized by the appropriate package, NameCert, DerivCert, AcceptGate, normalizer, bridge, or reuse recognizer, or marked as a certificate obligation;*
- *ledger soundness records definition sources, theorem dependencies, proof dependencies, certificate dependencies, hidden abbreviations, classifier quotients, normal-address relations, bridge obligations, cannot-claim causes, and status justifications;*
- *cannot-claim soundness requires the chapter cannot-claim flow to match the chapter proof, certificate, and status state;*
- *status soundness requires each definition, lemma, theorem, certificate, bridge, and implementation target status to match its evidence.*

Definition 9232.18 (Sound chapter-flow)**.** Lean4 (definition) `BEDC.GroundCompiler.ChapterManuscript.SoundChapt`

A recognized chapter-flow C is sound *when complete chapter recognition holds and the dependency, definition, theorem, proof, certificate, ledger, cannot-claim, and status soundness clauses all hold.*

Theorem 9232.19 (Sound chapter-flow establishes chapter code)**.** Lean4✓ `BEDC.GroundCompiler.ChapterManuscr` `chapter code`

If C is a sound chapter-flow, then one may define

$$\mathsf{ChapterCode}(C) := \mathsf{Compile}(C),$$

and this code is a lossless channel encoding of C.

Proof. The flow C is an event subflow, so $\mathsf{Compile}(C)$ is defined. By the channel bijection, compilation is lossless on event flows. By sound chapter-flow, C contains the required chapter subflows and soundness evidence. Hence its compiled stream may serve as chapter code. □

Theorem 9232.20 (Chapter code is injective on raw chapter-flows)**.** Lean4✓ `BEDC.GroundCompiler.ChapterManus` `code injective`

If C and D are sound chapter-flows and

$$\mathsf{ChapterCode}(C) = \mathsf{ChapterCode}(D),$$

then $C = D$.

Proof. By definition, the equality is $\mathsf{Compile}(C) = \mathsf{Compile}(D)$. Injectivity of the channel compiler gives $C = D$. □

Corollary 9232.21 (Chapter code equality is stronger than topic equivalence)**.** Lean4✓ `BEDC.GroundCompiler.Cha` `code not topic`

Equal chapter codes imply equal raw chapter-flows. Two chapters with the same topic, such as NameCert, need not have equal chapter codes.

9232.5 Manuscript-flow recognition

Definition 9232.22 (Manuscript candidate and recognizer). *Lean4 (definition)* `BEDC.GroundCompiler.ChapterManus` *Lean4 (definition)* `BEDC.GroundCompiler.ChapterManuscript.GeneratedManuscriptRecognizer` *Lean4 (definition)* `BEDC.GroundCompiler.ChapterManuscript.RecognizesManuscript`

A manuscript candidate *is an event subflow $M \subseteq S$ not yet recognized as a manuscript-flow. A* generated manuscript recognizer *is an event flow $R_M \in \mathsf{EventFlow}$ supporting*

$$\mathsf{RecognizesManuscript}(R_M, S, M).$$

Definition 9232.23 (Manuscript subflows). *Lean4 (definition)* `BEDC.GroundCompiler.ChapterManuscript.Manuscri`

If $\mathsf{RecognizesManuscript}(R_M, S, M)$*, then R_M may identify:*

$$\begin{aligned}
&\mathsf{MsStart}_{R_M}(M, M_0),\\
&\mathsf{MsChapters}_{R_M}(M, M_1),\\
&\mathsf{MsDependencies}_{R_M}(M, M_2),\\
&\mathsf{MsNotation}_{R_M}(M, M_3),\\
&\mathsf{MsCertificates}_{R_M}(M, M_4),\\
&\mathsf{MsLedger}_{R_M}(M, M_5),\\
&\mathsf{MsCannotClaims}_{R_M}(M, M_6),\\
&\mathsf{MsStatus}_{R_M}(M, M_7),\\
&\mathsf{MsBridgeObligations}_{R_M}(M, M_8),\\
&\mathsf{MsImplementationTargets}_{R_M}(M, M_9),\\
&\mathsf{MsSeal}_{R_M}(M, \sigma_M).
\end{aligned}$$

Definition 9232.24 (Complete manuscript recognition). *Lean4 (definition)* `BEDC.GroundCompiler.ChapterManuscri`

The recognition $\mathsf{RecognizesManuscript}(R_M, S, M)$ *is* complete *when all manuscript subflows in Definition 9232.23 are recognized.*

Principle 9232.25 (No manuscript without complete manuscript subflows). *Lean4 ✓* `BEDC.GroundCompiler.Chapt` `incomplete manuscript`

A manuscript-flow must contain recognized start, chapter sequence, global dependencies, notation, certificates, ledger, cannot-claims, status, bridge obligations, implementation targets, and seal. If any required subflow is missing, the flow remains a manuscript candidate.

Theorem 9232.26 (Incomplete manuscript candidate cannot be manuscript-flow). *Lean4 ✓* `BEDC.GroundCompiler` `manuscript flow not manuscript`

If a manuscript candidate M lacks any required manuscript subflow, then M cannot become a recognized manuscript-flow.

Proof. Manuscript-flow recognition requires complete manuscript recognition. Missing any required subflow prevents complete recognition, so M cannot be used as a recognized manuscript-flow. □

Corollary 9232.27 (Table of contents alone is not manuscript). *Lean4 ✓* `BEDC.GroundCompiler.ChapterManuscrip` `of contents alone not manuscript`

A chapter sequence or table-of-contents-like flow alone is not a manuscript-flow.

9232.6 Manuscript soundness and code

Definition 9232.28 (Manuscript soundness clauses). Lean4 (definition) BEDC.GroundCompiler.ChapterManuscript..

For a recognized manuscript-flow:

- *chapter soundness requires every chapter-flow to be sound or explicitly marked as pending or cannot-claim chapter;*
- *dependency soundness requires chapter dependencies to form a well-founded dependency structure, unless a dependency is marked deferred, open, or future bridge obligation;*
- *notation soundness requires notation, abbreviations, and symbolic aliases to trace to event-flow definitions or recognized NameCert-flows;*
- *certificate soundness requires NameCert, DerivCert, AcceptGate, bridge, reuse, and normalizer flows used by chapters to be globally recorded and traceable;*
- *ledger soundness tracks chapter ledgers, cross-chapter dependencies, hidden abbreviations, classifier quotients, normal-address relations, bridge obligations, implementation targets, and bootstrap obligations;*
- *cannot-claim soundness requires all undischarged cannot-claim entries to appear in the global registry;*
- *status soundness requires global chapter, theorem, certificate, implementation target, and bridge-obligation status to agree with local chapter status;*
- *implementation soundness records Lean targets, reference executable targets, round-trip tests, no-host-leak audits, bootstrap obligations, and self-hosting status consistently with the relevant flows.*

Definition 9232.29 (Sound manuscript-flow). Lean4 (definition) BEDC.GroundCompiler.ChapterManuscript.SoundM

A recognized manuscript-flow M is sound *when complete manuscript recognition holds and the chapter, dependency, notation, certificate, ledger, cannot-claim, status, and implementation soundness clauses all hold.*

Theorem 9232.30 (Sound manuscript-flow establishes manuscript code). Lean4 ✓ BEDC.GroundCompiler.Chapter manuscript code

If M is a sound manuscript-flow, then one may define

$$\mathsf{ManuscriptCode}(M) := \mathsf{Compile}(M),$$

and this code is a lossless channel encoding of M.

Proof. The flow M is an event subflow, so $\mathsf{Compile}(M)$ is defined. The channel bijection makes this encoding lossless. Sound manuscript-flow provides the required chapter sequence, global dependencies, certificates, ledger, cannot-claims, status, implementation targets, and seal. Hence the compiled stream may serve as manuscript code. □

Theorem 9232.31 (Manuscript code is injective on raw manuscript-flows). Lean4 ✓ BEDC.GroundCompiler.Chapte code injective

If M and N are sound manuscript-flows and

$$\mathsf{ManuscriptCode}(M) = \mathsf{ManuscriptCode}(N),$$

then $M = N$.

Proof. By definition, the equality is $\mathsf{Compile}(M) = \mathsf{Compile}(N)$. Injectivity of the channel compiler gives $M = N$. □

Corollary 9232.32 (Manuscript code equality is stronger than topic equivalence). Lean4✓ `BEDC.GroundCompiler.code not topic`

Equal manuscript codes imply equal raw manuscript-flows. Two manuscripts that discuss the same compiler topic need not have equal manuscript codes.

9232.7 Reports and soundness

Definition 9232.33 (P_8 report). Lean4 (definition) `BEDC.GroundCompiler.ChapterManuscript.P8Report`

A P_8 report is an output view containing decoded event flow, chapter candidates, recognized chapter-flows, chapter field status, soundness status per chapter, chapter codes, manuscript candidates, recognized manuscript-flows, manuscript field status, manuscript soundness status, manuscript code, missing fields, dependency failures, ledger failures, cannot-claim gaps, status inconsistencies, implementation target gaps, warnings, and cannot-claim annotations.

Definition 9232.34 (Chapter and manuscript field status). Lean4 (definition) `BEDC.GroundCompiler.ChapterManusc`

For each chapter candidate, the report records status for start, dependencies, definitions, lemmas, theorems, proofs, certificates, ledger, cannot-claims, status, and seal as present, missing, or candidate-only. For each manuscript candidate, the report records status for start, chapters, dependencies, notation, certificates, ledger, cannot-claims, status, bridge obligations, implementation targets, and seal as present, missing, or candidate-only.

Definition 9232.35 (P_8 cannot-claim annotations). Lean4 (definition) `BEDC.GroundCompiler.ChapterManuscript.C`

A P_8 report must include cannot-claim annotations stating that chapter title alone is not chapter, theorem list alone is not chapter, table of contents alone is not manuscript, chapter code is not theorem proof, manuscript code does not imply all claims accepted, sound chapter does not imply all objects mentioned in the chapter accepted, sound manuscript does not imply all bridge obligations discharged, missing global cannot-claim registry blocks manuscript soundness, implementation target list is not checked implementation, and manuscript topic equality does not imply manuscript code equality.

Definition 9232.36 (Sound P_8 report). Lean4 (definition) `BEDC.GroundCompiler.ChapterManuscript.SoundP8Repor`

A P_8 report is sound *when every recognized chapter-flow is backed by a generated chapter recognizer, every recognized chapter-flow satisfies complete recognition, every sound chapter-flow claim satisfies chapter soundness, every chapter code is $\mathsf{Compile}(C)$ for the corresponding chapter-flow, every recognized manuscript-flow is backed by a generated manuscript recognizer, every recognized manuscript-flow satisfies complete recognition, every sound manuscript-flow claim satisfies manuscript soundness, manuscript code is $\mathsf{Compile}(M)$ for the corresponding manuscript-flow, missing fields and failures are explicit, and candidate-only entries are not reported as recognized.*

Theorem 9232.37 (Sound P_8 report theorem). Lean4✓ `BEDC.GroundCompiler.ChapterManuscript.sound p8 report`

If P_8 outputs a sound P_8 report, then every chapter code in the report corresponds to a sound chapter-flow, and every manuscript code in the report corresponds to a sound manuscript-flow.

Proof. By soundness of the report, chapter code may only be reported from a sound recognized chapter-flow, and manuscript code may only be reported from a sound recognized manuscript-flow. Hence every reported code has event-flow evidence of the stated kind. □

Corollary 9232.38 (Sound manuscript code is flow-mediated). Lean4✓ BEDC.GroundCompiler.ChapterManuscript code flow mediated

Manuscript code is not a file name, article title, or table of contents. It is the channel compilation of a sound manuscript-flow.

9232.8 Adequacy

Definition 9232.39 (P_8 audit checklist). Lean4 (definition) BEDC.GroundCompiler.ChapterManuscript.P8AuditChec

A P_8 prototype must satisfy:

1. *all P_7 audit requirements;*
2. *it separates chapter candidates from recognized chapter-flows;*
3. *recognized chapter-flow requires generated chapter recognizer;*
4. *recognized chapter-flow requires complete chapter subflows;*
5. *sound chapter claims require chapter soundness;*
6. *it separates manuscript candidates from recognized manuscript-flows;*
7. *recognized manuscript-flow requires generated manuscript recognizer;*
8. *recognized manuscript-flow requires complete manuscript subflows;*
9. *sound manuscript claims require manuscript soundness;*
10. *missing fields are explicit;*
11. *dependency failures are recorded;*
12. *ledger failures are recorded;*
13. *cannot-claim gaps are recorded;*
14. *status inconsistencies are recorded;*
15. *implementation target gaps are recorded;*
16. *YAML, LaTeX, Markdown, and file paths are not treated as formal input;*
17. *cannot-claim annotations are included.*

Theorem 9232.40 (P_8 adequacy theorem). Lean4✓ BEDC.GroundCompiler.ChapterManuscript.p8 adequacy

If a prototype satisfies the P_8 audit checklist, uses sound P_7 reports, and every chapter or manuscript recognition claim is backed by generated recognizers and soundness evidence, then it is adequate as a chapter and manuscript recognition prototype.

Proof. The audit checklist separates candidates from recognized flows, requires generated recognizers, enforces complete subflows and soundness, records failures, forbids YAML, LaTeX, Markdown, and file paths as formal inputs, and requires cannot-claim annotations. Sound P_7 reports provide reliable theorem and proof evidence when referenced. Thus the prototype is adequate at level P_8. □

Corollary 9232.41 (P_8 adequacy does not imply higher adequacy)**.** Lean4✓ BEDC.GroundCompiler.ChapterManusc
adequacy not higher

A P_8 prototype recognizes chapter and manuscript flows, but it is not yet a self-hosting compiler, full bridge-certifier, or global implementation verifier unless those recognizers and certificates are supplied.

9232.9 Examples

Example 9232.42 (Chapter candidate with theorem list only)**.** *A report may show theorem-flow list and proof-flow list present, while chapter ledger, cannot-claim registry, status-flow, and chapter seal are missing. The conclusion is that there is no recognized chapter-flow and no chapter code. The required cannot-claim is that a theorem list alone is not a chapter.*

Example 9232.43 (Sound compiler chapter)**.** *A sound chapter-flow for the channel compiler may contain chapter start, dependencies on raw event, event flow, and* LegalZStream*, definitions of ζ,* Ev*,* Compile*, and* Decode*, lemmas such as no internal* 11 *and first terminator uniqueness, theorems for both round trips, proofs by induction on raw events and event flows, channel conservativity certificates, source/channel separation certificates, ledger recording raw flow, channel stream, and decoded flow, cannot-claims for code-is-not-proof and channel-substring-is-not-source-event, status, and chapter seal. Then* $\mathsf{ChapterCode}(C_{\text{channel}}) = \mathsf{Compile}(C_{\text{channel}})$.

Example 9232.44 (Manuscript candidate missing global cannot-claim registry)**.** *A manuscript candidate may have chapters, dependencies, certificates, ledger, status, and seal, while global cannot-claims are missing. The report must say that sound manuscript-flow is absent, because the global cannot-claim registry is missing.*

Example 9232.45 (Sound manuscript-flow)**.** *A sound manuscript-flow may contain manuscript start, the chapter sequence for the no-hidden-input streaming compiler part, global dependency order, global notation for* EventFlow*,* LegalZStream*,* Compile*,* Decode*, and recognizer relations, global certificates for channel bijection, recognizer generatedness, certificate-mediated export, theorem-flow soundness, and chapter-flow soundness, global ledger for event-flow provenance, raw/channel distinction, bootstrap obligations, and recognizer hierarchy, cannot-claim entries, status, bridge obligations, implementation targets for prototype layers, and manuscript seal. Then* $\mathsf{ManuscriptCode}(M) = \mathsf{Compile}(M)$.

9232.10 Conservativity

Theorem 9232.46 (P_8 is conservative over the finite kernel)**.** Lean4✓ BEDC.GroundCompiler.ChapterManuscript.p
conservative over finite kernel

Adding chapter-flow recognition, manuscript-flow recognition, chapter codes, manuscript codes, chapter reports, manuscript reports, and global status, cannot-claim, and ledger reports does not add new raw marks, history constructors, sameness rules, continuation rules, object-equality rules, bridge rules, or mature-object export rules.

Proof. P_8 operates on decoded event flows and generated recognition relations. It does not generate new b_0, b_1, does not add msame, hsame, or psame rules, does not alter Ext/Cont, and does not license mature objects beyond already recognized certificate-mediated flows. Chapter and manuscript recognition organize event-flow structures; they do not add finite-kernel rules. □

Corollary 9232.47 (P_8 is not full self-hosting compiler)**.** `Lean4✓ BEDC.GroundCompiler.ChapterManuscript.p8 not full self hosting`

P_8 can recognize chapters and manuscripts, but without compiler self-hosting and global implementation verification it is not a fully self-hosted compiler.

9232.11 Summary

This chapter defines P_8, the chapter and manuscript recognition prototype. It adds definition recognizers, lemma recognizers, chapter candidates, generated chapter recognizers, chapter subflows, complete chapter recognition, chapter soundness, chapter code, manuscript candidates, generated manuscript recognizers, manuscript subflows, complete manuscript recognition, manuscript soundness, manuscript code, P_8 reports, and the P_8 audit checklist.

The main conclusions are:

1. chapter and manuscript are not inputs;
2. unsound definitions block chapter-flow soundness;
3. lemma-flow is theorem-like but site-local;
4. incomplete chapter candidates cannot become chapter-flows;
5. title alone and theorem list alone are not chapters;
6. sound chapter-flow establishes chapter code;
7. chapter code is injective on raw chapter-flows;
8. topic equivalence does not imply chapter-code equality;
9. incomplete manuscript candidates cannot become manuscript-flows;
10. table of contents alone is not manuscript;
11. sound manuscript-flow establishes manuscript code;
12. manuscript code is injective on raw manuscript-flows;
13. manuscript topic equivalence does not imply manuscript-code equality;
14. sound P_8 reports give chapter and manuscript flow evidence;
15. P_8 adequacy requires generated recognizers, complete subflows, soundness, missing-field reports, and cannot-claims;
16. P_8 adequacy does not imply higher adequacy;
17. P_8 is conservative over the finite kernel;
18. P_8 is a manuscript-reporting layer, not a full self-hosting compiler.

Theorem 9232.48 (Sound manuscript covers chapter cannot-claims globally)**.** *Let M be a sound manuscript-flow recognized by R_M, and let C be a chapter-flow in the manuscript chapter sequence $\mathsf{MsChapters}_{R_M}(M, M_1)$. If e is an undischarged cannot-claim entry in the chapter cannot-claim flow $\mathsf{ChapCannotClaims}_{R_C}(C, C_8)$, then e appears in the manuscript global cannot-claim registry $\mathsf{MsCannotClaims}_{R_M}(M, M_6)$.*

Proof. By Definition 9232.29, soundness of M includes the manuscript cannot-claim soundness clause. By Definition 9232.28, that clause requires all undischarged cannot-claim entries to appear in the global registry. Since C is one of the chapter-flows in the manuscript chapter sequence, the undischarged chapter entry e is one of the manuscript's undischarged cannot-claim entries. Applying the cannot-claim soundness clause places e in $\mathsf{MsCannotClaims}_{R_M}(M, M_6)$. □

Chapter 9233

Self-Hosting Compiler and Global Verification Prototype

chapter 9232 defines P_8, the chapter and manuscript recognition prototype. It recognizes chapter flows, manuscript flows, definition flows, lemma flows, theorem-flow lists, proof-flow lists, certificate-flow lists, chapter ledgers, global cannot-claim registries, global status flows, and manuscript seals.

It is still not a complete no-hidden-input compiler. Even if chapters, manuscripts, theorems, and certificates are recognized, the compiler that recognizes them could still be an external program, host parser, elaborator, utility program, reader, or manual convention.

This chapter defines the final prototype level:

$$\boxed{P_9 = P_8 + \text{compiler-flow recognition} + \text{compiler certificate-flow} + \text{bootstrap obligation-flow} + \text{self-compilation-flo}}$$

This is the closing layer of the no-hidden-input compiler architecture. The core boundary is:

$$\boxed{\text{the compiler is not input; the compiler itself must be an event flow.}}$$

Full no-hidden-input status may be claimed only under self-hosting with no remaining obligations, or under an explicitly declared bootstrap boundary.

9233.1 P_9 prototype interface

Definition 9233.1 (Self-hosting compiler prototype)**.** *Lean4 (definition)* `BEDC.GroundCompiler.SelfHostingCompile`

A self-hosting compiler prototype *is an executable prototype P_9 satisfying:*

1. *P_9 includes all P_8 functions;*
2. *P_9 recognizes compiler flows;*
3. *P_9 recognizes compiler certificate flows;*
4. *P_9 recognizes bootstrap-obligation flows;*
5. *P_9 recognizes compiler behavior flows;*
6. *P_9 recognizes self-compilation flows;*
7. *P_9 recognizes behavior-equivalence flows;*
8. *P_9 generates self-hosting ledgers;*

9. *P_9 generates global verification reports;*
10. *P_9 does not treat host executables, file paths, binary hashes, build procedures, data manifests, or host environments as compiler identity;*
11. *P_9 does not treat behavior equivalence as raw event-flow equality;*
12. *P_9 does not claim full no-hidden-input compiler status while bootstrap obligations remain undisclosed or undischarged.*

Write

$$\mathsf{SelfHostingPrototype}(P_9).$$

Principle 9233.2 (Compiler is not input)**.** *Lean4✓ BEDC.GroundCompiler.SelfHostingCompilerFlow.host compiler identity not input*

There is no formal input

$$\mathsf{HostCompiler} \to \mathsf{Code},$$

nor formal inputs

$$\mathsf{ExecutablePath} \to \mathsf{CompilerFlow}, \qquad \mathsf{BinaryHash} \to \mathsf{CompilerFlow}, \qquad \mathsf{BuildScript} \to \mathsf{CompilerFlow}.$$

The only formal input remains EventFlow *or* LegalZStream*. If a compiler enters the system, it must appear as a recognized compiler-flow inside a decoded event flow.*

Definition 9233.3 (Compiler candidate and recognizer)**.** *Lean4 (definition) BEDC.GroundCompiler.SelfHostingComp Lean4 (definition) BEDC.GroundCompiler.SelfHostingCompilerFlow.P9RecognizesCompiler Lean4 (definition) BEDC.GroundCompiler.SelfHostingCompilerFlow.P9RecognizedCompilerFlow*

A compiler candidate flow *is an event subflow $C \subseteq S$ not yet recognized as compiler-flow. Write* $\mathsf{CompilerCand}(S, C)$.

A generated compiler recognizer *is an event flow $R_C \in \mathsf{EventFlow}$ supporting*

$$\mathsf{RecognizesCompiler}(R_C, S, C).$$

If this holds, C is a recognized compiler-flow in S. Write

$$\mathsf{CompilerFlow}_{R_C}(S, C).$$

9233.2 Compiler certificate-flow

Definition 9233.4 (Compiler certificate candidate and recognizer)**.** *Lean4 (definition) BEDC.GroundCompiler.SelfHo Lean4 (definition) BEDC.GroundCompiler.SelfHostingCompilerFlow.P9RecognizesCompilerCert*

A compiler certificate candidate *is an event subflow $K_C \subseteq S$ claiming to certify compilation capability for compiler-flow C. Write* $\mathsf{CompilerCertCand}(S, K_C, C)$.

A generated compiler-certificate recognizer *is an event flow $R_K \in \mathsf{EventFlow}$ supporting*

$$\mathsf{RecognizesCompilerCert}(R_K, S, K_C, C).$$

Definition 9233.5 (Compiler certificate subflows)**.** *Lean4 (definition) BEDC.GroundCompiler.SelfHostingCompilerF*

If $\mathsf{RecognizesCompilerCert}(R_K, S, K_C, C)$*, then* R_K *may identify:*

$$\begin{aligned}
&\mathsf{CompInputDom}_{R_K}(K_C, K_0),\\
&\mathsf{CompOutputDom}_{R_K}(K_C, K_1),\\
&\mathsf{CompEncodingRule}_{R_K}(K_C, K_2),\\
&\mathsf{CompDecodingRule}_{R_K}(K_C, K_3),\\
&\mathsf{CompRoundTrip}_{R_K}(K_C, K_4),\\
&\mathsf{CompRecognizerHierarchy}_{R_K}(K_C, K_5),\\
&\mathsf{CompFailure}_{R_K}(K_C, K_6),\\
&\mathsf{CompLedger}_{R_K}(K_C, K_7),\\
&\mathsf{CompNoHostLeak}_{R_K}(K_C, K_8),\\
&\mathsf{CompKernelConservativity}_{R_K}(K_C, K_9),\\
&\mathsf{CompSelfDescription}_{R_K}(K_C, K_{10}),\\
&\mathsf{CompSeal}_{R_K}(K_C, \sigma_C).
\end{aligned}$$

Definition 9233.6 (Complete compiler certificate recognition)**.** *Lean4 (definition)* `BEDC.GroundCompiler.SelfHosti`

The recognition $\mathsf{RecognizesCompilerCert}(R_K, S, K_C, C)$ *is* complete *when all compiler certificate subflows in Definition 9233.5 are recognized.*

Principle 9233.7 (No compiler without certificate)**.** *Lean4✓* `BEDC.GroundCompiler.SelfHostingCompilerFlow.p9` `no compiler without complete certificate`

A compiler-flow cannot be used as a formal compiler unless it has complete compiler certificate-flow. Recognizing $\mathsf{CompilerFlow}_{R_C}(S, C)$ *alone is insufficient for formal compilation judgments.*

Theorem 9233.8 (Uncertified compiler-flow cannot compile formally)**.** *Lean4✓* `BEDC.GroundCompiler.SelfHostin` `uncertified cannot compile`

If C *is a recognized compiler-flow but no complete compiler certificate-flow* K_C *exists for* C*, then* $\mathsf{Compiles}_C(X, Y)$ *cannot be used as a formal judgment.*

Proof. Formal compilation requires event-flow evidence for input domain, output domain, encoding rules, decoding rules, round-trip behavior, failure behavior, ledger, no-host-leak status, and kernel conservativity. Without compiler certificate-flow, these behaviors are unsupported by internal evidence. Using C formally would introduce hidden compiler input. □

Corollary 9233.9 (Recognized compiler-flow is weaker than certified compiler)**.** *Lean4✓* `BEDC.GroundCompiler.Se` `certified compiler has recognized flow`

Certified compiler status includes recognized compiler-flow, but recognized compiler-flow by itself records only compiler-shaped event-flow structure. Formal compiler use requires compiler certificate-flow.

9233.3 Compiler behavior-flow

Definition 9233.10 (Compiler behavior relation)**.** *Lean4 (definition)* `BEDC.GroundCompiler.SelfHostingCompilerFl`

The relation

$$\mathsf{Compiles}_C(X, Y)$$

has $C, X, Y \in \mathsf{EventFlow}$ *and reads: compiler-flow* C *compiles input event flow* X *into output event flow* Y*. It is a source-level relation over event flows, not a host function call.*

Definition 9233.11 (Behavior record). *Lean4 (definition)* `BEDC.GroundCompiler.SelfHostingCompilerFlow.P9Behav`

A behavior record *is an event subflow B_C recording compiler-flow C, input flow X, output flow Y, the compilation relation $C : X \mapsto Y$, failure branches, and ledger. Write*

$$\mathsf{BehaviorRecord}(B_C, C, X, Y).$$

Definition 9233.12 (Behavior soundness). *Lean4 (definition)* `BEDC.GroundCompiler.SelfHostingCompilerFlow.P9B`

A behavior record B_C is sound *when its recorded* $\mathsf{Compiles}_C(X, Y)$ *relation agrees with the encoding, decoding, and recognition rules in C's compiler certificate-flow, and when failure-flow and ledger-flow are complete.*

Theorem 9233.13 (Sound behavior record establishes compiler action). *Lean4✓* `BEDC.GroundCompiler.SelfHosti` `sound behavior record establishes action`

If B_C is a sound behavior record for (C, X, Y), then $\mathsf{Compiles}_C(X, Y)$ *may be used formally.*

Proof. Sound behavior records contain the compiler, input, output, compilation relation, failure behavior, and ledger, and verify consistency with the compiler certificate-flow. They therefore provide event-flow evidence for the compiler action. □

9233.4 Bootstrap obligations

Definition 9233.14 (Bootstrap component). *Lean4 (definition)* `BEDC.GroundCompiler.SelfHostingCompilerFlow.B`

A bootstrap component *is an implementation component not yet fully generated or verified by self-hosting compiler-flow. Examples include initial channel encoders, initial decoders, initial recognizer-certificate checkers, proof-checker bridges, host executables, and kernel reliance.*

Definition 9233.15 (Bootstrap-obligation flow). *Lean4 (definition)* `BEDC.GroundCompiler.SelfHostingCompilerFlo`

A bootstrap-obligation flow *is an event subflow B recording the bootstrap component, its role, why it is needed, what is not internally generated yet, what would discharge it, current status, ledger, and cannot-claim entries. Write*

$$\mathsf{BootstrapObligationFlow}(B).$$

Principle 9233.16 (No invisible bootstrap). *Lean4✓* `BEDC.GroundCompiler.SelfHostingCompilerFlow.no` `invisible bootstrap`

Every undisclosed or undischarged bootstrap component used by a formal judgment must have bootstrap-obligation flow. No bootstrap assumption may hide inside host implementation.

Theorem 9233.17 (Invisible bootstrap invalidates full no-hidden-input claim). *Lean4✓* `BEDC.GroundCompiler.Se` `bootstrap invalidates full claim`

If a formal judgment depends on a bootstrap component B but no corresponding bootstrap-obligation flow exists, then the system cannot claim full no-hidden-input compiler status.

Proof. Full no-hidden-input status requires every used structure to come from event flow, recognized structure, certificate-flow, or explicit bootstrap obligation. If B is used but not recorded, its source remains external and hidden. The full claim is therefore invalid. □

Corollary 9233.18 (Bootstrap boundary must be reportable). *Lean4✓* `BEDC.GroundCompiler.SelfHostingCompil` `boundary reportable`

Every P_9 report must list all remaining bootstrap obligations.

9233.5 Self-compilation

Definition 9233.19 (Self-compilation flow). *Lean4 (definition)* `BEDC.GroundCompiler.SelfHostingCompilerFlow.Se`

A self-compilation flow *is a recognized event flow SC containing compiler-flow C, input flow C, compiled output flow C', behavior record $C : C \mapsto C'$, and self-compilation ledger. Write*

$$\mathsf{SelfCompilationFlow}(SC, C, C').$$

Definition 9233.20 (Self-compilation ledger). *Lean4 (definition)* `BEDC.GroundCompiler.SelfHostingCompilerFlow.`

A self-compilation ledger *is an event subflow L_{SC} recording raw compiler-flow C, channel code* $\mathsf{Compile}(C)$*, decoded or output compiler-flow C', behavior record, failure branches, bootstrap obligations used, bootstrap obligations discharged, and remaining bootstrap obligations. Write*

$$\mathsf{SelfCompilationLedger}(L_{SC}, C, C').$$

Principle 9233.21 (No self-compilation without ledger). *Lean4 ✓* `BEDC.GroundCompiler.SelfHostingCompilerFlo` `self compilation without ledger`

A self-compilation claim requires self-compilation ledger. Thus $\mathsf{SelfCompilationFlow}(SC, C, C')$ *must include* $\mathsf{SelfCompilationLedger}(L_{SC}, C, C')$.

Theorem 9233.22 (Self-compilation flow preserves compiler provenance). *Lean4 ✓* `BEDC.GroundCompiler.SelfHos` `compilation preserves provenance`

If $\mathsf{SelfCompilationFlow}(SC, C, C')$ *holds and its ledger is sound, then the raw compiler C, compiled output C', and compilation provenance are traceable from the ledger.*

Proof. The self-compilation ledger records C, C', the behavior record, failure branches, bootstrap obligations, and discharge status. Ledger soundness makes these records complete. Hence compiler provenance is traceable. □

9233.6 Compiler behavior equivalence

Definition 9233.23 (Compiler behavior equivalence). *Lean4 (definition)* `BEDC.GroundCompiler.SelfHostingCompil`

Write

$$C \equiv_{\text{comp}} C'$$

when a compiler-behavior classifier witnesses both compiler certificates and the two directional behavior implications between C and C' for all event-flow inputs and outputs.

This is a compiler-behavior classifier. It is not raw event-flow equality, not hsame*, and not kernel equality.*

Proposition 9233.24 (Behavior equivalence is weaker than raw equality). *Lean4 ✓* `BEDC.GroundCompiler.SelfHos` `behavior equivalence not raw equality`

There exist compiler-flow candidates C and C' and a compiler-behavior classifier such that

$$C' \equiv_{\text{comp}} C \qquad \textit{and} \qquad C' \neq C.$$

Thus behavior equivalence is a behavior-level relation and is not raw event-flow equality.

Proof. Take two distinct certified event flows and a behavior relation that ignores raw compiler identity while preserving the same input-output behavior under both certified flows. The classifier records certificates and the two directional behavior implications. Since the two underlying event flows remain distinct, the behavior-equivalence judgment does not collapse to raw equality. □

Corollary 9233.25 (Self-hosting is behavior-level stability). Lean4 ✓ BEDC.GroundCompiler.SelfHostingCompiler
self hosting behavior level stability

Self-hosting proves $C' \equiv_{\text{comp}} C$, not raw equality $C' = C$.

9233.7 Self-hosting compiler-flow

Definition 9233.26 (Self-hosting compiler-flow). Lean4 (definition) BEDC.GroundCompiler.SelfHostingCompilerFlo

A compiler-flow C is self-hosting *when there exist C', a self-compilation flow SC, a behavior-equivalence flow, and a self-compilation ledger L_{SC} such that:*

1. *C is certified compiler-flow;*
2. $\mathsf{SelfCompilationFlow}(SC, C, C')$*;*
3. $\mathsf{SelfCompilationLedger}(L_{SC}, C, C')$*;*
4. *$C' \equiv_{\text{comp}} C$;*
5. *remaining bootstrap obligations are listed;*
6. *discharged bootstrap obligations are recorded;*
7. *no-host-leak audit passes or failed items are listed.*

Write $\mathsf{SelfHostingCompiler}(C)$.

Theorem 9233.27 (Self-hosting removes compiler-as-hidden-input up to obligations). Lean4 ✓
BEDC.GroundCompiler.SelfHostingCompilerFlow.self hosting removes hidden compiler

If $\mathsf{SelfHostingCompiler}(C)$ *holds and the recognizer hierarchy covers the compiler tower, then the compiler is no longer a hidden input: C is represented by self-hosting event-flow evidence, the compiler tower is recognized, and a self-hosting ledger exists. Every remaining external dependency must occur among the remaining bootstrap obligations.*

Proof. Self-hosting represents the compiler as event flow C and supplies compiler certificate-flow, self-compilation flow, behavior-equivalence flow, and self-compilation ledger. Its behavior is recorded by event-flow evidence. Any remaining external dependency must be listed as a bootstrap obligation by definition, so no compiler hidden input remains unrecorded. □

Corollary 9233.28 (Remaining obligations block full discharge). Lean4 ✓ BEDC.GroundCompiler.SelfHostingComp
obligations block full discharge

If $\mathsf{SelfHostingCompiler}(C)$ *holds but remaining bootstrap obligations are nonempty, then the system may claim self-hosting with declared obligations, but not fully discharged no-hidden-input compiler status.*

Definition 9233.29 (Fully discharged compiler-flow). Lean4 (definition) BEDC.GroundCompiler.SelfHostingCompile

A self-hosting compiler-flow C is fully discharged *when* $\mathsf{SelfHostingCompiler}(C)$ *holds and the remaining bootstrap-obligation list is empty. Write* $\mathsf{FullyDischargedCompiler}(C)$.

Theorem 9233.30 (Fully discharged compiler supports full no-hidden-input claim). Lean4 ✓
BEDC.GroundCompiler.SelfHostingCompilerFlow.fully discharged supports full claim

If $\mathsf{FullyDischargedCompiler}(C)$*, then C supports the full no-hidden-input compiler claim: the compiler is no longer a hidden input and there is no remaining recorded bootstrap boundary.*

Proof. Fully discharged compiler-flow is self-hosting and has no remaining bootstrap obligations. By Definition 9233.27, the compiler is not unrecorded hidden input. Since every external dependency has been discharged, no bootstrap boundary remains. □

9233.8 Global verification-flow

Definition 9233.31 (Global verification-flow). Lean4 (definition) BEDC.GroundCompiler.SelfHostingCompilerFlow.

A global verification-flow *is a recognized event flow G containing manuscript-flow, chapter-flow list, theorem-flow list, accepted-object-flow list, compiler-flow, self-hosting status, bootstrap-obligation registry, cannot-claim registry, implementation target status, no-host-leak audit, global ledger, and global status seal. Write*

$$\mathsf{GlobalVerificationFlow}(G).$$

Definition 9233.32 (Global verification soundness). Lean4 (definition) BEDC.GroundCompiler.SelfHostingCompiler

A global verification-flow G is sound *when the manuscript-flow is sound, all chapter-flow statuses are recorded, all theorem-flow statuses are recorded, all accepted-object-flow statuses are recorded, compiler-flow is recognized, self-hosting status is recorded, bootstrap obligations are complete, cannot-claim registry is complete, implementation targets are audited, no-host-leak audit is complete, global ledger is complete, and global seal is present.*

Theorem 9233.33 (Sound global verification-flow establishes system status). Lean4✓ BEDC.GroundCompiler.Self
global verification status

If G is a sound global verification-flow, then it may serve as the global status certificate-flow for the compiler and manuscript system.

Proof. Global verification-flow records manuscript, chapters, theorems, objects, compiler, bootstrap obligations, cannot-claims, implementation targets, ledger, and no-host-leak audit. Soundness ensures that these subsystem states are consistent and ledger-backed. Thus G can serve as global status certificate-flow. □

Corollary 9233.34 (Global verification adds no new mathematics). Lean4✓ BEDC.GroundCompiler.SelfHostingC
verification no new math

Global verification-flow records system status. It does not add new theorems, new objects, or new kernel rules.

9233.9 Reports and soundness

Definition 9233.35 (P_9 report). Lean4 (definition) BEDC.GroundCompiler.SelfHostingReports.P9Report

A P_9 report is an output view containing decoded event flow, compiler candidates, recognized compiler-flows, compiler certificate status, behavior records, self-compilation candidates, recognized self-compilation flows, behavior-equivalence status, self-hosting ledger, bootstrap obligations, fully discharged status, global verification-flow status, no-host-leak audit, implementation target audit, remaining obligations, warnings, and cannot-claim annotations.

Definition 9233.36 (Compiler field and self-hosting status). Lean4 (definition) BEDC.GroundCompiler.SelfHostingR
Lean4 (definition) BEDC.GroundCompiler.SelfHostingReports.P9SelfHostingStatusRecord

For each compiler candidate C, the report records recognized compiler-flow status, compiler certificate-flow status, input-domain flow, output-domain flow, encoding-rule flow, decoding-rule flow, round-trip proof flow, recognizer-hierarchy flow, ledger flow, failure flow, no-host-leak flow, kernel-conservativity flow, self-description flow, and seal flow.

Self-hosting status records compiler-flow C, self-compilation flow SC, output compiler-flow C', behavior-equivalence $C' \equiv_{\mathrm{comp}} C$, self-compilation ledger, discharged obligations, remaining obligations, no-host-leak audit result, and status as not self-hosting, self-hosting with obligations, or fully discharged.

Definition 9233.37 (P_9 cannot-claim annotations). Lean4 (definition) BEDC.GroundCompiler.SelfHostingReports..

A P_9 report must include cannot-claim annotations stating that recognized compiler-flow alone is not certified compiler, certified compiler alone is not self-hosting, self-compilation alone is not behavior equivalence, behavior equivalence is not raw equality, self-hosting with obligations is not fully discharged, host executable is not compiler identity, binary hash is not compiler-flow, global verification-flow is not a new theorem, implementation report is not proof, and full no-hidden-input claim requires no remaining obligations.

Definition 9233.38 (Sound P_9 report). Lean4 (definition) BEDC.GroundCompiler.SelfHostingReports.SoundP9Repo

A P_9 report is sound *when every recognized compiler-flow is backed by generated compiler recognizer, every certified compiler claim has complete compiler certificate-flow, every behavior record satisfies behavior soundness, every self-compilation claim has self-compilation ledger, every behavior-equivalence claim has recognized behavior-equivalence flow, all bootstrap obligations are listed, fully discharged status appears only when remaining obligations are empty, global verification-flow claims have soundness evidence, no-host-leak audit either passes or lists failed items, and cannot-claim annotations are complete.*

Theorem 9233.39 (Sound P_9 report theorem). Lean4 ✓ BEDC.GroundCompiler.SelfHostingReports.sound p9 report supports self hosting

↪ variant BEDC.GroundCompiler.SelfHostingReports.sound p9 report full claim requires empty obligations

If P_9 outputs a sound P_9 report, then every self-hosting claim is backed by certified compiler-flow, self-compilation-flow, behavior-equivalence-flow, and self-hosting ledger; every full no-hidden-input claim requires no remaining bootstrap obligations.

Proof. Sound P_9 report requires compiler certificate, self-compilation ledger, and behavior-equivalence flow for self-hosting claims. It also permits fully discharged status only when the remaining obligation list is empty. Hence the stated support is required. □

Corollary 9233.40 (Sound P_9 report distinguishes compiler statuses). Lean4 ✓ BEDC.GroundCompiler.SelfHostin statuses distinct

A sound P_9 report distinguishes compiler candidate, recognized compiler-flow, certified compiler-flow, self-compiling compiler-flow, self-hosting compiler-flow, self-hosting with obligations, and fully discharged compiler-flow.

9233.10 Adequacy

Definition 9233.41 (P_9 audit checklist). Lean4 (definition) BEDC.GroundCompiler.SelfHostingReports.P9AuditChe

A P_9 prototype must satisfy:

1. *all P_8 audit requirements;*
2. *it separates compiler candidates from recognized compiler-flows;*
3. *recognized compiler-flow requires generated compiler recognizer;*
4. *recognized compiler-flow is separated from certified compiler-flow;*
5. *certified compiler-flow requires complete compiler certificate-flow;*
6. *compiler behavior records are separated from host execution traces;*
7. *behavior records require behavior soundness;*

8. *self-compilation candidates are separated from self-compilation flows;*
9. *self-compilation claims require self-compilation ledger;*
10. *behavior equivalence is separated from raw equality;*
11. *bootstrap obligations are recorded;*
12. *self-hosting with obligations is separated from fully discharged status;*
13. *no-host-leak audit is required;*
14. *global status claims require global verification-flow;*
15. *executable paths, binary hashes, and build procedures are not compiler identity;*
16. *P_9 cannot-claim annotations are included.*

Theorem 9233.42 (P_9 adequacy theorem)**.** `Lean4✓ BEDC.GroundCompiler.SelfHostingReports.p9 adequacy`

If a prototype satisfies the P_9 audit checklist, uses sound P_8 reports, and every compiler, self-hosting, and global verification claim is backed by generated recognizers, certificates, ledgers, and bootstrap accounting, then it is adequate as a self-hosting compiler and global verification prototype.

Proof. The audit checklist enforces separation of candidate, recognized, certified, self-compiling, self-hosting, and fully discharged statuses. It requires compiler certificates, behavior records, self-compilation ledger, behavior equivalence, bootstrap accounting, no-host-leak audit, and global verification-flow. Sound P_8 reports provide manuscript, chapter, and theorem layer correctness. Therefore the prototype is adequate at level P_9. □

Corollary 9233.43 (P_9 adequacy is top prototype adequacy)**.** `Lean4✓ BEDC.GroundCompiler.SelfHostingReports top adequacy`

Within this prototype ladder, P_9 is the first level capable of supporting a full no-hidden-input compiler claim, provided remaining bootstrap obligations are empty.

9233.11 Examples

Example 9233.44 (Compiler candidate without certificate)**.** *A report may show compiler candidate present and recognized compiler-flow present, while compiler certificate-flow is missing. The conclusion is that there is no certified compiler and no self-hosting compiler. The required cannot-claim is that recognized compiler-flow alone is not certified compiler.*

Example 9233.45 (Certified compiler without self-compilation)**.** *A report may show recognized compiler-flow and complete compiler certificate-flow, while self-compilation-flow is missing. The conclusion is certified compiler yes, self-hosting no. Certified compiler does not imply self-hosting.*

Example 9233.46 (Self-compilation without behavior equivalence)**.** *A report may show compiler-flow C, self-compilation output C', and no behavior-equivalence flow. The conclusion is self-compilation candidate yes, self-hosting no. Self-compilation output does not imply $C' \equiv_{\text{comp}} C$.*

Example 9233.47 (Self-hosting with obligations)**.** *A report may show certified compiler C, self-compilation, behavior equivalence, self-hosting ledger, and remaining obligations such as an initial proof-checker bridge or no-host-leak audit failure. The conclusion is self-hosting with obligations, not fully discharged.*

Example 9233.48 (Fully discharged compiler)**.** *A report may show certified compiler C, self-compilation, behavior equivalence, self-hosting ledger, no bootstrap obligations, passed no-host-leak audit, and sound global verification-flow. The conclusion is fully discharged compiler and support for the full no-hidden-input claim.*

9233.12 Conservativity and ladder theorem

Theorem 9233.49 (P_9 is conservative over the finite kernel)**.** Lean4✓ `BEDC.GroundCompiler.SelfHostingReports.conservative over finite kernel`

Adding compiler-flow recognition, compiler certificate-flow, bootstrap-obligation-flow, self-compilation-flow, behavior-equivalence-flow, self-hosting ledger, global verification-flow, and P_9 reports does not add new raw marks, history constructors, sameness rules, continuation rules, object-equality rules, theorem rules, or bridge rules.

Proof. All P_9 structures are event flows or relations over event flows. Compiler behavior equivalence is a classifier over compiler flows, not kernel equality. Self-hosting records behavior-level stability, not new raw marks or sameness rules. Global verification records system status; it does not add mathematical objects or theorems. Hence P_9 is conservative over the finite kernel. □

Corollary 9233.50 (P_9 is verification layer)**.** Lean4✓ `BEDC.GroundCompiler.SelfHostingReports.p9 verification layer`

P_9 verifies compiler status and no-hidden-input conditions. It does not create new BEDC kernel objects or mature mathematical objects.

Theorem 9233.51 (Prototype ladder theorem)**.** Lean4✓ `BEDC.GroundCompiler.SelfHostingCompilerFlow.prototo ladder`

The prototype ladder

$$P_0 \to P_1 \to P_2 \to P_3 \to P_4 \to P_5 \to P_6 \to P_7 \to P_8 \to P_9$$

has the following interpretation: P_0 is channel encoding and decoding; P_1 is source-event reporting; P_2 is source-level normalizer ledger reporting; P_3 is motif reporting; P_4 is metric reporting; P_5 is package and NameCert recognition; P_6 is DerivCert and AcceptGate recognition; P_7 is theorem and proof recognition; P_8 is chapter and manuscript recognition; P_9 is self-hosting compiler and global verification. Each P_i extends the previous prototype by adding recognized event-flow structures and corresponding reports, without changing the channel compiler or finite kernel.

Proof. Each prototype level was defined as the previous level plus explicitly stated recognition or reporting capability. Each extension acts on decoded event flows, requires generated recognizers and ledgers where nontrivial, and remains conservative over the finite kernel. Therefore the ladder interpretation holds. □

Corollary 9233.52 (Full compiler claim is P_9-level)**.** Lean4✓ `BEDC.GroundCompiler.SelfHostingCompilerFlow.fu claim p9 level`

A system below P_9 cannot claim full self-hosting no-hidden-input compiler status. It may only claim the capabilities of its achieved prototype level.

9233.13 Summary

This chapter defines P_9, the self-hosting compiler and global verification prototype. It adds compiler candidates, generated compiler recognizers, recognized compiler-flows, compiler certificate-flow, compiler behavior relation, behavior records, bootstrap components, bootstrap-obligation flows, self-compilation flows, self-compilation ledgers, compiler behavior equivalence, self-hosting compiler-flow, fully discharged compiler-flow, global verification-flow, P_9 reports, the P_9 audit checklist, and the prototype ladder theorem.

The main conclusions are:

1. compiler is not input;
2. recognized compiler-flow alone is not certified compiler;
3. uncertified compiler cannot compile formally;
4. sound behavior record establishes compiler action;
5. invisible bootstrap invalidates full no-hidden-input status;
6. self-compilation requires ledger;
7. behavior equivalence is weaker than raw equality;
8. self-hosting is behavior-level stability;
9. self-hosting removes compiler-as-hidden-input up to declared obligations;
10. fully discharged compiler supports the full no-hidden-input claim;
11. sound global verification-flow establishes system status;
12. sound P_9 reports support self-hosting and full discharge claims only under required evidence;
13. P_9 adequacy requires compiler certificates, behavior records, self-compilation ledger, behavior equivalence, bootstrap accounting, no-host-leak audit, and global verification-flow;
14. P_9 adequacy is the top prototype adequacy;
15. P_9 is conservative over the finite kernel;
16. P_9 is a verification layer, not new mathematics;
17. the full prototype ladder P_0 through P_9 is established.

Chapter 9234

Programmatic Realization of the Prototype Ladder

chapter 9233 closes the prototype ladder at P_9. This chapter records the implementation reading of that ladder. The whole mechanism is programmatically realizable, but three claims must remain separate:

$$\boxed{\text{executable implementation} \neq \text{formally verified implementation} \neq \text{fully self-hosting implementation.}}$$

The executable layers can run as ordinary programs. The recognition and certificate layers require event-flow recognizers, checkers, ledgers, and failure records. The self-hosting layer requires compiler-flow evidence, behavior equivalence, and bootstrap-obligation accounting.

9234.1 Executable base

Definition 9234.1 (Executable channel core)**.** *Lean4 (definition)* `BEDC.GroundCompiler.ProgrammaticRealization.`

The executable channel core is the deterministic program layer implementing:

1. *source raw mark* 0 *encodes as channel word* 0*;*
2. *source raw mark* 1 *encodes as channel word* 10*;*
3. *event end encodes as channel word* 11*;*
4. *event flow compilation concatenates encoded events;*
5. *decoding rejects dangling or malformed channel words.*

Equivalently,

$$\mathsf{Ev}(w) = \zeta(w)11, \qquad \zeta(0) = 0, \qquad \zeta(1) = 10.$$

Proposition 9234.2 (The base language is stream-regular)**.** *Lean4✓* `BEDC.GroundCompiler.ProgrammaticRealiza` `language stream regular`

The legal channel stream language for the executable channel core is

$$((0 \mid 10)^*11)^*.$$

It is recognized by a finite streaming automaton.

Proof. Inside an event body the decoder accepts either 0 or the two-bit word 10. The word 11 terminates the current event. A single trailing 1 is rejected, and any non-binary mark is rejected before decoding. Thus each event has body $(0 \mid 10)^*$ followed by terminator 11, and legal streams are finite concatenations of such event words. This is a regular expression, hence a finite automaton recognizes it. □

Definition 9234.3 (Executable P_0 realization)**.** Lean4 (definition) `BEDC.GroundCompiler.ProgrammaticRealization`

An executable P_0 realization provides deterministic procedures for:

1. *encoding one raw event;*
2. *encoding a finite event flow;*
3. *checking legal channel streams;*
4. *decoding legal channel streams;*
5. *rejecting illegal channel streams;*
6. *running round-trip tests.*

This realization is executable code. It is not, by itself, a certificate that later recognizers, proofs, packages, or objects exist.

Example 9234.4 (Channel core trace)**.** *For the source event flow*

$$0 \mid 00 \mid 000 \mid 01 \mid 011 \mid 100,$$

the executable channel core computes

$$011001100011010110101011100011.$$

Decoding that channel stream recovers the same event flow.

9234.2 Report and metric layers

Definition 9234.5 (Executable report layer)**.** Lean4 (definition) `BEDC.GroundCompiler.ProgrammaticRealization.E`

The executable report layer consists of P_1 through P_4 report routines:

1. *P_1 source-event report generation;*
2. *P_2 adjacent-pair and normalizer-candidate ledger reporting;*
3. *P_3 motif candidate and recognized motif reporting;*
4. *P_4 admissible metric reporting.*

These routines may compute displays, candidate sections, missing-recognizer items, undefined metrics, and cannot-claim annotations.

Principle 9234.6 (Programs do not upgrade candidates)**.** Lean4 ✓ `BEDC.GroundCompiler.ProgrammaticRealizati` `do not upgrade candidates`

An executable report routine may discover candidate shapes, but it may not upgrade a candidate to a recognized structure without the corresponding recognizer-flow, certificate-flow, ledger-flow, or proof-checker-flow.

Example 9234.7 (Candidate pair boundary)**.** *The adjacent pair*

$$011 \mid 100$$

may be reported as a candidate normalizer pair by an executable routine. It may be reported as a recognized carry ledger only when a generated normalizer recognizer and its ledger support that judgment. The executable routine alone does not establish $\mathsf{ZeckendorfCarry}(011, 100)$*, equality, or* hsame*.*

Proposition 9234.8 (P_1 through P_4 are executable report layers)**.** Lean4✓ BEDC.GroundCompiler.ProgrammaticRe
p4 executable

P_1 through P_4 can be implemented as deterministic report and analysis procedures over decoded event flows, relative to any recognized recognizers and metric protocols supplied as event flows.

Proof. P_1 reads decoded events and their channel segments. P_2 enumerates adjacent source events and records candidate or recognized normalizer ledgers according to available policy and recognizer evidence. P_3 separates candidate motifs from recognized motifs. P_4 computes only admissible metrics and explicitly records undefined items. Each step is a finite computation over decoded event-flow data and recognized evidence already present in the input environment. Hence each step is executable. □

9234.3 Recognizer virtual machine

Definition 9234.9 (Recognizer virtual machine)**.** Lean4 (definition) BEDC.GroundCompiler.ProgrammaticRealizatio

A recognizer virtual machine *is an executable interpreter whose formal inputs are:*

1. *an ambient decoded event flow S;*
2. *a recognizer-flow R;*
3. *an optional candidate support subflow $M \subseteq S$.*

Its output is a report containing recognition judgments, ledger records, missing-field records, failure records, and cannot-claim annotations.

Principle 9234.10 (Recognizer programs are not recognizer evidence)**.** Lean4✓ BEDC.GroundCompiler.Programmat
not evidence

The host interpreter for a recognizer virtual machine is not itself formal recognizer evidence. Formal recognition evidence is the event-flow recognizer, its certificate, its ledger, and its failure behavior. Host execution is an implementation vehicle until covered by compiler certificates or bootstrap obligations.

Definition 9234.11 (Recognizer VM discipline)**.** Lean4 (definition) BEDC.GroundCompiler.ProgrammaticRealizatio

The recognizer virtual machine must enforce the following discipline:

1. *no external structured input replaces decoded event flow;*
2. *no manifest, schema, table, label, file path, or host object becomes a formal package, certificate, theorem, chapter, or compiler;*
3. *every nontrivial recognition result carries a ledger or a missing-ledger failure;*
4. *every failed recognition records the field or soundness condition that failed;*
5. *every overinterpretation risk receives a cannot-claim annotation.*

Theorem 9234.12 (Recognizer VM realizes the P_5 through P_8 interface)**.** Lean4✓ BEDC.GroundCompiler.Programm
realizes p5 p8

A recognizer virtual machine satisfying Definition 9234.11 can implement the executable interface of P_5 through P_8 without accepting external package objects, certificate objects, theorem labels, chapter trees, or manuscript files as formal input.

Proof. P_5 requires package-flow and NameCert-flow recognition; P_6 requires strength, DerivCert, and AcceptGate recognition; P_7 requires statement, proof, theorem, and proof-checking recognition; P_8 requires chapter and manuscript recognition. In each case the formal inputs are decoded event flows and generated recognizer flows. The recognizer virtual machine interprets those flows and emits judgments, ledgers, field-status records, and failure records. Since the machine never treats external structured data as formal input, it realizes the executable interface while preserving the no-hidden-input boundary. □

9234.4 Certificates, proofs, and acceptance

Definition 9234.13 (Certificate checker layer)**.** Lean4 (definition) BEDC.GroundCompiler.ProgrammaticRealization

The certificate checker layer is the executable layer that checks recognized certificate flows and proof-checker flows. It covers:

1. *package and NameCert field completeness;*
2. *DerivCert field completeness and soundness;*
3. *AcceptGate composition from matching NameCert and DerivCert flows;*
4. *theorem proof checking against statement and dependency flows;*
5. *chapter and manuscript soundness checks;*
6. *compiler certificate and global verification checks.*

Principle 9234.14 (Programs check certificates; they do not replace them)**.** Lean4✓ BEDC.GroundCompiler.Progr
program not certificate evidence

An executable checker may verify a certificate-flow or proof-flow, but it may not replace the certificate-flow or proof-flow. In particular, successful host computation is not the same judgment as recognized proof-flow, recognized DerivCert-flow, recognized AcceptGate-flow, or recognized theorem-flow.

Proposition 9234.15 (Acceptance is certificate-mediated in programs)**.** Lean4✓ BEDC.GroundCompiler.Programm
certificate mediated

In a programmatic realization, accepted object code and accepted theorem code can be emitted only from recognized acceptance or theorem flows satisfying their certificate and proof obligations.

Proof. Accepted object code at P_6 is compiled from a sound AcceptGate-flow. The AcceptGate-flow must include matching NameCert-flow, DerivCert-flow, strength-flow, and gate seal. Accepted theorem code at P_7 is compiled from an accepted theorem-flow whose proof and certificates have been checked by generated flows. Thus the executable program emits acceptance codes only after the corresponding event-flow evidence is present. □

9234.5 Self-hosting route

Definition 9234.16 (Programmatic self-hosting route)**.** Lean4 (definition) BEDC.GroundCompiler.ProgrammaticReal

The programmatic self-hosting route consists of:

1. *a host reference runtime for the executable channel and report layers;*
2. *event-flow descriptions of the channel rules and recognizer rules;*
3. *a recognizer virtual machine for event-flow recognizers;*
4. *compiler-flow recognition for the compiler description;*
5. *compiler certificate-flow recognition for its behavior;*
6. *self-compilation-flow recording $C : C \mapsto C'$;*
7. *behavior-equivalence-flow recording $C' \equiv_{\text{comp}} C$;*
8. *bootstrap-obligation flows for every remaining host reliance.*

Principle 9234.17 (Self-hosting is not mere execution)**.** Lean4 ✓ BEDC.GroundCompiler.ProgrammaticRealization hosting not execution

Running a program that compiles a compiler description is not yet self-hosting. Self-hosting requires certified compiler-flow, self-compilation-flow, behavior-equivalence-flow, self-compilation ledger, no-host-leak audit, and complete bootstrap-obligation accounting.

Theorem 9234.18 (Programmatic realization reaches P_9 only with compiler evidence)**.** Lean4 ✓ BEDC.GroundCompiler.ProgrammaticRealization.programmatic realization reaches p9 with evidence

An executable implementation reaches the P_9 status only when its compiler identity, compiler behavior, self-compilation, behavior equivalence, bootstrap obligations, no-host-leak audit, and global verification status are represented by recognized event-flow evidence.

Proof. P_9 is defined by compiler-flow recognition, compiler certificate-flow, bootstrap-obligation-flow, self-compilation-flow, behavior-equivalence-flow, self-hosting ledger, and global verification-flow. Ordinary host execution supplies none of these as formal event-flow judgments. Therefore the executable implementation reaches P_9 only when these structures are represented and recognized inside the event-flow system. □

9234.6 Implementation architecture

Definition 9234.19 (Four implementation layers)**.** Lean4 (definition) BEDC.GroundCompiler.ProgrammaticRealizat

A faithful implementation architecture has four layers:

1. *an executable runtime layer for encoding, decoding, legality checking, reporting, and tests;*
2. *a formal relation layer exposing event-flow relations such as legal stream, compile, decode, recognition, checking, and acceptance;*
3. *a recognizer and certificate layer interpreting recognizer flows, certificate flows, proof-checker flows, ledgers, failures, and seals;*
4. *a self-hosting and global verification layer tracking compiler-flow, compiler certificates, self-compilation, behavior equivalence, bootstrap obligations, and global status.*

Definition 9234.20 (Implementation module partition). Lean4 (definition) BEDC.GroundCompiler.ProgrammaticRea

A concrete implementation may be partitioned into modules for:

1. *channel encoding, decoding, legality, and round-trip tests;*
2. *source reports, adjacent-pair reports, normalizer candidates, motif reports, and metric reports;*
3. *recognizer virtual machine execution;*
4. *package, NameCert, DerivCert, AcceptGate, theorem, chapter, manuscript, and compiler recognizers;*
5. *certificate soundness, ledger extraction, failure records, status records, and cannot-claim audits;*
6. *bootstrap obligations, self-hosting records, behavior equivalence, and global verification.*

This partition is engineering structure only. It is not a formal source of BEDC objects.

Proposition 9234.21 (Automatic computation has bounded authority). Lean4 ✓ BEDC.GroundCompiler.Programm computation bounded authority

The executable implementation may automatically compute channel round trips, source reports, candidate listings, field-status reports, missing-field reports, undefined metric items, cannot-claim annotations, and any recognized judgment whose recognizer and checker evidence is present. It may not automatically assert mathematical identity, object acceptance, theoremhood, bridge certification, or full self-hosting status without the required event-flow certificates.

Proof. The first group consists of finite computations over decoded event flows and already recognized evidence. The second group crosses into certificate-mediated or proof-mediated judgments. By the prototype ladder definitions, those judgments require generated recognizers, certificate flows, proof-checker flows, ledgers, gates, or compiler verification flows. Hence automatic computation has bounded authority. □

9234.7 Deliverable ladder

Definition 9234.22 (Executable deliverable ladder). Lean4 (definition) BEDC.GroundCompiler.ProgrammaticRealiz

The executable deliverable ladder is:

1. *channel encode, decode, legality, and round-trip;*
2. *source-event report;*
3. *source-level adjacent-pair and normalizer-candidate ledger report;*
4. *motif candidate report with a small recognized motif example;*
5. *metric report under an explicit metric protocol;*
6. *package and NameCert recognizer for a small certificate example;*
7. *DerivCert and AcceptGate recognizer for a small accepted-object example;*
8. *theorem-flow recognizer and proof-checker-flow for a channel round-trip theorem;*
9. *chapter-flow recognizer for a compiler chapter;*
10. *compiler-flow and self-hosting scaffold with explicit bootstrap obligations.*

Principle 9234.23 (Executable completeness is not certificate completeness)**.** `Lean4✓` `BEDC.GroundCompiler.Prog` `not certificate complete`

Completing the executable deliverable ladder does not by itself discharge all certificate obligations. It supplies a running system in which obligations are explicit, checkable, and reportable.

9234.8 Summary

The prototype ladder is programmatically realizable. The channel layer is a small deterministic streaming compiler. The report layers are finite computations over decoded event flows. The recognition layers are implemented by a recognizer virtual machine whose formal inputs are event-flow recognizers. The certificate and proof layers are implemented by checkers that validate event-flow certificates and proof flows. The self-hosting layer is implemented only when compiler-flow, compiler certificate-flow, self-compilation-flow, behavior-equivalence-flow, bootstrap obligations, no-host-leak audit, and global verification-flow are all represented in the event-flow system.

The central implementation boundary is:

programs may implement the mechanism; programs do not replace certificates.

Chapter 9235

Self-Compilation Surface

BEDC's reflection capabilities live on a stratified surface. This chapter distinguishes what BEDC formally achieves (L1, L4-mid), what it explicitly does not claim (L4a, L4c), and the research boundaries of the MetaCIC reconstruction. Subsequent sections record each stratum's current scope and the meta-theoretic constraints (Godel-Tarski) that fix its ceiling.

9235.1 The L1-L4 Stratification

The phrase "BEDC compiles itself" has several inequivalent readings. The paper uses a stratified reading rather than a single slogan. Each layer states which object is visible, which checker acts on it, and which ceiling prevents a stronger reading.

L1 is static paper-Lean alignment. A paper site names a Lean target through '`\leanchecked`', '`\leanvariant`', '`\leanstmt`', '`\leandef`', or a closure-status '`\leantarget`'. The external audit script '`lean4/scripts/bedc_ci.py audit`' reads those names and checks that the referenced Lean declarations exist under '`lean4/BEDC`'. L1 therefore does not ask BEDC to prove its own metatheory. It asks the repository to expose a typed correspondence between paper claims and Lean declarations, with failed name resolution treated as a build-time fault.

L1 has three important limits. First, it is syntactic at the boundary between paper and Lean: a marker can name a declaration, but it does not itself explain the declaration's proof. Second, the audit is a Python-side repository check, not a Lean theorem about LaTeX. Third, the closure axis and the verification axis remain distinct: a Lean target can be checked while the paper-side theory claim is only scoped, and a paper claim can be theoretically delimited while its formal marker is only a target.

L2 is internal base reflection. At this layer BEDC represents selected parts of its own kernel vocabulary as Lean data and proves internal self-consistency facts about them. The base reflection surface covers package reflection, signature-object reflection, domain reflection, token uniqueness replacements, and witness-chain descriptions of generated sameness. Its job is not to certify the whole Lean kernel. Its job is to show that BEDC can place its own finite kernel objects under typed constructors and prove the advertised local coherence facts inside CIC.

In symbols, the intended shape of L2 is:

$$\text{finite BEDC object} \longmapsto \text{Lean-coded reflection datum},$$
$$\text{reflection datum} \longmapsto \text{local coherence theorem}.$$

The arrow is intentionally local. It does not assert that every paper sentence, every Lean declaration, or every semantic reading of BEDC is reflected. It asserts that the finite kernel

interfaces identified by the base-reflection surface admit typed internal witnesses.

L3 is the NameCert obligation surface. Here BEDC records that concrete mathematical interfaces expose obligation packets rather than finished external mathematics. Holonomy, KKT, and SpectralMeasure are representative cases: their Lean declarations register the shape of the name-certificate obligation, not a public closure theorem for the surrounding domain. The L3 surface is therefore a disciplined boundary between a typed internal packet and the mathematical work required to discharge a domain-specific certificate.

L3 matters for self-compilation because it prevents reflection from becoming a claim-laundering device. A reflected name-certificate packet can say, in Lean, which obligations belong to the interface. It cannot, merely by being named, turn those obligations into domain theorems. The packet is a typed surface for inspection and later discharge; it is not a bridge from syntax to truth.

L4 is not a single level. It splits into four readings, only one of which is claimed here.

L4a is an axiom-free completeness theorem for BEDC inside CIC. This would say that BEDC internally proves the complete soundness or completeness of the host logic sufficient to certify all of its own proof checking. BEDC does not claim L4a. Since BEDC is formalized inside the host Calculus of Inductive Constructions, Tarski undefinability and Godel's second incompleteness theorem block the relevant global truth and consistency assertions from being obtained as axiom-free internal theorems of the same strength.

L4-mid is the finite type-checked Manifest of paper-anchored theorems. This is the achieved self-compilation surface. BEDC contains a Lean-side manifest whose entries pair paper labels, Lean names, propositions, and proof terms. The dependent field '`proof : prop`' makes type correctness a kernel obligation when the manifest elaborates. The observable theorem '`BEDC.Manifest.manifest_wellformed` then exposes, for every manifest entry, a witness of the registered proposition.

L4b is an elaboration-time Lean audit that replaces the external Python name audit. Such a layer would move more of L1 from repository tooling into Lean's own elaboration and reflection facilities. The present chapter does not claim L4b. It isolates the target shape: Lean-visible declarations, Lean-visible paper anchors or generated manifest entries, and an elaboration-time failure mode when the surface does not match.

L4c is a bijection between the theory-closure axis and the verification-status axis. BEDC rejects L4c as a matter of governance. Paper-side closure and Lean-side verification are intentionally independent coordinates. Their joint reporting is a product condition, not a fixed point:

$$\mathrm{VerifiedGate}(N, c, v) := \mathrm{TheoryGate}(N, c) \wedge \mathrm{FormalStatus}(N, v).$$

This product form is part of the self-compilation surface. It lets BEDC say exactly which fragment is internally checked, which fragment is theoretically closed, and which bridge remains absent, without collapsing those statements into a single certification number.

9235.2 Internal Manifest

The internal Manifest is the L4-mid surface in its most concrete form. It is a finite Lean object that records selected paper-anchored theorem claims as kernel-checked entries. Each entry carries a paper label, a fully qualified Lean name, the proposition being recorded, and a proof of that proposition.

The core shape is the Lean structure '`BEDC.Manifest.ClaimEntry`':

$$\begin{aligned}\text{ClaimEntry} = \{\, &\text{paper_label} : \text{String},\\ &\text{lean_name} : \text{String},\\ &\text{prop} : \text{Prop},\\ &\text{proof} : \text{prop}\,\}.\end{aligned}$$

The last field is the essential one. The manifest does not store an untyped string saying that a proof exists. It stores a proof term whose type is the entry's own proposition. When Lean elaborates the list of entries, the kernel checks that each proof term inhabits the proposition supplied by that same entry. A malformed pair cannot be silently accepted as a well-typed entry.

This makes Manifest wellformedness kernel-decidable in the practical sense used by this paper: the Lean kernel either accepts the manifest term or rejects it during checking. The paper does not claim that BEDC internally decides arbitrary truth. It claims the finite manifest has a type-checking boundary. For each entry already present in the finite list, Lean checks the displayed proof against the displayed proposition.

The Manifest therefore separates three surfaces that are easy to confuse. The paper label is a human-facing anchor into the LaTeX document. The Lean name is a string that records the declaration intended by the entry. The proposition and proof field are the kernel-facing content. The manifest theorem below speaks about the kernel-facing content; repository audits continue to police paper marker names and file-level correspondence.

Lean4 ✓ `BEDC.Manifest.manifest wellformed`

The theorem '`BEDC.Manifest.manifest_wellformed`' is an observable corollary of this dependent representation. It says that every entry in '`BEDC.Manifest.manifest`' has a nonempty proposition:

$$\forall e,\ e \in \text{manifest} \longrightarrow \text{Nonempty}(e.\text{prop}).$$

Its proof is direct: the entry already contains '`e.proof`', so the witness is '`\langle e.proof\rangle`'. The content is not hidden in that short proof term. The work is performed by the typing of '`ClaimEntry`' and by the kernel's acceptance of each manifest entry.

This is why the Manifest is L4-mid rather than L4a. It is internal, finite, and type checked. It does not define Lean truth for Lean inside Lean. It does not prove that every possible BEDC paper claim has a corresponding proof. It does not certify arbitrary external mathematics. It certifies that the listed paper-anchored theorem entries have proof terms accepted by the host kernel.

The Manifest also clarifies the relation between paper governance and Lean verification. A Manifest entry can support a paper marker and can make the corresponding proof term visible as data. It does not erase the need for the paper-side closure fields: '`\theoryclosure`', '`\scopeclosed`', '`\formalstatus`', '`\bridgestatus`', '`\notclaimed`', and '`\upgradepath`'. Those fields state the theoretical scope around the claim. The Manifest states that selected Lean propositions have typed proof terms.

Consequently, the self-compilation claim at this layer is precise. BEDC can carry a finite manifest of its own paper-anchored Lean theorems as Lean data, and the kernel can reject ill-typed entries. That is a real internal reflection surface, but it is deliberately not a global self-certification theorem.

9235.3 MetaCIC Reconstruction

The MetaCIC reconstruction surface asks how much of the host calculus can be represented as BEDC data and predicates. It is a reconstruction analysis, not a replacement of the host. The relevant namespace is '`BEDC.MetaCIC`', whose role is to name the current surface on which CIC syntax, typing, and reduction can be discussed as first-class BEDC objects.

The structural reconstruction layer constructs syntax, contexts, terms, universe annotations as needed, beta-reduction, and typing judgments as inductive objects or inductive predicates over BEDC histories.

Lean4 (definition) `BEDC.MetaCIC.Term`
Lean4 (definition) `BEDC.MetaCIC.BetaStep`
Lean4 (definition) `BEDC.MetaCIC.HasType`

The result is not a claim that BEDC has reimplemented Lean. It is a claim that the grammar and judgment forms of a CIC fragment can be represented directly enough to support quantification and induction over them.

The difference between behavior and structure is central. A Turing-machine simulation of Lean execution can describe observed runs:

$$\exists t,\ \mathrm{MachineTrace}(\mathrm{Lean}, x, t) \wedge \mathrm{Accepts}(t).$$

Such a statement is behavioral and trace-based. It predicts or records a finite execution. A direct inductive predicate has a different form:

$$\Gamma \vdash_{\mathrm{MetaCIC}} t : T.$$

This is a first-class judgment. BEDC can quantify over contexts, terms, and derivations, and can prove results by induction on the derivation. TM simulation gives Sigma-one execution traces; direct reconstruction gives typed judgment objects. The base sort judgment is inhabited in the empty context.

Lean4 ✓ `BEDC.MetaCIC.sort in empty ctx`

The same fragment carries concrete checked examples. A polymorphic identity term over 'Sort' is well typed, and its Pi type is itself a represented typing judgment.

Lean4 ✓ `BEDC.MetaCIC.id sort well typed`
Lean4 ✓ `BEDC.MetaCIC.pi sort sort well typed`

Applying that identity to 'Sort' has the expected represented application typing, and the corresponding beta step contracts to the argument.

Lean4 ✓ `BEDC.MetaCIC.id sort applied`

The construction surface covers syntax and judgments. It supports statements of the form "for every represented derivation with this constructor shape, the following structural property holds." It also supports explicit boundary claims: which syntax is represented, which conversion relation is present, which typing rules are included, and which host-kernel features remain outside the fragment.

The metatheory layer covers structural claims about represented derivations. Subject reduction says that typing survives reduction:

$$\Gamma \vdash t : T \wedge t \to_\beta u \longrightarrow \Gamma \vdash u : T.$$

Confluence says that divergent reductions can be joined. These theorems are structural metatheorems about the represented calculus, and their checked fragments must be stated over the explicit syntax, reduction, and typing relations carried by the reconstruction.

The encoded confluence surface separates ordinary multi-step beta reduction from parallel reduction. BetaStarStep is the reflexive-transitive closure of one-step β; BetaParallel is a one-round parallel relation with identity clauses for variables and sort, componentwise clauses for application, lambda, and Pi, and a beta clause that contracts a lambda redex after reducing the domain, body, and argument in parallel. The checked diamond material is therefore shape-local. The sort and variable sources have genuine joins because their parallel reductions can only return the same atom, while application, lambda, and Pi constructors have join assemblers when their component joins are supplied. At the ordinary multi-step level, the atom cases are closed by showing that a beta-star path out of a sort or variable has the same endpoint.

Lean4 ✓ `BEDC.MetaCIC.betaStar var join`

Lean4 ✓ `BEDC.MetaCIC.betaStar sort join`

9235.3.1 Encoding Overview

The encoding in `BEDC.MetaCIC` is a direct Lean representation of the fragment. `Term` is an inductive syntax type with five constructors: `var`, `app`, `lam`, `pi`, and `sort`. Contexts are the abbreviation `Ctx := List Term`, and `Ctx.lookup` synchronizes lookup with de Bruijn shifting across binder slots.

The substitution and shift operations are the standard de Bruijn operations: descent below a binder raises the depth by one, and the substituted value is shifted by `shift 0 1`. The typing predicate `HasType` is inductive and uses a shift-aware binder slot, namely shift 0 1 dom, when checking lambda and Pi bodies.

Reduction is split into three inductive relations. `BetaStep` gives single-step β contraction with congruence rules; `BetaStarStep` gives the multi-step closure; and `BetaParallel` gives the Tait–Martin-Löf parallel relation. Closure is represented by the indexed inductive judgment `ClosedAt`. All of these objects are ordinary Lean 4 inductive types or definitions, use no axioms, and have exactly the strength of the host CIC that checks them.

9235.3.2 Syntax Constructor Table

Constructor	Description
`Term.var i`	de Bruijn variable, $i \in \mathbb{N}$
`Term.app f a`	function application $f\ a$
`Term.lam d b`	abstraction $\lambda x : d.\ b$ with domain d and body b
`Term.pi d c`	dependent product $\Pi x : d.\ c$
`Term.sort`	single universe sort literal

Each constructor is a pure inductive constructor, with no host metaprogramming.

9235.3.3 Paper vs Mechanization

The paper and the mechanized Lean module describe the same reconstruction surface at different levels of notation. The paper uses LaTeX judgments such as $\Gamma \vdash t : T$ to present typing, while the mechanization uses an inductive proposition such as `HasType Gamma t T` to make the judgment a host-checked object.

Paper-side markers record the correspondence explicitly. A marker written as `\leanchecked`, `\leandef`, or `\leanstmt` names the Lean target that carries the corresponding theorem, definition, or statement-only surface.

Thus each paper-claimed theorem has a visible formal status: direct theorem via `\leanchecked`, inductive or definitional encoding via `\leandef`, or statement-only target via `\leanstmt`. The paper therefore does not silently identify prose, notation, and kernel objects.

`bedc_ci.py audit` continuously checks those marker names against `lean4/BEDC/`. A missing or renamed Lean target is an audit failure, so the paper text and mechanized module cannot drift silently.

9235.3.4 Host Fragment Coverage

The represented host fragment is the dependent-function core of CIC, with explicit de Bruijn variables, one sort constructor, application, lambda, Pi, beta reduction, and a shift-aware typing judgment. The coverage boundary is:

Host feature	BEDC.MetaCIC	Status
`Term.app` / `lam` / `pi` / `var` / `sort`	`Term` inductive	covered
β-reduction	`BetaStep` + `BetaStarStep` + `BetaParallel`	covered
Typing judgment	`HasType`	covered, shift-aware substrate
Universe polymorphism	none	not covered
η-conversion	none	not covered
Inductive types beyond Pi/sort	none	not covered
Equality types (`Eq`)	none	not covered
Definitional unfolding	`substitute` composition	partial coverage
Reduction strategies (CBV/CBN)	non-deterministic `BetaStep`	abstract

Thus `BEDC.MetaCIC` is not a model of the full host kernel. It is the host-checked representation of the small CIC fragment needed for the local syntax, reduction, typing, and binder-mechanics claims.

9235.3.5 Correctness Claims

The correctness meaning of the `BEDC.MetaCIC` mechanization is internal to the host calculus. `BEDC.MetaCIC.HasType` is an inductive proposition. An inhabitant of this proposition is therefore a derivation object accepted by the host kernel. If the host is consistent, such inhabitants are real typing derivations for the represented CIC fragment whose rules are given by the constructors of `HasType`.

`BEDC.MetaCIC.BetaStep` has the same status for one-step reduction. It is a host `inductive Prop`, and each inhabitant is a kernel-checked witness of exactly one constructor-generated single-step beta reduction in the represented syntax.

The operations `substitute` and `shift` are host `def` declarations. Their closed-form values are computed by the host kernel through small-step simplification of those definitions, rather than by an external evaluator or a meta-level convention.

Consequently, theorems such as `sort_in_empty_ctx`, `id_sort_well_typed`, and the related MetaCIC examples are host-verified claims about the represented CIC fragment. Host consistency implies the soundness of those BEDC.MetaCIC derivations and reductions within that fragment.

9235.3.6 Representation vs Mockup

A mockup form places a host program in front of a separate syntax. For example, one may write a Lean tactic that runs a BNF parser, builds an external abstract syntax tree, and then reports whether the parsed expression satisfies a hand-coded relation. Such a program may be useful as tooling, but its behavior is not thereby formally tied to the host's actual type checker. The host checks the tactic implementation and any theorem it finally emits; it does not make the parser's accepted syntax into the host's own typing judgment.

`BEDC.MetaCIC` uses a representation form instead. `Term` is a host data type, and `HasType` is a host inductive proposition. When the host kernel elaborates BEDC theorems about `HasType`, it is at the same time verifying the represented typing claims and their proof consequences.

Thus `BEDC.MetaCIC` is not about mimicking the host from outside. It directly specifies the grammar and typing rules of a host-CIC fragment, and lets the host kernel check the consequences of those specifications.

9235.3.7 Positioning Within BEDC

The `BEDC.MetaCIC` namespace occupies a calculus-reconstruction position within the BEDC codebase. `BEDC.FKernel` is the foundational kernel layer, carrying the `BMark`, `BHist`, and probe primitives. `BEDC.Derived` builds derived mathematical structures such as real objects, groups, modules, and related packets on top of that base.

`BEDC.Manifest` is the paper-anchored theorem registry: it records named theorem entries as kernel-typed artifacts. `BEDC.Reflection` handles closure and certificate forms, including package-facing identification principles and name-certificate surfaces. These modules give the project its object layer, registry layer, and certificate layer.

`BEDC.MetaCIC` is complementary to those layers rather than downstream of them. It gives an inductive description of a CIC fragment itself: terms, contexts, reduction, typing, and closure as represented syntax and judgments. It therefore formalizes a calculus fragment in isolation from the derived structure, manifest, and reflection APIs, while sharing the same axiom-free Lean checking discipline as the rest of BEDC.

MetaCIC does not replace the host CIC or serve as a second kernel beside Lean. It represents a fragment inside the host, so theorems about represented derivations remain host-checked BEDC theorems. The foundational guarantee is the same project-wide one: the surface is built from inductive definitions and checked proofs, with no additional axioms.

9235.3.8 Stratification Recap

Within `BEDC.MetaCIC`, L1 is the registration level. BEDC records paper-claimed theorems as host-checked Lean data through `BEDC.Manifest`, and the MetaCIC reconstruction is the syntactic surface on which the registered calculus-facing claims can be named.

L4-mid is the internal representation level. BEDC expresses the inductive structure of a CIC fragment, together with selected metatheory, as Lean objects and predicates. MetaCIC therefore supplies representation and derivation forms; it does not attempt to prove the host's consistency.

L4a is blocked by the Godel boundary. Since BEDC is checked inside the host, BEDC cannot prove the host's own consistency from within that same host. MetaCIC keeps this boundary intact and does not turn reconstruction into a consistency proof for Lean.

L4c is rejected. BEDC does not replace the host CIC, and MetaCIC is not an alternative foundation. The reconstruction is an inside-host formalization of syntax, reduction, typing, and selected metatheory, all under the checking authority of the host calculus.

9235.3.9 Fragments and Limitations

`BEDC.MetaCIC` represents a minimal CIC syntactic fragment. The included term grammar has variables, a single sort, dependent function types, lambda abstraction, and application. Binders use de Bruijn indices rather than names, and the substrate is shift-aware: context lookup, binder descent, and substitution all account for the index movement caused by crossing binders.

Several host-CIC features are outside this represented fragment. There is no universe hierarchy or universe polymorphism: the syntax has one sort and no `Type i` annotation. There are no standalone inductive types beyond Pi and sort, so objects such as natural numbers or lists are not represented as primitive inductive families in this layer. There is also no represented equality type, no inference hint or coercion layer, and no eta-conversion: `BetaStep` contains beta contraction and beta congruence only.

The design intent is correspondingly narrow. The fragment is large enough to demonstrate the self-compilation idea as syntax, typing, reduction, and binder mechanics internalized as BEDC data and predicates. It is not a full host-CIC model and does not aim to cover Lean's complete kernel language.

9235.3.10 Typing Rules

The represented typing judgment HasType $\Gamma\ t\ A$ is generated by five rules. They are the whole typing surface for the local MetaCIC fragment:

$$
\begin{aligned}
\text{sortRule}: &\quad \Gamma \vdash \text{sort} : \text{sort},\\
\text{varRule}: &\quad \Gamma.\text{lookup}\ i = \text{some}\ A \Rightarrow \Gamma \vdash \text{var}\ i : A,\\
\text{piRule}: &\quad \Gamma \vdash \text{dom} : \text{sort},\ (\text{shift}\ 0\ 1\ \text{dom}) :: \Gamma \vdash \text{cod} : \text{sort} \Rightarrow \Gamma \vdash \pi\,\text{dom}\,\text{cod} : \text{sort},\\
\text{lamRule}: &\quad \Gamma \vdash \text{dom} : \text{sort},\ (\text{shift}\ 0\ 1\ \text{dom}) :: \Gamma \vdash \text{body} : \text{cod} \Rightarrow \Gamma \vdash \lambda\,\text{dom}\,\text{body} : \pi\,\text{dom}\,\text{cod},\\
\text{appRule}: &\quad \Gamma \vdash f : \pi\,\text{dom}\,\text{cod},\ \Gamma \vdash a : \text{dom} \Rightarrow \Gamma \vdash f\,a : \text{substitute}\ 0\ a\ \text{cod}.
\end{aligned}
$$

9235.3.11 Typing Inference Rules Table

Rule	Conclusion
sortRule	$\Gamma \vdash \text{sort} : \text{sort}$
varRule	$\Gamma.\text{lookup}\ i = \text{some}\ A \Rightarrow \Gamma \vdash \text{var}\ i : A$
piRule	(shift-aware) $\Gamma \vdash \text{pi}\ d\ c : \text{sort}$ from $\Gamma \vdash d : \text{sort}$, $(\text{shift}\ 0\ 1\ d) :: \Gamma \vdash c : \text{sort}$
lamRule	(shift-aware) $\Gamma \vdash \text{lam}\ d\ b : \text{pi}\ d\ \text{cod}$ from the same Pi-rule binder slot and body type cod
appRule	$\Gamma \vdash f\ a : \text{substitute}\ 0\ a\ \text{cod}$ from $\Gamma \vdash f : \text{pi}\ d\ \text{cod}$, $\Gamma \vdash a : d$

The shift-aware binder slot appears in the Pi and lambda rules as $(\text{shift}\ 0\ 1\ d) :: \Gamma$, rather than as $d :: \Gamma$.

9235.3.12 Typing Relation vs Host CIC

`BEDC.MetaCIC.HasType` is an inductive proposition inside the host calculus. It represents a typing relation for the MetaCIC fragment: an inhabitant of HasType $\Gamma\ t\ A$ is a derivation object built from the five constructors listed above, not the algorithm that checks Lean terms.

The checking algorithm belongs to the host CIC kernel. That kernel elaborates and type-checks Lean terms inside the implementation, with executable kernel code running in the OCaml/Rust compiler/runtime environment. BEDC does not replace that kernel; every theorem about `HasType` is accepted only when the host kernel checks its proof term.

The represented relation is intentionally narrower than host typing. It describes the fragment's Pi, lambda, application, variable, and sort rules, together with explicit beta reduction. It does not simulate the full host reduction and elaboration stack: eta-conversion, universe polymorphism, and inductive types beyond the represented Pi/Sort fragment are outside this local relation.

The main sanity condition is proof-theoretic. `HasType` is axiom-free, and each displayed `HasType` derivation is a Lean term checked by the host kernel. The strict axiom-purity audit also verifies that the checked MetaCIC theorem dependencies do not use `propext`, `Classical.choice`, or `Quot.sound`.

9235.3.13 Context Mechanics

A context is the Lean stdlib list Ctx = List Term. Its entries are represented types, stored as a de Bruijn stack: the head is the type of variable 0, the next entry is the type of variable 1, and so on down the list. The operation Γ.lookup i returns the ith entry of Γ, counted from this top position.

The important invariant is that lookup and binder crossing perform the same index accounting. When a fresh binder contributes a top entry B, the top variable is read directly, while every deeper lookup is raised by shift 0 1:

$$(B :: \Gamma).\text{lookup } 0 = \text{some } B,$$

$$(B :: \Gamma).\text{lookup } (i+1) = \begin{cases} \text{some (shift } 0\ 1\ T), & \Gamma.\text{lookup } i = \text{some } T, \\ \text{none}, & \Gamma.\text{lookup } i = \text{none}. \end{cases}$$

Lean4 ✓ `BEDC.MetaCIC.lookup cons zero`

Lean4 ✓ `BEDC.MetaCIC.lookup cons succ`

Thus the type of a deeper variable automatically accumulates exactly the number of binders crossed. This is the context-side companion to the shift-aware design of substitute under binders.

9235.3.14 Reduction Layer Summary

The reduction layer has three relations. BetaStep is single-step β reduction: root beta plus congruence under application heads and arguments, lambda bodies and domains, and Pi codomains and domains.

Lean4 (definition) `BEDC.MetaCIC.BetaStep`

BetaStarStep is the reflexive-transitive closure, generated by reflexive and one-step extension constructors, with checked transitivity for finite path composition.

Lean4 (definition) `BEDC.MetaCIC.BetaStarStep`

Lean4 ✓ `BEDC.MetaCIC.betaStar trans`

BetaParallel is the Tait–Martin-Löf one-round parallel relation: variables and sort reduce to themselves; Pi, lambda, and application reduce componentwise; beta reduces domain, body, and argument before contraction.

Lean4 (definition) `BEDC.MetaCIC.BetaParallel`

The checked containment spine records reflexivity, BetaStep $\subseteq$ BetaParallel, and BetaParallel $\subseteq$ BetaStarStep.

Lean4 ✓ `BEDC.MetaCIC.betaParallel refl`

Lean4 ✓ `BEDC.MetaCIC.betaStep to parallel`
Lean4 ✓ `BEDC.MetaCIC.betaParallel to betaStar`

9235.3.15 Reduction Relations

Relation	Description
`BetaStep t t'`	single-step β plus congruence in `MetaCIC.Beta`
`BetaStarStep t t'`	reflexive-transitive closure of `BetaStep`
`BetaParallel t t'`	Tait–Martin-Löf parallel reduction

`BetaStarStep` and `BetaParallel` are separate inductive propositions, connected by atom-diamond facts and congruence lemmas. There is no implicit conversion between them.

9235.3.16 No Eta-Conversion

`BEDC.MetaCIC.Beta` contains no η-conversion, either as η-expansion or as η-reduction. Its one-step relation is generated only by root β contraction and the congruence constructors for application, lambda, and Pi terms.

This has concrete consequences. The represented terms `lam d (app f (var 0))` and `f` do not reduce to each other through `BetaStep`, even when `f` is closed. The multi-step relation `BetaStarStep` and the parallel relation `BetaParallel` are built from the same β surface, so they do not blur this boundary into η-equality.

Accordingly, subject reduction and confluence in this reconstruction are statements about β-equivalence only. A calculus containing η-conversion has a different reduction signature: it requires an additional `BetaStep` constructor, such as an `etaStep`, and separate compatibility proofs between that constructor and the existing β metatheory.

The normalization facts are deliberately atomic. sort_no_beta and closed_var_no_beta say that the sort constructor and a variable constructor are not beta-redex heads; there is no one-step reduction whose source has either shape. The typed closed-atom theorem packages this as a normal-form statement: if a closed represented term typed at sort is either the sort atom or a variable atom, then no beta successor exists. In this bounded sense, closed atoms are already normal forms in the represented calculus.

Lean4 ✓ `BEDC.MetaCIC.closed atom normal form`

Strong normalization has a different status. A global strong-normalization theorem strong enough to recover consistency of the represented host calculus meets the Godel-II boundary when the represented calculus is comparable in strength to the host in which the proof is carried out. BEDC can study bounded or fragment-specific termination claims, and it can state which hypotheses make those claims available. It does not obtain an axiom-free global consistency certificate for its own host by internal reconstruction.

The replacement reading would make BEDC the foundation instead of CIC. This is not a claim of the paper. BEDC is formalized inside the host CIC. All Lean theorems in the project are checked by that host. The MetaCIC surface may represent syntax and prove fragment metatheory, but it does not move BEDC outside the host or give BEDC a stronger foundational status than the kernel that checks it.

This yields the governing inclusion:

$$\text{BEDC formalization} \subseteq \text{host CIC}.$$

The inclusion is methodological, not merely notational. A theorem about a represented calculus is a theorem inside the host. It can be useful, precise, and internally quantified, but it cannot serve as a host-independent foundation for the host without crossing the Godel-Tarski boundary.

The MetaCIC reconstruction surface thus complements the Manifest. The Manifest registers finite paper-anchored theorem entries as checked Lean data. MetaCIC reconstruction studies the syntax and judgment structure of the calculus in which such checking is meaningful. Together they explain why "BEDC compiles itself" has a legitimate L4-mid reading and no legitimate L4a or replacement reading.

9235.3.17 Self-Compilation Completeness

In this chapter, self-compilation has a precise BEDC meaning. It does not mean that BEDC compiles BEDC into an executable binary, nor that BEDC replaces the host kernel. It means that BEDC represents enough of a CIC fragment for the paper's quantified judgments about syntax, typing, reduction, closure, and substitution to be stated as Lean-checkable inductive objects and theorems.

The completed mechanized surface covers the paper claims for syntax, typing rules, atom-shape preservation, atom normalization, and closed-domain substitution preservation. These claims are expressed over the represented MetaCIC terms, contexts, beta relations, closure predicate, and typing judgment, so Lean checks them as ordinary theorems about inductively generated data.

The surface does not close substitute preservation for arbitrary binder domains, strong normalization, or a decidable type checker for arbitrary represented terms. Those targets require binder-domain transport, global termination structure, or complete inference coverage beyond the represented fragment used here.

Thus the self-compilation status is L1 plus L4-mid. It is a syntax-and-judgment reconstruction layer together with finite Lean-checked paper claims. It is not L4a, because BEDC is not closed over the host that checks it, and it is not L4c, because BEDC does not replace the host kernel or identify paper closure with kernel verification.

9235.3.18 Host CIC Relation

MetaCIC is represented inside the host Lean calculus, not beside it. The objects named `BEDC.MetaCIC.Term`, `BEDC.MetaCIC.HasType`, and `BEDC.MetaCIC.BetaStep` are implemented as inductive types or inductive predicates in the host CIC. They are therefore first-order objects for the host: Lean can quantify over represented terms, represented typing derivations, and represented beta steps exactly as it quantifies over any other inductively generated data.

The important boundary is axiomatic. The host Lean environment has available constants such as `propext`, `Quot.sound`, and `Classical.choice` when developments choose to depend on them. `BEDC.MetaCIC` does not use those constants. Its syntax, reduction, typing, and checked metatheory are built in the pure CIC fragment by inductive definitions and structural proofs.

The verification relation is one-way. The host CIC kernel type-checks each BEDC theorem. Within that checked development, a MetaCIC typing derivation is an inhabitant of the inductive predicate `HasType`, and reasoning about typing inference is ordinary induction over that predicate. There is no circular dependence: the host checks BEDC, while BEDC encodes a CIC fragment as data and judgments.

This also fixes the Godel-Tarski boundary. `BEDC.MetaCIC` is not outside the host and cannot prove the consistency of the host that checks it. It can state and prove fragment metatheory for the represented calculus, but it does not create a host-independent consistency proof.

9235.3.19 Godel-Tarski Boundary

`BEDC.MetaCIC` does not try to cross the Godel-II or Tarski undefinability boundaries. It is a representation of a CIC fragment inside the host CIC, not an external standpoint from which the host can certify itself.

The typing judgment `BEDC.MetaCIC.HasType` is an inductive proposition in the host. Its inhabitants are host-checked derivation objects for the represented calculus, but the existence of such a predicate does not supply a proof of the host's own consistency without an external consistency assumption for that host.

Likewise, a strong-normalization theorem for the represented calculus, if proved, would be a theorem using the host's full proof strength. In Lean this includes the kernel's accepted structural and well-founded recursion principles and the definitional computation of dependent-function reduction. Such a theorem would establish normalization for the represented syntax under host checking; it would not be a host-independent normalization proof for Lean itself.

Finally, `BEDC.MetaCIC.Term` ranges over represented terms only. It can state and prove claims about this syntax and its generated judgments, but it cannot quantify over every host term and assert that each host term has a normal form without moving beyond the strength of the same host being represented.

9235.3.20 Host Internalization

`BEDC.MetaCIC` is an internalization of the host CIC, not a mock interpreter. `BEDC.MetaCIC.Term` is the host's `inductive Term` type, so represented syntax is genuine host data. `BEDC.MetaCIC.HasType` is the host's inductive proposition for typing derivations, so represented typing is genuine host proposition structure.

The operations `BEDC.MetaCIC.substitute` and `BEDC.MetaCIC.shift` are host `def` declarations. They are therefore genuine host computations on the represented syntax, not external notations or parser artifacts. When the Lean kernel type-checks `BEDC.MetaCIC` theorems, the same kernel is also checking the BEDC `HasType` propositions that occur inside those theorem statements.

This differs from a mock interpreter. BEDC does not stub out a fake parser and then reason about traces of that parser. It directly represents the inductive structure of a CIC fragment as host inductive data, host inductive propositions, and host recursive definitions. Consequently, an inconsistency in the host kernel would imply an inconsistency in BEDC, because BEDC lives inside that host. The converse implication does not follow: a contradiction in the represented BEDC surface would not by itself establish host-kernel inconsistency.

9235.3.21 Axiom Purity Guarantee

The axiom-purity guarantee for `BEDC.MetaCIC` is the same guarantee applied to the rest of the BEDC formalization. At the source level, the project has zero tolerance for the raw `axiom` keyword in `lean4/BEDC/`: `tools/check-axioms.py` scans the BEDC Lean tree for any `axiom` declaration and exits with status 1 when one is found.

At the theorem-dependency level, `BEDC.MetaCIC` is audited together with the other BEDC modules by `python3 lean4/scripts/bedc_ci.py axiom-purity -strict`. The audit uses Lean's `#print axioms` output to inspect the transitive dependencies of each checked theorem. The forbidden dependency set is `Classical.choice`, `Quot.sound`, and `propext`: excluded respectively as excluded-middle or choice dependence, quotient-type axiom dependence, and propositional-extensionality dependence.

More than 9000 BEDC theorem declarations pass this strict audit with zero forbidden dependencies. The formal content used by the MetaCIC reconstruction therefore remains inside the pure CIC fragment checked by Lean's kernel, rather than importing additional Lean stdlib axioms through either declarations or transitive proof dependencies.

9235.3.22 Pure CIC Fragment

`BEDC.MetaCIC` represents a pure CIC fragment. It does not depend on any axiom introduced by the Lean standard library, including `Classical.choice`, `Quot.sound`, and `propext`. This premise is audited by `bedc_ci.py axiom-purity --strict`, which checks each theorem's transitive dependencies against the forbidden axiom set.

The PCIC fragment has the following concrete features:

- no quotient types and no propositional-extensionality strengthening of propositional equality;
- no law of excluded middle and no dependent choice;
- no universe polymorphism;
- `pi`, `lam`, `app`, `sort`, and `var` as the only represented term constructors.

9235.3.23 Encoding Choice

The reconstruction uses a de Bruijn, shift-aware substrate for binders. Named binders are convenient for informal prose, but a checked development must then carry freshness side conditions through weakening, substitution, and binder descent. Those side conditions are not part of the mathematical point of the fragment, so the substrate uses numeric binder positions instead.

Naive de Bruijn encoding is still not sufficient. If a binder simply extends a context by placing dom at the head, as dom :: Γ, then the body sees var 0 both as the binder slot and as an index sharing the outer context convention. Under substitution or descent below another binder, this creates exactly the capture phenomenon the encoding is meant to avoid.

The shift-aware substrate stores the binder slot type as shift 0 1 dom. Inside the body, var 0 therefore points strictly to the binder, while the old context has been moved under that new slot. This matches the host CIC's internal de Bruijn discipline: crossing a binder changes the reference depth, and the represented context records that change explicitly.

The price is that some attractive unconditional preservation statements are not true at this level of representation. In particular, shift adjustment and substitution do not commute freely under an open binder. Substitution preservation therefore carries closure hypotheses in the binder cases; those hypotheses make the shifted domain stable and let the represented typing context line up without capture.

9235.3.24 Closure Discipline

The main substitute-preservation theorems are closure-conditioned because the binder domain participates directly in the represented context. In the shift-aware typing rule, a lambda or Pi body is checked under (shift 0 1 dom) :: Γ, so preservation under substitution must keep that domain aligned with the context obtained after the binder is crossed.

The closed-domain hypothesis supplies exactly that alignment. When ClosedAt 0 dom holds, the closed-shift lemma gives shift 0 1 dom = dom. The lift/lower path inside substitute then has a stable binder entry: descending under the binder raises the substitution depth and shifts the incoming term, but the domain stored in the context is unchanged.

For open binder domains, the same preservation shape requires a general shift-substitute commutation theorem strong enough to transport the open domain through both operations. That commutation theorem is not part of the available substrate. The explicit condition keeps the theorem statement at the proved boundary rather than hiding a missing transport principle.

ClosedAt is the inductive predicate defined in `BEDC.MetaCIC.ClosedTerm`: var i is closed at n when $i < n$, and compound terms are closed exactly when their immediate subterms are closed at the appropriate binder depth.

9235.3.25 Shift Mechanism Detail

The operation shift cutoff amount t takes a cutoff threshold, an addition amount, and a represented term t. On a variable var i, it compares i with the cutoff. If $i \geq$ cutoff, the variable is mapped to var $(i + \text{amount})$; if $i <$ cutoff, it is left unchanged.

The operation is structural on applications and sorts. Under a lambda or Pi binder, the domain is shifted at the same cutoff, while the body is shifted at cutoff $+ 1$. The extra unit records the binder slot that now occupies one de Bruijn index position before the surrounding variables.

This is the mechanism behind capture-aware substitution. When substitute descends below a binder, it raises the substitution depth and shifts the incoming term by shift 0 1, so the incoming term passes around the binder slot instead of being captured by it.

The core lemmas state the bookkeeping equalities used downstream: `shift_closed` says shifting at a closed boundary leaves the term unchanged; `substitute_shift_at_eq` says substitution at depth n undoes a same-depth one-step shift; and `substitute_closed` says substitution at a closed boundary leaves the term unchanged.

9235.3.26 Substitution Operation

The operation substitute depth v t takes a de Bruijn replacement depth, an incoming replacement value v, and an original represented term t. It is the capture-aware operation used by beta contraction and by the substitution-preservation surface.

On a variable var i, the operation compares i with the replacement depth. If $i =$ depth, the variable is replaced by v. If $i >$ depth, the variable crosses the removed binder slot and becomes var $(i - 1)$. If $i <$ depth, the variable is below the active replacement boundary and is left unchanged.

Lean4 ✓ `BEDC.MetaCIC.substitute var zero`

Lean4 ✓ `BEDC.MetaCIC.substitute var succ zero`

The operation is structural on application, sort, lambda, and Pi terms. Under a binder, the body is processed at depth $+1$, and the incoming value is simultaneously raised to shift 0 1 v. This synchronized shift makes v pass the new binder slot without capture.

The syntax-level lemmas summarize the arithmetic used downstream: `substitute_var_zero` gives replacement at depth zero; `substitute_var_succ_zero` gives the positive-variable decrement; `substitute_closed` says closed terms are unaffected by substitution; and `substitute_shift_at_eq` says substitution at depth n cancels a same-depth one-step shift.

Lean4 ✓ `BEDC.MetaCIC.substitute closed`

Lean4 ✓ `BEDC.MetaCIC.substitute shift at eq`

9235.3.27 Glossary

The following terms name the local reconstruction conventions used in this section:

- A shift-aware binder context is a lambda or Pi binder slot whose stored domain is shift 0 1 dom rather than dom; this choice prevents capture by var 0.
- A closed binder domain is the domain of that lambda or Pi satisfying ClosedAt 0.
- BetaStarStep is the reflexive-transitive closure of one-step BetaStep.
- BetaParallel is Tait–Martin-Löf style parallel reduction.
- An atom shape is a term whose shape is either sort or var i.

9235.3.28 Construction Style

The MetaCIC layer is built in the first instance from pure inductive objects. Term is an inductive syntax type, while HasType, BetaStep, BetaStarStep, BetaParallel, and ClosedAt are inductive predicates. No constructor in this surface depends on an additional axiom.

Binders are represented by de Bruijn indices. Variables have the form Term.var i for an index i, and substitution is the explicit operation substitute depth v t. Lambda and Pi binders are handled by the same shift-aware discipline used by the typing judgment: crossing a binder raises the depth and shifts the incoming term so that capture is not introduced by representation.

The main substitution-preservation statements are conditioned by closure. They work under hypotheses such as ClosedAt 0 dom, because a closed binder domain is stable under the binder shift: shift 0 1 dom = dom. This is the local fact that lets the represented binder context and the substituted context line up.

Many checked lemmas are intentionally statement-shape lemmas. Names such as `betaSubstitutionPreservat` `betaSubstitutionPreservation_pi_body`, `betaSubstitutionPreservation_lam_body`, and `betaSubstitutior` isolate the term shape under which substitution preservation is proved. The full picture is assembled from these shape-local facts rather than from an opaque global argument.

9235.3.29 Derivation Style

The MetaCIC proof layer follows a derivation style tied closely to the inductive term and judgment constructors. Most local lemmas proceed by case analysis on the represented term or typing witness. In the atom cases of subject reduction and substitution preservation, a proof often reduces to term-level inversion by `cases ht`: when the source term is sort or var i, the impossible typing constructors are eliminated and the surviving constructor exposes exactly the required premises.

Many theorems are therefore shape-restricted. A case-specific preservation result may assume a syntactic side condition such as $t = \text{sort} \vee \exists i,\ t = \text{var } i$, rather than claiming the unrestricted preservation theorem directly. The global proof surface is assembled by chaining such case lemmas, with separate entries for sort/variable atoms, Pi bodies, lambda bodies, and application bodies.

The proofs are also closure-conditioned. Hypotheses such as ClosedAt 0 dom keep binder-domain shifts from changing the represented type, so the shifted context used by the typing rule agrees with the context obtained after substitution. This is the point at which the de Bruijn bookkeeping becomes a local equality instead of a global transport problem.

Finally, the formalization separates statements from proof instances. Clean targets such as BetaSubstitutionPreservation name the proposition needed downstream, while the checked lemmas prove that target under specific term shapes and closure hypotheses. The development does not hide the remaining unrestricted theorem inside one monolithic proof; it exposes the proof-relevant shapes that make each derivation go through.

9235.3.30 Induction Style

The induction style in `BEDC.MetaCIC` follows the object being analyzed. Term induction is used for syntactic properties of represented terms. A proof may proceed by `induction t with | sort => ... | var => ... | app f a ihf iha => ...`, with the recursive hypotheses supplied exactly for the immediate subterms. This is the natural shape for results such as `substitute_closed`, where the claim is driven by the constructors of `Term`.

Judgment induction is used for structural properties of derivations. Proofs about typing and reduction inspect the evidence itself, for example by `induction ht` over a `HasType` witness or by induction over a `BetaStep` witness. This is the appropriate style for subject-reduction case analysis, where each typing or beta constructor exposes the premises that the corresponding preservation case may use.

Most case lemmas are therefore local in shape: for an atom source, a concrete congruence constructor, or a fixed binder form, the required property holds. The main theorem surface is assembled by combining these lemmas with ordinary `cases` and induction over the relevant term or derivation. No proof relies on well-founded recursion beyond Lean's built-in recursion principles for `Nat`, `List`, and the inductive objects defined in the MetaCIC surface.

9235.3.31 Namespace Rationale

The `BEDC.MetaCIC` namespace is divided by proof responsibility rather than by presentation order. `BEDC.MetaCIC.Syntax` contains the syntactic core: Term, shift, substitution, and contexts. `BEDC.MetaCIC.Beta` contains one-step β reduction, while `BEDC.MetaCIC.Typing` contains the typing relation over that syntax. `BEDC.MetaCIC.SubjectReduction` names the subject-reduction theorem suite, so that preservation claims remain downstream of both reduction and typing. `BEDC.MetaCIC.Confluence` contains multi-step reduction and parallel reduction, because join arguments use a different induction shape from one-step contraction. `BEDC.MetaCIC.Normalization` records the atom normal-form facts. `BEDC.MetaCIC.AtomInfer` and `BEDC.MetaCIC.TypedExamples` are demonstration and inference surfaces, kept outside the metatheory namespaces so that examples do not determine the core proof interfaces. Each sub-namespace is axiom-free under the strict `bedc_ci.py axiom-purity -strict` audit.

9235.3.32 Lean Module Topology

The Lean dependency topology for `BEDC.MetaCIC` is a directed acyclic graph. `BEDC.MetaCIC.Syntax` is the foundation: it imports `BEDC.FKernel.Mark` and defines Term, Ctx, shift, and substitute. On that base, `BEDC.MetaCIC.ClosedTerm` and `BEDC.MetaCIC.Beta` depend only on syntax. The substitution family `BEDC.MetaCIC.Substitution.NatShift`, `BEDC.MetaCIC.Substitution.Basic`, `BEDC.MetaCIC.Substitution.Core`, and `BEDC.MetaCIC.Substitution.Statements` depends on syntax and closed terms, while `BEDC.MetaCIC.Substitution` re-exports that surface. `BEDC.MetaCIC.Typing.Core` `BEDC.MetaCIC.Typing.SubstitutionSurface`, and `BEDC.MetaCIC.Typing.ClosedBinderDomains` depend on syntax and the substitution surface. `BEDC.MetaCIC.SubjectReduction` depends on typing and beta reduction; `BEDC.MetaCIC.Confluence` depends on beta reduction; `BEDC.MetaCIC.Normalization` depends on beta reduction and closed terms; and `BEDC.MetaCIC.AtomInfer` and `BEDC.MetaCIC.TypedExamples` depend on typing. No module in this topology imports back into one of its prerequisites.

9235.3.33 Tactic Discipline

The MetaCIC Lean modules are kept under a restricted proof discipline. Tactics such as `simp`, `decide`, and `omega` are not used in this layer, because they can introduce transitive dependencies on `propext`, decision procedures, or classical reasoning.

The permitted proof surface is the structural fragment needed by the reconstruction: `match`, `cases`, `rfl`, `exact`, `apply`, `intro`, `contradiction`, `rw`, `unfold`, `induction`, and `change`. These commands keep proofs close to the generated inductive structure of the syntax, typing, reduction, and substrate definitions.

This discipline is a necessary condition for preserving the axiom-free status of the MetaCIC reconstruction. The strict purity audit `python3 lean4/scripts/bedc_ci.py axiom-purity -strict` checks each theorem's transitive dependencies against the forbidden constants `Classical.choice`, `Quot.sound`, and `propext`; the gate passes only when the forbidden set is empty for every audited theorem.

9235.3.34 Build and Audit Process

The complete local verification gate for `BEDC.MetaCIC` is the Lean build followed by the paper and axiom audits:

```
cd lean4 && lake build
python3 tools/check-axioms.py
python3 lean4/scripts/bedc_ci.py audit
python3 lean4/scripts/bedc_ci.py axiom-purity --strict
python3 lean4/scripts/bedc_ci.py conservativity-audit
```

The first command checks that the Lean modules build with no accepted `sorry` terms and no project axioms. The axiom audit enforces the source-level ban on `axiom`. The drift audit resolves the paper's Lean markers against the actual `lean4/BEDC/` namespace. The strict axiom-purity audit checks transitive theorem dependencies, excluding `propext`, `Classical.choice`, and `Quot.sound`. The conservativity audit is the metalogical gate for the reconstruction surface. Each command must exit with status 0. The chain passes only when the paper invariant and the mechanized state agree, and that agreement is the local shipping condition for the MetaCIC reconstruction.

9235.3.35 Axiom-Free Claim

The axiom-free claim for `BEDC.MetaCIC` has two distinct parts. First, no `BEDC.MetaCIC` module declares a host axiom. This is a project-wide hard invariant: `tools/check-axioms.py` exits with failure if an axiom declaration appears in the BEDC Lean sources.

Second, the checked `BEDC.MetaCIC` theorems do not depend on Lean stdlib axioms such as `Classical.choice`, `Quot.sound`, or `propext`. This dependency claim is audited by `bedc_ci.py axiom-purity -strict`, which queries Lean through `#print axioms` and rejects those extra axiom dependencies.

Thus the commitment is stronger than the absence of local axiom declarations: the reconstructed MetaCIC layer is a pure constructive fragment inside CIC, with no reliance on Lean's additional axioms beyond CIC. The audit currently covers more than 9,000 checked theorems, and the exact count is allowed to change with the theorem set.

9235.3.36 Internal Manifest Coverage

`BEDC.Manifest` is the Lean-side registry for paper-facing theorem claims. Its core record is `BEDC.Manifest.ClaimEntry`, with fields for the paper label, fully qualified Lean name, proposition, and proof witness. The field `proof : prop` is dependent: a manifest entry elaborates only when Lean's kernel accepts the supplied proof term at the recorded proposition. Thus manifest well-formedness is not a string audit; it is kernel type checking of the `List ClaimEntry`.

The registry has 65 Lean-side entries in the unfiltered manifest-coverage report. Its breadth includes paper Lean-checked theorems from base reflection, ground compiler results, F-kernel gap transport, capstone fable-machine claims, reflection claims, derived structures for holonomy, KKT, and spectral measure packets, and the six primary MetaCIC examples in this section: `BEDC.MetaCIC.sort_in_empty_ctx`, `BEDC.MetaCIC.id_sort_well_typed`, `BEDC.MetaCIC.pi_sort_sort_well_`
`BEDC.MetaCIC.id_sort_applied`, `BEDC.MetaCIC.id_sort_beta`, and `BEDC.MetaCIC.var_zero_in_sort_ctx`.

The audit command `bedc_ci.py manifest-coverage` compares two sets: paper targets named by `\leanchecked`$\{X\}$ and Lean targets registered in `BEDC.Manifest.manifest`. It reports the marker count, manifest-entry count, coverage ratio, and a sample of paper markers that are not represented by manifest entries. The unfiltered report gives 7831 paper markers and 65 manifest entries, for `65/7831 = 0.83%`. With the literal namespace filter `-scope all`, the same command reports zero markers and zero entries, because no Lean target has prefix `all`.

The gap is therefore marker-heavy rather than manifest-heavy. The manifest contains a selected kernel-typed spine, while many paper markers remain outside the internal registry. In this section, the six primary MetaCIC markers above are manifest entries; the substitution, subject-reduction, and binder-transport markers below are Lean-checked paper markers without manifest entries. The audit makes this distinction mechanical: every paper-claimed theorem must be visible either through the ordinary `\leanchecked` marker stream or through the stronger internal manifest entry stream.

9235.3.37 Shift-Aware Metatheory Progress

The shift-aware substrate is represented by `BEDC.MetaCIC.Typing`. Its sanity layer covers the sort, Pi, identity, application, and dependent identity examples, and its atomic substitution layer is no longer a schematic placeholder: sort and variable atoms are checked directly.

Lean4 ✓ `BEDC.MetaCIC.substitute preserves typing sort var`

The captured-substitution demonstration also has a positive source typing derivation and a rejected captured target.

Lean4 ✓ `BEDC.MetaCIC.r11 substitute preserves typing`

The Pi and lambda cases expose the shift-aware shift discipline directly. Their substitution-preservation lemmas are checked under closed-domain and atomic-shape hypotheses, with weakening across the shifted binder premise.

↪ variant `BEDC.MetaCIC.substitute preserves typing pi`

↪ variant `BEDC.MetaCIC.substitute preserves typing lam`

Lean4 ✓ `BEDC.MetaCIC.hasType shift weaken sort var`

The beta case of subject reduction is therefore isolated in `BEDC.MetaCIC.SubjectReduction`. It is provable from a clean substitution-preservation lemma:

Lean4 (definition) `BEDC.MetaCIC.BetaSubstitutionPreservation`

Lean4 (definition) `BEDC.MetaCIC.AppArgTypeStable`

Lean4 (definition) `BEDC.MetaCIC.LamDomainSubjectReduction`

Lean4 (definition) `BEDC.MetaCIC.PiDomainSubjectReduction`

Lean4 ✓ `BEDC.MetaCIC.subject reduction beta`

↪ variant `BEDC.MetaCIC.subject reduction`

This puts the beta subject-reduction burden exactly on BetaSubstitutionPreservation, without adding an extra operational premise to beta reduction itself. Application congruence is checked separately at the preserved-type boundary.

↪ variant `BEDC.MetaCIC.subject reduction congApp1`

The binder-transport lemmas identify the semantic footprint of the shift-aware binder context. The shift inserted under the binder is judgmentally absorbed by closedness on closed binder domains.

9235.3.38 Substrate Stack

The MetaCIC reconstruction is a layered stack of Lean modules. Each module contributes a specific fragment of the represented type theory's substrate. The stack is finite, ordered by formal dependency, and audited by the standing paper and Lean checks.

Syntax layer. `BEDC.MetaCIC.Syntax` provides Term (an inductive with five constructors: var, app, lam, pi, sort), shift (de Bruijn lifting at cutoff with explicit amount, dispatching on Boolean Nat.ble), and substitute (capture-aware substitution at arbitrary depth, dispatching on Boolean Nat.beq and Nat.blt; the Bool-level branching avoids the propext exposure that Prop-level decidable-if would introduce for generalized substitute lemmas).

Typing layer. `BEDC.MetaCIC.Typing` provides Ctx as a list of represented types, Ctx.lookup with depth-aware shift on tail-looked-up types, and the inductive predicate

$$\text{HasType} : \text{Ctx} \to \text{Term} \to \text{Term} \to \text{Prop}.$$

Its formation rules are sortRule, varRule, piRule, lamRule, and appRule.

Reduction layer. `BEDC.MetaCIC.Beta` provides BetaStep with one base beta rule and congruence rules for application heads, application arguments, lambda bodies, lambda domains, Pi codomains, and Pi domains.

Well-formedness layer. `BEDC.MetaCIC.ContextWF` provides WellFormedCtx with empty and cons formation rules. The cons rule requires the head type to be derivable at Sort in the predecessor context. This premise is required for substitution preservation: without it, ill-typed contexts admit refutations of preservation.

Substitution-preservation layer. `BEDC.MetaCIC.Substitution` hosts the substitution-preservation target with the WellFormedCtx premise. Its proof body is the active research target.

Subject-reduction layer. `BEDC.MetaCIC.SubjectReduction` depends on substitution preservation and is the next downstream target.

Operational layer. `BEDC.MetaCIC.Examples` carries concrete HasType witnesses for representative terms: the base sort judgment, the polymorphic identity, and variable lookup. `BEDC.MetaCIC.LeanBridge` carries one worked encoding of a host CIC term into MetaCIC with its HasType derivation.

Decidable layer. `BEDC.MetaCIC.Checker` provides Term.beq, structural equality on terms, with soundness Term.beq_eq; infer, type inference returning Option Term, with soundness infer_sound; and check, decidable typing check, with soundness check_sound.

Display and elaboration layer. `BEDC.MetaCIC.PrettyPrint` provides a display function Term → String. `BEDC.MetaCIC.Elaborator` provides ElabFailure, ElabResult, normalizeOneStep for single-step beta reduction, and

$$\text{elaborate} : \text{Ctx} \to \text{Term} \to \text{ElabResult}.$$

Reflection bridge implementation status. `BEDC.MetaCIC.HostBridge`.reflectExpr covers eight host Lean Expr constructors: sort, bvar, app, lam, forallE, const, fvar returning none, and mdata as a passthrough. Two elaboration commands surface the encoding to BEDC automation: #reflect_metacic e prints the Term form, and #metacic_decide e runs infer on the reflected Term and prints the inferred MetaCIC type. The latter is the end-to-end demonstration of the host-MetaCIC pipeline.

Atomic inference and concrete typing gallery. `BEDC.MetaCIC.AtomInfer` carries a minimal type-inference procedure for closed atoms: a sort literal infers to itself, a de Bruijn variable infers to its context lookup.

Lean4 (definition) `BEDC.MetaCIC.inferAtom`

Lean4 ✓ `BEDC.MetaCIC.inferAtom sort sound`

Lean4 ✓ `BEDC.MetaCIC.inferAtom var sound`

`BEDC.MetaCIC.TypedExamples` carries a gallery of concrete typed terms over the shift-aware substrate: sort and Pi types in singleton and binary contexts, the dependent identity that exhibits shift-aware binder tracking, and a beta-reducible identity application.

Lean4 ✓ `BEDC.MetaCIC.var zero in sort ctx`

Lean4 ✓ `BEDC.MetaCIC.var one in double sort ctx`

Lean4 ✓ `BEDC.MetaCIC.pi var sort in sort ctx`

Lean4 ✓ `BEDC.MetaCIC.lam dependent identity`

Lean4 ✓ `BEDC.MetaCIC.pi sort sort in empty ctx`

Lean4 ✓ `BEDC.MetaCIC.app id sort in empty ctx`

`BEDC.MetaCIC.Normalization` records that sort and variable atoms are reduction-stable: no β-step starts from a sort or variable constructor, so closed atoms typed at sort are normal forms.

Lean4 ✓ `BEDC.MetaCIC.sort no beta`

Lean4 ✓ `BEDC.MetaCIC.closed var no beta`

Audit gating. Every module in the stack is gated by `check-axioms.py`, which rejects raw `axiom` declarations; `bedc_ci.py axiom-purity -strict`, which rejects transitive `propext`, `Classical.choice`, and `Quot.sound` dependencies; `bedc_ci.py audit`, which rejects paper-Lean marker drift; and `bedc_ci.py marker-existence-audit`, which rejects paper references to non-existent Lean names. A module that fails any of these audits is rejected at PR merge time.

Stack closure. The substrate stack is open at the substitution-preservation layer and closed elsewhere: the remaining layers carry definitions and theorems that are axiom-free under `#print axioms`. Subject reduction depends on substitution preservation; closing the substitution layer is the prerequisite for opening the subject-reduction layer. No layer is closed by importing unverified content from outside the stack.

9235.3.39 Substrate Components Table

Component	Lean Module
Term + Ctx + shift + substitute	`BEDC.MetaCIC.Syntax`
ClosedAt predicate	`BEDC.MetaCIC.ClosedTerm`
BetaStep + congruence	`BEDC.MetaCIC.Beta`
Substitute syntactic lemmas	`BEDC.MetaCIC.Substitution.{NatShift,Basic,Core,Statements}`
Typing relation	`BEDC.MetaCIC.Typing.{Core,SubstitutionSurface,ClosedBinderDomai`
Subject reduction	`BEDC.MetaCIC.SubjectReduction`
Confluence relations	`BEDC.MetaCIC.Confluence.{Core,AtomShape,AtomJoin}`
Normalization atoms	`BEDC.MetaCIC.Normalization`
Atom inference	`BEDC.MetaCIC.AtomInfer`
Typed examples gallery	`BEDC.MetaCIC.TypedExamples`

9235.3.40 Current State of the Reconstruction

This subsection records the state of the MetaCIC reconstruction as encoded in BEDC's Lean library.

Definitions in place. The represented type theory exposes Term, Ctx, HasType, BetaStep, shift, substitute, WellFormedCtx, infer, check, Term.beq, pp, normalizeOneStep, and elaborate. Each definition is axiom-free under `#print axioms`.

Theorems with full proofs. The library carries axiom-free proofs for:

- Sanity instances of HasType: sort in the empty context, polymorphic identity at the Sort level, Pi types, and variable lookup in singleton contexts.
- A worked encoding of host single-sort polymorphic identity as a MetaCIC Term with its HasType derivation (section 9235.3).
- Soundness of Term.beq as structural equality.
- Soundness of infer against HasType.
- Soundness of check against HasType.

Theorems with statements pending proof. The library carries the unrestricted target, substitute_preserves_typing, guarded by a WellFormedCtx premise. Its proof requires weakening of HasType, substitution-shift composition, and binder substitution composition. The same substrate also supports closed_term_substitute_preserves_typing as a more tractable closed-term variant. The unrestricted target depends on the WellFormedCtx requirement, binder-shift propagation, and the induction-based assembly of the available helper lemmas.

Closed-term substitute preservation. The library carries a closed-term restriction of substitute preservation:

$$\begin{aligned}\text{closed_term_substitute_preserves_typing} : \text{WellFormedCtx } (B :: \Gamma) \to \text{ClosedAt } 0\ B \to \text{ClosedAt } 0\ s \to \\ \text{HasType } (B :: \Gamma)\ t\ A \to \text{HasType } \Gamma\ s\ B \to \\ \text{HasType } \Gamma\ (\text{substitute } 0\ s\ t)\ (\text{substitute } 0\ s\ A).\end{aligned}$$

The statement is registered as ClosedTermSubstitutePreservesTypingStatement. The infrastructure—ClosedAt inductive, shift_closed, substitute_closed, substitute_shift_at_eq—is in place with axiom-free proofs.

Closed-term substitute preservation: case status. The closed-term restriction has axiom-free case lemmas covering all five inductive cases of the typing derivation. The variable case is split by depth, and the application helper carries a type-equality premise:

- substitute_sort_preserves_typing_closed_anchor (sort case);
- substitute_var_zero_preserves_typing_closed_anchor (variable, depth 0);
- substitute_var_nonzero_preserves_typing_closed_anchor (variable, depth > 0);
- substitute_pi_preserves_typing_closed_anchor (Pi);
- substitute_lam_preserves_typing_closed_anchor (lambda, proved via term induction; the corresponding HasType-induction path depends on binder-shift propagation);
- substitute_app_preserves_typing_closed_anchor_with_type_eq (application, conditional on a substitute composition equation).

The main theorem depends on two proof obligations:

1. Prove the substitute composition equation substitute 0 s (substitute 0 a cod) = substitute 0 (substitute 0 s a) (su discharging the application conditional.
2. Run the outer induction on the typing derivation, supplying each case lemma's recursive premises and assembling them into the main theorem.

The closed-term restriction avoids the binder-shift propagation obstruction by ensuring the substitution targets and source terms have no free variables that would expose it.

Substitute composition. The closure-restricted form of the substitute composition equation

$$\text{substitute } 0\ s\ (\text{substitute } 0\ a\ \text{cod}) = \text{substitute } 0\ (\text{substitute } 0\ s\ a)\ (\text{substitute } 1\ s\ \text{cod})$$

is established for five of five inductive cases of `cod`: sort, var, app, lam, and pi. The sort case is unconditional, the var case assumes ClosedAt 0 s, the app case uses two recursive premises, and the lam and pi cases are conditional on a shift-substitute commutation lemma

$$\text{shift } 0\ 1\ (\text{substitute } 0\ s\ a) = \text{substitute } 1\ (\text{shift } 0\ 1\ s)\ (\text{shift } 0\ 1\ a).$$

The commutation lemma is the required premise for full unconditional composition closure.

Host reflection bridge. `BEDC.MetaCIC.HostBridge`.reflectExpr covers eight host Lean Expr constructors: sort, bvar, app, lam, forallE, const, fvar returning none, and mdata as a passthrough. The elaboration commands #reflect_metacic e and #metacic_decide e expose the bridge: the former prints the reflected Term, and the latter runs infer on that reflected term and prints the inferred MetaCIC type.

Out of scope. The reconstruction does not currently implement strong normalization, confluence, full universe hierarchy, inductive declarations within MetaCIC, or a verified embedding into the host Lean kernel. These remain research targets as outlined in section 9235.6.

Audit guarantees. The reconstruction's status is maintained by four standing audits at PR merge time:

- `check-axioms.py` rejects any `axiom` declaration.
- `bedc_ci.py axiom-purity -strict` rejects theorems whose transitive axiom dependency includes `Classical.choice`, `Quot.sound`, or `propext`.
- `bedc_ci.py audit` rejects \`leanchecked{$X$} markers whose $X$ does not exist in `lean4/BEDC/`.
- `bedc_ci.py marker-existence-audit` reports the same information as a standing first-class audit.

The current state is coherent. Formal targets without full proof terms are reported as such, and the audit guarantees make this distinction enforceable.

9235.3.41 Evolution Trajectory

The MetaCIC surface admits several coherent directions while retaining its inside-host reconstruction role. One direction is a richer conversion relation: eta-conversion can be added to `BetaStep` and `BetaParallel`, with eta-reduction for functions represented beside beta contraction. Another direction is a universe hierarchy, replacing the single sort by indexed Type i levels and typing rules that track universe movement. A third direction is syntax for inductive families beyond Pi and Sort, so that families with constructors and eliminators become represented objects.

Deeper metatheory would strengthen the current shape-local surface. A full substitution-preservation theorem would transport arbitrary binder domains through shift and substitution, rather than relying only on closed-domain cases. Strong normalization for closed sort-typed terms would naturally follow a Tait reducibility route, with reducibility predicates indexed by represented types. A complete Church–Rosser theorem would turn the local parallel diamond components into confluence for the full represented reduction system.

A host bridge would add reflection in the other direction: selected `Lean.Expr` values could be translated into BEDC `Term` values under an explicit reconstruction certificate. On that basis, a command such as `#metacic_decide` could ask the host to quote a term, reconstruct the corresponding MetaCIC object, and discharge represented typing or conversion goals against the internal BEDC surface.

9235.3.42 Open Targets

The reconstruction does not yet close the following metatheoretic targets:

- Substitute preservation for open binder domains. The checked theorem covers closed binder-domain hypotheses; open domains still require a general binder-shift and substitution transport argument.
- Subject reduction without body-shape restrictions. The closed body cases are represented, while arbitrary lambda and Pi bodies still require binder-drop handling that commutes with typing projections.
- Confluence as a full diamond property for parallel reduction across all term shapes. The atom cases are closed; Pi, lambda, and application cases still depend on general join assemblers for their components.
- Strong normalization for closed sort-typed terms.

- Decidable type checking for arbitrary Pi, lambda, and application terms. The checked AtomInfer surface covers only sort and variable atoms.

9235.3.43 Results Overview

The formalized MetaCIC result set covers the main closed reconstruction claims needed by this chapter. Closed binder-domain substitute preservation is proved by substitute_preserves_typing_closed_binder_d giving the complete closed theorem over the shift-aware typing substrate. Subject reduction is represented by the main theorem subject_reduction together with the beta case, the application congruence cases such as subject_reduction_congApp1, and the closed body cases for lambda and Pi constructors.

The confluence layer supplies the parallel reduction framework BetaParallel, beta-star transport lemmas betaStarStep_∗, and atom-shape diamond components for variables and sorts. The normalization layer proves that atoms do not reduce: sort_no_beta, closed_var_no_beta, and closed_atom_normal_form close the represented normal-form facts for the atomic fragment.

The executable demonstration layer contains the closed-atom inference theorems inferAtom_sort_sound and inferAtom_var_sound, plus a concrete typed-term gallery with roughly fifteen examples spanning variables, Pi terms, dependent identity terms, and applications. All listed results are axiom-free under `#print axioms`; the audited dependency sets contain no `propext`, `Classical.choice`, or `Quot.sound`.

9235.3.44 Reconstruction Summary

The MetaCIC reconstruction has three foundation layers in Lean: `BEDC.MetaCIC.Syntax` defines the de Bruijn term grammar, contexts, lookup, shift, and substitution; `BEDC.MetaCIC.Beta` defines one-step beta reduction with congruence constructors; and `BEDC.MetaCIC.ClosedTerm` defines closure at a de Bruijn boundary together with the closure lemmas for shift and substitution. On this base, `BEDC.MetaCIC.Typing` exposes the shift-aware typing relation and its substitution surface.

Substitution preservation is represented inside `BEDC.MetaCIC.Typing`. The closed binder-domain form, substitute_preserves_typing_closed_binder_domains, gives the binder-domain complete closed variant: when the substituted domain, source term, and binder-domain typing surface are closed at the relevant boundary, substitution preserves the resulting typing judgment. The same module family records the closedness, prefix-removal, and HasType projection lemmas used by that theorem.

Subject reduction is represented by `BEDC.MetaCIC.SubjectReduction`. It contains the beta case, the main subject-reduction theorem parameterized by the substitution-preservation and stability premises, and the congruence cases for application heads, application arguments, lambda bodies, and Pi codomains. The confluence surface in `BEDC.MetaCIC.Confluence` supplies beta-star and parallel beta relations, the embedding of one-step beta into parallel beta, and diamond components for the variable, sort, application, lambda, and Pi cases. The normalization surface in `BEDC.MetaCIC.Normalization` proves the atomic no-step cases for sorts and closed variables, including the closed atomic normal-form theorem.

The demonstration layer consists of `BEDC.MetaCIC.AtomInfer`, which infers and proves soundness for sort and variable atoms, and `BEDC.MetaCIC.TypedExamples`, which gives concrete typing derivations for variables, Pi terms, lambda identity terms, and applications. The whole MetaCIC reconstruction is maintained as axiom-free under `#print axioms`: the audited theorem dependencies do not include `propext`, `Classical.choice`, or `Quot.sound`.

Shift-Aware Metatheory: Case-Level Closure

The shift-aware MetaCIC layer isolates subject reduction into local closure contracts for substitution, beta contraction, and congruence. The scope is deliberately case-level: each theorem states a structurally checkable condition on the represented syntax and typing derivation, and the final assembly records the remaining interface hypotheses.

Atom-shaped binder substitution. Substitution preserves typing for the Pi and lambda constructors under closedness and atom-shape hypotheses. For Pi terms, the domain and codomain premises reduce to the sort-or-variable fragment after binder-head transport.

Lean4 ✓ `BEDC.MetaCIC.substitute preserves typing pi`

For lambda terms, the same pattern applies to the body under the shifted binder context, yielding a typed substituted lambda against the substituted Pi type.

Lean4 ✓ `BEDC.MetaCIC.substitute preserves typing lam`

The shared binder transport step is represented explicitly as the equality which turns substitution under a shifted closed head into the shifted substituted head.

Lean4 ✓ `BEDC.MetaCIC.substitute preserves typing binder head shape`

The lower-level constructor assemblers expose the same decomposition without the atom-shape discharge:

Lean4 ✓ `BEDC.MetaCIC.substitute preserves typing pi if subderivations`

Lean4 ✓ `BEDC.MetaCIC.substitute preserves typing lam if subderivations`

The closed binder-domain surface removes the atom-shape restriction when every binder domain in the source derivation is closed at its local depth. In that surface, removing the substituted hypothesis preserves the represented derivation, and closedness makes substitution definitionally inert on both the term and its type. This gives a direct closed-domain substitution-preservation theorem for the represented typing judgment.

Lean4 (definition) `BEDC.MetaCIC.ClosedBinderDomainTyping`

Lean4 (definition) `BEDC.MetaCIC.ClosedBinderDomainsSubstitutionSurface`

Lean4 ✓ `BEDC.MetaCIC.substitute preserves typing closed binder domains`

Beta-substitution cases. The clean beta-substitution contract is BetaSubstitutionPreservation: a typed body under the shifted domain context remains typed after substituting a typed argument into both body and codomain. The sort and variable cases are fully closed by direct inversion on the body derivation.

Lean4 ✓ `BEDC.MetaCIC.betaSubstitutionPreservation sort var`

The depth-one form supplies the same atom-shaped argument inside an additional binder frame, which is the common recursive premise used by binder bodies.

Lean4 ✓ `BEDC.MetaCIC.betaSubstitutionPreservation depth one sort var`

Pi bodies, lambda bodies, and application bodies are then separated into constructor-specific clean lemmas. The Pi case reconstructs a typed Pi after cleaning the substituted domain and proving the codomain in the shifted context.

Lean4 ✓ `BEDC.MetaCIC.betaSubstitutionPreservation pi body`

The lambda case follows the same domain-cleaning pattern and reconstructs the lambda rule with the body under the shifted substituted domain.

Lean4 ✓ `BEDC.MetaCIC.betaSubstitutionPreservation lam body`

The application case factors through typed substituted function and argument premises, then closes the result type by a shape-bounded substitute composition equation for the application

codomain.

Lean4 ✓ BEDC.MetaCIC.betaSubstitutionPreservation app body

Parallel-reduction confluence frame. The confluence layer separates ordinary beta steps from a parallel reduction relation. One-step beta embeds into the parallel relation, while reflexivity is available for every represented term. The diamond goal is recorded as the closed proposition BetaParallelDiamond, and the constructor-level join assemblers close the variable, sort, application, lambda, and Pi component cases.

Lean4 (definition) BEDC.MetaCIC.BetaStarStep
Lean4 (definition) BEDC.MetaCIC.BetaStarConfluent
Lean4 (definition) BEDC.MetaCIC.BetaParallel
Lean4 (definition) BEDC.MetaCIC.BetaParallelDiamond
↪ variant BEDC.MetaCIC.betaParallel refl
↪ variant BEDC.MetaCIC.betaStep to parallel
Lean4 ✓ BEDC.MetaCIC.betaParallel var diamond
Lean4 ✓ BEDC.MetaCIC.betaParallel sort diamond
Lean4 ✓ BEDC.MetaCIC.betaParallel app diamond of components
Lean4 ✓ BEDC.MetaCIC.betaParallel lam diamond of components
Lean4 ✓ BEDC.MetaCIC.betaParallel pi diamond of components

Subject-reduction assembly. Subject reduction is split across beta contraction and congruence rules. The beta contraction step is the abstract interface from BetaSubstitutionPreservation to the application redex typing judgment. The congruence steps preserve typing when reduction happens in the function, argument, lambda body, or Pi codomain position:

Lean4 ✓ BEDC.MetaCIC.subject reduction congApp1
Lean4 ✓ BEDC.MetaCIC.subject reduction congApp2
Lean4 ✓ BEDC.MetaCIC.subject reduction congLam
Lean4 ✓ BEDC.MetaCIC.subject reduction congPi

The main theorem assembles these cases by induction on the represented beta step. It takes beta-substitution preservation and application-argument type stability as explicit hypotheses, then returns preservation of the same represented type across a single beta step.

Lean4 ✓ BEDC.MetaCIC.subject reduction

The closed-term boundary is also represented explicitly. A closed lambda can contain a beta redex whose local argument is the bound variable of the enclosing lambda; the whole term is closed, the inner beta contraction steps under the binder, but the contracted argument is not closed at depth zero. This records the precise local obstruction that a closed-term subject-reduction theorem must discharge: closedness of the outer term alone does not provide zero-depth closedness for every local redex argument.

Lean4 (definition) BEDC.MetaCIC.closedBinderRedexTerm
Lean4 ✓ BEDC.MetaCIC.closedBinderRedexTerm closed
Lean4 ✓ BEDC.MetaCIC.closedBinderRedexTerm steps
Lean4 ✓ BEDC.MetaCIC.closedBinderRedexTerm argument not closed
Lean4 ✓ BEDC.MetaCIC.closed term step has unclosed local argument

9235.4 Representational Adequacy for the MetaCIC Fragment

The adequacy question for `BEDC.MetaCIC` is not whether BEDC replaces the host calculus. It is whether the represented fragment has enough syntax, typing structure, and reduction structure to stand for the corresponding host CIC fragment without changing the derivational content of the examples under discussion. The relevant fragment is the closed dependent-function fragment with variables, application, lambda abstraction, Pi formation, one base sort, and β-reduction.

9235.4.1 Adequacy Criterion

Let t be a closed term of the host CIC fragment generated by one base sort, dependent products, lambda abstraction, application, and bound variables. A representational adequacy statement for `BEDC.MetaCIC` has three parts. First, there is a representation map

$$\ulcorner - \urcorner : \mathrm{HostTerm}_{0,\Pi,\lambda,\mathrm{app}} \longrightarrow \texttt{BEDC.MetaCIC.Term}.$$

Second, host typing derivations for that fragment correspond to represented typing derivations:

$$\varnothing \vdash_{\mathrm{host}} t : T \quad \Longleftrightarrow \quad \texttt{BEDC.MetaCIC.HasType}\ []\ \ulcorner t \urcorner\ \ulcorner T \urcorner.$$

Third, the correspondence is derivational rather than merely extensional: constructor uses in the host fragment are matched by constructor uses in `HasType`. Sort formation corresponds to `sortRule`, variable lookup corresponds to `varRule`, Pi formation corresponds to `piRule`, lambda introduction corresponds to `lamRule`, and application elimination corresponds to `appRule`. Thus the represented object is not only a pretty-printed term. It is a term together with a checked inhabitant of the represented typing judgment.

This criterion is intentionally fragment-relative. It does not assert adequacy for the whole host kernel, and it does not assert that the host elaborator can be recovered from the represented syntax. It says that every closed derivation in the specified fragment has a represented term and a corresponding `HasType` derivation, and that every represented derivation in the fragment reads back to a host derivation of the same dependent-function form.

9235.4.2 Mechanized Witnesses

The Lean file `BEDC.MetaCIC.TypedExamples` gives concrete witnesses for the representation criterion. These examples are not a general translation theorem. They are checked anchors showing that the rules used by familiar host CIC identity and projection terms are present in the represented calculus.

Host fragment form	MetaCIC representative	Checked witness
Identity in a sort-indexed context, $\lambda x : A.\ x$	`Term.lam (Term.var 0) (Term.var 0)` with type `Term.pi (Term.var 0) (Term.var 1)`	`carrier_identity_in_sort_ctx`
First projection from two inhabitants, $\lambda A.\lambda x : A.\lambda y : A.\ x$	Three nested lambdas returning the de Bruijn variable for the first argument	`first_of_two`
Second projection from two inhabitants, $\lambda A.\lambda x : A.\lambda y : A.\ y$	Three nested lambdas returning the de Bruijn variable for the second argument	`second_of_two`
Identity on a Pi value, $\lambda f : (\Pi x : \mathrm{Sort}.\mathrm{Sort}).\ f$	`Term.lam (Term.pi Term.sort Term.sort) (Term.var 0)`	`id_on_pi_sort_sort`
Application of a function argument, $\lambda A.\lambda x : A.\lambda f : (A \to \mathrm{Sort}).\ f\ x$	Nested lambdas ending in `Term.app (Term.var 0) (Term.var 1)`	`apply_function_arg`

Lean4 ✓ `BEDC.MetaCIC.carrier identity in sort ctx`
Lean4 ✓ `BEDC.MetaCIC.first of two`
Lean4 ✓ `BEDC.MetaCIC.second of two`
Lean4 ✓ `BEDC.MetaCIC.id on pi sort sort`
Lean4 ✓ `BEDC.MetaCIC.apply function arg`

The witnesses cover the core constructor pattern. The identity examples use lambda introduction and variable lookup under a binder. The projection examples test multiple nested binders and the index discipline needed to distinguish earlier and later arguments. The Pi-value identity shows that the fragment can quantify over represented function types, not merely over the base sort. The function-argument example combines Pi typing, binder shifting, variable lookup, and application elimination in one derivation.

The table should be read as a finite mechanized adequacy gallery. It supports the claim that the represented rules are aligned with the host fragment on these canonical terms. A full adequacy theorem would quantify over all closed terms in the fragment and prove the two readback directions by induction on host and represented derivations.

9235.4.3 Substrate Differences

The representation is not textually identical to the host surface. Three substrate differences are essential.

De Bruijn binders and named binders. The host presentation usually uses named binders, while `BEDC.MetaCIC.Term` uses de Bruijn indices. This is an encoding choice, not a change in binding structure. A closed named term has a de Bruijn translation determined by the binder stack, and alpha-equivalent named terms translate to the same de Bruijn term. Conversely, a de Bruijn term can be read back to a named term by choosing fresh binder names. The correspondence is therefore isomorphic up to alpha-renaming for the closed fragment.

Single universe and a universe hierarchy. The represented syntax has one constructor `Term.sort`. It therefore covers only the universe-zero presentation of the fragment used here. Host terms whose derivations rely on explicit universe levels, cumulative constraints, or polymorphic

universe parameters are outside this section's adequacy criterion. Within the one-sort fragment, `sortRule` supplies the represented sort judgment used by the witness derivations.

β-only reduction and $\beta + \eta$ conversion. `BEDC.MetaCIC.BetaStep` contains beta contraction and congruence rules. It does not contain eta-conversion. Adequacy for this section is therefore adequacy for a beta-conversion fragment. Host arguments that rely on eta-equality are not represented as definitional equality in this layer.

Substrate point	Host-side surface	MetaCIC surface
Binders	Named binders modulo alpha-renaming	De Bruijn indices with shift-aware substitution
Universes	Universe hierarchy and polymorphic levels	One represented `Term.sort`
Conversion	Host definitional equality may include more than beta for specific fragments	Explicit beta-step relation without eta

9235.4.4 Coverage Boundary

The adequacy claim is bounded by the represented grammar and judgment rules. The following host-kernel features are not covered by the section's criterion:

Feature	Status in `BEDC.MetaCIC`
Universe polymorphism	Not represented; there are no universe variables, levels, constraints, or cumulative universe rules.
Inductive families	Not represented; the grammar has Pi, lambda, application, variables, and sort, but no family declarations or eliminators.
Propositions versus sets	Not separated; the one-sort fragment has no distinct `Prop`/`Type` split.
Eta conversion	Not represented; beta is the explicit conversion relation.
Host elaboration	Not represented; elaborator behavior, coercions, typeclass search, and notation expansion are outside the term grammar.

These boundaries are part of the adequacy statement. The represented calculus is adequate only for the stated closed dependent-function fragment. It is not an adequate representation of Lean's complete kernel language, nor of the surface language accepted by the elaborator. Within its boundary, however, the mechanized examples demonstrate that the core identity, projection, Pi, and application patterns have BEDC.MetaCIC terms whose `HasType` derivations mirror the corresponding host CIC derivations.

9235.5 Bounds: What This Surface Does Not Claim

The self-compilation surface is bounded by explicit negative claims. These bounds are part of the theory, because without them a reflection result can be misread as a stronger foundational theorem.

First, BEDC does not claim L4a. Since the formalization sits inside the host Calculus of Inductive Constructions, an internal axiom-free theorem asserting the relevant complete truth, soundness, or consistency of that same host-scale calculus is blocked by the Godel-Tarski boundary. Tarski undefinability blocks an internal truth predicate with the required global behavior. Godel's second incompleteness theorem blocks a sufficiently strong, consistent system from proving its own consistency in the corresponding internal form.

Second, BEDC rejects L4c. The paper's governance discipline keeps theory closure and verification status as independent axes. The policy is recorded in chapter 9466. A scoped paper theorem can be paired with a Lean target, a checked Lean theorem can sit inside a deliberately narrow paper scope, and a bridge can be absent even when both coordinates are clear. This is not a defect in the surface. It is the mechanism that prevents a proof marker from becoming a claim of public mathematical closure.

Third, TM simulation does not subsume CIC reconstruction. A simulator can make behavioral statements about execution traces. Such statements have the shape of finite runs, accept states, and observed outputs. CIC reconstruction gives structural statements about syntax, contexts, typing, and reduction. These objects can occur under universal quantifiers and induction principles:

$$\forall d,\ \mathrm{TypingDerivation}(d) \longrightarrow \mathrm{Property}(d).$$

That judgmental form is not the same as predicting that a machine accepts a file. Both surfaces are useful, but they support different theorems.

Fourth, the reflection bridge between MetaCIC and the host kernel is outside the present scope. A bridge would have to relate represented judgments to actual host elaboration or kernel checking with enough precision to transfer meaningful proof obligations. That is a metatheoretic-program target. The present surface records the construction and boundary of represented syntax, represented typing, finite checked manifest entries, and external paper-Lean audits.

These bounds fix the intended reading. BEDC can internally carry finite checked theorem entries, represent parts of its own kernel vocabulary, and expose obligation packets for concrete name certificates. It cannot, from inside the same host logic and without additional axioms, certify the global truth or consistency of the host that checks it.

MetaCIC Mechanization Status Dashboard

The `BEDC.MetaCIC` formalization is a mathlib-free, zero-axiom, zero-sorry Lean 4 development over a first-principles represented calculus. The dashboard below reads that development against a standard CIC metatheory checklist. It distinguishes proved Lean targets, statement-level interfaces, finite galleries, and open textbook theorems without upgrading any open entry into a closure claim.

Metatheory property	**BEDC status**	**Lean target**	**Notes**
Object syntax grammar	encoded	`BEDC.MetaCIC.Term`	de Bruijn terms with sort, variable, application, lambda, and Pi shapes
Context lookup	encoded	`BEDC.MetaCIC.Ctx.lookup`	structural list lookup for represented contexts

Metatheory property	BEDC status	Lean target	Notes
Shift operation	encoded	`BEDC.MetaCIC.shift`	native structural recursion over represented terms
Substitution operation	encoded	`BEDC.MetaCIC.substitute`	capture-aware de Bruijn substitution with binder shift
Typing judgment	encoded	`BEDC.MetaCIC.HasType`	inductive represented typing relation
One-step beta reduction	encoded	`BEDC.MetaCIC.BetaStep`	contraction plus app, lambda, and Pi congruence shapes
Closure predicate	encoded	`BEDC.MetaCIC.ClosedAt`	boundary-indexed local closedness predicate
Closed shift stability	proved	`BEDC.MetaCIC.shift_closed`	shift is inert at a closed boundary
Closed substitution stability	proved	`BEDC.MetaCIC.substitute_closed`	substitution is inert at a closed boundary
Same-depth shift/substitute cancellation	proved	`BEDC.MetaCIC.substitute_shift_at_zero`	de Bruijn bookkeeping equality
Substitution preservation on sort/variable atoms	proved	`BEDC.MetaCIC.substitute_preserves_typing_sort_var`	atom-shape preservation surface
Substitution preservation for Pi	proved	`BEDC.MetaCIC.substitute_preserves_typing_pi`	closed typing and atom-shape hypotheses
Substitution preservation for lambda	proved	`BEDC.MetaCIC.substitute_preserves_typing_lam`	closed typing and atom-shape hypotheses
Substitution preservation for closed binder domains	proved	`BEDC.MetaCIC.substitute_preserves_typing_lam_closed_binder_d`	closed domain surface
Naive substitution composition	refuted	`BEDC.MetaCIC.substitute_substitute_zero_zero_unclosed_co`	fails without closure discipline
Closed substitution composition, sort case	proved	`BEDC.MetaCIC.substitute_substitute_zero_zero_closed_sort`	closed sort case
Closed substitution composition, variable case	proved	`BEDC.MetaCIC.substitute_substitute_zero_zero_closed_var`	closed variable case
Closed substitution composition, app case	proved	`BEDC.MetaCIC.substitute_substitute_zero_zero_closed_app`	closed app case
Closed substitution composition, lambda anchor	proved	`BEDC.MetaCIC.substitute_substitute_zero_zero_lam_closed_`	closed lambda anchor case

Metatheory property	BEDC status	Lean target	Notes
Closed substitution composition, Pi anchor	proved	`BEDC.MetaCIC.substitute_substitute_anchor_zero_zero_pi_closed_a`	substitution composition case
Beta substitution preservation interface	statement	`BEDC.MetaCIC.BetaSubstitutionPreservation`	general preservation used by subject reduction
Beta substitution preservation, sort/variable cases	proved	`BEDC.MetaCIC.betaSubstitutionPreservation_sort_var`	beta preservation over sort/variable cases
Beta substitution preservation, depth-one atoms	proved	`BEDC.MetaCIC.betaSubstitutionPreservation_depth_one_sort`	beta preservation depth-one atom case
Beta substitution preservation, Pi body	proved	`BEDC.MetaCIC.betaSubstitutionPreservation_pi_body`	beta preservation specific Pi body case lemma
Beta substitution preservation, lambda body	proved	`BEDC.MetaCIC.betaSubstitutionPreservation_lam_body`	beta preservation specific lambda body case lemma
Beta substitution preservation, app body	proved	`BEDC.MetaCIC.betaSubstitutionPreservation_app_body`	beta preservation specific application body case lemma
Closure preservation under beta	proved	`BEDC.MetaCIC.betaStep_preserves_ClosurePreservation`	beta step preserves closure preservation module
Closure preservation under beta-star	proved	`BEDC.MetaCIC.betaStarStep_preserves_closure`	beta-star preserves closure over beta-star
Beta-star relation	encoded	`BEDC.MetaCIC.BetaStarStep`	reflexive transitive closure over one-step beta
Beta-star transitivity	proved	`BEDC.MetaCIC.betaStar_trans`	composition of beta-star evidence
Beta-star app congruence	proved	`BEDC.MetaCIC.betaStarStep_app_double`	componentwise multi-step application congruence
Beta-star lambda congruence	proved	`BEDC.MetaCIC.betaStarStep_lam_double`	domain and body multi-step congruence
Beta-star Pi congruence	proved	`BEDC.MetaCIC.betaStarStep_pi_double`	domain and codomain multi-step congruence
Confluence, beta-star sort atom	proved	`BEDC.MetaCIC.betaStarStep_diamond_sort`	sort diamond component
Confluence, beta-star variable atom	proved	`BEDC.MetaCIC.betaStarStep_diamond_var`	variable diamond component
Parallel beta relation	encoded	`BEDC.MetaCIC.BetaParallel`	parallel reduction substrate for diamond assembly
Parallel beta reflexivity	proved	`BEDC.MetaCIC.betaParallel_refl`	reflexive parallel reduction
One-step beta embeds in parallel beta	proved	`BEDC.MetaCIC.betaStep_to_parallel`	ordinary beta step to parallel step

Metatheory property	BEDC status	Lean target	Notes
Parallel beta to beta-star	proved	`BEDC.MetaCIC.betaParallel_to_betaStar`	parallel step embeds in beta-star
Parallel confluence, variable atom	proved	`BEDC.MetaCIC.betaParallel_var_diamond`	variable component of parallel diamond
Parallel confluence, sort atom	proved	`BEDC.MetaCIC.betaParallel_sort_diamond`	sort component of parallel diamond
Parallel confluence, application component	proved	`BEDC.MetaCIC.betaParallel_app_diamond_of_components`	component diamonds assembler
Parallel confluence, lambda component	proved	`BEDC.MetaCIC.betaParallel_lam_diamond_of_components`	component diamonds assembler
Parallel confluence, Pi component	proved	`BEDC.MetaCIC.betaParallel_pi_diamond_of_components`	component diamonds assembler
Full beta confluence	open	*none*	extension from component diamonds to the full textbook theorem
Subject reduction, beta contraction	hypothesis-based	`BEDC.MetaCIC.subject_reduction_beta`	uses the beta-substitution preservation interface
Subject reduction, app function congruence	proved	`BEDC.MetaCIC.subject_reduction_congApp1`	preserves represented type under function-step congruence
Subject reduction, app argument congruence	proved	`BEDC.MetaCIC.subject_reduction_congApp2`	application-argument type stability
Subject reduction, lambda body congruence	proved	`BEDC.MetaCIC.subject_reduction_congLam`	body-step congruence case
Subject reduction, Pi codomain congruence	proved	`BEDC.MetaCIC.subject_reduction_congPi`	codomain-step congruence case
Subject reduction, closed terms	hypothesis-based	`BEDC.MetaCIC.subject_reduction`	requires beta substitution, app-argument stability, and binder-domain stability hypotheses
Subject reduction, retyping wrapper	hypothesis-based	`BEDC.MetaCIC.subject_reduction_retype`	packages type preservation as existence of a post-step typing witness
Lambda-domain stability interface	statement	`BEDC.MetaCIC.LamDomainSubjectReduction`	domain-stability hypothesis for subject reduction
Pi-domain stability interface	statement	`BEDC.MetaCIC.PiDomainSubjectReduction`	domain-stability hypothesis for subject reduction

Metatheory property	BEDC status	Lean target	Notes
Application argument stability interface	statement	`BEDC.MetaCIC.AppArgTypeStable`	argument-step type-stability hypothesis for subject reduction
Closed local-redex obstruction	proved	`BEDC.MetaCIC.closed_term_step_has_unclosed_local_argumen`	closed terms can contain locally open redex arguments
Strong normalization	open	*none*	no global termination theorem for beta reduction
Bounded normalizer	operational	`parts/self_compilation/08_metatheory_normalization`	fuel-bounded normalization reading, with closure preservation carried by finite beta traces
Atomic normal forms	proved	`BEDC.MetaCIC.closed_atom_normal_form`	closed atom-shaped typed terms cannot beta-step
Sort has no beta target	proved	`BEDC.MetaCIC.sort_no_beta`	normal-form component
Variable has no beta target	proved	`BEDC.MetaCIC.closed_var_no_beta`	normal-form component
Atom inference, sort	proved	`BEDC.MetaCIC.inferAtom_sort_sound`	minimal inference procedure sound on sort
Atom inference, variable	proved	`BEDC.MetaCIC.inferAtom_var_sound`	minimal inference procedure sound on context lookup
Representational adequacy	partial	`parts/self_compilation/04_metatheory_representational_ad`	finite typed representation witnesses, not a full adequacy theorem
Host-kernel reflection bridge	open	*none*	no checked bridge from represented typing to the host kernel

What is not claimed

The dashboard does not claim universe polymorphism, cumulative universes, inductive families, large eliminations, proof irrelevance, eta conversion, quotients, classical choice, or a bridge from represented typing into Lean's kernel typing judgment. It also does not claim full beta confluence, strong normalization, decidable type checking for the represented calculus, or a global representational adequacy theorem. The checked entries are exactly the Lean targets named above and the already marked MetaCIC targets cited elsewhere in this chapter.

9235.6 Reflection Bridge to the Host Kernel

The structural reconstruction in section 9235.3 represents CIC syntax and typing inside BEDC as inductive predicates. A natural question is whether this represented system can be connected back to the host Lean kernel that elaborates BEDC itself. This section outlines what such a reflection bridge would entail and why the bridge sits above the present scope.

9235.6.1 Bridge Form

A bridge between '`BEDC.MetaCIC.HasType`' and the host kernel would take one of two shapes.

Embedding bridge. A function $\mathsf{embed} : \mathrm{Term} \to \mathrm{Expr}_{\mathsf{Lean}}$ takes a MetaCIC term to a Lean expression, paired with a soundness theorem

$$\mathsf{embed\text{-}sound} : \mathrm{HasType}\ \Gamma\ t\ A \to \texttt{Lean.elab}\ (\mathsf{embed}\ t)\ (\mathsf{embed}\ A).$$

The function embed would be defined by structural recursion on Term. The soundness theorem would require the host's elaboration semantics to be exposed as a first-class object inside BEDC, which it currently is not.

Correspondence bridge. An inductive relation $\mathsf{Corresponds} : \mathrm{Term} \to \mathrm{Expr}_{\mathsf{Lean}} \to \mathrm{Prop}$ relates a MetaCIC term to a Lean expression structurally, without claiming elaboration soundness. This is weaker than the embedding bridge but more tractable: only the syntactic shape needs to align, not the kernel's behavior.

9235.6.2 Formal Obstacles

Three obstacles prevent immediate implementation.

First, Lean expressions are not first-class BEDC objects. The host kernel's Expr type lives in '`Lean`' meta machinery, including the elaboration monad. Importing Expr as a BEDC inductive would require either using '`Lean.Expr`' from Lean's own module hierarchy, which would couple BEDC to non-mathlib Lean meta, or duplicating Expr as a fresh inductive inside BEDC, which pays for syntactic divergence.

Second, elaboration is not a closed-form function. '`Lean.elab`' involves unification, universe polymorphism, instance search, and reduction steps that are not expressible as a pure CIC inductive predicate. The soundness theorem above is not a target the present MetaCIC framework can state, let alone prove.

Third, soundness would require reflection inside CIC. Even if embed and Corresponds are defined, a soundness theorem connecting represented derivations to host elaboration is itself a metatheoretic statement of the kind blocked by Tarski, as described in section 9235.5.

9235.6.3 Tractable Subgoals

Several subgoals are tractable in isolation.

Subgoal A: pretty-printing. A pure function Term → String renders MetaCIC terms in a human-readable syntax. This requires no host coupling; it is an exercise in pure BEDC.

Subgoal B: a checker. A decidable function check : Ctx → Term → Term → Bool returns `true` exactly when HasType Γ t A is derivable, paired with soundness and completeness theorems against the inductive judgment. This is entirely internal to MetaCIC and a natural metatheory target.

Subgoal C: a reified elaborator. A pure BEDC function returns a result with explicit failure modes when given an ill-formed MetaCIC term, plus an evaluator returning normal forms when typing succeeds. This still does not couple to the host kernel, but it produces an artifact that resembles one.

9235.6.4 Position

The reflection bridge is research-stage and outside the present self-compilation surface. The chapter records its form so that later work can address the subgoals above without re-deriving the question. The bridge is not currently a delivery commitment of BEDC.

9235.7 Shift-Aware Substrate Design

The substrate for `BEDC.MetaCIC` is part of the formal claim, not only a notation choice. The represented calculus needs binders, substitution, beta contraction, typing under contexts, and induction over syntax while preserving the project-wide axiom-free discipline. The chosen substrate is therefore a pure de Bruijn representation with explicit shift and substitution. It is small enough to be defined from first principles, but explicit enough to expose the binder-index invariant needed by beta reduction and typing.

9235.7.1 Substrate Alternatives Surveyed

Several binder substrates are mathematically standard. They do not have the same fit for an axiom-free, self-contained Lean reconstruction.

Literal binders. A literal-binder encoding stores a variable name at each binder and each occurrence. It is close to ordinary mathematical notation: lambda terms carry names, and alpha-renaming is treated as irrelevant. The formal cost is that the syntax quotient by alpha-equivalence becomes part of the substrate. Equality of terms is no longer the constructor equality of an inductive type; it is a quotient-respecting equality. In Lean this pulls the representation toward quotient reasoning or proposition extensionality for the equality of alpha-equivalence classes. That

cost conflicts with the BEDC invariant that the MetaCIC layer remains axiom-free and uses no hidden quotient axiom.

Nominal sets. A nominal substrate treats names, freshness, and finite supports as primitive structure. It can express alpha-equivalence elegantly, but it requires a fresh-name mechanism and finite-support reasoning. Those mechanisms introduce additional infrastructure around finite sets, name permutation, and support transport before the calculus itself appears. For BEDC this is the wrong dependency direction: the calculus substrate should be a closed inductive object, not an object whose well-formedness rests on a separate freshness algebra.

HOAS. A higher-order abstract syntax substrate represents object binders by host binders. This removes many manual substitution lemmas, but it moves binder behavior into the host. BEDC.MetaCIC needs the opposite direction: object terms, object binders, and object reductions must be ordinary data and relations over which BEDC can quantify. A HOAS body has host function type, so its substitution behavior is supplied by the host binder rather than internalized as a represented operation. That makes full self-reflection of the object binder mechanics unavailable at the MetaCIC layer.

Shift-aware de Bruijn. The chosen substrate uses natural-number indices and explicit operations: `shift` raises free indices at or above a cutoff, and `substitute` replaces the variable at a given depth while shifting the substituted value under binders.

Lean4 (definition) `BEDC.MetaCIC.shift`

Lean4 (definition) `BEDC.MetaCIC.substitute`

The term grammar remains an ordinary inductive type, and all binder behavior is visible as recursive functions on that type. No quotient, freshness oracle, or host-level binder semantics is needed.

This representation is less pleasant for informal notation because every binder movement must account for indices. That inconvenience is also its advantage: the object-language bookkeeping becomes part of the checked substrate rather than an implicit convention outside the formal surface.

9235.7.2 Why De Bruijn Alone Is Insufficient

Bare de Bruijn indices solve alpha-equivalence by construction, but they do not by themselves solve binder transport. A variable index is depth-relative: the same numeral denotes a different surrounding binder after descent below a lambda or Pi. Any operation that crosses a binder must record this change in depth.

Substitution without shift loses that invariant. Consider a body under a binder and an argument inserted below another binder. If the argument is copied under the inner binder without raising its free indices, its free variable zero is captured by the inner binder. Conversely, when a substituted variable is removed, variables above the removed depth must decrease by one. The operation therefore has two distinct duties: insert the replacement at the selected depth, and maintain the de Bruijn coordinate system around the removed binder.

In `BEDC.MetaCIC.Syntax`, these duties are encoded directly. For a variable, `substitute` replaces exactly the matching depth, lowers indices above that depth, and leaves lower indices unchanged. For binders, it recurses at depth $d + 1$ and replaces the inserted value by `shift` 0 1 v. This is the explicit form of the depth-relative invariant: when the operation enters a binder, the

object-language environment has one more bound variable, so free variables of the inserted value must be raised away from capture.

The typing rules use the same invariant. The lambda and Pi body premises are checked in a context headed by `shift` 0 1 dom rather than by the unshifted domain. The domain was defined outside the binder body; when it is placed into the body context, its free indices must be read one binder deeper. Thus shift is not an auxiliary convenience. It is the operation that makes the context-extension rule match the de Bruijn meaning of binder descent.

9235.7.3 Mechanized Properties

The substrate is represented by three layers of checked facts.

Closed terms are stable at their boundary. `ClosedAt n t` says that every free variable of t is below n. Shifting at the closure boundary does not change the syntax, and substituting at the closure boundary is inert:

Lean4 ✓ `BEDC.MetaCIC.shift closed`

`BEDC.MetaCIC.substitute_closed` is marked at the reconstruction substrate site. These facts are the base sanity checks for the substrate. They say that operations aimed outside the free-variable support of a term have no effect.

Shift and substitution commute in the closed anchor cases. The one-step cancellation law `substitute_shift_at_eq` records that substituting at the same depth undoes a single shift at that depth; its primary marker is also at the reconstruction substrate site. The closed-source commuting law `shift_substitute_zero_zero_closed` records the binder-head transport shape used by typing preservation:

Lean4 ✓ `BEDC.MetaCIC.shift substitute zero zero closed`

This is the algebraic reason the substituted binder domain can be moved into a shifted context without changing its represented meaning.

Closedness is preserved by substitution and beta reduction. Substitution preserves closure when the replacement is closed at the target boundary and the source term is closed one boundary higher:

Lean4 ✓ `BEDC.MetaCIC.substitute preserves closed at`

Since beta contraction is implemented by substitution, this feeds directly into the closure preservation theorem for one beta step and then for beta-star:

↪ variant `BEDC.MetaCIC.betaStep preserves closed`

↪ variant `BEDC.MetaCIC.betaStarStep preserves closed`

Typing preservation exposes the same binder transport. The typing surface contains constructor-local substitution results for Pi, lambda, and application terms, together with the main case analysis over the represented syntax. The broad term-induction surface states that, under the closedness and shape hypotheses required by the fragment, typing is preserved after substitution:

Lean4 ✓ `BEDC.MetaCIC.substitute preserves typing via term induction`

The subject-reduction assembly then uses substitution preservation as an explicit hypothesis and proves that a represented beta step preserves the same represented type. The main subject-reduction theorem is marked at the case-level metatheory site in this chapter.

9235.7.4 Open Algebraic Gap

The substrate deliberately does not assume that every familiar textbook substitution law transfers in its most direct form. A naive composition law for zero-depth substitution is false for the represented operations.

Take $d = 0$, $v = \text{sort}$, $u = \text{sort}$, and $t = \text{var } 1$ in the naive law

$$\text{substitute } d\ v\,(\text{substitute } d\ u\ t) = \text{substitute } d\,(\text{substitute } d\ v\ u)\ t.$$

The left side first lowers var 1 to var 0 and then replaces it by sort. The right side simplifies substitute 0 sort sort to sort and then substitutes at depth zero in var 1, which lowers to var 0. Thus the left side is sort and the right side is var 0.

The checked counterexample in the Lean substrate records the same obstruction using an unclosed zero-depth anchor. With

$$\begin{aligned} s &= \text{var } 0, \\ a &= \text{sort}, \\ t &= \text{var } 1, \end{aligned}$$

the checked counterexample is

$$\text{substitute } 0\ s\,(\text{substitute } 0\ a\ t) \neq \text{substitute } 0\,(\text{substitute } 0\ s\ a)\,(\text{substitute } 1\ s\ t).$$

Lean4 ✓ `BEDC.MetaCIC.substitute substitute zero zero unclosed counterexample`

Here the left side is var 0, while the right side is sort. The point is not that substitution composition is unavailable in all forms. The point is that the exact law must account for closure, shifting, and binder depth. BEDC therefore derives the composition shapes it uses, instead of importing a nominal-looking lemma whose hypotheses do not match this substrate.

9235.7.5 Comparison to the Host CIC

Lean 4's kernel and elaborator expose a richer implementation environment than the MetaCIC fragment. The host surface accepts named binders in user syntax, elaborates them through local constants and internal binder representations, and manages levels, metavariables, definitional unfolding, and kernel conversion. BEDC.MetaCIC does not mirror that implementation.

The MetaCIC substrate is intentionally smaller. It has one sort constructor, variables, application, lambda, Pi, beta contraction, and a shift-aware typing relation over explicit contexts. Names are absent from the object syntax, and there is no attempt to reproduce Lean's elaboration pipeline or the exact locally nameless machinery used by host internals.

This separation keeps the claim precise. The host kernel checks the Lean files that define the MetaCIC syntax and prove its lemmas. The object calculus inside `BEDC.MetaCIC` is a represented fragment with its own explicit binder mechanics. Its substrate is not a reimplementation of the host kernel; it is a small inductive calculus whose shift and substitution rules can be inspected, proved about, and audited inside the project.

9235.8 MetaCIC Confluence Status

The confluence surface for `BEDC.MetaCIC` is intentionally split into three layers. The first layer is the inductive reduction interface: one-step beta reduction, its reflexive-transitive closure, and

parallel beta reduction. The second layer contains shape and join lemmas for terms whose source shape prevents a real beta fork. The third layer records the component-wise diamond principles available for application, lambda, and Pi terms, together with the case distinctions that remain outside the checked surface.

This section records exactly what is represented in Lean and what is still a mathematical obligation for a full Church-Rosser theorem over the represented beta system. The statement is deliberately local to the object calculus in `BEDC.MetaCIC`: it does not appeal to Lean kernel conversion and does not import a confluence theorem from the host calculus.

9235.8.1 Setting

The primitive one-step relation is `BetaStep`, defined in `BEDC.MetaCIC.Beta`. Its constructors are the represented beta contraction and the congruence rules under application, lambda body, lambda domain, Pi codomain, and Pi domain:

$$(\lambda d.\, b)\ a \longrightarrow_\beta b[0 := a].$$

`BEDC.MetaCIC.BetaStep` is the checked name for this interface.

The reflexive-transitive closure is `BetaStarStep`. It has only reflexivity and left-consing by one `BetaStep`. The confluence predicate `BetaStarConfluent` is the ordinary joinability condition for two `BetaStarStep` paths with the same source:

$$\text{BetaStarConfluent} \quad \equiv \quad \forall t, u_1, u_2.\ t \longrightarrow_\beta^* u_1 \to t \longrightarrow_\beta^* u_2 \to \exists v.\ u_1 \longrightarrow_\beta^* v \wedge u_2 \longrightarrow_\beta^* v.$$

`BEDC.MetaCIC.BetaStarStep` and `BEDC.MetaCIC.BetaStarConfluent` are the checked names for these two interfaces.

The parallel relation `BetaParallel` is the standard proof vehicle for diamond arguments. It reduces independent subterms in one represented parallel step and also contracts an application whose function side is already a lambda after a parallel step. The associated predicate `BetaParallelDiamond` asks for a one-step parallel join:

$$\text{BetaParallelDiamond} \quad \equiv \quad \forall t, u_1, u_2.\ t \Rightarrow u_1 \to t \Rightarrow u_2 \to \exists v.\ u_1 \Rightarrow v \wedge u_2 \Rightarrow v.$$

`BEDC.MetaCIC.BetaParallel` and `BEDC.MetaCIC.BetaParallelDiamond` are the checked names for these two interfaces.

The bridge between the two relations is already mechanized in the direction needed for a Tait-Martin-Lof style proof: one-step beta embeds into parallel beta, and a parallel step is simulated by beta-star. `BEDC.MetaCIC.betaStep_to_parallel` and `BEDC.MetaCIC.betaParallel_to_betaStar` are the checked bridge lemmas. Thus, a checked full parallel diamond would be enough substrate for a beta-star Church-Rosser theorem, provided the standard multi-step lifting is also assembled inside the same object calculus.

9235.8.2 Atom-Shape Diamond

The atom fragment consists of `Term.sort` and variables. These terms have no beta redex at the root and no subterm position in which a congruence constructor can act. For one-step beta, this is recorded by impossibility lemmas:

```
↪ variant  BEDC.MetaCIC.betaStep sort absurd
↪ variant  BEDC.MetaCIC.betaStep var absurd
```

Consequently, beta-star paths out of atoms are forced to be reflexive. The target uniqueness lemmas state that a beta-star target of a sort is the same sort, and a beta-star target of a variable is the same variable:

```
↪ variant BEDC.MetaCIC.betaStarStep sort unique target
↪ variant BEDC.MetaCIC.betaStarStep var unique target
```

The join lemmas are therefore immediate. Two beta-star paths out of `Term.sort` join at `Term.sort`; two beta-star paths out of `Term.var i` join at `Term.var i`. `BEDC.MetaCIC.betaStarStep_diamond_s` and `BEDC.MetaCIC.betaStarStep_diamond_var` are the checked join theorems.

The same fact is also available on the parallel side. Parallel reduction from an atom has a unique target, so the two branches of a parallel fork have the source atom itself as their common reduct: `BEDC.MetaCIC.betaParallel_sort_diamond` and `BEDC.MetaCIC.betaParallel_var_diamond` are the corresponding parallel join theorems.

This is the precise sense in which atom confluence is closed in `BEDC.MetaCIC`. There is no redex that can make the two branches choose different residual structure. The proof is shape analysis over the constructors of the represented reduction relation, not an appeal to normalization or typing.

9235.8.3 Application, Lambda, and Pi Shapes

For compound terms, BEDC has mechanized important shape and component lemmas, but not the full diamond theorem over all application, lambda, and Pi forks. The checked component lemmas say that, if corresponding subcomponents already have parallel joins, then the compound terms have a parallel join: `BEDC.MetaCIC.betaParallel_app_diamond_of_components`, `BEDC.MetaCIC.betaParallel_lam_diamond_of_components`, and `BEDC.MetaCIC.betaParallel_pi_diamond_of`

For lambda and Pi sources, the checked shape diamond lemmas reduce the compound fork to diamond obligations for the domain and body or codomain:

```
Lean4 ✓ BEDC.MetaCIC.betaParallel lam shape diamond
Lean4 ✓ BEDC.MetaCIC.betaParallel pi shape diamond
```

These lemmas do not prove the recursive premises. They are local assembly principles: once the domain and body joins are supplied, the outer constructor is joined by congruence.

Applications are where the complete proof becomes more delicate. The checked surface contains a full shape inversion for parallel reduction from an application:

```
Lean4 ✓ BEDC.MetaCIC.betaParallel app full inv
```

It separates two target forms. Either the target is another application whose function and argument are parallel reducts of the source components, or the target is a beta contractum obtained after the function side reduces in parallel to a lambda.

The full application diamond must account for four fork shapes.

Congruence against congruence. Both branches keep the application shape:

$$f\ a \Rightarrow f_1\ a_1,$$
$$f\ a \Rightarrow f_2\ a_2.$$

This case is exactly the component-wise argument: join f_1 with f_2, join a_1 with a_2, and rebuild the application.

Congruence against beta. One branch keeps application shape while the other branch contracts after the function side exposes a lambda:

$$f\ a \Rightarrow f_1\ a_1,$$
$$f\ a \Rightarrow b_2[0 := a_2].$$

The missing obligation is a residual statement: the application branch must be shown to reduce toward a shape compatible with the contractum branch, and the contracted body must commute with the residual reductions of the argument.

Beta against congruence. This is the symmetric case. The source branch that contracts first produces a substitution instance, while the other branch keeps the application wrapper. The join must show that the wrapper branch can expose a compatible lambda and then contract to the same residual substitution target.

Beta against beta. Both branches expose lambda structure and contract:

$$f\ a \Rightarrow b_1[0 := a_1],$$
$$f\ a \Rightarrow b_2[0 := a_2].$$

The join depends on a simultaneous residual argument for the two lambda bodies and the two arguments, plus the substitution-commutation law that connects parallel residuals before and after substituting the argument into the body.

Lambda and Pi terms avoid root beta contraction, but their complete diamond proof still requires recursive joins for all binder subcomponents. For lambda, the cases are:

Domain against domain. Both branches reduce the domain and keep the body branch compatible. The join is rebuilt by the lambda congruence constructor.

Body against body. Both branches reduce the body. The join is rebuilt under the binder after the body residuals are joined.

Cross branch. One branch reduces the domain and the other reduces the body. The diamond must commute these independent moves and rebuild the lambda over the joined domain and body. The checked `betaParallel_lam_shape_diamond` lemma packages this once the recursive component joins are supplied.

Pi terms have the same pattern with domain and codomain in place of lambda domain and body. The checked `betaParallel_pi_shape_diamond` lemma again performs the outer constructor assembly, but it does not supply the recursive induction principle for the subcomponents.

9235.8.4 Strategy Notes

The standard route to Church-Rosser for beta reduction is the Tait-Martin-Lof parallel-reduction method. One proves a diamond property for parallel reduction, shows that ordinary beta steps embed into parallel reduction, shows that parallel steps are included in beta-star, and then lifts the parallel diamond to confluence of beta-star.

BEDC has the first-order interface and many constructor-local lemmas needed by that route. What is absent is the complete induction that covers every constructor of `BetaParallel` with the

correct residual term in the application beta cases. In informal notation the residual target is natural: parallel-reduce the body and argument, then substitute the residual argument into the residual body. In the BEDC substrate, that sentence expands into shift-aware de Bruijn algebra.

The hard point is the congruence-beta family of application cases. A branch may first reduce the function position to a lambda while the other branch contracts after a different exposure of lambda structure. Joining these branches requires a theorem saying that substitution commutes with the parallel residuals in exactly the represented form:

$$b \Rightarrow b' \wedge a \Rightarrow a' \quad \Longrightarrow \quad b[0 := a] \Rightarrow^* b'[0 := a'].$$

The displayed formula is schematic. In the actual substrate, descent under a binder changes the cutoff and shifts the inserted term. The open algebraic gap therefore is not merely the absence of a textbook substitution lemma; it is the absence of the exact shift-aware commutation theorem that matches `BEDC.MetaCIC.substitute`. subsection 9235.7.4 shows why a naive zero-depth composition law is false for unclosed anchors, and section 9235.7 explains the binder transport invariant that any usable law must respect.

This is also why the atom fragment is not representative of the general case. Atoms need no residual calculus, no binder descent, and no substitution transport. Application beta cases need all three.

9235.8.5 BEDC Scope

Within the closed-atom fragment, BEDC already has the confluence behavior it uses. Sorts and closed variables are normal forms for represented beta reduction, and forks out of those sources are forced to join at the source itself. This covers the atomic normal-form statements used in the self-compilation discussion: `BEDC.MetaCIC.closed_atom_normal_form`.

The scope changes once reducible closed terms are admitted. A closed term can contain an application redex, and then a fork may choose between reducing inside subcomponents and contracting the exposed lambda. BEDC has checked closure preservation for beta steps and beta-star, and it has checked subject-reduction under the stated substitution-preservation interface, but those facts are not a full diamond theorem: `BEDC.MetaCIC.betaStep_preserves_closed`, `BEDC.MetaCIC.betaStarStep_preserves_closed`, and `BEDC.MetaCIC.subject_reduction`.

The resulting boundary is sharp. Atom sources are closed under the diamond argument because their reduction relation is trivial. Reducible closed terms remain within the represented closed world under reduction, but full joinability for all their beta forks requires the application residual proof and the shift-aware substitution commutation lemmas described above.

9235.9 Normalization Status for the MetaCIC Fragment

The normalization surface of `BEDC.MetaCIC` has two distinct layers. The first layer is operational: reduction is represented by a first-principles syntax, a beta-step relation, and finite reduction chains. This layer supports bounded computation and checked closure preservation. The second layer is the textbook strong-normalization theorem for the represented dependent-function calculus. BEDC does not prove that theorem. The difference matters because the bounded layer is an effective, fuel-indexed operational account, while strong normalization is a global theorem over all well-typed reduction sequences.

9235.9.1 Bounded Normalizer

A bounded normalizer for the represented calculus has the shape

$$\texttt{BEDC.MetaCIC.normalizeBounded} : \mathrm{Nat} \to \texttt{BEDC.MetaCIC.Term} \to \texttt{BEDC.MetaCIC.Term}.$$

Its intended reading is fuel driven. At fuel 0 it returns the input term. At fuel $k+1$ it attempts one head reduction step and then continues with fuel k on the reduct; if no head step is available, it returns the current term. Termination of this procedure is inherited from structural recursion on the natural-number fuel, not from any theorem that the represented calculus is strongly normalizing.

This bounded interface is therefore not a strong-normalization certificate. It says that every chosen run of the evaluator has a finite host computation because the host recursion argument decreases. It does not say that every well-typed represented term admits no infinite beta-reduction path, and it does not identify the returned term as a unique normal form for arbitrary fuel. A run may stop because a normal form has been reached, or because the fuel budget has been exhausted.

The available checked metatheory around this operational layer is closure preservation. If a fuel-driven run is decomposed into zero or more `BetaStep` transitions, each transition preserves the closedness predicate, and induction on the finite step trace preserves closedness at the end of the run. The proof is not a termination argument. It is an invariant argument over the finite trace that the bounded computation actually takes.

9235.9.2 Closure Preservation Under Reduction

The mechanized closure theorem for one-step beta reduction is

$$\texttt{betaStep_preserves_closed} : \texttt{ClosedAt}\ n\ t \to \texttt{BetaStep}\ t\ t' \to \texttt{ClosedAt}\ n\ t'.$$

The proof lives in `lean4/BEDC/MetaCIC/ClosurePreservation.lean`. Its beta-contraction case uses the closure-preserving substitution theorem. Its congruence cases peel the corresponding `ClosedAt` constructor and apply the induction hypothesis to the reduced component. Thus closedness is not treated as a syntactic side condition on whole terms only; it is propagated through application, lambda, and Pi constructors.

The finite-chain theorem is

$$\texttt{betaStarStep_preserves_closed} : \texttt{ClosedAt}\ n\ t \to \texttt{BetaStarStep}\ t\ t' \to \texttt{ClosedAt}\ n\ t'.$$

It is induction on the represented reflexive-transitive closure. The reflexive case returns the original closedness proof. The step case applies `betaStep_preserves_closed` to the first transition and then invokes the induction hypothesis on the remaining chain.

```
↪ variant  BEDC.MetaCIC.betaStep preserves closed
↪ variant  BEDC.MetaCIC.betaStarStep preserves closed
```

These two checked targets are the normalizer-relevant safety results available inside BEDC. They justify the following operational statement: for any finite reduction trace produced by a bounded evaluator, closed input remains closed at every subsequent represented term. They do not assert progress, uniqueness of normal forms, confluence for all represented terms, or strong normalization.

Theorem 9235.1 (Bounded normalization trace closure)**.** *Let t be a represented MetaCIC term closed at index n. If a bounded evaluator run displays a finite beta trace*

$$t \to^* t'$$

from t to t', interpreted as a `BEDC.MetaCIC.BetaStarStep` *witness, then t' is closed at the same index n. The statement does not assert progress, fuel sufficiency, unique normal form, confluence, or strong normalization.*

Proof. Read the evaluator output only through the displayed finite `BetaStarStep` trace. The initial hypothesis supplies `ClosedAt` n t, and the trace supplies the finite chain from t to t'.

Apply `betaStarStep_preserves_closed`. Its reflexive case returns the original closedness proof, and its step case uses `betaStep_preserves_closed` before applying the induction hypothesis to the remaining finite trace.

No claim about the evaluator's fuel budget or global reduction behavior enters the argument. The theorem records only preservation of closedness along the finite trace that is actually displayed. □

9235.9.3 Strong Normalization

Strong normalization for the represented calculus would state that every well-typed term in the intended admissible fragment has no infinite `BetaStep` chain. The standard proof route for a dependent-function calculus is a logical-relations or reducibility-candidates argument. Such a proof requires a predicate of admissible represented types and a semantic interpretation that is stable under the type formers of the calculus.

BEDC does not currently carry that infrastructure. In particular, the current substrate lacks an inductive predicate of admissible types strong enough to support reducibility candidates. It also lacks preservation hypotheses in the form needed under Pi, lambda, and application constructors. The available subject-reduction surface is intentionally local: it records beta and congruence preservation facts, plus hypothesis-based interfaces for domain and argument stability. Those interfaces are useful for finite local metatheory, but they are not a logical-relations model.

A strong-normalization proof would therefore need at least the following ingredients:

- an inductive definition of the admissible type fragment;
- a reducibility interpretation for sort, Pi, lambda, and application shapes;
- closure of the interpretation under beta expansion and beta contraction;
- preservation lemmas whose hypotheses are stable under the relevant binder constructors;
- an induction principle linking represented typing derivations to the reducibility interpretation.

None of these is a consequence of having a fuel-indexed evaluator. Fuel gives an executable finite approximation. Strong normalization is a proof that no unbounded reduction path exists for well-typed represented terms in the chosen fragment.

9235.9.4 Practical Impact

The practical BEDC examples sit far below the strong-normalization boundary. The closed atom results prove that sort and closed variable atoms have no beta successor, and the typed closed-atom theorem packages this as a normal-form fact for the atomic cases.

↪variant BEDC.MetaCIC.closed atom normal form

The `TypedExamples` gallery is also operationally tame. Its witnesses are built from sort, Pi, lambda, variable, and application constructors in small closed shapes. The identity and projection examples have lambda or Pi heads until they are applied; the sort-headed and variable-headed components are already beta-inert; and the application examples expose the ordinary single beta contraction at the represented head when the function is a lambda. For these examples, a bounded evaluator gives an effective semantics: with enough fuel, the finite computation reaches the expected beta-normal representative and stops because there is no next reduction step along that chosen strategy.

This is the operational content needed by the paper's examples. The examples do not require a theorem that all well-typed represented terms strongly normalize. They require a checked syntax, checked typing witnesses, checked beta-step rules, and checked preservation of closedness along the finite reduction traces under discussion.

9235.9.5 Comparison with the Host Calculus

Lean 4's host kernel is trusted as the checker for this development. Its metatheory includes the normalization and consistency facts needed for the host's own dependent type theory at the meta level of the project. BEDC does not import those facts as axioms about `BEDC.MetaCIC`. The represented calculus is a first-principles object language built with inductive syntax, inductive typing, and inductive reduction relations. Its metatheory must be proved over those represented objects.

This is the same boundary recorded in section 9235.4. Representational adequacy for the finite gallery says that selected host-fragment terms have corresponding represented terms and typing derivations. It does not transfer the host kernel's global strong-normalization theorem into a checked theorem about `BEDC.MetaCIC`. Such a transfer would require a formal bridge whose statement and proof are not present here.

The normalization status is consequently precise. BEDC has a finite operational reduction layer and mechanized closure preservation for one-step and finite-chain beta reduction. It has atomic normal-form facts and concrete closed examples whose reductions are finite and explicit. It does not claim a strong-normalization theorem for the represented calculus.

9235.9.6 Status Summary

Topic	BEDC status	Exact reading
Fuel-bounded normalization	operational	finite host computation controlled by a natural-number fuel argument
Closure under one beta step	checked	closedness is preserved by each represented `BetaStep` transition
Closure under finite beta chains	checked	closedness is preserved by induction over `BetaStarStep` traces
Atomic normal forms	checked	sort and closed variable atoms have no beta successor
Typed examples	finite gallery	closed witnesses reduce only through explicit, finite beta traces
Strong normalization	open	no theorem rules out all infinite beta paths for all admissible typed terms
Host-kernel transfer	open	host normalization is not imported as a theorem about represented MetaCIC

The table is deliberately two-axis. A checked closure theorem is a Lean-side verification fact about a represented relation. An open strong-normalization entry is a theory-side boundary about the represented calculus as a whole. The fuel-bounded operational layer is useful precisely because it gives finite computation without pretending to close the global theorem.

9235.10 MetaCIC Metatheory Roadmap

This section gives a consolidated reading map for the MetaCIC metatheory surface. The substrate is `BEDC.MetaCIC`: a first-principles represented dependent-function fragment used by the self-compilation chapter as its formal metatheory base. The Lean development for this surface is mathlib-free, carries no project axioms, and contains no `sorry` placeholders. The paper side reports only the properties that are represented or proved for this object calculus; it does not import host-kernel metatheory as a theorem about the represented terms.

9235.10.1 Setting

`BEDC.MetaCIC` contains the syntax, typing judgment, substitution operation, beta relation, beta-star closure, parallel beta relation, closure predicate, and finite galleries used by the self-compilation discussion. The objects under discussion are represented terms, not Lean elaborator syntax. Their binders are de Bruijn indices, and binder transport is handled by the explicit `shift` and `substitute` functions.

The surrounding siblings have different roles. The representational-adequacy section explains how selected host-fragment terms are mirrored by checked MetaCIC witnesses. The mechanization dashboard enumerates proved targets, statement-level interfaces, and open textbook theorems. The substrate-design section explains why the de Bruijn shift discipline is part of the claim. The confluence and normalization sections isolate the checked fragments and the remaining global metatheory obligations.

9235.10.2 Mechanized Surface

The following items are available as checked Lean targets or checked finite galleries for the represented calculus.

- Closed atom diamond behavior for beta-star and parallel beta. Atom sources have forced targets, so forks out of `Term.sort` and `Term.var i` join at the source shape.

  ↪ variant `BEDC.MetaCIC.betaStarStep diamond sort`

  ↪ variant `BEDC.MetaCIC.betaStarStep diamond var`

  ↪ variant `BEDC.MetaCIC.betaParallel sort diamond`

  ↪ variant `BEDC.MetaCIC.betaParallel var diamond`

- Closure preservation under one-step beta and beta-star. If a term is closed at a boundary, each represented beta step and each finite beta-star trace keeps it closed at the same boundary.

  ↪ variant `BEDC.MetaCIC.betaStep preserves closed`

  ↪ variant `BEDC.MetaCIC.betaStarStep preserves closed`

- Bounded normalizer safety is a finite-trace safety statement: any concrete beta trace taken by a fuel-indexed run inherits the preceding closure-preservation theorem. It is an operational invariant, not a strong-normalization theorem.

- Representational adequacy is witnessed by checked typed examples for identity, projections, Pi-shaped identity, and function application in the represented dependent-function fragment.

  ↪ variant `BEDC.MetaCIC.carrier identity in sort ctx`

  ↪ variant `BEDC.MetaCIC.first of two`

  ↪ variant `BEDC.MetaCIC.second of two`

  ↪ variant `BEDC.MetaCIC.id on pi sort sort`

  ↪ variant `BEDC.MetaCIC.apply function arg`

- The `BHist` substrate embedding has checked closedness and injectivity witnesses. The map packages a history object as a MetaCIC term while preserving enough structure to recover the original history from equality of encoded terms.

  ↪ variant `BEDC.MetaCIC.BHistSubstrate.bhistToTerm closed`

  ↪ variant `BEDC.MetaCIC.BHistSubstrate.bhistToTerm injective`

9235.10.3 Open Statements

The following entries are mathematical targets for the represented calculus, but they are not checked theorems in the MetaCIC surface.

Statement	Exact boundary
Full `BetaParallel` diamond	Atom cases, component assemblers, lambda and Pi shape assemblers, and application inversion are checked; the complete app, lambda, and Pi induction over all fork shapes is not packaged as a theorem.
Strong normalization	The bounded evaluator is fuel-indexed and total as a host computation, but no theorem rules out all infinite represented beta paths for every admissible well-typed term.
Subject reduction without hypotheses	The assembled theorem is hypothesis-based. Its beta, application-argument, lambda-domain, and Pi-domain stability assumptions isolate the substitution and domain transport facts needed by the full statement.
Naive substitution composition	The direct zero-depth law is false for unclosed anchors. The substrate needs closure- and shift-aware composition statements rather than a nominal-looking formula.

9235.10.4 Why These Gaps Are Specific

The missing confluence cases are concentrated in the interaction between application beta and congruence. A branch may keep an application wrapper while another branch exposes a lambda and contracts. Joining those residuals requires a statement saying that represented substitution commutes with parallel residuals after binder descent. In the chosen substrate, binder descent changes the cutoff and shifts the inserted term, so the needed theorem is not the ordinary informal substitution slogan.

The same shift-aware issue explains the subject-reduction boundary. The three stable interfaces used by the subject-reduction theorem are substitution-level and domain-transport properties. They are stated explicitly because the project has not collapsed them into a global substitution lemma for the whole represented calculus.

Strong normalization has a different shape. Its standard proof route uses logical relations or reducibility candidates. That requires an inductive predicate of admissible represented types, a semantic interpretation of those types, and closure of the interpretation under the represented constructors. The MetaCIC layer has syntax, typing, reduction, and finite examples; it does not yet carry that reducibility framework.

The false substitution-composition law in the substrate-design section is the sanity check for this roadmap. It shows that the open algebra is not a missing line of routine rewriting. The correct statement must mention the closure and shift hypotheses that make the de Bruijn coordinates stable.

9235.10.5 Reading Guide

Reader question	Next section	What it supplies
What is represented?	section 9235.4	Finite typed witnesses for the host-fragment identity, projection, Pi, and application patterns.
What is checked?	section 9235.5	A dashboard separating encoded definitions, checked theorems, statement-level interfaces, and open textbook targets.
Why this binder substrate?	section 9235.7	The de Bruijn shift discipline, closure lemmas, and the counterexample to a naive substitution-composition law.
How far does confluence go?	section 9235.8	Atom diamonds, component and shape assemblers, application inversion, and the residual cases needed for full parallel confluence.
How far does normalization go?	section 9235.9	Fuel-bounded computation, closure preservation along finite traces, atomic normal forms, and the boundary of strong normalization.

The dependency order is therefore:

- adequacy witnesses depend on the represented syntax and typing rules;
- closure preservation depends on the shift-aware substitution substrate;
- bounded normalizer safety depends on closure preservation for finite beta traces;
- full subject reduction depends on the stable substitution and domain transport interfaces;
- full confluence depends on residual substitution commutation for application beta forks;
- strong normalization depends on a reducibility framework for the admissible represented type fragment.

9235.11 BHist Substrate Bridge

The binary-history substrate is the smallest data layer that BEDC carries through its finite certificates. In the kernel layer it is not a derived numeric notation, a string encoding, or a host-side serialization format. It is the freely generated history type with one empty history and two visible extension constructors.

9235.11.1 What BHist Is

The core history type is defined in `lean4/BEDC/FKernel/Hist.lean`. Its constructor shape is

$$\mathsf{BHist} ::= \mathsf{Empty} \mid \mathsf{e0}(\mathsf{BHist}) \mid \mathsf{e1}(\mathsf{BHist}).$$

The manuscript writes the visible constructors as $b0$ and $b1$ when the emphasis is on binary digits, and as $\mathsf{E0}(-)$ and $\mathsf{E1}(-)$ when the emphasis is on generated history structure. The Lean constructors are `BHist.Empty`, `BHist.e0`, and `BHist.e1`. The important invariant is the same in every notation: a history is a finite binary digit sequence, built by closing the empty sequence under the two single-bit extensions.

This makes BHist a primitive carrier for BEDC's internal evidence. The relation hsame on histories is definitional equality in the kernel layer, and the visible no-confusion theorems for empty, $b0$, and $b1$ are proved by induction over that generated type. Thus the object used by package rows, continuations, signatures, and name certificates is not an external byte array. It is an inductive value whose constructors are visible to the proof language.

9235.11.2 Why Bridge BHist to Term

The MetaCIC reconstruction has a separate object language, `BEDC.MetaCIC.Term`. That language represents the syntax of a small dependent-function calculus: variables, applications, lambdas, Pi types, and sort. Self-compilation needs a way for the raw BEDC carrier data to appear inside that object language. Otherwise the substrate and the represented calculus would remain adjacent artefacts rather than a single typed internal surface.

The bridge supplied by `BEDC.MetaCIC.BHistSubstrate` serves exactly this role. It embeds host-side histories into represented terms. The input is a Lean value of the BEDC history type. The output is a MetaCIC term that can be placed under the ordinary syntactic and metatheoretic predicates of the represented calculus.

The point is not to claim that every MetaCIC term denotes a history. The point is more precise: every BEDC history has a canonical represented value. This turns the finite binary-history carrier into a Church-style data structure inside the MetaCIC substrate, so that raw BEDC rows can be mentioned by the same object calculus that carries the self-compilation surface.

9235.11.3 The Mechanized Embedding

The embedding is the function

$$\texttt{BEDC.MetaCIC.BHistSubstrate.bhistToTerm} : \mathsf{BHist} \to \texttt{BEDC.MetaCIC.Term}.$$

Lean4 (definition) `BEDC.MetaCIC.BHistSubstrate.bhistToTerm`

In Lean the local name of the source type is `BHistIdx`, an abbreviation for `BEDC.FKernel.Hist.BHist`. The abbreviation records that the substrate module treats histories as the index values being encoded into MetaCIC terms; it does not create a separate history type.

The encoding has the shape of a three-argument Church case analysis. The outer term binds three represented arguments. The payload uses variable 2 for the empty-history case, variable 1 for the $b0$ branch, and variable 0 for the $b1$ branch. A visible bit extension is represented by applying the corresponding branch variable to the recursively encoded tail, protected under the same three-binder interface.

For the empty history the payload is the represented variable for the empty case:

$$\mathsf{payload}(\mathsf{Empty}) = \mathrm{var}\ 2.$$

For a $b0$ extension the payload applies the $b0$ branch to the recursively encoded tail:

$$\mathsf{payload}(\mathsf{e0}(h)) = \text{app (var 1) } (\lambda_0.\lambda_1.\lambda_2.\ \mathsf{payload}(h)).$$

For a $b1$ extension the payload is analogous, using the other branch variable:

$$\mathsf{payload}(\mathsf{e1}(h)) = \text{app (var 0) } (\lambda_0.\lambda_1.\lambda_2.\ \mathsf{payload}(h)).$$

The full embedding wraps this payload in the three lambdas that bind the empty, $b0$, and $b1$ eliminator branches. In de Bruijn notation the branch variables are local to that wrapper, so the represented value is closed at depth 0.

The mechanized closure theorem is

$$\texttt{bhistToTerm_closed}\ (h : \mathsf{BHist}) : \texttt{ClosedAt}\ 0\ (\texttt{bhistToTerm}\ h).$$

Lean4 ✓ `BEDC.MetaCIC.BHistSubstrate.bhistToTerm closed`

This is the primary checked fact for the bridge. It is the property needed by the self-compilation surface: a raw finite history becomes a closed represented term, hence it can enter the closed-term side of the MetaCIC metatheory without free-variable debt.

The same module also proves injectivity of the encoding:

$$\texttt{bhistToTerm_injective} : \texttt{bhistToTerm}\ h = \texttt{bhistToTerm}\ k \to h = k.$$

↪ variant `BEDC.MetaCIC.BHistSubstrate.bhistToTerm injective`

Injectivity is a useful shape fact: distinct generated histories do not collapse under the represented encoding. It is not used here as the canonical closure site, but it records that the Church-style representation preserves the visible generated structure.

9235.11.4 What the Bridge Gives

The immediate result is a typed-substrate design point. BEDC's finite binary histories can appear as ordinary represented data in the MetaCIC syntax layer. The bridge does not need a host evaluator, a parser, or a binary-string library. It is a structural map from the inductive history carrier into the inductive term carrier.

Because the output is closed, all closed-term invariants apply to the image of the bridge. A represented history can be placed in contexts where the MetaCIC development reasons about closedness, beta-step preservation, finite reduction traces, confluence statements, and bounded normalization behavior. Those metatheorems remain theorems about `Term`; the bridge supplies a large family of concrete closed `Term` inputs coming from the BEDC history substrate.

This is the relevant self-compilation step. Host-side certificate rows are generated as finite histories. The MetaCIC substrate needs closed represented values for such rows. The embedding gives that interface without changing the definition of BHist and without adding a new primitive constructor to `Term`.

9235.11.5 Unproved Boundaries

Three boundaries remain outside the checked bridge.

First, no surjectivity theorem is claimed. The module does not characterize which closed normal forms of `Term` are exactly in the image of `bhistToTerm`. Such a theorem would need a normal-form predicate and a recognizer theorem connecting the Church-style shape to the source history.

Second, no inverse decoding theorem is used by the paper. The module contains partial decoding functions from represented terms back to optional histories, but this section does not claim a full inverse theorem for all closed represented terms, nor a completeness theorem over beta-equivalent normal forms.

Third, no commutation theorem is mechanized between host-side history operations and represented MetaCIC operations. The bridge preserves the generated shape and closedness of histories, but it does not prove that every host operation on histories has a corresponding represented program whose execution commutes with `bhistToTerm`.

These boundaries keep the statement exact. The bridge establishes a closed, injective, Church-style embedding from the BEDC history carrier into the represented calculus. It does not identify the whole represented-history fragment, does not certify total decoding, and does not internalize the history-operation algebra as MetaCIC programs.

Lemma 9235.2 (Represented BHist payload decoder left inverse)**.** *For every source history h : BHist, the payload-level partial decoder returns the same history after payload encoding:*

$$\texttt{bhistFromPayloadTerm?}(\texttt{bhistPayloadToTerm}(h)) = \mathrm{some}(h).$$

Proof. Proceed by induction on the generated history h. If h is empty, the payload encoding is the represented variable for the empty branch, namely var 2. The first decoder clause sends that variable to some(e), which is exactly some(h).

Suppose $h = \mathsf{E0}(r)$. The payload encoding is the represented $b0$ branch applied to the triple-lambda wrapper around the payload encoding of r. The matching decoder clause strips this visible $b0$ shape, recursively decodes the inner payload, and repacks the result with $\mathsf{E0}$. By the induction hypothesis, the recursive decode of the inner payload is some(r). Therefore the outer clause returns some($\mathsf{E0}(r)$), which is some(h).

Suppose $h = \mathsf{E1}(r)$. The proof is the same branch computation with the represented $b1$ variable. The decoder clause strips the visible $b1$ shape, recursively decodes the inner payload, and repacks the result with $\mathsf{E1}$. The induction hypothesis gives some(r) for the recursive call, hence the outer clause returns some($\mathsf{E1}(r)$) = some(h). □

Theorem 9235.3 (Represented BHist decoder left inverse on encoded histories)**.** *For every source history h : BHist, applying the represented-history partial decoder to the encoded term of h recovers h:*

$$\texttt{bhistFromTerm?}(\texttt{bhistToTerm}(h)) = \mathrm{some}(h).$$

Equivalently, the partial decoder is a left inverse of `bhistToTerm` *on the image of the BEDC history substrate.*

Proof. By the embedding description in subsection 9235.11.3, `bhistToTerm` wraps `bhistPayloadToTerm` in the three lambdas that bind the empty, $b0$, and $b1$ branches. The top-level decoder `bhistFromTerm?` has exactly the matching wrapper clause: on a three-lambda represented history it strips the wrapper and calls `bhistFromPayloadTerm?` on the body. The remaining computation is precisely Definition 9235.2, so the result is some(h).

This proves only the image-side inverse. It does not classify all represented terms that the partial decoder accepts and does not assert surjectivity of closed `Term` values onto BHist, matching the boundary stated in subsection 9235.11.5. □

9235.12 Substrate Stack Summary

`BEDC.MetaCIC` is a first-principles substrate for the object calculus used by the self-compilation surface. Its stack starts with a closed inductive syntax, adds de Bruijn mechanics, reduction, typing, and local metatheory, and then exposes concrete examples and BEDC-carrier embeddings. Each layer is a Lean module family with a bounded responsibility. No layer imports mathlib, adds an axiom, or treats a host-kernel theorem as a theorem about the represented object calculus.

9235.12.1 Layered View

Layer	Lean surface	Role in the stack
5	`TypedExamples.*`, `BHistSubstrate`	Concrete typed terms and embeddings from BEDC carrier data into closed represented terms.
4	`Confluence.*`, `SubjectReduction.*`, `Normalization`	Local metatheory: atom diamonds, hypothesis-based subject reduction, and fuel-bounded normalization facts.
3	`Typing.Core`, `Typing.SubstitutionSurface`, `Typing.ClosedBinderDomains`	The represented typing judgment and the guard surfaces needed by binder-aware substitution.
2	`Beta`, `ClosurePreservation`	One-step beta, finite beta chains, parallel beta, and closure preservation under represented reduction.
1	`Substitution`, `ClosedTerm`, `ClosedTerm.Helpers`	Shift, substitution, closedness at a de Bruijn boundary, and syntactic helper facts.
0	`Syntax`	The term grammar: sort, variable, lambda, Pi, and application.

The arrows in this table point upward. Syntax is the object over which every other layer recurses. Substrate mechanics define the admissible movement of de Bruijn indices. Reduction consumes those mechanics in beta contraction. Typing states the object judgment over the same terms and contexts. Metatheory proves local preservation and joining facts over the represented relations. Examples and embeddings give concrete closed inhabitants of the same substrate.

9235.12.2 Layer 0: Term Syntax

The base layer is `BEDC.MetaCIC.Syntax`. It defines `Term` as a closed inductive object with five constructors: `sort`, `var`, `lam`, `pi`, and `app`. Binders are de-named. Variable occurrence is represented by a natural-number de Bruijn index, so alpha-equivalent presentations have the same constructor shape once written in this substrate.

This layer deliberately contains no nominal freshness algebra, no quotient by alpha-equivalence, and no host-level binder function. The cost is explicit index arithmetic. The gain is that all binder movement is ordinary recursive data processing over `Term`, visible to the Lean kernel and to the paper-Lean audit.

9235.12.3 Layer 1: Substrate Mechanics

The mechanics layer is split across `BEDC.MetaCIC.Substitution`, `BEDC.MetaCIC.ClosedTerm`, and `BEDC.MetaCIC.ClosedTerm.Helpers`. The two central operations are `shift` and `substitute`. Shift raises free indices at or above a cutoff. Substitution replaces the variable at a selected depth, lowers indices above the removed variable, and shifts the inserted term when the operation crosses a binder.

`ClosedAt` records the boundary at which a term has no free variables. The helper layer supplies the constructor-local facts that make this boundary usable under application, lambda, and Pi shapes. These definitions are the substrate's bookkeeping contract: every higher result about beta reduction or typing inherits the same de Bruijn boundary discipline.

9235.12.4 Layer 2: Reduction

Reduction lives in `BEDC.MetaCIC.Beta`. The primitive relation `BetaStep` has a root beta-contraction rule and congruence rules for application heads, application arguments, lambda domains, lambda bodies, Pi domains, and Pi codomains. `BetaStarStep` is the finite reflexive-transitive closure used for finite traces. `BetaParallel` is the parallel relation used by the confluence surface.

`BEDC.MetaCIC.ClosurePreservation` connects reduction back to the mechanics layer. A beta contraction is implemented by substitution, so closure preservation for reduction depends on the closure-preserving substitution facts from Layer 1. This is the first place where the stack forces the algebra of binders to match the operational semantics.

9235.12.5 Layer 3: Typing

Typing is centered on `BEDC.MetaCIC.Typing.Core`. Its main predicate is `HasType`, an inductive relation between contexts, represented terms, and represented types. The formation rules cover sorts, variables, Pi types, lambdas, and applications over the explicit-context de Bruijn substrate.

The guard surfaces live in `BEDC.MetaCIC.Typing.SubstitutionSurface` and `BEDC.MetaCIC.Typing.ClosedB` They isolate the substitution and binder-domain hypotheses needed by typing preservation arguments. This matters because a domain introduced outside a binder must be read one level deeper inside the body. The typing layer therefore uses the same shift-aware interpretation as the syntax and substitution layers, rather than treating binder domains as inert annotations.

9235.12.6 Layer 4: Metatheory

The confluence surface is in `BEDC.MetaCIC.Confluence.*`. Atom diamonds are mechanized for sort and variable sources, where no real beta fork can occur. The full diamond over all compound beta forks is not asserted. Application forks need residual reasoning that commutes parallel reduction with shift-aware substitution, and that theorem is exactly where the represented substrate remains restrictive.

The subject-reduction surface is in `BEDC.MetaCIC.SubjectReduction.*`. It is hypothesis-based: the beta case and congruence cases are assembled under the substitution-preservation and domain-stability assumptions stated by the typing surface. Thus subject reduction is not obtained by importing a host theorem. It is a theorem over the represented `HasType` and `BetaStep` relations, at the strength supported by the current substrate hypotheses.

`BEDC.MetaCIC.Normalization` supplies a bounded normalizer and atomic normal-form facts. The normalizer terminates because its fuel decreases in the host recursion, not because the repre-

sented calculus has a checked strong normalization theorem. The normalization layer is therefore operational and finite-trace oriented.

9235.12.7 Layer 5: Examples and Embeddings

The example layer is the concrete gallery under `BEDC.MetaCIC.TypedExamples.*`. It contains sort, Pi, identity, application, projection, constant-form, and polymorphic witnesses over the same `HasType` relation used by the metatheory. These examples are not a separate evaluator surface. They are ordinary represented terms with ordinary typing derivations.

`BEDC.MetaCIC.BHistSubstrate` connects the finite BEDC history carrier to the MetaCIC term language. Its embedding sends each generated binary history to a closed represented term. This supplies a bridge from raw BEDC certificate data into the object calculus without adding a primitive history constructor to `Term`.

9235.12.8 Cross-Cutting Invariants

The whole stack is mathlib-free. Its Lean files are built from the Lean 4 standard environment and project-local inductive definitions, functions, and theorems. The project gate rejects `axiom` declarations and maintains the zero-`sorry` discipline for public theorem bodies.

The stricter purity audit also checks transitive dependencies. It rejects `Classical.choice`, `Quot.sound`, and `propext`. Thus the checked MetaCIC theorems are CIC-derived in the relevant project sense: constructive, quotient-free, and not backed by hidden classical or extensional host principles.

The paper markers are an independent audit axis. A Lean-side theorem marker must name an object that exists under `lean4/BEDC/`. Conversely, a marker does not close an informal theorem by itself. The stack is reported on two axes: what the paper claims about the represented calculus, and what Lean has checked for the corresponding definitions and theorems.

9235.12.9 Open Seam

The limiting algebraic point is substitution composition. In the naive zero-depth form, composition is false for the represented operations; the counterexample is recorded in subsection 9235.7.4. The failure is not a peripheral notation issue. It shows that the substrate must account for closure, shifting, and binder depth before a composition theorem can be used safely.

This same constraint reaches the upper layers. Full confluence needs residual substitution lemmas for application beta forks. Subject reduction depends on substitution preservation at the strength stated by the typing guard surface. Strong normalization would need an admissible-type and reducibility infrastructure stable under the same binder mechanics. The stack is therefore coherent from bottom to top: the highest open metatheory is bounded by the lowest shift-aware algebra that the substrate has made available.

9235.13 Typed Examples Gallery

The typed examples gallery is the reader-facing index for closed-term witnesses inside ‘`BEDC.MetaCIC.TypedExampl`
It complements the representational adequacy argument in section 9235.4: the adequacy claim explains why the first-principles substrate is the right target, while this gallery lists the concrete closed terms whose typing or reduction facts have been mechanized on that substrate.

9235.13.1 Why a gallery

'`BEDC.MetaCIC`' is a first-principles substrate. It does not inherit a host-kernel reflection API, a built-in quotation mechanism, or a host-level '`decide`' path for typing judgments. Each displayed typing fact is built by an explicit chain of constructors for the object syntax, object typing relation, and object reduction relation. The gallery is therefore not a convenience catalogue alone: it is the compact map of the mechanized closed-term witnesses that exercise the representational layer.

9235.13.2 Sibling index

Lean sibling	Role
'`Sorts.lean`'	Sort-level and variable lookup typing examples over small contexts.
'`Identity.lean`'	Identity-shaped $\lambda x : T.\ x$ witnesses, dependent identity forms, and simple projections.
'`ConstForms.lean`'	Constant-function forms and their staged applications.
'`AppForms.lean`'	Application-shaped witnesses, including reduced and unreduced forms over empty and small contexts.
'`PiForms.lean`'	Pi-type formation and lambda terms whose types are Pi forms.
'`BetaRedex.lean`'	Beta-redex witnesses and corresponding '`BetaStep`' or '`BetaStarStep`' instances.
'`ChurchGallery.lean`'	Church encodings for Booleans, naturals, pairs, and options.
'`Polymorphic.lean`'	Pi-polymorphic identity, constant, apply, flip, and compose forms.

9235.13.3 Mechanized witnesses

Example	Lean witness	Description
Sorts	↪variant `BEDC.MetaCIC.var zero in sort ctx`	Variable zero in a one-sort context.
Sorts	↪variant `BEDC.MetaCIC.var one in double sort ctx`	Variable one in a two-sort context.
Sorts	↪variant `BEDC.MetaCIC.middle var in triple sort`	Middle variable lookup in a three-sort context.
Sorts	↪variant `BEDC.MetaCIC.deep var in quad sort`	Deep variable lookup in a four-sort context.
Sorts	↪variant `BEDC.MetaCIC.mixed ctx vars`	Variable lookup in a mixed sort-and-Pi context.
Sorts	↪variant `BEDC.MetaCIC.mixed ctx var zero`	Front variable lookup in a mixed context.
Sorts	↪variant `BEDC.MetaCIC.mixed var in three ctx`	Interior variable lookup in a mixed three-entry context.
Sorts	↪variant `BEDC.MetaCIC.var in quint sort`	Deep variable lookup in a five-sort context.
Identity	↪variant `BEDC.MetaCIC.lam dependent identity`	Dependent identity lambda.
Identity	↪variant `BEDC.MetaCIC.carrier identity in sort ctx`	Identity over a carrier variable in a sort context.

Identity	↪ variant BEDC.MetaCIC.lam inner to outer in double sort	Lambda returning an outer variable.
Identity	↪ variant BEDC.MetaCIC.triple sort lam	Three-level sort lambda witness.
Identity	↪ variant BEDC.MetaCIC.polymorphic identity	Pi-polymorphic identity witness.
Identity	↪ variant BEDC.MetaCIC.nested poly id	Nested polymorphic identity witness.
Identity	↪ variant BEDC.MetaCIC.lam constructs dependent pi	Lambda forming a dependent Pi target.
Identity	↪ variant BEDC.MetaCIC.double lam pi construct	Two-lambda Pi construction.
Identity	↪ variant BEDC.MetaCIC.first of two	First projection over two arguments.
Identity	↪ variant BEDC.MetaCIC.second of two	Second projection over two arguments.
Identity	↪ variant BEDC.MetaCIC.ignore arg	Lambda that ignores an argument.
Identity	↪ variant BEDC.MetaCIC.double poly first	Polymorphic first projection.
Identity	↪ variant BEDC.MetaCIC.second proj	Second projection witness.
ConstForms	↪ variant BEDC.MetaCIC.app const sort in empty ctx	Constant sort function applied in the empty context.
ConstForms	↪ variant BEDC.MetaCIC.const sort app	Application of a constant sort function.
ConstForms	↪ variant BEDC.MetaCIC.double lam const	Two-argument constant lambda.
ConstForms	↪ variant BEDC.MetaCIC.double lam const first app	First application of a two-argument constant lambda.
ConstForms	↪ variant BEDC.MetaCIC.double lam const repeated app	Repeated application of a two-argument constant lambda.
ConstForms	↪ variant BEDC.MetaCIC.twice applied const	Fully applied constant function witness.
ConstForms	↪ variant BEDC.MetaCIC.first arg proj	First-argument projection as a constant form.
ConstForms	↪ variant BEDC.MetaCIC.second arg proj	Second-argument projection as a constant form.
ConstForms	↪ variant BEDC.MetaCIC.const sort 1 applied	One-step application of a sort constant.
ConstForms	↪ variant BEDC.MetaCIC.applied const sort	Applied constant-sort witness.
AppForms	↪ variant BEDC.MetaCIC.id applied to sort type	Type of identity applied to sort.
AppForms	↪ variant BEDC.MetaCIC.poly id at sort full	Fully instantiated polymorphic identity at sort.

AppForms	↪ variant BEDC.MetaCIC.poly id double app	Polymorphic identity with two applications.
AppForms	↪ variant BEDC.MetaCIC.poly id to pi type	Polymorphic identity applied to a Pi type.
AppForms	↪ variant BEDC.MetaCIC.app id sort in empty ctx	Identity application in the empty context.
AppForms	↪ variant BEDC.MetaCIC.id to id in empty	Identity function applied to identity in the empty context.
AppForms	↪ variant BEDC.MetaCIC.applied pi constructor in empty	Applied Pi constructor in the empty context.
AppForms	↪ variant BEDC.MetaCIC.applied pi constructor in empty result eq	Result equality for the applied Pi constructor.
AppForms	↪ variant BEDC.MetaCIC.id applied to pi	Identity applied to a Pi expression.
AppForms	↪ variant BEDC.MetaCIC.id applied pi value	Value witness for identity applied to Pi.
AppForms	↪ variant BEDC.MetaCIC.id applied to pi result eq	Result equality for identity applied to Pi.
AppForms	↪ variant BEDC.MetaCIC.id on pi sort sort	Identity on the sort-to-sort Pi type.
AppForms	↪ variant BEDC.MetaCIC.pi value id	Identity value for a Pi-shaped term.
AppForms	↪ variant BEDC.MetaCIC.proj for pi arg	Projection with a Pi argument.
AppForms	↪ variant BEDC.MetaCIC.identity on pi type	Identity over a Pi type.
AppForms	↪ variant BEDC.MetaCIC.id for pi applied	Applied identity for a Pi argument.
AppForms	↪ variant BEDC.MetaCIC.app id var in sort ctx	Identity applied to a variable in a sort context.
AppForms	↪ variant BEDC.MetaCIC.dep id applied to arg in sort ctx	Dependent identity applied to a parameter in a sort context.
AppForms	↪ variant BEDC.MetaCIC.dep id applied to arg result in sort ctx	Result typing for dependent identity application.
AppForms	↪ variant BEDC.MetaCIC.applied dep id in double sort ctx	Applied dependent identity in a two-sort context.
AppForms	↪ variant BEDC.MetaCIC.app with pi context	Application in a context containing a Pi type.
AppForms	↪ variant BEDC.MetaCIC.app pi var to sort	Pi variable applied to sort.
AppForms	↪ variant BEDC.MetaCIC.app pi function	Application of a Pi-typed function.
AppForms	↪ variant BEDC.MetaCIC.app pi ctx to sort	Pi-context application targeting sort.
AppForms	↪ variant BEDC.MetaCIC.app two pi vars	Application between two Pi-context variables.

AppForms	↪ variant BEDC.MetaCIC.app pi deep var	Application involving a deeper Pi variable.
AppForms	↪ variant BEDC.MetaCIC.apply function arg in empty	Function-argument application in the empty context.
AppForms	↪ variant BEDC.MetaCIC.app id pi var sort in sort ctx	Identity application over a Pi variable in a sort context.
AppForms	↪ variant BEDC.MetaCIC.pi var sort then sort id app in sort ctx	Pi variable followed by sort identity application.
AppForms	↪ variant BEDC.MetaCIC.apply function arg in value ctx	Function-argument application in a value context.
AppForms	↪ variant BEDC.MetaCIC.dep pi app	Dependent Pi application.
AppForms	↪ variant BEDC.MetaCIC.apply function arg	Function-argument application witness.
AppForms	↪ variant BEDC.MetaCIC.applied poly id	Applied polymorphic identity witness.
PiForms	↪ variant BEDC.MetaCIC.two sort vars	Pair of sort variables in context.
PiForms	↪ variant BEDC.MetaCIC.lam pi var0 var1	Lambda whose type is a Pi over variables zero and one.
PiForms	↪ variant BEDC.MetaCIC.lam pi var var	Lambda over variable-shaped Pi data.
PiForms	↪ variant BEDC.MetaCIC.pi var sort in sort ctx	Pi formation from a variable to sort.
PiForms	↪ variant BEDC.MetaCIC.pi using arrow in ctx	Arrow-like Pi formation in context.
PiForms	↪ variant BEDC.MetaCIC.pi sort sort in empty ctx	Sort-to-sort Pi in the empty context.
PiForms	↪ variant BEDC.MetaCIC.pi sort dependent	Dependent Pi over sort.
PiForms	↪ variant BEDC.MetaCIC.nested pi sort sort	Nested sort-to-sort Pi.
PiForms	↪ variant BEDC.MetaCIC.triple pi sort	Three-level Pi over sort.
PiForms	↪ variant BEDC.MetaCIC.nested pi dep in empty	Nested dependent Pi in the empty context.
PiForms	↪ variant BEDC.MetaCIC.nested pi var sort	Nested Pi using a variable and sort.
PiForms	↪ variant BEDC.MetaCIC.map pi in sort ctx	Map-like Pi in a sort context.
PiForms	↪ variant BEDC.MetaCIC.triple lam pi construction	Three-lambda Pi construction.
PiForms	↪ variant BEDC.MetaCIC.double poly pi	Double-polymorphic Pi witness.
PiForms	↪ variant BEDC.MetaCIC.double arrow in sort	Double-arrow Pi in sort.
PiForms	↪ variant BEDC.MetaCIC.pi var var in quad sort	Pi over variables in a four-sort context.

PiForms	↪variant BEDC.MetaCIC.nested pi chain	Chain of nested Pi forms.
PiForms	↪variant BEDC.MetaCIC.pi function to sort in empty	Function-to-sort Pi in the empty context.
PiForms	↪variant BEDC.MetaCIC.function of function	Function-of-function Pi witness.
PiForms	↪variant BEDC.MetaCIC.nested shifted pi in sort	Nested shifted Pi in sort.
BetaRedex	↪variant BEDC.MetaCIC.id sort redex	Beta step for identity at sort.
BetaRedex	↪variant BEDC.MetaCIC.id sort redex typed	Typing fact for identity-at-sort redex.
BetaRedex	↪variant BEDC.MetaCIC.fn sort to sort redex	Beta step for a sort-to-sort function.
BetaRedex	↪variant BEDC.MetaCIC.fn sort to sort redex typed	Typing fact for the sort-to-sort redex.
BetaRedex	↪variant BEDC.MetaCIC.const sort redex	Beta step for a constant sort function.
BetaRedex	↪variant BEDC.MetaCIC.const sort redex typed	Typing fact for the constant sort redex.
BetaRedex	↪variant BEDC.MetaCIC.inner id redex	Beta step inside an identity-shaped term.
BetaRedex	↪variant BEDC.MetaCIC.inner sort id redex	Inner sort identity beta step.
BetaRedex	↪variant BEDC.MetaCIC.inner sort id redex typed	Typing fact for the inner sort identity redex.
BetaRedex	↪variant BEDC.MetaCIC.app right id sort redex	Beta step in the right side of an application.
BetaRedex	↪variant BEDC.MetaCIC.app right id sort redex typed	Typing fact for the right-application redex.

9235.13.4 Boundary of the gallery

The gallery records closed-term witness patterns. It does not claim a catalogue of non-closed terms, although the object syntax and context machinery can state such judgments. It also does not present general typing in arbitrary non-empty contexts: several witnesses use small explicit contexts, but the dominant path for the self-compilation metatheory is the closed-term path. Finally, it does not claim reduction over open terms; the displayed reduction witnesses are closed

or are paired with closed typing facts where the file states them.

9235.13.5 Contributor discipline

A witness belongs in this gallery when it is a concrete '`theorem`' inside '`lean4/BEDC/MetaCIC/TypedExamples/`' and its target name is stable under '`BEDC.MetaCIC`'. Choose the sibling by term shape rather than by proof technique: sort and variable facts go in '`Sorts.lean`', identity-like lambda terms in '`Identity.lean`', constant functions in '`ConstForms.lean`', applications in '`AppForms.lean`', Pi formation in '`PiForms.lean`', beta witnesses in '`BetaRedex.lean`', Church encodings in '`ChurchGallery.lean`', and Pi-polymorphic combinators in '`Polymorphic.lean`'. The paper row should use '`\leanvariant`', not '`\leanchecked`', because the gallery is an index of sibling witnesses rather than the canonical primary site for a single paper theorem.

9235.14 Metatheory Milestone Consolidation

This section gives a single reader-facing account of the metatheory now available around `BEDC.MetaCIC`. The account is deliberately two-sided. On one side it records the checked Lean surface: represented syntax, closure, substitution, reduction, confluence components, subject reduction interfaces, typed examples, host-gallery transport, and the BHist embedding. On the other side it places that surface next to the standard textbook routes for the Calculus of Inductive Constructions and related pure type systems.

The point of the comparison is scope control. BEDC is not a replacement kernel and not a full formalization of CIC. It is a mathlib-free, zero-axiom, zero-sorry represented calculus inside Lean 4, with enough first-principles metatheory to support the self-compilation surface used in this paper. The checked pieces are meaningful because they are proved over the represented object language itself, not imported from host conversion, host normalization, or a library theorem about lambda calculus.

9235.14.1 What `BEDC.MetaCIC` Achieves

The represented substrate is a single-sort dependent-function core. Its term syntax has five constructors: sort, de Bruijn variable, application, lambda, and Pi. Context lookup is a first-principles list lookup. Shift and substitution are native recursive operations on the represented syntax, and the closure predicate `ClosedAt` records exactly which de Bruijn variables are in scope at a given boundary.

The substrate is shift-aware in the strict de Bruijn sense. Descent under a binder changes the relevant cutoff, and substitution below a binder shifts the inserted term. This is why closure preservation is a theorem rather than a notation convention. The checked closure layer says that closed terms remain closed under shift and substitution at the relevant boundary, and that beta reduction preserves the same closure predicate.

```
↪ variant  BEDC.MetaCIC.shift closed
↪ variant  BEDC.MetaCIC.substitute closed
↪ variant  BEDC.MetaCIC.substitute preserves closed at
↪ variant  BEDC.MetaCIC.betaStep preserves closed
↪ variant  BEDC.MetaCIC.betaStarStep preserves closed
```

These facts are not cosmetic. They are the algebraic guardrail that keeps the MetaCIC reduction relation inside the intended closed fragment. In particular, the one-step theorem covers beta contraction and all congruence constructors; the finite-chain theorem lifts it along the represented

reflexive-transitive closure `BetaStarStep`. Hence every finite represented beta trace starting from a closed term remains closed at every displayed point of the trace.

The confluence surface is split into atom results and compound-shape assemblers. For atoms, sort and variable sources cannot produce a genuine fork. Their beta-star and parallel-beta forks join at the source itself. The checked atom diamonds record the fully closed part of the confluence story:

```
↪variant BEDC.MetaCIC.betaStarStep diamond sort
↪variant BEDC.MetaCIC.betaStarStep diamond var
↪variant BEDC.MetaCIC.betaParallel sort diamond
↪variant BEDC.MetaCIC.betaParallel var diamond
```

For compound terms, the checked layer supplies the structural components needed by the standard parallel-reduction path. Application, lambda, and Pi diamonds can be assembled from diamonds of their components. Lambda and Pi shape forks reduce to domain-body and domain-codomain obligations. Application forks are exposed by a full inversion theorem, because an application branch may either remain an application or contract after the function side exposes a lambda.

```
↪variant BEDC.MetaCIC.betaParallel app diamond of components
↪variant BEDC.MetaCIC.betaParallel lam diamond of components
↪variant BEDC.MetaCIC.betaParallel pi diamond of components
↪variant BEDC.MetaCIC.betaParallel lam shape diamond
↪variant BEDC.MetaCIC.betaParallel pi shape diamond
↪variant BEDC.MetaCIC.betaParallel app full inv
↪variant BEDC.MetaCIC.betaParallel app shape diamond from substitution
↪variant BEDC.MetaCIC.betaParallel diamond from substitution
```

The last two targets make the boundary explicit. A full parallel diamond is available from a substitution-compatibility hypothesis. The Lean theorem does not hide that hypothesis; it states exactly where the remaining algebraic content must enter. In textbook prose the missing law is often described as "substitution commutes with residual reduction." In this substrate it must be a concrete law about `substitute 0` with the same shifts and cutoffs used by `BEDC.MetaCIC.substitute`.

Subject reduction has a similarly explicit shape. The central theorem is a hypothesis-based theorem over the represented typing and beta-step relations. Its beta case uses the beta-substitution-preservation interface; its congruence cases use the application-argument and binder-domain stability interfaces. This is stronger than a mere statement of intent, because the ordinary beta, app, lambda, and Pi cases are checked as Lean theorems over the object calculus.

```
↪variant BEDC.MetaCIC.subject reduction beta
↪variant BEDC.MetaCIC.subject reduction congApp1
↪variant BEDC.MetaCIC.subject reduction congApp2
↪variant BEDC.MetaCIC.subject reduction congLam
↪variant BEDC.MetaCIC.subject reduction congPi
↪variant BEDC.MetaCIC.subject reduction
↪variant BEDC.MetaCIC.subject reduction retype
Lean4✓ BEDC.MetaCIC.not subjectReductionDischargeBundle
```

The subject-reduction theorem should be read as a precise local theorem, not as a disguised claim that all standard preservation obligations have been discharged. The beta-substitution interface remains a carrier obligation, while the application-argument, lambda-domain, and Pi-domain interfaces are blocked by checked obstruction facts. The closed-term path is also constrained by the

checked obstruction showing that a closed outer term may contain a locally open redex argument when the redex is examined under binders.

↪ variant BEDC.MetaCIC.closedBinderRedexTerm closed
↪ variant BEDC.MetaCIC.closedBinderRedexTerm steps
↪ variant BEDC.MetaCIC.closedBinderRedexTerm argument not closed
↪ variant BEDC.MetaCIC.closed term step has unclosed local argument

The normalization surface is intentionally modest. Operationally, the paper uses a bounded normalizer reading: a fuel-indexed host computation follows a chosen finite beta path, and closure preservation is carried by the checked finite-trace theorems. The checked atom-level termination content is the normal-form behavior of sort and closed variable atoms: no beta successor can start from such a source, and a typed closed atom is therefore beta-inert.

↪ variant BEDC.MetaCIC.sort no beta
↪ variant BEDC.MetaCIC.closed var no beta
↪ variant BEDC.MetaCIC.closed atom normal form

This is the atom-level strong-normalization reading used here: for atom sources there is no first step, so every beta path is already finished. It is not a global strong-normalization theorem for all well-typed represented terms. The reducibility-candidates route is therefore a frontier for the represented calculus, not a completed adequacy theorem in the Lean surface.

The typed examples gallery gives concrete pressure on the syntax, typing, and reduction definitions. It contains Church-encoded Booleans, naturals, pairs, and options; polymorphic identity, constant, flip, and compose forms; and a family of beta-redex witnesses. The examples are not produced by quotation from Lean expressions. They are represented terms whose typing and reduction evidence is constructed inside `BEDC.MetaCIC`.

↪ variant BEDC.MetaCIC.church bool type
↪ variant BEDC.MetaCIC.church true
↪ variant BEDC.MetaCIC.church false
↪ variant BEDC.MetaCIC.church nat type
↪ variant BEDC.MetaCIC.church zero
↪ variant BEDC.MetaCIC.church one
↪ variant BEDC.MetaCIC.church pair type
↪ variant BEDC.MetaCIC.church mk pair
↪ variant BEDC.MetaCIC.church option type
↪ variant BEDC.MetaCIC.church none
↪ variant BEDC.MetaCIC.church some
↪ variant BEDC.MetaCIC.poly identity type
↪ variant BEDC.MetaCIC.poly const type
↪ variant BEDC.MetaCIC.poly flip type
↪ variant BEDC.MetaCIC.poly compose type
↪ variant BEDC.MetaCIC.id sort redex
↪ variant BEDC.MetaCIC.id sort redex typed
↪ variant BEDC.MetaCIC.poly id two step redex
↪ variant BEDC.MetaCIC.poly id two step redex typed
↪ variant BEDC.MetaCIC.k sort two step redex
↪ variant BEDC.MetaCIC.k sort two step redex typed

The host bridge gives a second view of the same gallery. Host-side Lean definitions record the familiar computational behavior of identity, constant, flip, compose, Church constructors, and selected redexes by reflexive equalities. The transport side then points to the represented MetaCIC

witnesses for corresponding typing and reduction facts. This is not a kernel soundness theorem from host elaboration to MetaCIC. It is a checked alignment gallery: named host examples and named represented examples are paired at the level of concrete witnesses.

```
↪ variant BEDC.HostBridge.MetaCICTransport.Host.host identity beta
↪ variant BEDC.HostBridge.MetaCICTransport.Host.host const beta
↪ variant BEDC.HostBridge.MetaCICTransport.Host.host flip beta
↪ variant BEDC.HostBridge.MetaCICTransport.Host.host compose beta
↪ variant BEDC.HostBridge.MetaCICTransport.transport identity well typed
↪ variant BEDC.HostBridge.MetaCICTransport.transport const well typed
↪ variant BEDC.HostBridge.MetaCICTransport.transport flip well typed
↪ variant BEDC.HostBridge.MetaCICTransport.transport compose well typed
↪ variant BEDC.HostBridge.MetaCICTransport.transport church true well typed
↪ variant BEDC.HostBridge.MetaCICTransport.transport church false well typed
↪ variant BEDC.HostBridge.MetaCICTransport.transport church zero well typed
↪ variant BEDC.HostBridge.MetaCICTransport.transport church one well typed
↪ variant BEDC.HostBridge.MetaCICTransport.transport id sort redex step
↪ variant BEDC.HostBridge.MetaCICTransport.transport id sort redex well typed
↪ variant BEDC.HostBridge.MetaCICTransport.transport poly id two step redex star
↪ variant BEDC.HostBridge.MetaCICTransport.transport poly id two step redex well typed
```

The BHist bridge connects the self-compilation substrate back to the finite-history world of BEDC. The embedding `bhistToTerm` turns a `BHistIdx` into a represented MetaCIC term, and the closure theorem says that the result is closed at boundary 0. This is exactly the kind of bridge needed by a closed-atom self-compilation surface: histories can be represented as terms without opening a de Bruijn variable.

```
↪ variant BEDC.MetaCIC.BHistSubstrate.bhistToTerm closed
↪ variant BEDC.MetaCIC.BHistSubstrate.bhistToTerm injective
```

9235.14.2 Comparison with Textbook CIC Metatheory

The textbook metatheory of CIC is usually organized around a rich kernel with universes, products, conversion, inductive objects, and a semantic or syntactic normalization argument. Coquand–Werner style presentations are commonly read through normalization by evaluation or closely related semantic normalization methods. Those routes exploit a carefully chosen semantic model of terms, types, and conversion. BEDC takes a more direct first-principles path: it defines the object syntax, object typing, object beta relation, and object metatheory inside Lean 4, then proves local facts about those inductive objects.

The difference is not merely aesthetic. Normalization by evaluation is a semantic proof architecture; the evaluator and reifier are part of the proof that well-typed terms normalize. BEDC's bounded normalizer is not such a semantic normalization proof. It is an operational finite approximation whose termination comes from host fuel. The checked theorem around it is closure preservation along represented beta traces, not a theorem that all well-typed represented terms normalize.

Pure type systems give another useful comparison point. In the Barendregt style, a calculus is presented by a set of sorts, axioms, and product rules. The BEDC fragment can be read as a single-sort sub-PTS: it has one represented sort, Pi formation, lambda introduction, application elimination, and explicit beta reduction, but it does not carry a universe hierarchy, cumulativity, or the full set of conversion principles used by CIC kernels. The single-sort choice keeps the object calculus small enough for mathlib-free proof from first principles.

Reducibility candidates provide the standard Girard/Tait route to strong normalization. That route interprets types as sets of strongly normalizing terms stable under reduction, then proves adequacy by induction on typing derivations. BEDC has the syntactic substrate needed to state this route: represented typing, represented beta, closure, finite reduction chains, and atom-level normal-form facts. What is not present is the full adequacy proof: an interpretation of every admissible represented type as a candidate and an induction showing that every typing derivation lands in the corresponding candidate.

The comparison therefore has a precise shape:

Textbook route	Standard role	BEDC reading
Coquand–Werner CIC	semantic normalization and kernel-scale conversion metatheory	direct object-language proofs over a narrower represented calculus
Pure type systems	sorts, axioms, and product rules as a parametric calculus schema	single-sort dependent-function sub-PTS with explicit beta only
Tait–Martin-Lof parallel reduction	diamond proof route for beta confluence	atom diamonds and compound-shape assemblers, with application residuals still isolated as substitution compatibility
Girard/Tait reducibility candidates	strong-normalization adequacy by semantic interpretation of types	frontier over the represented calculus, with atom-level normal-form facts already checked

This reading keeps the standard references conceptually visible without pretending that their full theorems have been imported. The BEDC theorem names are theorem names about the represented calculus. They do not mention the host kernel's own conversion relation, and they do not rely on host metatheory as a black box.

9235.14.3 Frontier

The first frontier is the full `BetaParallel` diamond without a closed-term precondition. The checked theorem `betaParallel_diamond_from_substitution` identifies the exact remaining input: parallel substitution compatibility. Proving that input in the present de Bruijn substrate requires a binder-aware commutation theorem for parallel residuals and substitution.

The second frontier is the complete discharge of the three subject-reduction hypotheses in the general form. The theorem `subject_reduction` already packages the main induction once beta substitution preservation, application-argument stability, lambda-domain stability, and Pi-domain stability are available. The closed-term path is natural, but the local-redex obstruction shows why closedness alone does not erase all binder bookkeeping.

The third frontier is a strong-normalization theorem for the represented calculus. The current checked facts prove that atoms are beta-inert and that finite traces preserve closedness. A full theorem would require an admissible type grammar, reducibility candidates for that grammar, and an adequacy proof over represented typing derivations.

The fourth frontier is the weak closed-term form of substitution composition. The unrestricted zero-depth equation is refuted by a checked counterexample. Positive shape-local facts already exist for closed sort, variable, application, lambda-anchor, and Pi-anchor cases, but the theorem needed by the application residual proof must be stated in the exact closed form that the shift-aware substitution operation satisfies.

```
↪ variant BEDC.MetaCIC.substitute substitute zero zero unclosed counterexample
↪ variant BEDC.MetaCIC.substitute substitute zero zero closed sort
↪ variant BEDC.MetaCIC.substitute substitute zero zero closed var
↪ variant BEDC.MetaCIC.substitute substitute zero zero closed app
↪ variant BEDC.MetaCIC.substitute substitute zero zero lam closed anchor
↪ variant BEDC.MetaCIC.substitute substitute zero zero pi closed anchor
```

9235.14.4 Boundary Statement

BEDC does not pursue a universe hierarchy or cumulativity in `BEDC.MetaCIC`. The represented calculus has a single sort and the paper reads it as a universe-zero dependent-function core. This excludes the kernel-scale universe constraints and cumulativity rules that a full CIC formalization would need.

BEDC does not pursue inductive families inside the MetaCIC substrate. The object language has no represented inductive declarations, constructors, recursors, motive elaboration, or large eliminators. Church encodings in the typed gallery are represented terms in the dependent-function fragment, not host inductive datatypes transported into the object calculus.

BEDC does not pursue propositional irrelevance. The object calculus has no separate proof-irrelevant proposition sort and no quotient by proof identity. All checked theorems are Lean theorems about the represented syntax and relations.

BEDC does not pursue eta-conversion. The reduction relation is beta-only: lambda eta and Pi eta are not reduction constructors, and the confluence and subject-reduction surfaces are stated for the beta relation that is actually encoded.

BEDC does not pursue pattern matching from inductive types beyond the closed atoms and Church-encoded examples displayed in the gallery. The object language has no case tree language and no pattern compiler. This keeps the self-compilation surface tied to the finite closed-term and closed-history bridge it needs.

9235.14.5 Why This Boundary

The first reason is axiom purity. The development is mathlib-free and audited against extra axioms. In particular, the project excludes reliance on `Classical.choice`, `Quot.sound`, and `propext` in the checked theorem dependency chain. That restriction rules out many convenient shortcuts for quotienting syntax, using classical well-founded arguments, or collapsing propositions by extensionality. The substrate must be built from inductive syntax, recursive functions, and explicit constructors.

The second reason is methodological. The self-compilation chapter values substrate coherence over maximal expressivity. A small represented calculus with explicit closure, substitution, beta, typing, and finite examples gives a clear audit trail. A larger calculus with universes, inductives, conversion, and pattern matching would be closer to a production kernel, but it would also move the paper away from the first-principles invariant that makes every claim traceable to a named Lean object.

The third reason is sufficiency for the BEDC goal. The self-compilation surface needs closed-atom and finite-history meta-reasoning, not a full mechanization of CIC. Histories must embed as closed represented terms. Gallery witnesses must exercise the dependent-function core. Reduction traces must preserve closedness. Atom sources must be beta-inert. These are exactly the checked components listed above. The larger textbook theorems remain the right comparison class, but the paper's claim is intentionally narrower.

The resulting boundary is neither a defect nor a hidden theorem. It is the chosen contract for this represented calculus: first-principles syntax and local metatheory, checked without additional axioms, supporting the self-compilation layer while leaving full CIC metatheory outside the claimed surface.

9235.15 Closed-Term Metatheory Completion

The closed-term surface of `BEDC.MetaCIC` is the part of the self-compilation substrate in which represented terms are read in the empty context and de Bruijn closure is an explicit hypothesis. The object calculus is the universe-0, beta-only, single-sort dependent-function fragment: represented syntax has sort, variable, application, lambda, and Pi; typing is an inductive judgment over represented contexts; beta reduction is an inductive relation over represented terms; and closure is the predicate `ClosedAt`. The proof objects live inside Lean 4 without mathlib, without project axioms, and without sorry placeholders.

The scope claim is deliberately narrow and binding. BEDC does not assert a full host-kernel theorem about Lean's own CIC, and it does not assert the full open-term metatheory of a production proof assistant. It asserts that the closed fragment needed by the self-compilation surface is represented from first principles, that the reduction and closure invariants needed by that surface are checked, and that the remaining theorem boundaries are exposed as named Lean statements rather than hidden behind prose.

9235.15.1 The Closed-Term Scope Claim

The represented calculus has a closed empty-context reading:

$$\mathrm{ClosedTermScope}(t, A) \quad \equiv \quad \texttt{ClosedAt}\ 0\ t \wedge \texttt{HasType}\ []\ t\ A.$$

Inside this reading, the three metatheoretic invariants used by BEDC's self-compilation account have checked representatives.

First, subject reduction is available as a hypothesis-explicit theorem over the represented typing and beta-step relations. The theorem states that beta substitution preservation, application-argument type stability, lambda-domain subject reduction, and Pi-domain subject reduction are exactly the interfaces needed to preserve the displayed type along one represented beta step. The ordinary beta case and the congruence cases are mechanized; the closed-scope discharge layer records which of the remaining interfaces is valid under the closed hypotheses and where the calculus rejects a stronger reading.

```
↪ variant BEDC.MetaCIC.subject reduction
↪ variant BEDC.MetaCIC.subject reduction beta
↪ variant BEDC.MetaCIC.subject reduction congApp1
↪ variant BEDC.MetaCIC.subject reduction congApp2
↪ variant BEDC.MetaCIC.subject reduction congLam
↪ variant BEDC.MetaCIC.subject reduction congPi
↪ variant BEDC.MetaCIC.subject reduction closed app independent codomain
```

Second, closure preservation is fully checked for one-step and finite-chain beta reduction. If a represented term is closed at boundary n, one `BetaStep` preserves closure at the same boundary. The finite-chain theorem lifts this to `BetaStarStep`. This is the core invariant that keeps the object-language evaluator inside the intended de Bruijn boundary: beta contraction, application

congruence, lambda congruence, and Pi congruence cannot create a free represented variable when the source term is closed.

```
↪variant BEDC.MetaCIC.betaStep preserves closed
↪variant BEDC.MetaCIC.betaStarStep preserves closed
↪variant BEDC.MetaCIC.substitute preserves closed at
```

Third, strong-normalization witnesses exist for the closed normal-form sub-scope used by the gallery and by the self-compilation reading. The normalization layer defines `StrongNormalizable`, beta-inert sources, candidates, closed candidates, Pi candidates, neutral normal forms, and closure of those witnesses under the relevant one-step reductions. It proves that sort and variables are strongly normalizable, that neutral applications are strongly normalizable when their parts are, that lambda and Pi preserve strong-normalization witnesses componentwise, and that the closed Church and polymorphic gallery terms carry concrete witnesses. This is not a theorem that every well-typed represented term normalizes; it is the checked normal-form and candidate sub-scope actually consumed by BEDC.

```
↪variant BEDC.MetaCIC.StrongNormalizable
↪variant BEDC.MetaCIC.sort is sn
↪variant BEDC.MetaCIC.var is sn
↪variant BEDC.MetaCIC.closed atom normal form
↪variant BEDC.MetaCIC.closed sort candidate
↪variant BEDC.MetaCIC.closedCandidate implies sn
↪variant BEDC.MetaCIC.PiAdequacy.piCandidate implies sn
↪variant BEDC.MetaCIC.churchTrueTm sn
↪variant BEDC.MetaCIC.churchFalseTm sn
↪variant BEDC.MetaCIC.churchZeroTm sn
↪variant BEDC.MetaCIC.churchOneTm sn
```

The bounded normalizer is the operational layer sitting next to these invariants. It is a fuel-indexed function on represented terms. Its equational laws connect concrete represented reductions with host CIC computation for the finite gallery. Its termination is structural recursion on fuel, while its metatheoretic safety is supplied by the closure-preservation theorems over represented beta traces.

```
↪variant BEDC.MetaCIC.normalizeBounded
↪variant BEDC.HostBridge.normalize id app sort
↪variant BEDC.HostBridge.normalize poly identity apply
↪variant BEDC.HostBridge.normalize church true apply
↪variant BEDC.HostBridge.normalize church zero apply
↪variant BEDC.HostBridge.id app sort beta star
↪variant BEDC.HostBridge.poly identity chain
```

9235.15.2 What This Scope Buys

The first payoff is a first-principles self-compilation boundary. The represented typed witnesses used by BEDC are not informal quotations of host Lean terms. They are object-language inhabitants built from the MetaCIC syntax constructors, checked by the MetaCIC typing relation, and reduced by the MetaCIC beta relation. When such a witness is closed and lies in the normal-form sub-scope, the project has both a termination witness and a type-preservation path appropriate to the exact local interface it uses.

The phrase "appropriate to the exact local interface" is important. The calculus validates broad subject reduction only under its named hypotheses. For applications with a closed independent codomain, the application-argument stability hypothesis is discharged directly. For reducible binder domains, Lean records counterexamples showing that the stronger lambda-domain and Pi-domain closed statements are not valid as stated. This is a positive metatheoretic result for BEDC's architecture: the paper does not need to guess where the closed scope ends, because the endpoint is itself mechanized.

```
↪ variant BEDC.MetaCIC.appArgTypeStable closed
↪ variant BEDC.MetaCIC.appArgTypeStable closed independent codomain
↪ variant BEDC.MetaCIC.lamDomainSR closed counterexample
↪ variant BEDC.MetaCIC.piDomainSR closed counterexample
↪ variant BEDC.MetaCIC.not subject reduction closed
```

The second payoff is representational adequacy for the finite gallery. The host bridge pairs ordinary host-level functions and Church encodings with represented MetaCIC terms, represented typing witnesses, and represented beta chains. The bridge is not a theorem that every host term has a represented image. It is a checked transport gallery for the exact functions used in the self-compilation account: identity, constant, flip, compose, Church Booleans, Church numerals, pairs, options, and selected beta-redex shapes.

```
↪ variant BEDC.HostBridge.MetaCICTransport.transport identity well typed
↪ variant BEDC.HostBridge.MetaCICTransport.transport const well typed
↪ variant BEDC.HostBridge.MetaCICTransport.transport flip well typed
↪ variant BEDC.HostBridge.MetaCICTransport.transport compose well typed
↪ variant BEDC.HostBridge.MetaCICTransport.transport church true well typed
↪ variant BEDC.HostBridge.MetaCICTransport.transport church false well typed
↪ variant BEDC.HostBridge.MetaCICTransport.transport church zero well typed
↪ variant BEDC.HostBridge.MetaCICTransport.transport church one well typed
↪ variant BEDC.HostBridge.MetaCICTransport.transport poly id two step redex star
```

The third payoff is executable normal-form operation without importing standard-library axioms. The bounded normalizer is a native recursive operation over the represented syntax. It decides the normal form of a finite run by host fuel and definitional equations, not by an excluded-middle search over arbitrary reduction paths. For the gallery, the equational laws state that enough fuel reaches the expected representative. For the paper's closed-term self-compilation surface, this is exactly the executable content needed: a finite evaluator, named beta traces, closure preservation for those traces, and concrete normal-form witnesses where termination is claimed.

9235.15.3 The Three-Hypothesis Chain

The subject-reduction theorem exposes three non-beta interfaces after beta substitution preservation. In the closed empty-context scope they have different resolutions. The application-argument interface is discharged for closed independent codomains; the reducible lambda-domain and Pi-domain interfaces are resolved by checked counterexamples. The following table is the binding reading of that chain.

Interface	Closed-scope resolution	Lean targets
`AppArgTypeStable`	Valid when the Pi codomain is closed at boundary 0, so substituting either the source argument or its reduct into that codomain returns the codomain itself. This is the application case BEDC uses for closed independent codomain witnesses.	↪variant `BEDC.MetaCIC.appArgTypeStable closed` ↪variant `BEDC.MetaCIC.subject reduction closed app independent codomain`
`LamDomainSubjectReduction`	Not valid as a blanket closed-term theorem. A closed lambda whose domain itself reduces can lose the displayed Pi type when the domain is rewritten without simultaneously transporting the codomain. The counterexample fixes the precise boundary.	↪variant `BEDC.MetaCIC.lamDomainSR closed counterexample` ↪variant `BEDC.MetaCIC.not lamDomainSR closed` ↪variant `BEDC.MetaCIC.not subject reduction closed lam`
`PiDomainSubjectReduction`	Not valid as a blanket closed-term theorem. A closed Pi source may have a codomain typed in the old shifted-domain context; reducing the domain changes the binder context, and the codomain need not retype under the new one.	↪variant `BEDC.MetaCIC.piDomainSR closed counterexample` ↪variant `BEDC.MetaCIC.not piDomainSR closed` ↪variant `BEDC.MetaCIC.not subject reduction closed pi`

This table is why the closed-term claim is stated as a scoped metatheory completion rather than as a hidden full-kernel preservation theorem. The application row supplies the positive discharge needed by the closed independent-codomain surface. The two domain rows prevent BEDC from treating closedness alone as a substitute for binder-context transport. The resulting architecture is stricter than a prose-only closure claim: every consumed interface is named, and every rejected strengthening is named as well.

9235.15.4 Closed Normalization and Candidate Witnesses

The normal-form sub-scope has two layers. The first layer is beta-strong inertia. A term is `BetaStrong` when it has no beta successor. Sort and variables satisfy this immediately by constructor inversion on `BetaStep`; `BetaStrong` implies `StrongNormalizable`; hence sort and variables are strongly normalizable. The closed-atom theorem packages the same fact for closed terms typed at sort when their shape is sort or variable.

↪variant `BEDC.MetaCIC.BetaStrong`
↪variant `BEDC.MetaCIC.betaStrong implies sn`
↪variant `BEDC.MetaCIC.sort betaStrong`
↪variant `BEDC.MetaCIC.var betaStrong`
↪variant `BEDC.MetaCIC.sort no betaStrong successor`
↪variant `BEDC.MetaCIC.var no betaStrong successor`

The second layer is candidate-based adequacy for the Pi and neutral-normal shapes used by the gallery. `Candidate` combines a `StrongNormalizable` witness with a type-head witness.

`PiCandidate` adds the application clause required for dependent functions. `ClosedCandidate` adds closure of both the type and the term. These objects are closed under one beta step when the target closure is available, and they imply strong normalization of the represented term.

```
↪ variant BEDC.MetaCIC.Candidate
↪ variant BEDC.MetaCIC.ClosedCandidate
↪ variant BEDC.MetaCIC.PiCandidate
↪ variant BEDC.MetaCIC.candidate closed under beta
↪ variant BEDC.MetaCIC.closedCandidate under beta with closed target
↪ variant BEDC.MetaCIC.pi candidate app
↪ variant BEDC.MetaCIC.piCandidate head sn
```

Neutral normal forms give the gallery its closed application witnesses. Variables are neutral. An application of a neutral function to a strongly normalizable argument is neutral. Neutral normal forms are stable under beta steps, and every neutral normal form is strongly normalizable. Lambda and Pi constructors preserve strong-normalization witnesses componentwise. The Church gallery then instantiates this small calculus of witnesses for the particular closed shapes used in the paper.

```
↪ variant BEDC.MetaCIC.NeutralNormal
↪ variant BEDC.MetaCIC.neutralNormal step
↪ variant BEDC.MetaCIC.neutralNormal implies sn
↪ variant BEDC.MetaCIC.neutralApp sn
↪ variant BEDC.MetaCIC.sn lam
↪ variant BEDC.MetaCIC.sn pi
↪ variant BEDC.MetaCIC.churchBoolTy sn
↪ variant BEDC.MetaCIC.churchNatTy sn
↪ variant BEDC.MetaCIC.churchSuccTm sn
```

This normalization layer is enough for the self-reflective use of the MetaCIC substrate. BEDC's self-compilation examples require finite typed witnesses, explicit beta traces, closedness preservation, and strong-normal witnesses for the closed gallery terms. They do not require a theorem that all admissible represented terms normalize under every possible reduction strategy.

9235.15.5 Bounded Normalizer as Operation

The bounded normalizer is executable because it is structurally recursive on fuel:

$$\begin{aligned}\texttt{normalizeBounded}\ 0\ t &= t,\\ \texttt{normalizeBounded}\ (k+1)\ \texttt{sort} &= \texttt{sort},\\ \texttt{normalizeBounded}\ (k+1)\ (\texttt{var}\ i) &= \texttt{var}\ i.\end{aligned}$$

For lambda and Pi it recursively normalizes components. For applications it normalizes the function and argument and contracts when the normalized function is a lambda. The operation is therefore deterministic as host computation, while the object-language safety statement remains the represented one: whenever the run is read as a finite `BetaStep` trace, `betaStarStep_preserves_closed` preserves closure from source to target.

The host bridge records that the same finite computations match host CIC equalities for the gallery. The left side is represented computation through `normalizeBounded`; the right side is a host definitional equality. The beta-chain lemmas give the object-language reduction witnesses for the same examples. Together they supply an operational bridge from host examples to represented examples without importing host normalization as an axiom about the represented calculus.

```
↪ variant BEDC.HostBridge.host id app sort
↪ variant BEDC.HostBridge.host poly identity apply
↪ variant BEDC.HostBridge.host church true apply
↪ variant BEDC.HostBridge.host church zero apply
↪ variant BEDC.HostBridge.church true apply chain
↪ variant BEDC.HostBridge.church false apply chain
↪ variant BEDC.HostBridge.church true apply step two
↪ variant BEDC.HostBridge.church false apply step two
```

9235.15.6 What Remains Outside the Closed-Term Scope

The frontier above the closed-term scope is explicit.

- Open-term subject reduction remains outside the checked claim. The obstruction is not merely bookkeeping: substitution composition under binders must account for shifting, local variables, and binder-context transport simultaneously.
- Full beta-parallel diamond over open terms remains outside the checked claim. Atom diamonds and compound-shape assemblers are mechanized, but the open application residual proof still depends on substitution compatibility across parallel residuals.
- Universe hierarchy remains outside the represented calculus. The object language has one sort, so it does not claim cumulativity, universe polymorphism, or universe-level consistency for a hierarchy.
- Inductive families remain outside the represented calculus. There are no represented constructors, eliminators, positivity conditions, recursion principles, or computation rules for inductive families.
- Proposition irrelevance remains outside the represented calculus. The fragment has typing, beta, Pi, lambda, application, variables, and sort; it does not include a proposition universe or proof-irrelevance principle.

These boundaries are architectural commitments. The closed-term MetaCIC surface is a substrate for BEDC's self-compilation account, not a replacement kernel for all of Lean and not a paper claim about every feature of CIC. The frontier is stated so that downstream BEDC arguments do not accidentally use universe hierarchy, inductive-family computation, proposition irrelevance, or open-term substitution algebra as if those facts were already part of the first-principles substrate.

9235.15.7 Meaning for the BEDC Architecture

`BEDC.MetaCIC` is the self-compilation substrate of the manuscript. It gives BEDC a represented language in which typed witnesses, reduction traces, normal-form evidence, and finite host-gallery transport can be discussed inside the project rather than only in metalinguistic prose. The closed-term scope covers the surface the self-reflective architecture truly consumes: closed represented terms, empty-context typing witnesses, beta-only finite reduction traces, candidate and neutral-normal witnesses for the gallery, and bounded normalizer equations for executable examples.

The finite-history bridge fits this reading. A `BHistIdx` can be embedded as a represented MetaCIC term, and the image is closed at boundary 0. This gives the self-compilation substrate a direct route back to BEDC's finite event-history world without opening the de Bruijn boundary.

```
↪ variant BEDC.MetaCIC.BHistSubstrate.bhistToTerm closed
```

↪ variant BEDC.MetaCIC.BHistSubstrate.bhistToTerm injective

Outside the closed-term scope, BEDC makes no first-principles claim. An argument that needs open-term subject reduction, a full parallel diamond, universe hierarchy, inductive families, or proposition irrelevance must carry that extra structure explicitly. The closed surface is therefore strong because it is exact: it proves the substrate BEDC actually uses, records the normal-form and operation facts needed by that substrate, and leaves the larger CIC frontier outside the claim.

9235.16 Session-Level Metatheory Claim

This section states the claim surface carried by `BEDC.MetaCIC` as a single formal object of the manuscript. The surface is intentionally narrow: it concerns the universe-0, beta-only, single-sort dependent-function fragment, read at closed represented terms and empty object contexts. Within that scope, the manuscript can cite a mathlib-free, axiom-free, sorry-free Lean 4 mechanization of the represented syntax, typing, beta reduction, closure discipline, selected confluence components, closed normalization witnesses, executable checking, host-gallery transport, Church-encoded data laws, and beta-conversion facts.

Scope claim. In the universe-0, beta-only, single-sort fragment with represented constructors `sort`, `var`, `app`, `lam`, and `pi`, and under the reading

$$\mathrm{ClosedEmptyCtx}(t, A) \quad \equiv \quad \texttt{ClosedAt}\ 0\ t \wedge \texttt{HasType}\ []\ t\ A,$$

`BEDC.MetaCIC` supplies first-principles mechanized metatheory inside Lean 4, without mathlib imports, without project axioms, and without sorry placeholders. The claim is about this represented object calculus, not about the full host Lean kernel.

9235.16.1 Claim 1: Substrate Invariants

The substrate invariant is that de Bruijn indices are not treated as informal names. The calculus defines shift and substitution as native recursive operations on represented terms. A descent under a binder changes the cutoff; substitution below a binder shifts the inserted term; closure is the predicate that records which indices are admissible at a boundary. The following targets are the basic shift-aware substrate facts used throughout the metatheory:

↪ variant BEDC.MetaCIC.shift closed
↪ variant BEDC.MetaCIC.substitute closed
↪ variant BEDC.MetaCIC.closedAt shift
↪ variant BEDC.MetaCIC.closedAt substitute
↪ variant BEDC.MetaCIC.closedAt succ
↪ variant BEDC.MetaCIC.closedAt zero at
↪ variant BEDC.MetaCIC.shift substitute at closed zero
↪ variant BEDC.MetaCIC.shift substitute zero zero closed

The typing substrate is correspondingly local. Substitution preservation is not asserted by a global slogan; it is exposed through first-principles subderivation theorems for the relevant shapes. The Pi, lambda, and application theorems say exactly which represented premises are sufficient to preserve typing across the local substitution operation:

↪ variant BEDC.MetaCIC.substitute preserves typing pi if subderivations
↪ variant BEDC.MetaCIC.substitute preserves typing lam if subderivations
↪ variant BEDC.MetaCIC.substitute preserves typing app if subderivations

```
↪ variant BEDC.MetaCIC.substitute preserves typing pi
↪ variant BEDC.MetaCIC.substitute preserves typing lam
↪ variant BEDC.MetaCIC.substitute preserves typing app cod sort var commutes
↪ variant BEDC.MetaCIC.substitute preserves typing via term induction
```

Closure is stable under represented beta computation. A one-step beta reduction from a term closed at boundary n has a target closed at the same boundary, and the reflexive-transitive beta chain preserves the same boundary. This is the guardrail that permits the self-compilation surface to execute finite represented beta traces without leaving the closed fragment:

```
↪ variant BEDC.MetaCIC.substitute preserves closed at
↪ variant BEDC.MetaCIC.betaStep preserves closed
↪ variant BEDC.MetaCIC.betaStarStep preserves closed
↪ variant BEDC.MetaCIC.betaParallel preserves closed
↪ variant BEDC.MetaCIC.betaParallel preserves closed zero
```

Read together, these targets justify the substrate part of the claim: the syntax, closure, substitution, and local typing algebra are not external assumptions. They are object-language theorems about the represented calculus, and all later claims depend on that explicit de Bruijn discipline.

9235.16.2 Claim 2: Subject Reduction in the Closed Scope

The central subject-reduction theorem has an explicit interface shape. It assumes the beta-substitution interface and three non-beta stability interfaces, then proves preservation of the displayed type along one represented beta step. The beta case and the congruence cases are checked directly over the represented typing and beta-step relations:

```
↪ variant BEDC.MetaCIC.subject reduction beta
↪ variant BEDC.MetaCIC.subject reduction congApp1
↪ variant BEDC.MetaCIC.subject reduction congApp2
↪ variant BEDC.MetaCIC.subject reduction congLam
↪ variant BEDC.MetaCIC.subject reduction congPi
↪ variant BEDC.MetaCIC.subject reduction
↪ variant BEDC.MetaCIC.subject reduction retype
```

Inside the closed empty-context reading, the application-argument stability interface has a positive closed use case. When the Pi codomain is already closed at boundary 0, substituting either the source argument or its beta reduct into that codomain returns the same codomain. This gives the closed independent-codomain application preservation theorem consumed by the self-compilation examples:

```
↪ variant BEDC.MetaCIC.appArgTypeStable closed independent codomain
↪ variant BEDC.MetaCIC.appArgTypeStable closed
↪ variant BEDC.MetaCIC.subject reduction closed app independent codomain
```

The closed scope also records the exact negative boundary for stronger blanket readings. A closed lambda may reduce in its displayed domain while the target no longer has the displayed Pi type. A closed Pi may reduce in its domain while its codomain was typed in the old shifted-domain context. Therefore closedness alone does not discharge the lambda-domain and Pi-domain interfaces as global theorems:

```
↪ variant BEDC.MetaCIC.lamDomainSR closed counterexample
↪ variant BEDC.MetaCIC.not lamDomainSR closed
↪ variant BEDC.MetaCIC.not subject reduction closed lam
↪ variant BEDC.MetaCIC.piDomainSR closed counterexample
↪ variant BEDC.MetaCIC.not piDomainSR closed
```

```
↪ variant BEDC.MetaCIC.not subject reduction closed pi
↪ variant BEDC.MetaCIC.not subject reduction closed
```

Thus the subject-reduction claim is exact. BEDC has a checked preservation theorem with explicit hypotheses, a checked positive closed application sub-scope, and checked counterexamples to the stronger closed binder-domain reading. The manuscript must not cite a blanket `subject_reduction_closed` theorem, because the represented calculus contains formal witnesses refuting that statement.

9235.16.3 Claim 3: Confluence in the Closed Scope

The confluence surface is split into atom facts, shape assemblers, and a closed-normal sub-scope. Atoms have trivial forks: a sort source and a variable source cannot produce a genuine beta fork. The beta-star and parallel-beta diamonds for atom sources therefore join at the source itself:

```
↪ variant BEDC.MetaCIC.betaStarStep diamond sort
↪ variant BEDC.MetaCIC.betaStarStep diamond var
↪ variant BEDC.MetaCIC.betaParallel sort diamond
↪ variant BEDC.MetaCIC.betaParallel var diamond
↪ variant BEDC.MetaCIC.betaParallel diamond sort
↪ variant BEDC.MetaCIC.betaParallel diamond var
```

For compound terms, the parallel relation exposes the expected structural components. Application, lambda, and Pi diamonds can be assembled from component diamonds. Shape-specific lambda and Pi diamonds are checked. Application forks are handled by an inversion theorem and by a conditional application-shape theorem whose remaining premise is the explicit substitution-compatibility property:

```
↪ variant BEDC.MetaCIC.betaParallel app diamond of components
↪ variant BEDC.MetaCIC.betaParallel lam diamond of components
↪ variant BEDC.MetaCIC.betaParallel pi diamond of components
↪ variant BEDC.MetaCIC.betaParallel lam shape diamond
↪ variant BEDC.MetaCIC.betaParallel pi shape diamond
↪ variant BEDC.MetaCIC.betaParallel app full inv
↪ variant BEDC.MetaCIC.betaParallel app cong cong diamond
↪ variant BEDC.MetaCIC.betaParallel app shape diamond from substitution
↪ variant BEDC.MetaCIC.betaParallel diamond from substitution
```

The unconditional closed part is available for normal sources. If a closed source is beta-normal, any parallel target or beta-star target is forced back to the source, so both forks join immediately. Sort is a closed normal source; a closed variable source is impossible at boundary 0, and the corresponding impossible cases are also named:

```
↪ variant BEDC.MetaCIC.BetaNormal
↪ variant BEDC.MetaCIC.betaNormal sort
↪ variant BEDC.MetaCIC.betaNormal var
↪ variant BEDC.MetaCIC.betaParallel diamond closed normal
↪ variant BEDC.MetaCIC.betaStarStep confluence closed normal
↪ variant BEDC.MetaCIC.betaParallel diamond closed sort
↪ variant BEDC.MetaCIC.betaStarStep confluence closed sort
↪ variant BEDC.MetaCIC.betaParallel diamond closed var impossible
↪ variant BEDC.MetaCIC.betaStarStep confluence closed var impossible
```

The Church-Rosser theorem for the whole closed fragment is therefore not read as an unqualified theorem here. What is checked is the atom diamond surface, the compound-shape machinery, the conditional full parallel diamond from substitution compatibility, and the unconditional closed-normal confluence surface. The missing global claim would require a closed substitution compatibility theorem strong enough to cover application residuals.

9235.16.4 Claim 4: Strong Normalization in the Closed Scope

The normalization layer defines the reducibility-candidate vocabulary used by the closed fragment. `StrongNormalizable` is an inductive predicate closed under one-step tails. Candidate, closed candidate, Pi candidate, and candidate-set structures package strong-normalization witnesses together with the type-head and closure facts needed by the represented calculus:

```
↪ variant BEDC.MetaCIC.StrongNormalizable
↪ variant BEDC.MetaCIC.strongNormalizable step
↪ variant BEDC.MetaCIC.strongNormalizable reduces once
↪ variant BEDC.MetaCIC.Candidate
↪ variant BEDC.MetaCIC.ClosedCandidate
↪ variant BEDC.MetaCIC.PiCandidate
↪ variant BEDC.MetaCIC.CandidateSet
↪ variant BEDC.MetaCIC.candidate implies sn
↪ variant BEDC.MetaCIC.closedCandidate implies sn
↪ variant BEDC.MetaCIC.piCandidate implies sn
↪ variant BEDC.MetaCIC.candidate closed under beta
↪ variant BEDC.MetaCIC.closedCandidate under beta with closed target
```

The Pi adequacy component says that a Pi candidate gives the expected application candidate and application strong-normalization witness. Neutral normal forms supply the closed application witnesses used in the gallery, and lambda and Pi constructors preserve strong-normalization from their parts:

```
↪ variant BEDC.MetaCIC.pi candidate app
↪ variant BEDC.MetaCIC.piCandidate head sn
↪ variant BEDC.MetaCIC.PiAdequacy.piCandidate implies sn
↪ variant BEDC.MetaCIC.NeutralNormal
↪ variant BEDC.MetaCIC.neutralNormal step
↪ variant BEDC.MetaCIC.neutralNormal implies sn
↪ variant BEDC.MetaCIC.neutralApp sn
↪ variant BEDC.MetaCIC.sn lam
↪ variant BEDC.MetaCIC.sn pi
```

The closed-typed-term layer turns those witnesses into theorem statements about empty-context terms. It does not assert that every closed typed term has a candidate. It asserts the exact theorem available from each of the candidate structures: if the candidate evidence is present, then the closed typed term is strongly normalizable and admits no infinite beta-reduction chain:

```
↪ variant BEDC.MetaCIC.ClosedTypedTerm
↪ variant BEDC.MetaCIC.ClosedTypedCandidate
↪ variant BEDC.MetaCIC.ClosedTypedPiCandidate
↪ variant BEDC.MetaCIC.closedTypedCandidate implies sn
↪ variant BEDC.MetaCIC.closedTypedPiCandidate implies sn
↪ variant BEDC.MetaCIC.closedTypedPiCandidate app sn
↪ variant BEDC.MetaCIC.closed typed term sn from candidate
```

```
↪ variant BEDC.MetaCIC.closed typed term sn from closedCandidate
↪ variant BEDC.MetaCIC.closed typed term sn from candidateSet
↪ variant BEDC.MetaCIC.strongNormalizable no infinite reduction
↪ variant BEDC.MetaCIC.closedTypedCandidate no infinite reduction
```

The gallery supplies concrete closed witnesses for the sort, Church Boolean, Church natural, identity, constant, and successor shapes used by the self-compilation account:

```
↪ variant BEDC.MetaCIC.closed sort sn
↪ variant BEDC.MetaCIC.closed lam sn from parts
↪ variant BEDC.MetaCIC.closed pi sn from parts
↪ variant BEDC.MetaCIC.closed neutral sn
↪ variant BEDC.MetaCIC.churchBoolTy sn
↪ variant BEDC.MetaCIC.churchNatTy sn
↪ variant BEDC.MetaCIC.churchIdentityTm sn
↪ variant BEDC.MetaCIC.churchIdentityTy sn
↪ variant BEDC.MetaCIC.churchTrueTm sn
↪ variant BEDC.MetaCIC.churchFalseTm sn
↪ variant BEDC.MetaCIC.churchZeroTm sn
↪ variant BEDC.MetaCIC.churchOneTm sn
↪ variant BEDC.MetaCIC.churchConstTy sn
↪ variant BEDC.MetaCIC.churchConstTm sn
↪ variant BEDC.MetaCIC.churchSuccTy sn
↪ variant BEDC.MetaCIC.churchSuccTm sn
```

This is the strong-normalization claim carried by the manuscript. The theorems are genuine Lean theorems with no axioms and no placeholders, but their quantifiers are candidate-scoped or gallery-scoped. A global theorem that every closed typed represented term has a reducibility candidate is not part of this claim.

9235.16.5 Claim 5: Decidable Type Checker

The executable checker is the function `inferTypeCtx`. It computes an optional represented type from a represented context and term, using native recursive equality checks and the same syntax and context lookup as the typing relation. Its closed version is the empty-context specialization:

```
↪ variant BEDC.MetaCIC.inferTypeCtx
↪ variant BEDC.MetaCIC.inferTypeCtxClosed
↪ variant BEDC.MetaCIC.inferTypeCtx eq inferType
```

Soundness states that a successful checker result gives a `HasType` witness. Completeness states that a represented typing derivation is found by the checker. The shape-specific completeness theorems expose the sort, variable, Pi, lambda, and application cases separately:

```
↪ variant BEDC.MetaCIC.inferTypeCtx sound
↪ variant BEDC.MetaCIC.inferTypeCtx complete
↪ variant BEDC.MetaCIC.inferTypeCtxClosed sound
↪ variant BEDC.MetaCIC.inferTypeCtxClosed complete
↪ variant BEDC.MetaCIC.CheckCompleteness.inferTypeCtx complete raw
↪ variant BEDC.MetaCIC.CheckCompleteness.inferTypeCtx complete total
↪ variant BEDC.MetaCIC.CheckCompleteness.inferTypeCtx complete sort
↪ variant BEDC.MetaCIC.CheckCompleteness.inferTypeCtx complete var
↪ variant BEDC.MetaCIC.CheckCompleteness.inferTypeCtx complete pi
↪ variant BEDC.MetaCIC.CheckCompleteness.inferTypeCtx complete lam
```

```
↪ variant BEDC.MetaCIC.CheckCompleteness.inferTypeCtx complete app
↪ variant BEDC.MetaCIC.inferTypeCtx complete strict
```

The lookup-based closed-atom layer records the boundary behavior at empty contexts. Sort checks as sort, variables are rejected in the empty context, and the inversion lemmas expose how a typed atom or compound term must have arisen:

```
↪ variant BEDC.MetaCIC.inferTypeCtx complete sort
↪ variant BEDC.MetaCIC.inferTypeCtxClosed var empty none
↪ variant BEDC.MetaCIC.hasType sort empty ctx
↪ variant BEDC.MetaCIC.hasType var ctx lookup
↪ variant BEDC.MetaCIC.hasType var empty ctx absurd
↪ variant BEDC.MetaCIC.hasType app empty ctx pi
↪ variant BEDC.MetaCIC.hasType lam empty ctx pi
↪ variant BEDC.MetaCIC.hasType pi empty ctx
```

The checker claim is therefore an executable metatheory claim. It is not a prose assertion that type checking is decidable in some external calculus; it is a concrete function together with soundness, completeness, and closed empty-context atom behavior over the represented calculus.

9235.16.6 Claim 6: Self-Representability via HostBridge

The host bridge relates ordinary host CIC examples to represented MetaCIC terms by a finite transport gallery. On the host side, identity, constant, flip, compose, Church Booleans, Church naturals, pairs, options, and selected redexes compute by reflexive equalities. These equalities are not imported as axioms about the represented calculus; they are paired with represented typing and reduction witnesses:

```
↪ variant BEDC.HostBridge.MetaCICTransport.Host.host identity beta
↪ variant BEDC.HostBridge.MetaCICTransport.Host.host const beta
↪ variant BEDC.HostBridge.MetaCICTransport.Host.host flip beta
↪ variant BEDC.HostBridge.MetaCICTransport.Host.host compose beta
↪ variant BEDC.HostBridge.MetaCICTransport.Host.host church true beta
↪ variant BEDC.HostBridge.MetaCICTransport.Host.host church false beta
↪ variant BEDC.HostBridge.MetaCICTransport.Host.host church zero beta
↪ variant BEDC.HostBridge.MetaCICTransport.Host.host church one beta
↪ variant BEDC.HostBridge.MetaCICTransport.Host.host pair fst beta
↪ variant BEDC.HostBridge.MetaCICTransport.Host.host pair snd beta
↪ variant BEDC.HostBridge.MetaCICTransport.Host.host none beta
↪ variant BEDC.HostBridge.MetaCICTransport.Host.host some beta
```

The transport layer gives the represented typing side of the same gallery. Each transport theorem is an empty-context `HasType` witness over the MetaCIC syntax:

```
↪ variant BEDC.HostBridge.MetaCICTransport.transport identity well typed
↪ variant BEDC.HostBridge.MetaCICTransport.transport const well typed
↪ variant BEDC.HostBridge.MetaCICTransport.transport flip well typed
↪ variant BEDC.HostBridge.MetaCICTransport.transport compose well typed
↪ variant BEDC.HostBridge.MetaCICTransport.transport church bool type well typed
↪ variant BEDC.HostBridge.MetaCICTransport.transport church true well typed
↪ variant BEDC.HostBridge.MetaCICTransport.transport church false well typed
↪ variant BEDC.HostBridge.MetaCICTransport.transport church nat type well typed
↪ variant BEDC.HostBridge.MetaCICTransport.transport church zero well typed
↪ variant BEDC.HostBridge.MetaCICTransport.transport church one well typed
```

```
↪ variant BEDC.HostBridge.MetaCICTransport.transport church succ well typed
↪ variant BEDC.HostBridge.MetaCICTransport.transport church pair type well typed
↪ variant BEDC.HostBridge.MetaCICTransport.transport church mk pair well typed
↪ variant BEDC.HostBridge.MetaCICTransport.transport church option type well typed
↪ variant BEDC.HostBridge.MetaCICTransport.transport church none well typed
↪ variant BEDC.HostBridge.MetaCICTransport.transport church some well typed
```

The bounded normalizer gives an operational companion to the transport gallery. It is a fuel-indexed recursive function over represented terms. Concrete equations state that sufficient fuel reaches the expected normal forms for the finite examples, and separate beta-chain theorems give the object-language reduction traces:

```
↪ variant BEDC.MetaCIC.normalizeBounded
↪ variant BEDC.HostBridge.normalize id app sort
↪ variant BEDC.HostBridge.normalize poly identity apply
↪ variant BEDC.HostBridge.normalize church true apply
↪ variant BEDC.HostBridge.normalize church false apply
↪ variant BEDC.HostBridge.normalize church zero apply
↪ variant BEDC.HostBridge.normalize church one apply
↪ variant BEDC.HostBridge.host id app sort
↪ variant BEDC.HostBridge.host poly identity apply
↪ variant BEDC.HostBridge.host church true apply
↪ variant BEDC.HostBridge.host church zero apply
↪ variant BEDC.HostBridge.id app sort beta star
↪ variant BEDC.HostBridge.poly identity chain
↪ variant BEDC.HostBridge.church true apply chain
↪ variant BEDC.HostBridge.church false apply chain
```

This is a self-representability claim for a finite gallery, not a theorem that arbitrary host Lean terms elaborate into MetaCIC terms. The bridge is exact because each transported example is named on both sides.

9235.16.7 Claim 7: Church-Encoded Data Structure Laws

The Church gallery is a typed object-language gallery. Booleans, naturals, pairs, options, and polymorphic function forms are represented as MetaCIC terms and typed in the empty context:

```
↪ variant BEDC.MetaCIC.church bool type
↪ variant BEDC.MetaCIC.church true
↪ variant BEDC.MetaCIC.church false
↪ variant BEDC.MetaCIC.church nat type
↪ variant BEDC.MetaCIC.church zero
↪ variant BEDC.MetaCIC.church one
↪ variant BEDC.MetaCIC.church succ type
↪ variant BEDC.MetaCIC.church succ
↪ variant BEDC.MetaCIC.church pair type
↪ variant BEDC.MetaCIC.church mk pair
↪ variant BEDC.MetaCIC.church fst
↪ variant BEDC.MetaCIC.church snd
↪ variant BEDC.MetaCIC.church option type
↪ variant BEDC.MetaCIC.church none
↪ variant BEDC.MetaCIC.church some
```

```
↪ variant BEDC.MetaCIC.church case option
↪ variant BEDC.MetaCIC.poly identity type
↪ variant BEDC.MetaCIC.poly const type
↪ variant BEDC.MetaCIC.poly flip type
↪ variant BEDC.MetaCIC.poly compose type
```

The algebraic laws are represented beta-star equalities, not host-side rewrite folklore. Boolean projections select the expected branch, Church zero and one apply as expected, polymorphic identity returns its argument, and pair elimination sends a Church pair to the selector applied to its two payloads:

```
↪ variant BEDC.MetaCIC.church true proj
↪ variant BEDC.MetaCIC.church false proj
↪ variant BEDC.MetaCIC.church zero apply
↪ variant BEDC.MetaCIC.church one apply
↪ variant BEDC.MetaCIC.poly identity apply
↪ variant BEDC.MetaCIC.churchPairPayload normalize
↪ variant BEDC.MetaCIC.church pair value to selector
```

The redex gallery connects the same algebraic surface to explicit `BetaStep` and `BetaStarStep` witnesses. These targets are the closed concrete traces used by the bounded normalizer and by the transport bridge:

```
↪ variant BEDC.MetaCIC.id sort redex
↪ variant BEDC.MetaCIC.id sort redex typed
↪ variant BEDC.MetaCIC.fn sort to sort redex
↪ variant BEDC.MetaCIC.fn sort to sort redex typed
↪ variant BEDC.MetaCIC.const sort redex
↪ variant BEDC.MetaCIC.const sort redex typed
↪ variant BEDC.MetaCIC.poly id two step redex
↪ variant BEDC.MetaCIC.poly id two step redex typed
↪ variant BEDC.MetaCIC.k sort two step redex
↪ variant BEDC.MetaCIC.k sort two step redex typed
```

The Church-encoded data claim is therefore a mechanized family of typed examples and beta-star laws for the represented calculus. It covers the finite data structures used in the self-compilation surface; it does not assert native inductive families in the represented object language.

9235.16.8 Claim 8: BetaConv Relation Properties

`BetaConv` is the joinability relation induced by `BetaStarStep`. Reflexivity, symmetry, inclusion of beta-star and one-step beta on either side, and conditional transitivity under a confluence input are all checked:

```
↪ variant BEDC.MetaCIC.BetaConv
↪ variant BEDC.MetaCIC.BetaConv.refl
↪ variant BEDC.MetaCIC.BetaConv.symm
↪ variant BEDC.MetaCIC.BetaConv.of betaStar left
↪ variant BEDC.MetaCIC.BetaConv.of betaStar right
↪ variant BEDC.MetaCIC.BetaConv.of betaStep left
↪ variant BEDC.MetaCIC.BetaConv.of betaStep right
↪ variant BEDC.MetaCIC.BetaConv.trans of confluence
```

There is also a closed-normal transitivity route. If the middle term is beta-strong, both conversion witnesses must meet at that normal middle, so conversion composes through it. Closed normal forms related by `BetaConv` are equal:

↪ variant `BEDC.MetaCIC.betaNormal of betaStrong`

↪ variant `BEDC.MetaCIC.BetaConv.trans normal middle`

↪ variant `BEDC.MetaCIC.BetaConv.trans closed normal middle`

↪ variant `BEDC.MetaCIC.BetaConv normal forms equal closed`

The important negative fact is also checked: empty-context typing is not invariant under `BetaConv` in full generality. The obstruction is a lambda-domain type example. The source and target are closed and beta-convertible, the source has the displayed type, and the target does not:

↪ variant `BEDC.MetaCIC.HasTypeBetaConvInvariantClosedStatement`

↪ variant `BEDC.MetaCIC.closedLamDomainTarget closed`

↪ variant `BEDC.MetaCIC.BetaConv closed lam domain type obstruction`

↪ variant `BEDC.MetaCIC.not HasType BetaConv invariant closed`

Consequently, the manuscript can use `BetaConv` as a checked joinability relation with equivalence-like behavior in the confluence or closed-normal sub-scope. It cannot use `BetaConv` as a blanket typing conversion rule for `HasType` over the closed empty-context fragment.

9235.16.9 Boundary Statement

The scope boundary is part of the claim. Open-term metatheory is outside the closed empty-context surface. The obstruction is concrete: the naive substitution-composition shape fails at depth 0 with $v = \texttt{var}\ 0$, $u = \texttt{sort}$, and $t = \texttt{var}\ 1$. The corresponding Lean target records the inequality directly, and the confluence layer exposes the same obstruction as a substitution-commutation boundary:

↪ variant `BEDC.MetaCIC.substitute substitute zero zero unclosed counterexample`

↪ variant `BEDC.MetaCIC.substitute commutation unclosed obstruction`

↪ variant `BEDC.MetaCIC.BetaParallelSubstitutionCompatibility`

The represented calculus also excludes a universe hierarchy, cumulative universes, native inductive families, eliminators for those families, propositional irrelevance, quotient principles, and eta-conversion. The syntax has one sort and beta reduction only. Any argument requiring those features must introduce a separate bridge or a separate represented calculus; it is not licensed by the claim in this section.

9235.16.10 Delivered Invariants

The delivered invariants are project-level as well as theorem-level. The `lean4/` development imports Lean 4 core facilities and project files, not mathlib. The project axiom audit rejects `axiom` declarations in `lean4/BEDC/`. The build is kept at zero sorry. The axiom-purity audit checks theorem dependencies against forbidden host principles, including `Classical.choice`, `Quot.sound`, and `propext`.

These invariants determine how the preceding claims are read. The markers in this section are not literary citations; each target is a Lean object in the project. The substrate, subject-reduction, confluence, normalization, checker, host-bridge, Church-algebra, and beta-conversion surfaces are therefore reproducible as mechanized claims over the represented calculus. The boundary clauses are equally binding: where a stronger statement is refuted or only conditional, the paper reads the formal target as a refusal to overstate the metatheory.

9235.17 Session Closing Summary

This closing section gathers the self-compilation surface as a single reader-facing account. The chapter has reached a point where the closed-term metatheory is represented inside Lean, the Church-encoded gallery is broad enough to exercise the object calculus, and the host bridge carries both directions of the intended comparison: ordinary Lean examples on one side, represented MetaCIC terms and beta traces on the other. The result is not a full kernel story. It is a closed, first-principles story about the fragment that BEDC uses when it treats its finite self-description as object language data.

The self-compilation chapter began from the L1/L4 distinction and the Godel–Tarski boundary. It then built the MetaCIC reconstruction as an explicit object calculus: syntax, contexts, closure, substitution, typing, beta reduction, finite beta chains, typed examples, bounded normalization, and bridges from finite BEDC histories. The present position is sharper than a catalogue of definitions. The calculus has closed-term preservation facts, subject-reduction interfaces with checked positive and negative resolutions, atom and closed-normal confluence results, candidate-based strong-normalization witnesses for the represented gallery, a decidable checker with soundness and completeness facts, Church-encoded data with beta laws, and HostBridge transport facts aligning represented examples with host computation.

The common invariant behind these pieces is that BEDC does not outsource the mathematics to a quotation facility or to mathlib. The represented syntax is an inductive datatype. De Bruijn shifting and substitution are recursive functions. Closure, typing, beta steps, beta-star chains, parallel beta, and conversion are object-language relations. Every Lean target cited below lives in this first-principles surface. The paper therefore reads the self-compilation chapter as a closed-term metatheory for the represented fragment, not as a statement about Lean's host kernel.

9235.17.1 Mechanized Theorems Table

The table records the principal theorem families used by the chapter. Each entry uses `\leanvariant` because this section is an index of already documented targets rather than the primary site for a single canonical paper theorem.

Layer	Mechanized content	Lean targets
Substrate	Closed terms, native substitution, shift-aware closure, and closure preservation across beta traces.	↪ variant `BEDC.MetaCIC.shift closed` ↪ variant `BEDC.MetaCIC.substitute closed` ↪ variant `BEDC.MetaCIC.closedAt shift` ↪ variant `BEDC.MetaCIC.closedAt substitute` ↪ variant `BEDC.MetaCIC.substitute preserves closed at` ↪ variant `BEDC.MetaCIC.betaStep preserves closed` ↪ variant `BEDC.MetaCIC.betaStarStep preserves closed`

Layer	Mechanized content	Lean targets
Typing rules	The object typing judgment, the beta-substitution interface, and shape-wise substitution preservation for Pi, lambda, and application.	↪ variant BEDC.MetaCIC.HasType ↪ variant BEDC.MetaCIC.BetaSubstitutionPreservation ↪ variant BEDC.MetaCIC.substitute preserves typing pi ↪ variant BEDC.MetaCIC.substitute preserves typing lam ↪ variant BEDC.MetaCIC.substitute preserves typing app cod sort var commutes ↪ variant BEDC.MetaCIC.substitute preserves typing via term induction
Subject reduction	The hypothesis-explicit subject-reduction theorem, its constructor cases, the closed independent-codomain application discharge, and the checked closed binder-domain obstructions.	↪ variant BEDC.MetaCIC.subject reduction beta ↪ variant BEDC.MetaCIC.subject reduction congApp1 ↪ variant BEDC.MetaCIC.subject reduction congApp2 ↪ variant BEDC.MetaCIC.subject reduction congLam ↪ variant BEDC.MetaCIC.subject reduction congPi ↪ variant BEDC.MetaCIC.subject reduction ↪ variant BEDC.MetaCIC.appArgTypeStable closed ↪ variant BEDC.MetaCIC.subject reduction closed app independent codomain ↪ variant BEDC.MetaCIC.not subject reduction closed

Layer	Mechanized content	Lean targets
Confluence	Atom diamonds, shape assemblers for compound terms, the conditional full parallel diamond, and the unconditional closed-normal surface.	↪ variant BEDC.MetaCIC.betaStarStep diamond sort ↪ variant BEDC.MetaCIC.betaStarStep diamond var ↪ variant BEDC.MetaCIC.betaParallel diamond sort ↪ variant BEDC.MetaCIC.betaParallel diamond var ↪ variant BEDC.MetaCIC.betaParallel app diamond of components ↪ variant BEDC.MetaCIC.betaParallel lam diamond of components ↪ variant BEDC.MetaCIC.betaParallel pi diamond of components ↪ variant BEDC.MetaCIC.betaParallel app shape diamond from substitution ↪ variant BEDC.MetaCIC.betaParallel diamond from substitution ↪ variant BEDC.MetaCIC.betaParallel diamond closed normal ↪ variant BEDC.MetaCIC.betaStarStep confluence closed normal

9235.17.2 How to Read the Table

The table is deliberately organized by proof pressure rather than by file path. A reader who starts from the substrate rows sees the object calculus as a small de Bruijn machine: terms are built by constructors, contexts are lists, closure is a boundary predicate, and substitution is the operation that must respect the boundary. This is the layer that prevents later examples from becoming informal syntax diagrams. The object calculus has to preserve its own scope before any self-compilation claim can use it.

The typing and subject-reduction rows then show how much of the ordinary metatheory is available at the represented level. The theorem named `subject_reduction` is intentionally hypothesis-explicit. It is not a paper promise that all conversion-sensitive facts hold automatically. It is a Lean theorem that lists the required stability interfaces and proves the constructor cases once those interfaces are supplied. The closed independent-codomain theorem is the positive closed case used by the gallery. The negative closed binder-domain targets explain why the paper does not silently strengthen the theorem beyond what the represented calculus proves.

The confluence row has the same discipline. The atom and closed-normal targets are unconditional. The application and full-diamond targets expose a substitution-compatibility premise. This matters because the self-compilation chapter uses confluence where its sources are atom-shaped, closed-normal, or part of the finite gallery. It does not need to pretend that every application residual of the represented calculus has been globally joined. The row therefore records both usable theorem content and the exact algebraic frontier.

The strong-normalization row should also be read as a scoped result. The project has a robust vocabulary of candidates, closed candidates, Pi candidates, neutral normal forms, and closed typed candidate consequences. That vocabulary is sufficient for the gallery witnesses and for the closed-term termination claims made in the chapter. It is not a semantic normalization theorem for every well-typed represented term. This distinction keeps the paper aligned with its Lean surface: the file names and theorem names show candidate adequacy where it is actually proved, not where a textbook proof might eventually go.

The decidable-checker row is the executable counterpart to the inductive typing relation. It closes a practical loop: the chapter can present a represented term, cite an inductive typing witness, and also cite a recursive checker whose soundness and completeness connect computation back to `HasType`. This is one of the reasons the self-compilation surface is not merely philosophical. The represented fragment can be used as data, and the project has a checked path for recognizing its closed typed examples.

The Church gallery and HostBridge rows give the computational content of the chapter. Church Booleans, naturals, pairs, options, and polymorphic combinators are familiar enough to act as inspection points. If the represented calculus mishandled binders, substitution, application, or closedness, these examples would be where the defect becomes visible. The host bridge then places those represented examples next to ordinary host Lean functions. The bridge does not collapse the two layers; it gives a finite alignment of examples across them.

The BetaConv row is a useful final row because it shows how the chapter treats conversion. Conversion is represented as a common-join relation over `BetaStarStep`. Reflexivity and symmetry are immediate from that definition. Transitivity is available under named confluence conditions and under the closed-normal middle case. The closed lambda-domain obstruction prevents the paper from claiming a blanket typing-invariance theorem for closed conversion. Thus even the conversion layer follows the same pattern: state the relation, prove the stable facts, and name the obstruction where the stronger reading fails.

9235.17.3 Closed Surface

The closed surface consists of the parts of the chapter that can be read without an unproved paper-side metatheoretic promise. The first closed part is the de Bruijn substrate. The calculus does not identify closedness with a typographic convention about missing variable names. It proves that the recursive operations respect the boundary they are meant to respect. This is the algebra behind every later finite evaluator trace: once a term is closed at boundary 0, beta contraction and beta congruence cannot manufacture a free represented variable.

The second closed part is the subject-reduction interface. The central theorem states the exact hypotheses needed for displayed-type preservation along one beta step. The beta case and congruence cases are checked directly. Inside the closed empty-context surface, the application-argument stability interface is discharged for independent codomains. The two binder-domain interfaces are not swept into prose: Lean supplies closed counterexamples showing that lambda-domain and Pi-domain blanket readings are false as stated. This gives the chapter a stronger boundary than an informal preservation paragraph would give. It says what works, what does not work, and which object-language witnesses enforce the distinction.

The third closed part is confluence at the level needed by the current self-compilation reading. Atom sources have no genuine beta forks. Closed normal sources have immediate joins. Compound terms have shape assemblers, and the full parallel diamond is available from the named substitution compatibility condition. The confluence story is therefore not hidden behind a universal Church–Rosser slogan. It is a structured surface: atom results, shape results, closed-normal results, and one explicit algebraic frontier for application residuals.

The fourth closed part is normalization for the represented gallery. The chapter uses strong-normalization witnesses and candidate structures, not a global theorem that every closed well-typed represented term normalizes. Sorts, variables, neutral applications, lambdas, Pis, Church Booleans, Church naturals, identity-shaped terms, and selected closed terms carry the witnesses needed by the paper. The main practical fact is enough for the BEDC surface: the concrete

represented programs used as examples come with closed typing, finite beta traces, or candidate-style termination evidence at the exact places where termination is cited.

The fifth closed part is the executable checker. The checker is not an oracle. It is a recursive function whose result is connected back to `HasType`. Soundness says that a returned type is justified by the inductive typing judgment. Completeness says that a derivable term is accepted by the checker at the displayed type. The closed wrapper specializes that story to the empty-context surface used by the chapter. This makes the gallery simultaneously human-readable and executable: a represented term can be shown in the paper, typed by an inductive proof, and checked by the decidable surface.

The sixth closed part is the Church gallery. The gallery covers Boolean choice, natural zero and one, successor, pairs, options, and polymorphic combinators. Its laws are beta-star laws over represented terms, not host-level reductions pasted into prose. The natural recursion surface closes successor and addition, including the relation between successor of zero and one, addition by zero on the left, application of addition, and the successor-left law. Multiplication and exponentiation are not cited here as mechanized targets because no Lean target with those names is present in the audited surface.

The seventh closed part is HostBridge. The bridge has two readings. On the host side, ordinary Lean functions compute by reflexivity. On the represented side, the corresponding MetaCIC terms have typing witnesses and beta traces. The bridge does not claim that host Lean elaboration is reflected into MetaCIC. It provides a checked finite transport gallery, large enough to say that the same examples that compute in the host also exist as represented object-language terms inside BEDC.

9235.17.4 Open Frontier

The open frontier is equally important to the chapter's meaning. The first frontier is open-term metatheory across binders. The closed empty-context surface is robust, but closedness at the outer boundary does not erase the local obligations created below lambdas and Pis. The checked binder-domain counterexamples show exactly why. A stronger theorem would need a transport discipline for binder contexts and displayed codomains, not merely a stronger wording of the closed theorem.

The second frontier is full confluence for `BetaStarStep` beyond the atom and closed-normal shapes. The atom diamonds are complete for atom sources, and the compound machinery exposes the right structure, but a full unconditional Church–Rosser result needs the remaining substitution compatibility law for application residuals. The chapter therefore treats `betaParallel_diamond_from_substitut` as a conditional theorem, not as a completed global confluence theorem.

The third frontier is the rest of Church natural arithmetic. Successor and addition are represented and mechanized. The present paper surface does not cite multiplication or exponentiation targets because the audited Lean tree does not contain them. Those operations fit the same object-language style, but the closing account reports only the checked targets that the audit can find.

The fourth frontier is the full host-kernel feature set: universe hierarchy, inductive families, propositional irrelevance, eta-conversion, cumulativity, quotients, and proof-irrelevant conversion. None of these is part of the present `BEDC.MetaCIC` scope. The calculus is a universe-0, beta-only, single-sort dependent-function fragment. This restriction is not an omission to hide. It is what keeps the formalization mathlib-free and axiom-free while still covering the represented terms used by the self-compilation story.

9235.17.5 Why This Surface Closes Here

This is the correct closing point because the closed-term metatheory now covers the substance of BEDC's self-compilation surface. The paper needs a finite represented syntax, a checked closure discipline, a typing relation, beta traces, a bounded evaluator, examples that exercise dependent functions, Church-encoded data, and a bridge to ordinary host examples. Those pieces are present. Their Lean targets are visible. Their restrictions are visible as well.

The zero-axiom invariant is central to the interpretation. BEDC's MetaCIC surface is not merely constructive in prose. It avoids project axioms, mathlib imports, sorry placeholders, and standard-library axiom dependencies in the validated discipline of the project. In that sense the represented metatheory sits in the same strict constructive class that one expects from a Brouwer or Bishop reading: theorems are derived from inductive definitions, recursive functions, structures, and prior theorems, not from an external logical extension.

The practical consequence is that the chapter can stop treating self-compilation as a metaphor. A finite BEDC history can be embedded as a closed represented term. A represented term can be typed. Finite represented beta traces can be checked. Closedness is preserved along those traces. Representative host computations have corresponding represented transport witnesses. The remaining task line is therefore not to argue again that reflection is possible in principle. It is to extend the BHist substrate bridge from closed atoms toward self-application while preserving the same audit discipline.

9235.17.6 Forward-Looking Summary

The next self-compilation work line is not a broader claim about every CIC feature. It is a deeper bridge from BEDC's finite-history substrate into the represented closed-term calculus. The current `BHistSubstrate` embedding already shows that a history index can be turned into a closed MetaCIC term and that the embedding is injective. The natural continuation is to give that embedding more semantic load: histories should not only enter the represented syntax as atoms, but should participate in typed represented programs that describe their own admissible transformations.

That direction keeps the chapter's scale under control. Instead of expanding the object calculus toward all of Lean, the project can ask a narrower question: which additional finite BEDC structures must be represented so that self-application is no longer merely a host-side explanation? The answer is likely to involve typed encodings of package signatures, bridge certificates, and closure-preserving transformations between history-shaped terms. Each candidate should enter by the same route used here: define the represented object, prove closure, prove typing, give finite beta behavior where computation is claimed, and expose every remaining hypothesis as a named Lean target.

The closed-term metatheory is already enough to support that route. It gives the low-level guarantee that represented self-application does not lose the boundary condition. It gives a subject-reduction theorem whose hypotheses tell the project which typing interfaces must be supplied. It gives a confluence surface for the atom and closed-normal cases likely to appear in finite certificate encodings. It gives candidate and strong-normalization witnesses for the small functional programs used as examples. It gives an executable checker for recognizing the typed fragment. Those are the ingredients needed for a disciplined expansion of the BHist bridge, provided each additional represented object remains inside the same audit rules.

The Church gallery suggests a useful design style for that expansion. The gallery does not begin with a universal theorem about all data encodings. It starts with concrete encodings whose

laws are inspectable. Booleans choose, naturals apply successors, pairs feed a selector, options choose between a default and a branch, and polymorphic functions exercise Pi structure. A self-application bridge can follow the same method: begin with finite, closed, typed objects whose behavior can be stated as beta-star or BetaConv laws, then use the resulting library as the surface that higher-level BEDC claims cite.

HostBridge also points to the right discipline. The host layer is valuable because it gives ordinary Lean computations that readers can recognize. The represented layer is valuable because it proves that corresponding examples exist inside the object calculus. Future bridge work should preserve that separation. A host computation can guide the example, but the represented term must carry its own typing and reduction evidence. A host theorem can explain the expected behavior, but the paper-side claim should cite the MetaCIC target that realizes the behavior in the represented language.

The open-term frontier should be approached only when the closed bridge requires it. The binder-domain counterexamples show that open contexts are not a matter of adding a quantifier to closed theorems. They require a context-transport account that respects shifted domains and displayed codomains. If self-application can be expressed through closed certificate objects and closed transformations, the project should keep using that route. If a later certificate necessarily crosses binders, the theorem statement should expose the transport structure directly rather than hiding it behind a closedness hypothesis.

The same caution applies to full confluence. A complete Church–Rosser theorem would be valuable, but the chapter already identifies the exact missing algebraic law. The correct next theorem would be the substitution compatibility needed by application residuals, stated over the actual `substitute` and `shift` functions of the represented calculus. Once that law is available, the existing conditional diamond target provides the route to the stronger result. Until then, the paper should continue to cite atom, shape, closed-normal, and conditional confluence targets with their actual scopes.

The arithmetic frontier is similarly concrete. Successor and addition are mechanized for Church naturals. Multiplication and exponentiation should be added only when their represented terms, closure facts, typing facts, and beta laws exist in Lean. The present closing section therefore treats them as mathematical next objects, not as paper facts. This is not a weakness of the self-compilation chapter; it is the rule that keeps the chapter audit-clean.

In short, the forward path is to make self-application less metaphorical while keeping the calculus small. Extend the finite-history bridge. Add represented certificate programs only when their closed typing and beta behavior are checked. Preserve the distinction between host computation and represented computation. Treat open binders, full confluence, richer arithmetic, universes, and inductive families as separate theorem projects. The closing surface is strong because it is narrow, visible, and mechanically audited.

9235.17.7 What BEDC Does Not Claim

BEDC does not claim to replace the Lean 4 kernel. The represented calculus is an object-language fragment inside Lean, not an implementation of Lean's elaborator, environment, universe constraints, inductive compiler, recursor generation, quotient layer, or kernel conversion checker. Host Lean remains the metalanguage in which BEDC proves facts about the represented object calculus.

BEDC also does not claim a universal mechanization of CIC. The present scope is deliberately constrained by three commitments: first-principles definitions, mathlib-free Lean, and zero project axioms. Those commitments make the proofs auditable, but they also keep the object calculus

narrow. The correct reading is a closed-term sub-fragment with a rich gallery and explicit bridges, not a general theorem about all terms and all type formers of CIC.

Finally, BEDC does not claim that every frontier has been discharged by naming it. Conditional theorems remain conditional. Counterexamples remain counterexamples. Open-term binder transport, full application-residual confluence, universe hierarchy, inductive families, propositional irrelevance, eta-conversion, multiplication, and exponentiation stay outside the closed surface reported here unless corresponding Lean targets enter the audited tree. This is the discipline that makes the closing meaningful: the chapter closes exactly the surface it can verify, and no larger one.

9235.18 What BEDC.MetaCIC Does Not Claim

This section fixes the load-bearing absences around `BEDC.MetaCIC`. The closed-term, empty-context surface is intentionally strong enough for the self-compilation account and intentionally too small to be read as a replacement for a production CIC kernel. The object calculus is represented inside Lean as a first-principles, mathlib-free development: it has represented terms, represented contexts, de Bruijn closure, shift, substitution, beta reduction, typed examples, bounded normalization, and a set of named metatheoretic interfaces. It is not a mirror of every feature that appears in Lean 4, Coq-style CIC, or the pure type systems literature.

The boundary matters because the positive results are now dense enough that a reader can overgeneralize them. A theorem about closed represented terms may look like a theorem about arbitrary open host terms. A beta-only reduction relation may look like definitional equality. A single-sort universe constant may look like a universe hierarchy. A gallery of Church encodings may look like native inductive families. Those readings are not the claims made here. The claim is narrower and more useful for BEDC: the represented closed fragment used by the self-compilation surface is explicit, checked, and bounded.

9235.18.1 Why This Boundary Is Stated

The self-compilation argument consumes finite represented artifacts. A BEDC reflection packet talks about names, histories, represented terms, typed closed witnesses, finite beta traces, and object-language certificates that are already inside the manuscript's finite surface. This use case does not require the whole host kernel. It requires a precise subcalculus whose syntax and metatheory can be inspected without importing untracked logical strength.

That is the reason `BEDC.MetaCIC` is formulated as an object calculus. The Lean kernel remains the trusted host that checks the formalization. The MetaCIC layer is not another implementation of that kernel. It is a represented calculus whose constructors and relations are small enough to be audited by the project gates. When the paper cites the MetaCIC surface, the reader should read the claim as a theorem about the represented fragment, not as a theorem about every term, universe, recursor, quotient, and definitional equality feature accepted by Lean.

The most important narrowing is the closed empty-context reading. The object-level invariant is:

$$\mathrm{ClosedEmptyMetaCIC}(t, A) \quad \equiv \quad \texttt{ClosedAt}\ 0\ t \wedge \texttt{HasType}\ []\ t\ A.$$

This is the surface on which the self-compilation examples live. It is also the surface on which closure preservation, selected subject-reduction interfaces, closed-normal confluence facts, candidate witnesses, executable checking, and finite HostBridge examples are read. The calculus

exposes stronger-looking open-term statements only when they have explicit hypotheses or checked obstructions. Therefore this section states the negative space in the same voice as the positive theorems: not as cautionary prose, but as part of the mathematical specification.

9235.18.2 Out of Scope by Design

Feature	Boundary in `BEDC.MetaCIC`	Rationale
Universe hierarchy	The represented syntax has a single universe-0 sort, not `Sort 0`, `Sort 1`, cumulativity, or universe polymorphism.	The self-compilation surface needs closed represented witnesses in one object-level sort. Adding universe levels would change the syntax, typing rules, conversion relation, and metatheory obligations.
Inductive families	The represented object language has the atomic term grammar `sort`, `var`, `app`, `lam`, and `pi`.	Church encodings are represented; native families such as `Vec n` or `List A` are not object-language constructors with recursors and computation rules.
Proposition irrelevance	The calculus does not separate `Prop` from `Type`.	There is one object sort. No proof-irrelevance principle is assumed, encoded, or needed for the closed self-compilation witnesses.
η-conversion	The reduction relation is strictly beta-only.	The mechanized reduction surface is generated by beta contraction and congruence. Extensional equality principles are not silently folded into conversion.
Pattern matching beyond term constructors	The proofs inspect represented syntax by constructor analysis, for example `cases ... with` over `Term`.	The object language does not contain a general pattern-matching eliminator. Meta-level proof scripts may analyze inductive syntax, but that is not an object-language feature.
General fixpoints and well-founded recursion	The calculus uses inductive relations and structurally recursive host functions where they are explicit.	There is no represented general recursive definition principle. Termination evidence is carried by inductive witnesses, candidates, fuel, or structural recursion in the host.
Open-term metatheory across binders	The manuscript does not claim the full open-term substitution and subject- reduction theory of a production kernel.	The substrate has a documented obstruction: the naive zero-depth substitution composition law fails for unclosed anchors, as recorded by counterexample #108 and by the named MetaCIC counterexample.

Universe hierarchy. The represented grammar contains a single sort constructor. The paper may write "universe-0" as a mnemonic for the object-level scale, but that is not a commitment to a hierarchy of object universes. There is no represented `Sort 1`, no lifting relation between universes, no cumulativity rule, and no universe-polymorphic binder discipline. Consequently, any theorem whose proof would use universe constraints, universe maximums, predicative stratification, or cumulativity transport lies outside the claim surface.

This omission is intentional. Universe hierarchy is not a cosmetic annotation on an existing calculus. It changes the formation rules for Pi, the shape of type inference, the statement of conversion, and the induction principles used in metatheory. BEDC's self-compilation surface does not need those rules. It needs closed represented terms whose typing witnesses can be checked without importing a second layer of universe bookkeeping.

Inductive families. The object language has dependent functions and application, but it does not have native inductive families. A family such as `Vec A n` would require object-level constructors, parameters, indices, eliminators, recursors, computation rules, and positivity or guardedness conditions. A production kernel has to define and check those interfaces. `BEDC.MetaCIC` does not.

The Church gallery should therefore be read correctly. Church Booleans, Church numerals, pairs, options, and combinators are represented as terms in the dependent-function fragment. They demonstrate that the fragment can carry useful closed encodings and beta laws. They are not a proof that the object language contains native inductive declarations, pattern matching, or recursor computation for arbitrary families.

Proposition irrelevance. The represented calculus does not distinguish `Prop` from `Type`. It has no separate impredicative proposition universe and no rule that identifies all proofs of the same proposition. Thus proposition irrelevance is not available as an object-language theorem, a conversion principle, or an implicit metatheoretic assumption.

This is also aligned with the axiom-purity discipline. BEDC avoids moving from logical equivalence to definitional identity unless a first-principles object-level construction supplies the equality in the represented calculus. That discipline is why `propext` is prohibited by audit rather than treated as a harmless background feature.

η-conversion. The reduction relation is beta-only. Lambda terms reduce by applying a lambda to an argument and substituting the argument into the body. Congruence allows beta steps under applications, lambdas, and Pis. No η rule says that a function is convertible to a lambda that applies it to a fresh variable. No record, pair, or function extensionality rule is folded into conversion.

This matters for subject reduction and confluence statements. A beta-only calculus has different normal forms, different residual obligations, and a smaller conversion relation than a beta-eta calculus. Any result that needs η-expansion, η-contraction, or extensional comparison of functions is outside the MetaCIC claim unless it is restated as an explicit additional relation with its own proof obligations.

Pattern matching beyond term constructors. The Lean proofs may analyze the inductive syntax of represented terms. This is ordinary host-side reasoning: a theorem about `Term` can proceed by cases over `sort`, `var`, `app`, `lam`, and `pi`. Such proof analysis does not mean that the represented object language has a general match expression or a dependent eliminator for every future object datatype.

The distinction is important. Host-side induction over the encoding is how the metatheory is proved. Object-side pattern matching would be a feature of the represented calculus itself, with typing rules, reduction rules, and subject-reduction obligations. BEDC uses the former and does not claim the latter.

General fixpoints and well-founded recursion. The object language does not contain a general fixpoint constructor. It also does not contain an object-level well-founded recursion principle. Where the formalization needs recursion, it uses ordinary Lean structural recursion on the encoded data, a fuel-indexed bounded function, or an inductively generated relation. Those are host-side implementation techniques and object-level relations, not an exported recursive programming language inside MetaCIC.

This boundary keeps termination evidence visible. Strong-normalization witnesses are carried by inductive predicates and candidate structures. Bounded normalization is controlled by fuel. Beta-star traces are finite inductive chains. None of these witnesses should be read as a general termination checker for arbitrary represented recursive definitions.

Open-term metatheory. The closed empty-context surface is not a disguised proof of full open-term metatheory. Open contexts require binder transport, shift/substitution interaction across changing cutoffs, and substitution-composition laws that are sensitive to closure hypotheses. The substrate obstruction is concrete: the naive zero-depth composition law for unclosed anchors is false, and the counterexample is documented as part of the MetaCIC boundary.

The existing closed facts therefore have an exact reading. Closure preservation says that beta steps do not create free variables from closed sources. The positive application subject-reduction result works for closed independent codomains. The binder-domain counterexamples show why closedness alone is not enough for blanket lambda-domain or Pi-domain preservation. Those are not gaps in an otherwise implicit open theorem. They are the formal end of the present claim surface.

9235.18.3 Comparison With Standard CIC Literature

Reference point	What it studies	BEDC reading
Coquand–Werner CIC	A rich dependent type theory with universes, inductives, conversion, and kernel-scale metatheory.	`BEDC.MetaCIC` is a represented single-sort beta-only fragment. It does not mirror normalization by evaluation or universe cumulativity.
Girard reducibility candidates	A semantic normalization method organized around candidates and adequacy.	BEDC has candidate vocabulary and checked candidate consequences for the closed gallery, but not a full mechanized adequacy chain for all represented typed terms.
Pure type systems	A framework parameterized by sorts, axioms, and product rules.	BEDC is best read as a single-sort sub-PTS encoded by an inductive typing relation, not as a general PTS framework.

Reference point	What it studies	BEDC reading
Lean 4 kernel	The host implementation that elaborates, reduces, and checks Lean code.	BEDC is checked by Lean but does not reimplement Lean. Its theorems avoid the standard-library axioms forbidden by the project audit.

Coquand–Werner CIC. The name MetaCIC signals the object of comparison, not identity of scope. Classical CIC presentations support a richer theory than the fragment used here: universe hierarchies, cumulativity, inductive types, eliminators, and a conversion relation integrated with the kernel. BEDC does not replicate that whole package. In particular, it does not present a normalization-by- evaluation algorithm for full CIC, and it does not mechanize universe cumulativity.

The comparison should be read as follows. BEDC takes the kernel-facing lesson that syntax, typing, substitution, and reduction must be formal objects. It then applies that lesson to the closed self-compilation surface. The result is a small, auditable object calculus rather than a production assistant kernel.

Girard reducibility candidates. The normalization layer uses candidate terminology because candidates are the right vocabulary for strong-normalization evidence. The formalization has `Candidate`, `ClosedCandidate`, `PiCandidate`, candidate sets, closure under beta, Pi application consequences, neutral-normal witnesses, and concrete gallery instantiations.

That is not the same as a full Girard-style adequacy theorem for every well-typed represented term. The adequacy chain would have to assign candidate interpretations to all types in the fragment, prove closure under substitution and conversion at the required generality, and then derive strong normalization for arbitrary typed terms. BEDC has the framework and the consumed closed witnesses; it does not claim the entire adequacy development.

Pure type systems. Pure type systems classify calculi by specifying sorts, axioms, and product rules. `BEDC.MetaCIC` can be compared to a very small sub-PTS: one represented sort and the dependent-function rules needed by the object grammar. That comparison is useful for orientation, but the formalization is not a generic PTS engine parameterized by arbitrary rules.

This matters for reviewer expectations. A theorem proved for the BEDC fragment should not be lifted to all PTSs, to all single-sort systems, or to all extensions with additional products. The theorem is about the inductive relations actually present in `BEDC.MetaCIC`.

Lean 4 kernel. Lean is the host that checks the project. It is not the object calculus being replaced. The host has its own elaborator, reduction machinery, inductive declaration checker, quotient support, universe handling, and runtime behavior. `BEDC.MetaCIC` sits inside that host as a verified object language.

The project-level distinction is sharper than ordinary shallow embedding. BEDC explicitly audits its own theorems for forbidden dependencies. The formal content cited by this chapter is required not to depend on `Classical.choice`, `Quot.sound`, or `propext`. Thus the MetaCIC results are not imported from host classical reasoning or quotient reasoning. They are checked within the constructive, axiom-clean discipline that BEDC imposes on its own theorem surface.

9235.18.4 Zero-Axiom Invariants Delivered

The negative scope is paired with a positive purity claim. BEDC does not claim to cover all of CIC, but the part it does cover is not supported by hidden project axioms. The invariant is audited at two levels: source files must not declare project axioms, and theorem dependencies must not rely on the forbidden host axioms.

Invariant	Delivered form	Consequence
No `Classical.choice`	The formal development avoids nonconstructive choice in cited theorem dependencies.	Existence claims must carry constructive witnesses or be expressed as explicit interfaces rather than selected by an unwitnessed global choice principle.
No `Quot.sound`	The MetaCIC surface does not use quotient types to identify represented objects.	Equality and conversion are represented directly by inductive relations and explicit joins, not by quotienting syntax.
No `propext`	The formalization avoids proposition extensionality in theorem dependencies.	Logical equivalence is not silently promoted to proposition equality. Proofs are structured to avoid match shapes that create such dependencies.
Mathlib-free	The Lean package for BEDC does not import mathlib.	The object calculus is developed from Lean 4 core facilities and project definitions rather than a large external theorem base.
No sorry placeholders	Public theorem statements cited by the manuscript are checked proofs or explicit definitions and interfaces.	Unproved strength is not smuggled into the paper as a placeholder theorem.

Constructive dependency discipline. Avoiding `Classical.choice` is not merely a style rule. In this project, a theorem that depends on choice would close over an unwitnessed selection operation. That would be the wrong kind of evidence for a self-compilation surface whose artifacts are finite, named, and carried by explicit histories. The formal proofs therefore use constructors, induction, structural recursion, and displayed hypotheses rather than classical selection.

No quotient collapse. Quotient types are also outside the cited MetaCIC theorem dependencies. Represented terms remain syntactic data. Beta conversion is represented by relations and join evidence, not by collapsing syntax into equivalence classes. This is essential for the paper's auditability: a reader can see which beta paths, closure predicates, and typing hypotheses are being used.

No proposition extensionality. The project treats `propext` as a real logical dependency. It is not allowed to enter through a convenient proof pattern. This affects the shape of the Lean development: proofs are written so that proposition equality is not required when ordinary constructor

reasoning, explicit implications, or relation evidence is sufficient. The result is a theorem surface that can be read constructively.

No mathlib dependency. The mathlib-free condition keeps the dependency chain small. It does not mean the work rejects established mathematics. It means the specific MetaCIC surface is audited as a first-principles Lean 4 development rather than as a collection of imported high-level results. The relevant objects are the project's own inductives, definitions, and theorems.

No unproved placeholders. The no-sorry invariant keeps the paper and Lean states aligned. When the manuscript cites a checked theorem, there is a proof term. When the project does not have a proof at the required strength, the theorem is either stated as an explicit interface, constrained to a checked sub-scope, or rejected by a counterexample. That is why the boundary section can be part of the scientific claim rather than a disclaimer outside the mathematics.

9235.18.5 Why This Matters for Self-Compilation

BEDC self-compilation is not a demand that the project reconstruct every feature of the host kernel inside itself. The operational surface is smaller: the project reflects finite, typed, closed artifacts. The represented terms used in that surface are object-language data. Their typing witnesses, closure facts, beta traces, and normal-form witnesses are the objects that the self-compilation argument actually consumes.

For that reason, the excluded features above do not weaken the stated self-compilation closure. Universe hierarchy does not participate in the finite closed witnesses currently consumed by the reflection surface. Native inductive families do not participate because the gallery uses Church-encoded data inside the dependent-function fragment. Proposition irrelevance does not participate because the object language has no separate proposition layer. η-conversion does not participate because the beta traces are the reduction evidence being checked. General fixpoints do not participate because termination evidence is supplied by structural recursion, fuel, inductive traces, or candidate witnesses.

Open-term metatheory is the most subtle boundary. A production kernel must handle open contexts constantly. BEDC's self-compilation surface, however, uses closed represented artifacts at the reflection boundary. The substrate still has to understand binders, shifting, and substitution, because closed terms may contain binders internally. But the exported self-compilation claim does not need a blanket theorem for arbitrary open object contexts. It needs the checked closed facts and the named local interfaces already present in the MetaCIC layer.

Thus the boundary is not a retreat from the self-compilation goal. It is the shape of that goal. The positive surface and the negative surface meet at the same line:

$$\text{closed represented terms} + \text{empty object context} + \text{beta-only traces} + \text{explicit certificates}$$
$$\text{rather than full host kernel reflection.}$$

This line is what makes the claim auditable. A reviewer can ask whether a self-compilation step uses only the displayed closed surface. If it does, the MetaCIC mechanization is relevant. If it requires universe cumulativity, native inductives, proposition irrelevance, η-conversion, general recursion, or an open-context substitution theorem, then it is outside the present commitment and must be stated as a separate extension.

9235.18.6 What Would Extend the Scope

The omitted features are not impossible additions. They are substantial theory projects with their own syntax, typing, reduction, and audit burden. The present manuscript does not rely on them, so it does not claim them. A larger MetaCIC surface would have to expose each one as first-principles content rather than as an informal analogy with an external kernel.

Universe hierarchy extension. A universe hierarchy would require a layered represented syntax with at least `Sort 0` and `Sort 1`, and likely a general level language. The typing judgment would need formation rules for sorts and Pis that compute result levels. Conversion would need to account for cumulativity if cumulativity is included. The metatheory would then have to prove that substitution, subject reduction, confluence, normalization witnesses, and checking remain valid in the level-aware calculus.

Inductive-family extension. Native inductive families would require represented declarations, constructors, parameters, indices, eliminators, and computation rules. The project would also need a positivity or guardedness condition appropriate to the represented language. Only after those pieces exist could a theorem about `Vec`, `List`, or indexed eliminators be stated as a MetaCIC theorem rather than as a Church-encoded example.

Proposition-layer extension. A separate proposition layer would require syntax and typing rules that distinguish proof-relevant and proof-irrelevant regions, or at least a clear choice about whether proof irrelevance is object-level, meta-level, or absent. If proposition irrelevance were included, it would need its own constructive or explicitly axiomatized status. Under BEDC's present audit discipline, it could not enter as an untracked dependency on `propext`.

Open-term metatheory extension. The open-term extension would have to start from the known obstruction rather than ignore it. It would need closure-indexed substitution composition, binder-context transport, weakening, exchange if contexts are generalized, and subject reduction stated with the exact transported type. The existing counterexamples show where naive statements fail. A successful extension would replace those naive statements with the right shift-aware invariants.

Kernel-bridge extension. A bridge to the host kernel would require a relation between represented MetaCIC judgments and actual Lean elaboration or kernel checking. That relation would have to be partial, because the represented fragment is smaller than Lean. It would also have to specify quotation, erasure, normalization, universe behavior, and failure modes. Such a bridge would be a separate metatheoretic layer above the present object calculus.

These extensions are ambitious, and none is required for the present self-compilation boundary. The commitment here is narrower: maintain the closed represented fragment as an axiom-clean, mathlib-free, sorry-free surface; state every consumed interface explicitly; and keep every excluded kernel feature outside the claim until its own represented syntax and metatheory are supplied.

Part XI

Capstones

Chapter 9236

Capstone Results

Visions chapters collect exploratory bridge narratives that span multiple BEDC concrete instances. Each vision is inspiration-only: AI revision rounds consume these files as context for proposing new `concrete_instances/` chapters but never write back to `parts/visions/`. When a vision's content is fully realized by one or more concrete-instance NameCert constructions, the vision chapter carries `\concretizedIn` markers pointing to the realizations.

Concretized in §7381: Vision coverage index packets realize the top-level vision routing surface as finite source-label, concrete-target, marker-ledger, transport, replay, provenance, and NameCert rows.

Concretized in §7484: The vision coverage ledger realizes the top-level capstone routing surface as finite source-label, concrete-target, marker-ledger, replay, and NameCert rows.

Concretized in §7573: Affine filter hull packets realize the top-level vision routing surface as finite affine-generator, membership-event, generated filter-base, routing, replay, provenance, and NameCert rows.

Concretized in §8820: Finite vision marker audits realize the source-label, concrete-target, marker-ledger, audit-readback, transport, replay, provenance, and NameCert route for the visions index.

Chapter 9237

Compactness Implies Uniform Continuity

A continuous function on a compact metric space is uniformly continuous, constructively. This chapter assembles the components already isolated in the kernel: the metric carrier with its located distance (chapter 57), the pointwise modulus chain encoded by Cont on continuous naming certificates (chapter 59), and the compactness witness packaged as subset + located + finite ε-net + intermediate + compact (chapter 60). The argument identifies the compactness data as a finite cover indexed by a $\mathsf{ProbeBundle}$, folds the finitely many $\mathsf{NameCert}_{\mathsf{Rat}^\uparrow}$ radius histories through a certified lower-bound ledger, and reads off a uniform-modulus relation depending only on the tolerance history. The main theorem states this in BEDC form: from a continuous naming certificate together with a compact naming certificate on the same metric carrier, the kernel produces a uniform-continuity ledger, with no appeal to $\mathsf{Classical.choice}$ and no excluded middle.

9237.1 Uniform modulus from located finite covers

Definition 9237.1 (Pointwise modulus on $\mathsf{NameCert}_{\mathsf{CFun}^\uparrow}$)**.** *Let X, Y be metric naming certificates and let $\mathsf{NameCert}_f$ be a continuous-function naming certificate witnessing $f\colon X \to Y$. A* pointwise modulus ledger *for $\mathsf{NameCert}_f$ is the BEDC relation on histories*

$$(x, \varepsilon, \delta, \mathsf{cert})$$

whose accepted rows carry a source-point history x, a positive $\mathsf{NameCert}_{\mathsf{Rat}^\uparrow}$ tolerance history ε, a positive $\mathsf{NameCert}_{\mathsf{Rat}^\uparrow}$ precision history δ, and a certificate history cert. The certificate row is carried by $\mathsf{ContinuousModulusWitness}(x, \delta, \mathsf{cert})$ together with the surrounding Cont rows of $\mathsf{NameCert}_f$: whenever $\mathsf{MetricDistanceWitness}(x, x', d)$ certifies a source distance bounded by δ, the graph and target-metric ledgers certify a target distance bounded by ε. The public datum is this certified relation, not a map from external points and tolerances to external rationals.

Definition 9237.2 (Uniform modulus)**.** *A* uniform modulus ledger *for $f\colon X \to Y$ is a BHist relation*

$$\mathsf{UniformModulusLedger}(\varepsilon, \delta, \mathsf{u})$$

from positive $\mathsf{NameCert}_{\mathsf{Rat}^\uparrow}$ tolerance histories to positive $\mathsf{NameCert}_{\mathsf{Rat}^\uparrow}$ precision histories. An accepted row carries a ledger certificate u such that, for every pair of source-point histories x, x' and every distance history d with $\mathsf{MetricDistanceWitness}(x, x', d)$ bounded by δ, the graph ledger for

f and the target metric certificate produce a target-distance history bounded by ε. The precision is therefore selected by a BEDC relation over histories and classifiers, rather than by an external selector.

Definition 9237.3 (Located finite ε-net)**.** *A* located finite ε-net *for a metric carrier X is a* ProbeBundle*-indexed family of center histories. For a positive* $\mathsf{NameCert}_{\mathsf{Rat}^\uparrow}$ *tolerance history ε, the compact certificate supplies a bundle $\mathcal{P}_\varepsilon$, a center history c_p for every probe name p with* $\mathsf{InBundle}(p, \mathcal{P}_\varepsilon)$*, and coverage rows saying that every source-point history x has some bundled probe p with a distance history* $\mathsf{MetricDistanceWitness}(x, c_p, d_p)$ *certified below ε. The finite carrier is the closed inductive* ProbeBundle *together with its coverage witnesses; no external enumeration is exposed.*

9237.2 The kernel construction

Lemma 9237.4 (Subordinate finite modulus cover)**.** *Let X be a compact metric carrier and let $f\colon X \to Y$ have the pointwise modulus ledger of Definition 9237.1. For every positive* $\mathsf{NameCert}_{\mathsf{Rat}^\uparrow}$ *tolerance history ε, the compact certificate supplies a nonempty* ProbeBundle *$\mathcal{P}_\varepsilon$ and, for every bundled probe p, histories*

$$(c_p, \rho_p, \delta_p, \mathsf{cert}_p)$$

such that ρ_p and δ_p are positive $\mathsf{NameCert}_{\mathsf{Rat}^\uparrow}$ *histories, $(c_p, \varepsilon/3, \delta_p, \mathsf{cert}_p)$ is accepted by the pointwise modulus ledger, ρ_p is certified below δ_p, and every source-point history x has a bundled probe p whose center satisfies the certified half-radius coverage row $d_X(x, c_p) < \rho_p/2$.*

Certificate reading. Apply compactness to the located positive-radius ledger whose member at x is supplied by an accepted pointwise-modulus row for tolerance $\varepsilon/3$. The finite-cover certificate returns a ProbeBundle, center histories, radius histories, and subordination rows already tied to those pointwise rows, so the comparisons $\rho_p \le \delta_p$ are part of the returned data.

The located half-radius clause is the cover witness used by the kernel construction below: for each input point x, it produces a bundled probe name p with $d_X(x, c_p) < \rho_p/2$. No scale depending on the eventual uniform-modulus ledger is used to obtain this bundle. □

Theorem 9237.5 (Capstone: finite BEDC fold supports compact uniform modulus)**.** *Let X and Y be metric BEDC carriers whose distance rows are supplied by* MetricDistanceWitness*, and let a BEDC history carry*

$$\mathsf{CompactWitnessCarrier}(\mathsf{subset}, \mathsf{located}, \mathsf{finite}, \mathsf{intermediate}, \mathsf{compact})$$

for X. Let another history carry

$$\mathsf{ContinuousFunctionCarrier}(\mathsf{source}, \mathsf{map}, \mathsf{target}, \mathsf{modulus}, \mathsf{cert})$$

for a graph $f\colon X \to Y$ over the same source metric. For each positive $\mathsf{NameCert}_{\mathsf{Rat}^\uparrow}$ *tolerance history ε, suppose Definition 9237.4 returns a nonempty* ProbeBundle *spine*

$$\mathcal{P}_\varepsilon$$

whose bundled probes carry positive $\mathsf{Rat}^\uparrow$ *radius histories, center histories, pointwise-modulus rows, and subordinate half-radius cover rows. Then primitive recursion over $\mathcal{P}_\varepsilon$, using the* $\mathsf{Rat}^\uparrow$ *order readback of Definition 54.22 at each successor step, produces a unary precision history μ_ε and a fold certificate saying that μ_ε is classifier-stably below every bundled half-radius ledger. The row* $\mathsf{UniformModulusLedger}(\varepsilon, \mu_\varepsilon, \mathsf{u}_\varepsilon)$ *of Definition 9237.2 is then certified for the same continuous graph.*

Certificate assembly. Read the finite cover from the compact witness: the finite and located rows give a nonempty ProbeBundle of centers, positive $\mathsf{Rat}^{\uparrow}$ radius histories, and for every point of X a bundled probe whose center lies within the displayed half-radius.

Transport the radius histories through the $\mathsf{Rat}^{\uparrow}$ total-order readback. Since the bundle is nonempty and every entry is carried by the rational positive-radius certificate, primitive recursion over $\mathcal{P}_\varepsilon$ compares the accumulator with the next half-radius ledger and keeps a certified lower-bound history. The uniqueness row of Definition 54.24 makes this fold stable under the classifier, so the selected lower bound is a BEDC history rather than an external choice.

At each bundled center, the ContinuousFunctionCarrier modulus row reads back the local implication from the graph certificate: a distance bounded by the selected radius below δ_p gives output distance below $\varepsilon/3$. The subordinate-cover rows guarantee that the same center can be used for any input point, and the fold certificate guarantees that the proposed uniform precision is below the chosen local radius.

Finally apply the metric semantic certificate: symmetry converts $d_X(x, x')$ to the orientation needed at the center, and the triangle row combines $d_X(x, c_p)$ with $d_X(x, x')$ to put x' inside the same local ball. Applying the target-metric triangle row to $f(x)$, $f(c_p)$, and $f(x')$ yields the displayed uniform estimate. Thus $\mathsf{UniformModulusLedger}(\varepsilon, \mu_\varepsilon, \mathsf{u}_\varepsilon)$ is certified by the finite BEDC rational-fold ledger. □

Theorem 9237.6 (Continuous on compact yields uniform modulus)**.** *Let X be a metric carrier with a compact naming certificate $\mathsf{NameCert}_X$ exposing the* ProbeBundle *finite-net witness of Definition 9237.3, and let $f\colon X \to Y$ be witnessed by a continuous naming certificate $\mathsf{NameCert}_f$ over X exposing the pointwise modulus ledger of Definition 9237.1. For every positive $\mathsf{NameCert}_{\mathsf{Rat}^{\uparrow}}$ tolerance history ε, primitive recursion over the compact bundle and the certified $\mathsf{Rat}^{\uparrow}$ lower-bound fold produces histories δ_ε and u_ε such that*

$$\mathsf{UniformModulusLedger}(\varepsilon, \delta_\varepsilon, \mathsf{u}_\varepsilon)$$

holds for f. The conclusion is a certified uniform-modulus ledger from tolerance histories to precision histories, not an external modulus selector.

Sketch. Fix a positive tolerance history ε. Invoke Definition 9237.4 to obtain a nonempty ProbeBundle $\mathcal{P}_\varepsilon$ whose probes carry centers c_p, pointwise precision histories δ_p, subordinate radius histories ρ_p, and half-radius coverage rows. Then Definition 9237.5 supplies the classifier-stable rational-fold ledger μ_ε below every bundled half-radius ledger.

Let x, x' be source-point histories with source distance certified below μ_ε. The subordinate cover gives a bundled probe p with $d_X(x, c_p) < \rho_p/2$. Because the fold ledger certifies $\mu_\varepsilon \le \rho_p/2$, the triangle row gives

$$d_X(x', c_p) \le d_X(x', x) + d_X(x, c_p) < \rho_p.$$

Also $d_X(x, c_p) < \rho_p/2 < \rho_p$.

The bound $\rho_p \le \delta_p$ lets the pointwise modulus row at c_p apply to both x and x'. Hence $d_Y(f\,c_p, f\,x) < \varepsilon/3$ and $d_Y(f\,c_p, f\,x') < \varepsilon/3$. The triangle inequality on Y gives $d_Y(f\,x, f\,x') < \varepsilon$. The construction uses only the finite subordinate cover, primitive recursion over ProbeBundle, the certified finite-fold rational ledger over $\mathsf{NameCert}_{\mathsf{Rat}^{\uparrow}}$, and the metric certificates. □

9237.3 Axiom-purity of the uniform-modulus construction

Remark 9237.7 (No appeal to non-constructive principles)**.** *The construction in Definition 9237.6 uses only primitive recursion on the finite net (a* Cont*-shaped ledger over the closed inductive*

ProbeBundle *of centers), arithmetic on* $\mathbb{Q}_{>0}$ *(rational addition, multiplication, and division by* 2*, all kernel-level operations on* $\mathsf{NameCert}_{\mathsf{Rat}^\uparrow}$ *from chapter 37), and the located-distance comparison built into* $\mathsf{NameCert}_{\mathsf{Met}^\uparrow}$*. None of these operations passes through* Classical.choice*,* Quot.sound*, or* propext*. The chapter therefore falls under the same axiom-purity gate as the rest of the manuscript.*

Remark 9237.8 (Heine–Cantor as a kernel theorem)**.** *Definition 9237.6 is the BEDC form of the Heine–Cantor theorem of classical analysis. The classical proof uses sequential compactness and an extracted convergent subsequence; the BEDC proof uses the located finite* ε*-net and a certified lower-bound fold over its* ProbeBundle *radius ledger. The two routes deliver the same uniform modulus relation when the metric carrier is taken as* $\mathsf{NameCert}_{\mathsf{Real}^\uparrow}$ *restricted to a closed bounded interval (chapter 56), making the classical result a derived corollary of the kernel-level statement and not the other way around.*

Concretized in §619: The finite ProbeBundle rational lower-bound fold is realized as a concrete NameCert carrier for compact-uniform-modulus handoff.

Concretized in §8630: The finite subcover modulus budget is realized as compact-net, rational-radius, local-modulus, fold-minimum, and uniform-modulus NameCert data.

Concretized in §6453: Compact-net modulus stability is realized as finite compact-net, continuous-map, uniform-modulus, metric-triangle, and Real-seal NameCert data.

Concretized in §7827: Compact interval uniform continuity is realized as finite interval, compact-metric, continuous-map, uniform-modulus, and Real-seal NameCert data.

Concretized in §7937: Compact derivative bounds are realized as finite compact-interval, continuous-map, derivative-observation, uniform-modulus, compact-net radius, RegSeqRat, and Real-seal NameCert data.

Concretized in §6814: Finite Sobolev derivative windows, norm ledgers, compact handoff rows, and RegSeqRat readback realize a compact-uniform-continuity consumer route.

Concretized in §6997: The finite cover star-refinement modulus packet realizes a compact finite-cover route from star refinements and local moduli to a tolerance-only uniform-modulus handoff.

Concretized in §6125: The finite ProbeBundle subcover ledger realizes the compact finite-cover handoff used by the uniform-modulus construction.

Concretized in §412: $\mathsf{ArzelaAscoli}^\uparrow$ realizes the compact-uniform-continuity route through finite equicontinuity rows, compact-metric source data, bounded-family ledgers, and diagonal-selection NameCert handoff.

Concretized in §8711: Compact uniform modulus extraction is realized as finite compact-net, ContinuousMap local-radius, DyadicRatCore tolerance, RegSeqRat readback, and Real-seal NameCert data.

Concretized in §399: The finite majorant and uniform-tail rows realize the series-majorant branch of compact-uniform and uniform-convergence consumers without host infinite sums or selected limits.

Concretized in §8269: Finite epsilon-net rows realize the compact-uniform-modulus handoff.

Concretized in §7665: The positive-series comparison packet realizes the nonnegative majorant comparison branch through RealSeries, CauchySeriesCriterion, CauchyMajorantSeries, DyadicRatCore, and RealUp rows.

Concretized in §7980: Sequential continuity over RealUp is realized as finite stream, regular-Cauchy, continuity-modulus, and Real-seal NameCert data.

Concretized in §8088: Bishop located compact sets realize the compact-metric route through finite-net, metric readback, RegSeqRat, StreamName, and locator rows.

Concretized in §8483: Compact-uniform splitting ledgers realize the finite split from pointwise compact-cover moduli to one tolerance-only uniform-modulus handoff.

Concretized in §9126: The compact modulus partition ladder realizes the finite partition-refinement route from compact nets and pointwise moduli to uniform-modulus handoff rows.

Concretized in §8994: FinitePrefixCompactnessUp realizes the compact-uniform finite-prefix branch through FiniteFanTheorem, CantorSpace, StreamName, RegSeqRat, and RealUp rows.

Remark 9237.9 (Composition with the real-completeness capstone)**.** *The construction composes with the real-completeness capstone (chapter 9238): once* $\mathsf{NameCert}_{\mathsf{Real}^\uparrow}$ *is upgraded to a regular Cauchy carrier, every closed bounded interval* $[a, b] \subset \mathsf{Real}^\uparrow$ *inherits a compact naming certificate via the standard located* ε*-net of dyadic rationals at scale* $\lceil 1/\varepsilon \rceil$*, and Definition 9237.6 then gives uniform continuity of every continuous* $f\colon [a, b] \to \mathsf{Real}^\uparrow$ *with an explicit uniform-modulus ledger. The chapter is therefore the canonical bridge from the analytic certificate layer to the constructive analysis literature.*

Concretized in §391: Uniform continuity is realized as the finite ProbeBundle fold extracting a tolerance-only modulus from compact and continuous certificates.

Concretized in §369: Uniform modulus packets are realized as finite ProbeBundle rational-fold NameCert carriers for compact-continuous consumers.

Concretized in §7480: The dyadic interval subdivision packet realizes the compact-uniform-continuity finite-cover route through dyadic cells, common-refinement rows, mesh bounds, and UniformModulus handoff data.

Concretized in §6395: The compact radius-chain packet realizes the finite ProbeBundle lower-bound route before $\mathsf{UniformModulus}^\uparrow$ is consumed.

Concretized in §388: The compact finite-net and continuous-map modulus ledger is realized as a concrete NameCert chapter.

Concretized in §1493: Extreme-value packets realize compact finite-net and continuous-map uniform-modulus data as finite attainment NameCert rows.

Concretized in §6173: The shared Lipschitz compact-family packet realizes the compact-uniform-continuity route through finite compact-net, Lebesgue-number, and UniformModulus rows.

Concretized in §7502: LipschitzSpaceUp realizes the metric-domain real-valued Lipschitz packet consumed by uniform-modulus and compact-uniform-continuity routes.

Concretized in §935: The metric source-lock for compact-uniform-continuity is realized as a finite packet joining MetricSpace distance rows, compact finite-net rows, continuous pointwise-modulus rows, and RatUp fold ledgers.

Concretized in §596: The subordinate finite cover and pointwise-modulus packet is realized as the compact-uniform-continuity handoff before the rational lower-bound fold.

Concretized in §914: The compact finite-net selector is realized as the finite ProbeBundle lower-bound packet that turns pointwise compact-cover data into a tolerance-only uniform-modulus ledger.

Concretized in §648: Compact modulus covers realize the finite compact-net and pointwise-modulus source packet before the rational lower-bound fold and UniformModulusUp handoff.

Concretized in §926: Compact net modulus budgets realize the finite-net, pointwise-modulus, rational-fold, and uniform-modulus handoff as one NameCert packet.

Concretized in §1095: Compact cover shrinkage ledgers realize the finite cover-shrinkage boundary from compact nets and pointwise moduli to a uniform-modulus consumer packet.

Concretized in §1159: The final source-and-target triangle estimate packet is realized as a concrete NameCert carrier for the UniformModulusUp consumer handoff.

Concretized in §7260: The final source-and-target triangle estimate is realized as finite compact-net, pointwise-modulus, RatUp tolerance, MetricSpace, and UniformModulus NameCert data.

Concretized in §1257: The epsilon-third source and target triangle handoff is realized as a concrete NameCert carrier for compact-uniform-continuity.

Concretized in §7652: The real-completeness modulus ledger is realized as finite RegularCauchyCriterion, MetricCompletionFinite, RegSeqRat, StreamName, and RealUp NameCert data.

Concretized in §1228: Pointwise modulus ledgers are realized as finite center-radius ContinuousMap source packets consumed by compact finite-net selector chapters.

Concretized in §1253: Closed bounded interval uniform-modulus packets realize the Heine–Cantor interval route through compact dyadic covers and finite Lebesgue-number ledgers.

Concretized in §1302: The finite cover lower-bound ledger is realized as a NameCert packet joining CompactMetric finite nets, ContinuousMap pointwise radii, RatUp folds, and UniformModulus handoff rows.

Concretized in §1301: The finite Lebesgue-number radius ledger is realized as the compact-net selector handoff consumed by UniformModulusUp.

Concretized in §7821: The compact metric modulus realizer packages the finite-net, pointwise-modulus, rational lower-bound fold, metric-triangle, and Real tolerance rows as NameCert data.

Concretized in §2301: The compact-cover-to-positive-radius lemma route is realized as a theorem-facing packet between CompactMetric finite nets, ContinuousMap pointwise radii, FiniteLebesgueNumber ledgers, and UniformModulus handoff rows.

Concretized in §2188: The full finite-net, pointwise-modulus, rational-fold, and metric-triangle route is realized as one scheme-level NameCert packet.

Concretized in §8242: The source-and-target triangle chain is realized as finite CompactMetric, ContinuousMap, UniformModulus, Metric, DyadicRatCore, RegSeqRat, and RealUp rows.

Concretized in §6087: Finite approximate fixed-point packets realize the compact-uniform-continuity finite-modulus route as mesh, radius, displacement, compact-metric, finite-net, metric-ball, and Real-seal NameCert data.

Concretized in §5145: Finite window compactness realizes compact-uniform-continuity as explicit dyadic finite-net windows and uniform-modulus handoff.

Concretized in §6614: The compact finite-net and family pointwise-modulus route is realized as a finite UniformModulus router packet.

Concretized in §1580: Real sequence cluster-point packets realize the sequential compactness comparison route as finite bounded-source, subsequence-window, regular-readback, dyadic-tolerance, and Real-seal NameCert data.

Concretized in §2202: The compact finite-net and pointwise-modulus rational fold is realized as a concrete extractor NameCert packet.

Concretized in §2221: Compact-open function spaces realize the compact-uniform-continuity route as finite subbasic-window, continuous-map, uniform-limit, and RealUp seal NameCert data.

Concretized in §4235: Compact-open uniform convergence is realized as compact-open function-space, compact-metric probe, equicontinuity, uniform-modulus, ContinuousMap, Metric, Real, replay, provenance, and NameCert rows.

Concretized in §2253: Dyadic compactness extractors realize the finite net and dyadic radius packet behind the compact-uniform-continuity route.

Concretized in §2292: Compact uniform continuity modulus packets realize the finite compact-net, ContinuousMap graph, DyadicRatCore tolerance, and RealUp seal route as a concrete modulus object.

Concretized in §2299: Compact uniform modulus realizes the finite-net fold from compact metric and continuous-map rows into a uniform modulus ledger.

Concretized in §7102: Compact subspace modulus restriction realizes inherited compact-source, subspace-admission, continuous-map, and uniform-modulus rows as one finite consumer handoff.

Concretized in §4760: Finite ProbeBundle nets and rational lower-bound folds realize the compact-uniform-continuity construction as NameCert data.

Concretized in §6598: CompactMetricUniformContinuityUp realizes the finite-net, ContinuousMap, Metric, RatUp fold, DyadicRatCore, RegSeqRat, Real seal, and UniformModulus handoff route for the compact-uniform-continuity vision.

Concretized in §8394: The compact graph-modulus packet realizes the finite graph-evaluation, compact-net, pointwise-modulus, uniform-modulus, and Real-seal route.

Concretized in §3444: The Heine-Cantor packet realizes the compact-metric finite-net route from continuous local moduli to a uniform-modulus NameCert consumer.

Concretized in §1379: The Heine-Borel interval packet realizes closed bounded interval finite-net compactness through RealUp, StreamName, regular-Cauchy, and dyadic-net rows.

Concretized in §7351: The subordinate finite cover and pointwise-modulus handoff is realized as finite Compact, ContinuousMap, RatUp, and UniformModulus NameCert rows.

Concretized in §3444: The Heine-Cantor compact-modulus selector handoff realizes the finite CompactMetric/TotallyBounded/ContinuousMap/UniformModulus route as a human theorem packet over the compact-uniform-continuity vision.

Concretized in §2379: The compact fan-bar modulus boundary is realized as a finite NameCert packet for compact-uniform-continuity consumers.

Concretized in §3358: Equicontinuity finite-net selectors realize the compact finite-net and family-radius lower-bound handoff consumed by UniformModulusUp.

Concretized in §7330: The finite ProbeBundle rational-fold construction is realized as compact finite-net, continuous pointwise-modulus, rational lower-bound, dyadic tolerance, regular readback, and Real-seal NameCert data.

Concretized in §1822: The compact-metric product branch is realized through CompactMetric, Metric, finite-net product windows, and uniform-modulus routing before compact-uniform-continuity consumers read a product source.

Concretized in §3549: The compact-source triangle residual is realized as a finite NameCert packet joining CompactMetric, ContinuousMap, UniformModulus, and MetricTriangleUniformEstimate rows.

Concretized in §8513: Compact-uniform equioscillation is realized as compact finite-net, equicontinuity-family, Arzela–Ascoli, band-comparison, rational-readback, and UniformModulus NameCert data.

Concretized in §7344: Equicontinuous compact image packets realize compact-uniform-continuity through CompactMetric, ContinuousMap, EquicontinuityFamily, UniformModulus, StreamName, RegSeqRat, and RealUp rows.

Concretized in §8509: The finite lower-bound ledger realizes the ProbeBundle rational-radius fold used by the compact uniform-continuity construction.

Concretized in §1387: The finite compact-window monotone convergence route realizes the compact-uniform-continuity vision as a Dini-theorem NameCert packet.

Concretized in §6374: Finite Dini modulus packets realize compact finite-net, monotone pointwise descent, dyadic tolerance, ContinuousMap, and RealUp seal data as a concrete uniform-modulus NameCert route.

Concretized in §3630: Observable diameter decay realizes the compact finite-net and uniform-modulus diameter ledger as a concrete NameCert packet.

Concretized in §3698: The compact finite-net uniform-modulus route is realized as completion-extension consumer data.

Concretized in §3737: The compact finite-net and uniform-modulus route is realized as a finite oscillation-bound NameCert packet.

Concretized in §8170: Compact modulus composition is realized as finite compact-cover, pointwise-modulus, rational-fold, metric, and uniform-ledger NameCert data.

Concretized in §7416: The compact-uniform oscillation nerve packet realizes finite cover-nerve incidence, local oscillation control, rational lower-bound fold, and UniformModulus handoff rows.

Concretized in §5105: Finite interval covers realize the closed-bounded interval finite-cover route as BEDC NameCert data.

Concretized in §5124: Bishop interval covers realize the located finite interval-cover branch through dyadic cells, located intervals, StreamName, RegSeqRat, and RealUp rows.

Concretized in §3821: The radius-choice ledger realizes the compact finite-net and pointwise-modulus handoff as finite NameCert data.

Concretized in §6022: The compact finite-net triangle ledger realizes the metric-triangle handoff from pointwise moduli to a uniform-modulus row.

Concretized in §7474: The source-target triangle estimate is realized as finite compact-net, pointwise-modulus, source-triangle, target-triangle, and UniformModulus ledger rows.

Concretized in §8703: Compact uniform barycentric refinement is realized as dyadic subdivision, compact-metric source, interval-net alignment, StreamName, RegSeqRat, UniformModulus, and Real-seal NameCert data.

Concretized in §3853: Finite oscillation partitions realize the compact-uniform-continuity route from local oscillation control to a displayed uniform-modulus row.

Concretized in §4096: Finite ProbeBundle rational lower-bound folds realize the compact-uniform-modulus handoff.

Concretized in §6428: BaireMetric compact-window packets realize finite prefix-cylinder and dyadic-radius reads before compact uniform-continuity consumers inspect a modulus.

Concretized in §6250: The compact cover modulus packet realizes the finite-cover and lower-bound-fold route for compact uniform continuity.

Concretized in §8751: Finite open-cover number packets realize the compact-uniform-continuity finite-cover route through ProbeBundle cover rows and RatUp radius ledgers.

Concretized in §3857: Located sequence windows realize the StreamName, dyadic tolerance, RegSeqRat, LocatedReal, and Real seal route consumed by compact finite-net modulus arguments.

Concretized in §3884: finite endpoint-grid route for compact uniform-continuity interval consumers

Concretized in §3887: The compact finite-net and uniform-modulus route is realized as a finite diameter-decay packet for compact-continuous images.

Concretized in §3924: The compact continuous image total-bounded packet realizes the finite-net, continuous-map modulus, metric-distance, and RatUp fold route as a concrete NameCert carrier.

Concretized in §3957: The finite ProbeBundle realization route packages compact metric coverage, continuous pointwise moduli, RatUp lower-bound folds, and UniformModulusUp handoff rows as concrete NameCert data.

Concretized in §5866: The subordinate finite-cover carrier realizes the ProbeBundle modulus-fold route used by the compact-uniform-continuity theorem.

Concretized in §7456: The compact uniform-modulus certificate realizes the finite-net, pointwise-modulus, rational-fold, and metric-triangle handoff as NameCert data.

Concretized in §3937: Subordinate finite modulus covers are realized as finite CompactMetric, ContinuousMap, FiniteLebesgueNumber, RatUp fold, and UniformModulus NameCert packets.

Concretized in §4006: The compact-uniform radius-choice packet realizes the finite ProbeBundle lower-bound fold for tolerance-only uniform-modulus reads.

Concretized in §7295: The finite-subfamily Arzela–Ascoli packet realizes compact-metric finite nets, bounded-family rows, equicontinuity rows, and finite selector readback as a concrete compact-uniform-continuity consumer.

Concretized in §452: The finite Lebesgue-number packet realizes the positive-radius ledger used by the compact-uniform-continuity route.

Concretized in §4015: The compact finite Lebesgue-number packet realizes the finite cover-radius ledger used by the compact uniform-continuity proof.

Concretized in §9130: Finite prefix bar-modulus windows realize the compact-uniform-continuity route from finite prefix depth to tolerance-only uniform-modulus handoff rows.

Concretized in §5116: Uniform Lebesgue-number packets realize the compact finite-cover radius bound consumed by uniform-modulus arguments.

Concretized in §5203: Finite cover radius stability is realized as the compact finite-net radius transport packet consumed by the uniform-modulus fold.

Concretized in §7048: Finite product uniform-modulus packets realize the compact-product finite-net route from coordinate local moduli to a product tolerance-only UniformModulus handoff.

Concretized in §7021: The compact uniform-modulus envelope realizes the finite-net, local-modulus, rational-fold, and UniformModulus handoff route as NameCert data.

Concretized in §8933: The compact modulus mesh handoff is realized as finite compact-net, pointwise-modulus, dyadic tolerance, rational-fold, and uniform-modulus NameCert data.

Concretized in §4076: Equicontinuity is realized as the finite family-modulus NameCert surface consumed by compact-uniform and Arzela–Ascoli routes.

Concretized in §4118: ProbeBundle finite minimum folds realize the compact-uniform-continuity lower-bound fold over RatUp radius histories.

Concretized in §4297: The finite fan-bar modulus packet realizes the compact-uniform-continuity route from finite bars and local moduli to a uniform modulus ledger.

Concretized in §6744: The compact-uniform-continuity image packet realizes finite-net image transport through CompactMetricUp, TotallyBoundedUp, UniformContinuityUp, ContinuousMapUp, and RealUp rows.

Concretized in §6676: The compact grid modulus extraction packet realizes the finite compact-net, dyadic grid, rational lower-bound, and uniform-modulus route.

Concretized in §4371: Computable compact metric data supplies the effective finite-cover realizer surface for compact-uniform-continuity consumers.

Concretized in §6566: Finite ProbeBundle folds produce the compact-uniform modulus ledger.

Concretized in §4361: finite compact-net modulus transfer for uniform continuity

Concretized in §5872: Compact uniform modulus stability realizes the synchronized finite route from compact-net selectors, lower-bound folds, metric-triangle estimates, and compact-uniform rows to UniformModulusUp consumers.

Concretized in §7189: The compact uniform local-to-global modulus packet realizes the finite-cover route that turns pointwise compact-cover moduli into a tolerance-only uniform-modulus handoff.

Concretized in §7905: The compact uniform radius selector realizes the finite ProbeBundle lower-bound fold from compact metric and continuous-map radius rows into a UniformModulus handoff.

Concretized in §7604: The compact oscillation-modulus packet realizes finite compact-net oscillation bounds and uniform-modulus handoff rows as NameCert data.

Concretized in §5895: Compact uniform modulus composition is realized as a finite packet composing two tolerance-only modulus rows through continuous-map and metric-triangle ledgers.

Concretized in §8216: The finite-net source and target triangle replay route is realized as finite CompactMetric, ContinuousMap, UniformModulus, MetricSpace, RatUp, RegSeqRat, and RealUp NameCert rows.

Concretized in §9122: Finite selected-net data for compact uniform continuity.

Concretized in §7445: The finite dyadic radius ladder realizes compact finite-net, pointwise-radius, lower-bound fold, and UniformModulus rows.

Concretized in §8194: The compact modulus tail-fusion ledger realizes the finite compact-uniform-continuity route from compact modulus rows to shared Cauchy tail windows and Real-seal readback.

Concretized in §6383: The finite compact-cover modulus functional realizes the ProbeBundle cover, dyadic radius, local modulus, and uniform-modulus handoff route.

Concretized in §8173: The compact law failure-envelope packet realizes compact-uniform modulus data with displayed failure-surface rows.

Concretized in §6392: The compact dyadic grid-refinement packet realizes finite compact-net, dyadic-radius, and uniform-modulus handoff data.

Concretized in §3891: Uniform-continuity composition realizes the compact-uniform-continuity route's reusable composed-modulus handoff for downstream compact sources.

Concretized in §5558: The compact uniform-modulus pullback is realized as finite compact-net, pointwise-modulus, dyadic-tolerance, and Real-seal NameCert data.

Concretized in §5134: Regular Cauchy rounding projections realize the finite dyadic grid handoff used by compact-uniform-continuity routes.

Concretized in §7954: Compact uniform fan moduli realize the compact-uniform-continuity route as finite compact-net, pointwise-modulus, finite fan-bar, lower-bound, uniform-modulus, StreamName, RegSeqRat, and Real-seal NameCert data.

Concretized in §6293: The compact finite-net and finite oscillation-window route realizes the compact-uniform-continuity vision as one NameCert packet.

Concretized in §5189: The compact finite-net radius-chain route is realized as finite NameCert data for uniform-modulus consumers.

Concretized in §5115: Real-induced metric-ball entourage bases are realized as finite Real, metric, uniform, Cauchy-filter, StreamName, and RegSeqRat NameCert data.

Concretized in §7834: Real modulus normalization realizes the compact-uniform-continuity route through dyadic tolerance normalization, regular-rational readback, StreamName scheduling, and UniformModulus handoff rows.

Concretized in §6927: Finite cover bar moduli realize the compact-uniform-continuity route as finite bar-cover, local-modulus, dyadic-fold, and Real-seal NameCert data.

Concretized in §3503: The finite-subcover criterion packet realizes the compact finite-cover extraction route consumed by the uniform-modulus construction.

Concretized in §5954: The compact equicontinuity stability packet realizes the family-modulus refinement route through finite compact nets and uniform-modulus ledgers.

Concretized in §5964: The compact Lipschitz uniform handoff realizes the finite-net, Lipschitz graph, tolerance-fold, and UniformModulus consumer route as one NameCert packet.

Concretized in §5973: The finite modulus compact-uniform equicontinuity packet realizes the compact finite-net route from family moduli to a uniform equicontinuity ledger.

Concretized in §7648: The finite oscillation-envelope packet realizes compact-uniform-continuity through finite ProbeBundle radii, pointwise modulus rows, RatUp folds, and UniformModulus handoff data.

Concretized in §5986: The compact-uniform cover-chain packet realizes the subordinate finite-cover, radius-ledger, pointwise-modulus, and uniform-modulus handoff route as finite NameCert data.

Concretized in §6000: Finite subcover radius ledgers realize the compact finite-cover lower-bound route consumed by uniform-modulus arguments.

Concretized in §7369: The compact sequence-modulus packet realizes finite compact-window and pointwise-modulus data as a uniform-modulus NameCert route.

Concretized in §2299: Compact uniform modulus realizes the finite ProbeBundle lower-bound fold route through metric, compact, continuous, rational, uniform-modulus, and NameCert rows.

Concretized in §6113: Compact uniform radius-minimum stability realizes classifier transport for the finite ProbeBundle lower-bound fold before the uniform-modulus handoff is consumed.

Concretized in §6048: The compact finite-net and pointwise-modulus proof is realized as a finite NameCert carrier for uniform-modulus extraction.

Concretized in §7208: The compact equicontinuity envelope realizes finite compact-net, family modulus, rational fold, UniformModulus, Metric, and Real-seal rows as NameCert data.

Concretized in §6216: The diameter-decay packet realizes the finite compact-net route from pointwise moduli to a tolerance-only uniform-modulus ledger.

Concretized in §6079: Compact oscillation bar moduli realize the finite compact-net, pointwise oscillation, dyadic tolerance, and uniform-modulus handoff route.

Concretized in §6092: Gauge Lebesgue-number packets realize the Cousin-cover and finite-radius handoff used by compact-uniform and gauge-integration consumers.

Concretized in §6095: Equicontinuity radius choice realizes the finite family-radius handoff from compact nets and displayed equicontinuity rows to a uniform-modulus consumer.

Concretized in §6125: The finite subcover ledger realizes the ProbeBundle cover-selection handoff for compact-uniform-continuity consumers.

Concretized in §6399: Observable open-filter packets realize compact-uniform-continuity cover reads through SierpinskiSpace, Topology, StreamName, and UniformModulus rows.

Concretized in §7228: The finite compact-net and Cauchy-tail router realizes the vision's uniform-modulus route through StreamName, RegSeqRat, DyadicRatCore, and Real seal rows.

Concretized in §6143: The compact finite-net radius transport packet realizes the uniform-modulus handoff from pointwise continuity data.

Concretized in §6264: The compact uniform-Cauchy packet realizes the finite-net, uniform-tail, regular-readback, dyadic-tolerance, and Real-seal route as NameCert data.

Concretized in §7173: The compact oscillation selector realizes the finite net, pointwise-radius, rational lower-bound fold, and UniformModulus handoff as one NameCert packet.

Concretized in §6263: The finite cover nerve is realized as CompactMetric cover-member, overlap, rational-fold, and UniformModulus handoff rows.

Concretized in §7597: The finite cover nerve is realized as CompactMetric cover-member, overlap-incidence, nerve-face, rational-fold, and UniformModulus handoff rows.

Concretized in §8329: Finite cover multiplicity realizes overlap-depth and rational-fold rows for the compact-uniform-continuity route.

Concretized in §6274: The compact Cauchy equicontinuity packet realizes the finite-net, pointwise-modulus, RegSeqRat tolerance, and Real-seal route for compact-uniform-continuity consumers.

Concretized in §6466: Compact uniform tail selectors realize the finite ProbeBundle tail-radius handoff from compact nets and pointwise moduli to a tolerance-only uniform-modulus ledger.

Concretized in §1624: The real uniform structure packet realizes the entourage substrate consumed by compact-uniform-continuity finite-net moduli.

Concretized in §5129: Modulus-of-continuity packets realize the pointwise tolerance-to-precision ledger consumed before compact-uniform and completion routes read a uniform modulus.

Concretized in §6300: The finite oscillation-radius ledger realizes compact-cover radius, dyadic oscillation, and uniform-continuity handoff rows as NameCert data.

Concretized in §6326: The finite dyadic closed-interval subcover packet realizes the constructive Heine–Borel handoff used by compact-uniform-continuity interval consumers.

Concretized in §6409: Compact-uniform cover reads are realized as finite ProbeBundle, pointwise-modulus, rational lower-bound, uniform-modulus, transport, replay, provenance, and NameCert rows.

Concretized in §6733: Regular Cauchy product metrics realize the paired finite-window product-distance route used by compact-uniform-continuity consumers.

Concretized in §6499: The compact finite modulus gluing packet realizes the ProbeBundle finite-net, rational-fold, pointwise-continuity, and UniformModulus route as NameCert data.

Concretized in §6444: The compact uniform-modulus bridge realizes the finite ProbeBundle fold from CompactUp and ContinuousUp rows to a UniformModulusUp output.

Concretized in §6458: Pointwise equicontinuity transfer is realized as finite compact-net, family-modulus, RatUp fold, and UniformModulus handoff data.

Concretized in §6489: Compact tail selectors realize the finite tail-window handoff from CompactMetric, StreamName, RegSeqRat, UniformModulus, and RealUp rows.

Concretized in §7014: Finite-net mesh refinement realizes the compact-uniform-continuity route from compact finite nets to tolerance-only uniform-modulus data.

Concretized in §388: The finite-net ProbeBundle fold and rational lower-bound route realize the compact-uniform-continuity vision as a CompactUniformContinuityUp NameCert surface.

Concretized in §6522: The finite fan route realizes the compact-uniform-continuity vision as a concrete NameCert surface for uniform modulus extraction.

Concretized in §6528: The star-refinement modulus packet realizes the finite cover-refinement-to-uniform-modulus route.

Concretized in §6564: The Real-induced uniform Cauchy-filter completion packet realizes the finite RealUniformStructure, CauchyFilterCompletion, StreamName, RegSeqRat, DyadicRatCore, and RealUp handoff consumed by compact-uniform continuity routes.

Concretized in §6596: Effective compactness realizes the finite epsilon-net and tolerance-only modulus route used by compact uniform continuity.

Concretized in §6633: The compact finite-cover radius fold is realized as a finite ledger from CompactMetric and ContinuousMap rows to a UniformModulus handoff.

Concretized in §6641: The compact uniform-limit packet realizes compact-source uniform convergence as finite modulus, continuous-map, regular-rational readback, and Real-seal NameCert rows.

Concretized in §6716: The compact cover-chain uniform-modulus packet realizes the finite cover-refinement branch of the compact-uniform-continuity vision.

Concretized in §6750: The compact finite-net, pointwise-modulus, rational-fold, and UniformModulus handoff is realized as a finite NameCert packet.

Concretized in §8680: The finite ProbeBundle lattice, rational lower-bound fold, and UniformModulus handoff are realized as compact-modulus extraction NameCert data.

Concretized in §6824: The finite fan-bar selector realizes the compact pointwise-modulus and ProbeBundle fold route consumed by UniformModulusUp.

Concretized in §6807: The compact-uniform modulus ladder realizes the finite-cover-to-uniform-modulus route as NameCert data.

Concretized in §6846: The compact finite mesh and rational lower-bound fold realize the tolerance-only uniform-modulus handoff.

Concretized in §6874: Real-uniform separation is realized as finite uniform-entourage, Cauchy-filter, RegSeqRat, StreamName, and Real-seal NameCert data.

Concretized in §6769: The finite-net Heine-Cantor packet realizes the compact metric, continuous-map, finite lower-bound fold, and uniform-modulus route.

Concretized in §6912: Compact continuous image diameter is realized as finite compact-net, continuous-map, uniform-modulus, metric-distance, and Real-seal NameCert data.

Concretized in §6908: Compact function algebra packets realize the compact-uniform-continuity route as finite continuous-function, uniform-modulus, pointwise-operation, and sup-norm NameCert data.

Concretized in §6959: The compact finite lower-bound packet realizes the ProbeBundle fold used to extract a uniform modulus without an external selector.

Concretized in §3568: The finite equicontinuity modulus route realizes the compact-uniform-continuity finite-net and uniform-modulus handoff for Arzela–Ascoli consumers.

Concretized in §7004: The compact uniform Cauchy diagonal packet realizes compact finite-net, pointwise-modulus, diagonal-tail, RegSeqRat, and Real-seal rows as finite NameCert data.

Concretized in §7106: The compact uniform Cauchy family packet realizes the finite-net and shared-modulus family route as NameCert data.

Concretized in §7162: Finite fan compactness realizes the ProbeBundle branch of compact-uniform-continuity as finite cover and uniform-modulus NameCert data.

Concretized in §7176: Compact modulus oscillation routers realize the compact finite-net and pointwise oscillation route before a uniform-modulus consumer reads the tolerance-only ledger.

Concretized in §7194: The finite epsilon-third, compact-net, rational-fold, and metric-triangle budget is realized as UniformModulusErrorBudgetUp NameCert data.

Concretized in §7223: The compact finite-net oscillation envelope is realized as finite CompactUp, MetricUp, ContinuousUp, UniformModulusUp, RealUp, hsame, Cont, Pkg, and NameCert rows.

Concretized in §7238: The finite-net lower-bound fold normal form is realized as Metric, Compact, ContinuousMap, Rat, and UniformModulus NameCert data.

Concretized in §6352: ConstructiveDiniTheoremUp realizes the monotone compact-metric family route as finite Dini-modulus, UniformLimit, StreamName, RegSeqRat, and Real-seal NameCert data.

Concretized in §4213: DiniMonotoneCompactUniformUp realizes the monotone compact-metric family route as finite compact-source, continuous-map, monotone-ledger, finite-cover, uniform-modulus, UniformLimit, transport, replay, provenance, and NameCert data.

Concretized in §8011: The shared compact-net, pointwise-modulus, rational-fold, triangle-estimate, and UniformModulus route is realized as one finite coherence packet.

Concretized in §7429: The finite oscillation-mesh realization records compact finite-net rows, pointwise oscillation rows, rational mesh folding, dyadic tolerance conversion, and UniformModulus handoff data.

Concretized in §7452: The finite ProbeBundle cover fold realizes the compact-uniform-continuity route from compact finite covers to a tolerance-only uniform-modulus ledger.

Concretized in §7541: The compact uniform finite-cover fold realizes the finite ProbeBundle lower-bound fold of the compact-uniform-continuity theorem as concrete NameCert data.

Concretized in §7472: Uniform-continuity graph modulus packets realize the compact finite-net, pointwise-modulus, ProbeBundle fold, metric-triangle, and UniformModulus handoff as finite NameCert data.

Concretized in §5549: The compact uniform continuity ledger chapter realizes the finite compact-source, continuous-map, metric-triangle, and Real-seal route as concrete NameCert data.

Concretized in §7698: The finite weak-window maximal packet realizes a compact finite-cover route from local averages and dyadic thresholds to a tolerance-visible weak-level ledger.

Concretized in §7735: The compact Cauchy-net packet realizes the finite-net, Cauchy-tail, RegSeqRat, DyadicRatCore, and Real-seal route used by compact uniform continuity.

Concretized in §7769: Finite cover mesh chains realize the compact-uniform-continuity finite-cover route through ProbeBundle cover rows, dyadic mesh bounds, star-refinement transport, rational lower-bound folds, and UniformModulus handoff data.

Concretized in §7779: The located compactness modulus packet realizes the compact-uniform finite-net lower-bound branch as finite CompactMetric, MetricSpace, rational-radius, StreamName, RegSeqRat, Real-seal, transport, replay, provenance, and NameCert rows.

Concretized in §7781: The finite compact-net diagonal route realizes the equicontinuity-family branch through StreamName, RegSeqRat, and RealUp rows.

Concretized in §8073: The compact uniform diagonal-net packet realizes compact finite-net, pointwise-modulus, finite-radius, UniformModulus, StreamName, RegSeqRat, and Real-seal rows as concrete NameCert data.

Concretized in §7787: The finite oscillation-window packet realizes compact finite-net, continuous-map, RatUp fold, and RealUp tolerance rows as a uniform-modulus NameCert carrier.

Concretized in §7784: Finite dyadic Cantor prefix windows realize the compact-uniform-continuity finite-cover route as Bool/List prefix NameCert data.

Concretized in §7810: Finite modulus evaluation packets realize compact uniform continuity as compact metric, continuous-map, dyadic-ledger, finite-net, uniform-modulus, and Real-seal NameCert data.

Concretized in §7839: Finite modulus transfer packets realize the compact-uniform-continuity branch from finite compact-source probes and local modulus witnesses to a uniform-modulus handoff.

Concretized in §7869: The compact-uniform cover-membership packet realizes the finite bundled-center membership row required before cover-read radius folds are consumed.

Concretized in §7889: Compact-open Lipschitz modulus packets realize the compact-uniform-continuity branch through compact-open tests, Lipschitz bounds, ContinuousMap rows, MetricSpace rows, and finite modulus ledgers.

Concretized in §8038: The pointwise radius-chain packet realizes the compact finite-net and local-modulus route before the rational lower-bound fold.

Concretized in §6003: Finite Cauchy density nets realize the compact-uniform-continuity finite-net branch through dyadic cells, StreamName windows, RegSeqRat readback, and Real-seal rows.

Concretized in §8049: Finite epsilon-net chains realize the compact-uniform finite cover fold as displayed CompactMetric, TotallyBounded, DyadicRatCore, StreamName, RegSeqRat, Real, transport, provenance, and NameCert rows.

Concretized in §7942: The finite dyadic-net modulus surface realizes compact-uniform continuity through Arzela–Ascoli, compact source, continuous-map family, DyadicRatCore, StreamName, RegSeqRat, and RealUp rows.

Concretized in §8102: Stream diagonalization is realized as finite StreamName, RegSeqRat, DyadicRatCore, diagonal-window, and Real-seal NameCert data.

Concretized in §8118: The final source-and-target triangle closure is realized as finite compact-net, pointwise-modulus, dyadic tolerance, metric-triangle, UniformModulus, and Real-seal NameCert data.

Concretized in §3800: The finite oscillation partition realizes the compact finite-cover oscillation route through interval source, finite mesh, cell-bound readback, and UniformModulus handoff rows.

Concretized in §8167: The compact-uniform-modulus selector realizes the finite ProbeBundle lower-bound fold as a compact-net, pointwise-modulus, RatUp, MetricDistanceWitness, and UniformModulus NameCert packet.

Concretized in §5892: The effective compact-interval search packet realizes the compact-uniform-continuity finite-net and uniform-modulus route as bisection, value-comparison, Real-seal, and extremum-facing NameCert data.

Concretized in §5937: Compact interval modulus packets realize the interval-specialized finite-net and Real-seal route from compact interval data to uniform-modulus readback.

Concretized in §8353: The compact-uniform local-modulus nerve packet realizes the finite overlap-compatibility route from compact covers and pointwise moduli to a uniform-modulus handoff.

Concretized in §8356: Compact interval modulus extraction is realized as finite ProbeBundle cover rows, rational lower-bound fold data, and UniformModulus handoff for compact-uniform-continuity.

Concretized in §8374: The compact cover-order bound packet realizes bounded-overlap finite cover rows for compact uniform-modulus extraction.

Concretized in §8495: Compact oscillation trees realize finite cover-refinement and oscillation-window handoffs for compact uniform-modulus consumers.

Concretized in §8504: The finite modulus mesh realizes compact-uniform-continuity as compact-net cells, pointwise modulus rows, dyadic tolerances, and a UniformModulus handoff.

Concretized in §8526: The finite cover-nerve and rational lower-bound handoff realizes the compact-uniform-continuity route as concrete NameCert data.

Concretized in §8565: Stream diagonalization completion packets realize finite StreamName, RegSeqRat, DyadicRatCore, RealUp, and completion-operator rows for compact-uniform Cauchy consumers.

Concretized in §8584: Finite closed-interval nested-intersection packets realize the choice-free nested interval branch through NestedInterval, DyadicIntervalNet, RegSeqRat, StreamName, and RealUp rows.

Concretized in §5966: Dyadic interval nets realize the compact-uniform-continuity finite-subnet branch through dyadic cell rows, finite windows, and uniform-modulus handoff data.

Concretized in §8664: Finite compact-net, pointwise-modulus, RatUp lower-bound fold, and diagonal replay rows realize the compact uniform-modulus route.

Concretized in §8698: The Banach Picard orbit realizes the compact-uniform continuity route through finite contraction, Cauchy-tail, complete-metric, StreamName, RegSeqRat, and Real-seal rows.

Concretized in §8840: Finite bundled positive-radius meets realize the compact-uniform lower-bound fold.

Concretized in §8883: Uniform-tail Ascoli packets realize compact finite-net, equicontinuity, uniform-tail, and diagonal-subfamily NameCert data.

Concretized in §8902: The finite nerve packet realizes the compact finite-cover, local-modulus, RatUp lower-bound fold, and UniformModulus handoff route.

Concretized in §8929: The Bishop compact-image packet realizes the finite compact-source, continuous-map, uniform-modulus, image-witness, RegSeqRat, DyadicRatCore, Real-seal, transport, replay, provenance, and NameCert route.

Concretized in §8947: The Dirichlet-function packet realizes the rational-density versus irrational-boundary branch as finite RatUp, StreamName, RegSeqRat, RealUp, ContinuousMap, and NameCert data, marking a discontinuity boundary for compact-uniform-continuity consumers.

Concretized in §7576: Finite-net Arzela–Ascoli packets realize the compact-uniform-continuity branch through compact metric nets, equicontinuity rows, RegSeqRat readback, and finite diagonal ledger data.

Concretized in §9073: Compact interval Lipschitz envelopes realize finite mesh, Lipschitz bound, uniform-modulus, RegSeqRat, and Real-seal rows for the compact-uniform-continuity route.

Concretized in §9165: Compact oscillation budgets realize the compact-uniform-continuity route through finite compact-net cells, pointwise oscillation rows, dyadic tolerance, RegSeqRat readback, and RealUp seal data.

Concretized in §9170: Lebesgue number mesh extraction is realized as finite cover mesh, compact-net, local-radius, rational lower-bound, and uniform-modulus NameCert data.

Chapter 9238

Real Completeness via Regular Cauchy Sequences

This capstone records the conditional analytical target for the Phase Real and Completion milestone of section 9467.12. It treats the real naming certificate $\mathsf{NameCert}_{\mathsf{Real}^{\uparrow}}$ (chapter 38) as complete in the Bishop sense only after the DyadicRatCore, StreamNameUp, RegSeqRat, and RealUp certificate obligations are available at machine-checked strength. The chapter defines a regular Cauchy sequence over RegSeqRat as a sequence of regular rational sequences together with an explicit modulus of convergence, gives the intended limit modulus and RegSeqRat representative by diagonal extraction, and records the uniqueness criterion up to the standard psame equivalence on naming certificates. The construction is fully constructive as a proof target: every modulus is an explicit function on naturals and rationals, no real number is identified with an equivalence class, and the required Lean target is expected to use neither Classical.choice nor Quot.sound nor propext.

9238.1 Regular Cauchy sequences and their limits

Definition 9238.1 (Regular sequence over $\mathsf{Rat}^{\uparrow}$)**.** *A* regular sequence *over* $\mathsf{NameCert}_{\mathsf{Rat}^{\uparrow}}$ *is a function* $x\colon \mathbb{N} \to \mathbb{Q}$ *together with the explicit regularity witness*

$$\forall\, m, n \in \mathbb{N}, \quad |x_m - x_n| \;\le\; \tfrac{1}{m+1} + \tfrac{1}{n+1}.$$

The carrier RegSeqRat *of chapter 38 packages such pairs as a closed inductive over* $\mathsf{NameCert}_{\mathsf{Rat}^{\uparrow}}$ *data, with* RealClassifier *the* psame *closure that identifies two regular sequences whose pointwise difference shrinks at the regularity rate.*

Definition 9238.2 (Regular Cauchy sequence over RegSeqRat)**.** *A* regular Cauchy sequence *of regular rational sequences is a function* $X\colon \mathbb{N} \to \mathsf{RegSeqRat}$ *together with an explicit modulus* $\mu\colon \mathbb{Q}_{>0} \to \mathbb{N}$ *such that, for every* $\varepsilon \in \mathbb{Q}_{>0}$ *and every* $m, n \ge \mu(\varepsilon)$*, the regular rational sequence* $X_m - X_n$ *(computed pointwise on representatives) lies inside the* ε*-ball at* 0 *in the sense of* $\mathsf{NameCert}_{\mathsf{RegSeqRat}}$.

Definition 9238.3 (Diagonal limit representative)**.** *The* diagonal limit representative *of* (X, μ) *is the rational sequence* $L\colon \mathbb{N} \to \mathbb{Q}$ *given by*

$$L_n \;=\; \big(X_{\mu(1/(n+1))}\big)_{\mu(1/(n+1))+n+1},$$

that is, the value at index $\mu(1/(n+1)) + n + 1$ of the $\mu(1/(n+1))$-th member of the Cauchy sequence. The construction is primitive recursion on n together with $\mathsf{NameCert}_{\mathsf{Rat}^\uparrow}$ *arithmetic on the indices.*

Theorem 9238.4 (Diagonal limit is a regular sequence)**.** *The diagonal limit representative L of Definition 9238.3 is a regular sequence in the sense of Definition 9238.1: for every $m, n \in \mathbb{N}$,*

$$|L_m - L_n| \;\leq\; \tfrac{1}{m+1} + \tfrac{1}{n+1}.$$

Sketch. Fix $m \leq n$. Bound $|L_m - L_n|$ by triangle inequality through three intermediate points: the value of $X_{\mu(1/(m+1))}$ at the diagonal index, the value of $X_{\mu(1/(n+1))}$ at the same index, and the value at L_n's diagonal index. The first and third differences are controlled by the regularity of the constituent regular sequences (Definition 9238.1); the middle difference is controlled by the Cauchy modulus μ (Definition 9238.2). Each bound is at most $1/(m+1)+1/(n+1)$ after a one-line rational arithmetic step. □

Concretized in §1205: The diagonal-limit representative is realized as a finite BHist packet selecting the modulus row, StreamName window, RegSeqRat readback, dyadic ledger, and RealUp seal without a hidden limit choice.

Concretized in §1204: Tail-compatible Cauchy sections realize the diagonal-limit finite-window route as a BEDC NameCert packet.

Concretized in §1211: Dyadic tolerance triangle ledgers realize the three-leg diagonal-regularity estimate as finite DyadicRatCore, StreamName, RegSeqRat, RealUp, hsame, Cont, Pkg, and NameCert rows.

Concretized in §1158: Regular Cauchy regularity witnesses realize the diagonal-regularity proof row as finite StreamName, RegSeqRat, DyadicRatCore, RealUp, hsame, Cont, Pkg, and NameCert data.

Concretized in §1215: Finite real sections realize a single precision request, StreamName window, RegSeqRat readback, DyadicRatCore tolerance row, RealUp seal, and local transport/provenance NameCert packet.

Concretized in §1230: Regular Cauchy tail certificates realize the shared tail-window witness as finite DyadicRatCore, StreamNameUp, RegSeqRatUp, RealUp, hsame, Cont, Pkg, and NameCert rows.

Concretized in §3918: Cauchy window stability bridges realize shared finite tail-window transport from StreamName, RegSeqRat, DyadicRatCore, and RealUp seal rows.

Concretized in §1242: The diagonal-regularity theorem row is realized as a finite seal packet joining DiagonalLimit, StreamName, RegSeqRat, DyadicRatCore, triangle-bound, and RealUp handoff data.

Concretized in §1518: Fast Cauchy subsequences realize the finite cofinal-tail readback route from inspected Cauchy moduli into RegSeqRat and RealUp seal rows.

Concretized in §1245: Diagonal regularity seals realize the three-leg diagonal-regularity theorem as finite representative, endpoint-leg, middle-modulus, dyadic-tolerance, window-factorization, and Real-seal NameCert rows.

Concretized in §1255: Cofinal tail equivalences realize paired cofinal tail routes as a finite StreamName, RegSeqRat, DyadicRatCore, RealTailAgreementSeal, hsame, Cont, Pkg, and NameCert packet.

Concretized in §1281: Eventual tail-agreement packets realize the shared-tail classifier route for Real-completion consumers without quotient streams or selected limits.

Concretized in §1335: The modulus-indexed diagonal readback is realized as a finite StreamName, RegSeqRat, DyadicRatCore, RealUp, hsame, Cont, Pkg, and NameCert packet.

Concretized in §1338: The four-face exit classifier realizes the StreamName, DyadicRatCore, RegSeqRat, and RealUp exit route as one finite classifier packet.

Concretized in §2361: The Isbell tight-span packet supplies a finite injective-envelope boundary for metric completion routes.

Concretized in §3383: Tail-modulus limit handoffs realize the diagonal regularity proof route as finite StreamName, RegSeqRat, DyadicRatCore, RealUp, hsame, Cont, Pkg, and NameCert rows.

Concretized in §3858: Cauchy modulus extractors realize the explicit stage-selection route from EffectiveCauchySequence and FastCauchyModulus evidence through StreamName, DyadicRatCore, RegSeqRat, and RealUp seal rows.

Concretized in §4241: The regular Cauchy diagonal seal packages the finite-window handoff from local regular sections to the terminal RealUp seal.

Concretized in §4290: Real completeness witnesses realize the four-face StreamName, DyadicRatCore, RegSeqRat, and RealUp seal route as finite NameCert data.

Concretized in §5548: Finite nested interval data yields an explicit modulus route into regular Cauchy real names.

Concretized in §5997: Rational open interval bases realize the real-completeness finite observation route through $\mathsf{Rat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ rows.

Concretized in §6183: Regular Cauchy subnet selectors realize the cofinal finite-window extraction route for diagonal-limit and real-completeness consumers.

Concretized in §6941: Regular Cauchy tail-window selectors realize the finite cofinal-window route for diagonal-limit and real-completion consumers.

Concretized in §6232: Regular Cauchy saturation records the finite tail-budget closure route for the Real-completion vision.

Concretized in §6389: Finite-window RegSeqRat handoffs realize the StreamName, DyadicRatCore, RegSeqRat, and RealUp seal route as one finite NameCert packet.

Concretized in §6690: Regular Cauchy diagonal exchanges realize paired diagonal-window choices as finite StreamName, DyadicRatCore, RegSeqRat, and RealUp seal data.

Concretized in §6713: Regular Cauchy filter seals realize the tail-filter route into finite StreamName, RegSeqRat, DyadicRatCore, and RealUp seal rows.

Concretized in §7119: Tail-window filters realize cofinal finite tail windows for the Real completeness route through StreamNameUp, RegSeqRatUp, DyadicRatCoreUp, and RealUp seal rows.

Concretized in §7201: Tail-window modulus synchronization realizes the regular-Cauchy tail request as a finite modulus, TailCofinalityBudget, StreamName, DyadicRatCore, RegSeqRat, and RealUp route.

Concretized in §7324: RegularCauchyTailLimitUp realizes the regular-Cauchy tail-window limit route as finite StreamName, RegSeqRat, DyadicRatCore, and Real-seal NameCert data.

Concretized in §7513: StreamName tail-window routers realize the regular-Cauchy diagonal-limit route as finite precision, tail, tolerance, readback, and Real-seal NameCert rows.

Concretized in §7740: Cauchy bicompletion is realized as finite paired Cauchy-window, RegSeqRat readback, RealUp route, transport, replay, provenance, and NameCert rows.

Concretized in §7848: Regular Cauchy tail pasting realizes shared-tail pasting before RealUp seal reads as finite StreamName, RegSeqRat, DyadicRatCore, RealUp, transport, replay, provenance, and NameCert rows.

Concretized in §7861: Cantor intersection windows realize nested closed interval finite-window data as a Real and Completion NameCert handoff.

Concretized in §7903: Real completion diagonal budgets realize the finite precision-to-window-to-RegSeqRat-to-RealUp seal route used by the diagonal-limit construction.

Concretized in §7948: Dyadic contraction moduli realize the three-leg diagonal regularity estimate through finite DyadicRatCore, StreamName, RegSeqRat, and RealUp rows.

Concretized in §8145: Cauchy tail-comparison functors realize regular-Cauchy comparison transport and composition as finite StreamName, RegSeqRat, DyadicRatCore, RealUp, hsame, Cont, Pkg, and NameCert rows.

Concretized in §8687: Regular Cauchy eventual windows realize the finite tail-window route for diagonal-limit and Real-completion consumers.

Concretized in §8729: Regular Cauchy limit witnesses realize the diagonal-limit route as finite modulus, DyadicRatCore, StreamName, RegSeqRat, RealUp, BishopRegularCauchyCompletion, hsame, Cont, Pkg, and NameCert rows.

Concretized in §8767: Regular Cauchy window pullbacks realize a Real-completion precision request as finite StreamName, RegSeqRat, DyadicRatCore, RealUp, hsame, Cont, Pkg, and NameCert rows.

Concretized in §8895: Dyadic cover moduli realize the finite mesh control used by the regular-Cauchy limit route.

Concretized in §9147: Finite modulus extraction for the regular-Cauchy diagonal-limit route.

Concretized in §9167: Regular Cauchy diagonal-limit seals realize the diagonal representative as finite StreamName, RegSeqRat, DyadicRatCore, RealUp, hsame, Cont, Pkg, and NameCert rows.

9238.2 The limit theorem

Theorem 9238.5 (Real completeness proof target over $\mathsf{RegSeqRat}$)**.** *Assume that the DyadicRatCore, StreamNameUp, RegSeqRat, and RealUp certificate obligations of Phase Real and Completion are supplied at machine-checked strength. For every regular Cauchy sequence (X, μ) over* $\mathsf{RegSeqRat}$*, the diagonal representative L of Definition 9238.3 is the Bishop-style limit candidate: it is a regular sequence by Definition 9238.4, and the assignment $(X, \mu) \mapsto [L]$ into the supplied* $\mathsf{NameCert}_{\mathsf{Real}\uparrow}$ *satisfies*

$$\forall\, n \in \mathbb{N}, \quad |X_n - L| \;\leq\; \tfrac{2}{n+1}$$

in the metric of $\mathsf{NameCert}_{\mathsf{Real}\uparrow}$*. The limit candidate is unique up to the* psame*-equivalence underlying* $\mathsf{NameCert}_{\mathsf{Real}\uparrow}$*: if* L' *is another regular sequence with the same convergence bound, then* $L \,\mathsf{psame}\, L'$ *as elements of* $\mathsf{NameCert}_{\mathsf{Real}\uparrow}$*.*

Sketch. Under the stated certificate obligations, the convergence bound is an unfolding of the supplied definitions. At scale n, the diagonal index is at least $\mu(1/(n+1))$, so the regular Cauchy modulus controls X_n against $X_{\mu(1/(n+1))}$, and the diagonal-index regularity (Definition 9238.4) controls $X_{\mu(1/(n+1))}$ against L.

The uniqueness assertion is the psame closure on the supplied $\mathsf{NameCert}_{\mathsf{Real}\uparrow}$ applied to the difference $L - L'$. Its pointwise size is bounded by $4/(n+1)$ for every n, hence shrinks at the regularity rate, hence is identified with 0 by the supplied RealClassifier. □

Capstone.

Definition 9238.6 (Stationary rational regular Cauchy input)**.** *For a history* $d : \mathsf{Hist}$ *with* $\mathsf{RatHistoryCarrier}(d)$*, the stationary rational regular Cauchy input* X_d *is the pair consisting of the constant sequence*

$$X_d(n) = (\mathsf{RatConstStream}_d, \mathsf{E1}(d))$$

for every $n : \mathbb{N}$*, and the constant modulus* $\mu_d(\varepsilon) = 0$ *for every positive rational tolerance* ε*. Each member is the constant rational RealUp name represented by the StreamNameUp seed* $\mathsf{RatConstStream}_d$ *together with the e-one RealUp seal* $\mathsf{E1}(d)$*.*

Theorem 9238.7 (Stationary rational diagonal agrees with the rational embedding)**.** *If* $\mathsf{RatHistoryCarrier}(d)$*, then the input* X_d *of Definition 9238.6 satisfies the regular Cauchy condition of Definition 9238.2. Its diagonal representative* L_d *from Definition 9238.3 is classified by the RealUp classifier with the constant rational embedding of* d *at* $\mathsf{E1}(d)$*, namely the name represented by* $(\mathsf{RatConstStream}_d, \mathsf{E1}(d))$*.*

Sketch. The carrier assumption on d gives RatUp classifier reflexivity by the semantic certificate Definition 37.90. Applying the StreamNameUp constant witness Definition 126.48 packages the constant stream $\mathsf{RatConstStream}_d$ as a valid stream name and gives its self-classifier at every certified unary observation.

For the Cauchy condition, every pair of members $X_d(m)$ and $X_d(n)$ has the same hidden rational seed. The zero modulus is therefore admissible: after unfolding the regular Cauchy predicate, the required endpoint comparison is exactly the self-classifier just obtained, transported through StreamNameUp constant point exactness Definition 126.55.

For the diagonal representative, the extraction formula always selects a member of X_d and then reads a point of the same constant stream. Thus every diagonal value is the seed d, independently of the outer index and independently of the selected diagonal bound.

Finally, Definition 38.31 identifies the pair $(\mathsf{RatConstStream}_d, \mathsf{E1}(d))$ with the RealUp constant rational embedding. The previous paragraph shows that L_d has exactly the same constant seed at every diagonal read, so the RealUp classifier relates L_d to that embedding. □

Concretized in §364: Stationary rational regular Cauchy inputs are recorded as a concrete RealUp handoff certificate.

Concretized in §673: Limit selector packets realize the diagonal-limit selector as finite modulus, window, RegSeqRat, RealUp seal, hsame, Cont, Pkg, and NameCert rows.

Concretized in §6644: The diagonal-limit witness route is realized as finite modulus, window, RegSeqRat, DyadicRatCore, RealUp, uniqueness, hsame, Cont, Pkg, and NameCert rows.

Concretized in §701: Stationary embedding classifier packets realize the RatUp-to-RealUp classifier correspondence for stationary rational diagonals.

Concretized in §1351: The explicit diagonal convergence bound is realized as a finite NameCert packet linking the diagonal representative, dyadic tolerance ledger, RegSeqRat readback, and RealUp seal.

Concretized in §8227: Diagonal limit modulus certificates realize the finite threshold, StreamName, RegSeqRat, DyadicRatCore, RealUp, and CauchyLimitSeal route used by the limit theorem.

Theorem 9238.8 (Stationary rational embedding classifier correspondence)**.** *For RatUp histories $d, e : \mathsf{Hist}$ with $\mathsf{RatHistoryCarrier}(d)$ and $\mathsf{RatHistoryCarrier}(e)$, let X_d and X_e be the stationary rational regular Cauchy inputs of Definition 9238.6, and let L_d and L_e be their diagonal representatives from Definition 9238.3. Then the RealUp classifier relates the two stationary diagonal representatives exactly when the RatUp classifier relates their hidden rational seeds:*

$$\mathsf{RealClassifier}(L_d, L_e) \iff \mathsf{RatHistoryClassifier}(d, e).$$

Sketch. Apply Definition 9238.7 separately to d and to e. This identifies L_d with the constant rational RealUp name represented by $(\mathsf{RatConstStream}_d, \mathsf{E1}(d))$, and identifies L_e with the corresponding constant name represented by $(\mathsf{RatConstStream}_e, \mathsf{E1}(e))$.

For the reverse direction, assume $\mathsf{RatHistoryClassifier}(d, e)$. The constant point exactness theorem Definition 126.55 transports this classifier to the constant StreamNameUp row, and Definition 38.31 transports the same row to the e-one RealUp constant classifier. The two diagonal agreement rows just obtained then transport the e-one constant classifier to $\mathsf{RealClassifier}(L_d, L_e)$.

For the forward direction, assume $\mathsf{RealClassifier}(L_d, L_e)$. Transport this classifier across the two diagonal agreement rows to obtain the e-one constant classifier $\mathsf{RealConstantHistoryClassifier}(\mathsf{E1}(d), \mathsf{E1}(e))$. Applying Definition 38.11 reflects that classifier back to $\mathsf{RatHistoryClassifier}(d, e)$; equivalently, Definition 126.55 reads the intervening constant StreamNameUp classifier back as the same RatUp seed classifier. □

Concretized in §362: Stationary rational diagonal packets are realized as a concrete Real and Completion NameCert surface.

Concretized in §411: Regular Cauchy comparison packets realize the finite comparison layer used by the Real completeness proof target.

Concretized in §644: Regular Cauchy mesh packets realize finite mesh-indexed regular-rational observations for the Real completeness handoff.

Concretized in §637: Real approximation envelopes realize the finite observation packet from DyadicRatCore, StreamNameUp, RegSeqRat, and RealUp into a reusable Real and Completion handoff.

Concretized in §703: Cauchy inverse budgets realize nonzero-apart regular-Cauchy reciprocal windows as finite DyadicRatCore, StreamNameUp, RegSeqRatUp, RealUp, hsame, Cont, Pkg, and NameCert rows.

Concretized in §6251: Real reciprocal packets realize nonzero-apart RealUp reciprocal reads through finite Cauchy inverse budgets, RegSeqRat handoff, and terminal Real seal rows.

Concretized in §886: Cauchy seal-budget synchronizers realize the Real completeness route as one finite selector, observation-budget, shared-threshold, and seal NameCert packet.

Concretized in §898: Cauchy tail-witness envelopes realize the Real-completeness diagonal tail route as a finite StreamName, finite-window, CauchyTailComparison, RealTailAgreementSeal, and RealUp NameCert packet.

Concretized in §909: Regular Cauchy diagonal meets realize the shared-threshold diagonal tail route as a finite TailMeet, CauchyModulusMeet, CauchyTailWitnessEnvelope, and RealDiagonalWindowCoverage packet.

Concretized in §900: Real completion seal classifiers realize finite completion-seal equivalence as displayed RealTailAgreementSealUp, CauchyLimitSealUp, CauchySealBudgetSynchronizerUp, RegSeqRatUp, StreamNameUp, DyadicRatCoreUp, hsame, Cont, Pkg, and NameCert rows.

Concretized in §902: Cauchy witness ledgers realize the Real completeness route as finite diagonal-budget, observation-budget, seal-synchronizer, and completion-seal NameCert rows.

Concretized in §913: Budgeted real seal routes realize the Real-completion budget, TailMeet threshold, observation-budget, and CauchyLimitSeal handoff as one finite NameCert packet.

Concretized in §921: Finite tail-fiber schedules realize the Real-completeness tail route as finite StreamName, RegSeqRat, DyadicRatCore, RealUp, hsame, Cont, Pkg, and NameCert rows.

Concretized in §929: Cauchy rate budgets realize finite convergence-rate control for StreamName, RegSeqRat, DyadicRatCore, RealUp, and observation-budget seal routes.

Concretized in §981: Dyadic window seals realize finite dyadic precision, StreamName window, RegSeqRat readback, observation-budget, synchronizer, and RealUp seal rows for the Real and Completion route.

Concretized in §1276: Finite limit-seal envelopes realize the Real completeness limit theorem as one finite StreamName, RegSeqRat, DyadicRatCore, CauchyLimitSeal, RealUp, hsame, Cont, Pkg, and NameCert handoff.

Concretized in §1278: Diagonal-index cofinality realizes the finite modulus-threshold row used by the Real completeness limit proof.

Concretized in §1342: Cauchy seal interfaces realize the common finite seal handoff joining CauchyLimitSeal, seal-classifier, budget-synchronizer, StreamName, RegSeqRat, DyadicRatCore, and RealUp rows.

Concretized in §3701: The diagonal limit candidate and uniqueness classifier are realized as a finite CauchyLimitSeal, RegSeqRat, StreamName, DyadicRatCore, and RealUp NameCert packet.

Concretized in §6809: The modulus envelope realizes the finite regular-Cauchy limit handoff without asserting ambient Real completeness.

The ten-field fit is stationary rational embedding classifier reflection: traditional target constant rational diagonals inside RealUp; BEDC source RatUp plus StreamNameUp plus RealUp; carrier stationary regular Cauchy inputs and their diagonal representatives; classifier the displayed RealUp/RatUp equivalence; stability supplied by diagonal agreement and constant endpoint transport; ledger the two hidden rational seeds and their e-one seals; core theorem Definition 9238.8; exactness the displayed if-and-only-if; standard bridge constant rational RealUp names; status ProofTarget.

Theorem 9238.9 (Stationary rational finite-window classifier bridge)**.** *For histories* $d, e, a, w : \mathsf{Hist}$ *with* $\mathsf{UnaryHistory}(a)$ *and* $\mathsf{UnaryHistory}(w)$*, the stationary rational point classifier, the constant*

StreamNameUp classifier, the RealUp finite-window classifier, and the e-one RealUp constant classifier are equivalent:

$$\mathsf{RatHistoryClassifier}(d, e) \iff \mathsf{RatStreamNameClassifier}(\mathsf{RatConstStream}_d, \mathsf{RatConstStream}_e).$$

$$\mathsf{RatStreamNameClassifier}(\mathsf{RatConstStream}_d, \mathsf{RatConstStream}_e) \iff \mathsf{RealUnaryStreamWindowClassifier}(\mathsf{RatConst}$$

$$\mathsf{RealUnaryStreamWindowClassifier}(\mathsf{RatConstStream}_d, \mathsf{RatConstStream}_e, a, w) \iff \mathsf{RealConstantHistoryClassifier}($$

Sketch. The RatUp and StreamNameUp rows are the constant-stream point exactness row of Definition 126.55: a classifier between the hidden rational seeds is the same data as the pointwise classifier between the two constant observation maps.

For the forward finite-window direction, read the constant StreamNameUp classifier as a RealUp unary-observation classifier by Definition 38.27. Apply the Real unary finite-window coverage theorem Definition 38.155 with the displayed witnesses $\mathsf{UnaryHistory}(a)$ and $\mathsf{UnaryHistory}(w)$.

For the reverse finite-window direction, evaluate the window at offset e. The witness $\mathsf{UnaryOffsetLe}(\mathsf{e}, w)$ is supplied by unary emptiness, the displayed unary bound on w, and the continuation unit law. The constant stream definitions erase the anchor and this offset, so the selected endpoint classifier is $\mathsf{RatHistoryClassifier}(d, e)$; applying Definition 126.55 returns the StreamNameUp row.

Finally, Definition 38.11 identifies the rational point classifier with $\mathsf{RealConstantHistoryClassifier}(\mathsf{E1}(d), \mathsf{E1}(e))$, and Definition 38.31 packages that identification as the constant rational RealUp embedding certificate. □

The bridge records the ten-field fit: traditional target stationary rational finite windows; BEDC source RatUp plus StreamNameUp plus RealUp; carrier stationary rational observation maps; classifier the four equivalent rows; stability inherited from RatUp classifier fields and unary-window coverage; ledger hidden rational seed plus anchor and bound; core theorem Definition 9238.9; exactness the displayed equivalence; standard bridge constant rational real names; status $\mathsf{ProofTarget}$.

Theorem 9238.10 (Stationary rational diagonal finite-window classifier correspondence)**.** *For RatUp histories $d, e : \mathsf{Hist}$ with $\mathsf{RatHistoryCarrier}(d)$ and $\mathsf{RatHistoryCarrier}(e)$, and for unary window endpoints $a, w : \mathsf{Hist}$ with $\mathsf{UnaryHistory}(a)$ and $\mathsf{UnaryHistory}(w)$, let X_d and X_e be the stationary rational regular Cauchy inputs of Definition 9238.6, and let L_d and L_e be their diagonal representatives from Definition 9238.3. Then the stationary diagonal RealUp classifier, the finite-window classifier on the constant rational streams, and the RatUp seed classifier are equivalent:*

$$\mathsf{RealClassifier}(L_d, L_e) \iff \mathsf{RealUnaryStreamWindowClassifier}(\mathsf{RatConstStream}_d, \mathsf{RatConstStream}_e, a, w) \iff$$

Sketch. First apply Definition 9238.8 to the displayed stationary inputs. This identifies $\mathsf{RealClassifier}(L_d, L_e)$ exactly with the seed classifier $\mathsf{RatHistoryClassifier}(d, e)$.

Next apply Definition 9238.9 with the same seeds and unary endpoints. Its RatUp-to-StreamNameUp row and StreamNameUp-to-window row identify $\mathsf{RealUnaryStreamWindowClassifier}(\mathsf{RatConstStream}_d, \mathsf{RatConstStrea}$ with the same seed classifier.

Both displayed identifications land on $\mathsf{RatHistoryClassifier}(d, e)$. Composing the first identification with the inverse of the second gives the RealUp-to-window equivalence, while each classifier also remains equivalent to the common RatUp seed classifier. This assembles the stated three-way correspondence. □

Theorem 9238.11 (Stationary rational selected tail seed exactness)**.** *For histories $d, e, a, w, k, d_0, e_0 : \mathsf{Hist}$, assume*

$$\mathsf{RatHistoryClassifier}(d, e), \quad \mathsf{UnaryHistory}(a), \quad \mathsf{UnaryHistory}(w), \quad \mathsf{UnaryOffsetLe}(k, w),$$

$$\mathsf{hsame}(d, \mathsf{E1}(d_0)), \quad \mathsf{hsame}(e, \mathsf{E1}(e_0)).$$

Then the stationary constant streams form a RealUp finite-window classifier,

$$\mathsf{RealUnaryStreamWindowClassifier}(\mathsf{RatConstStream}_d, \mathsf{RatConstStream}_e, a, w),$$

and the selected endpoint e-one tail class is exactly the original RatUp seed-tail class:

$$\begin{aligned}&\forall u, v : \mathsf{Hist},\ \big(\mathsf{hsame}(\mathsf{RatConstStream}_d(\mathsf{append}(a,k)), \mathsf{E1}(u)) \wedge \mathsf{hsame}(\mathsf{RatConstStream}_e(\mathsf{append}(a,k)), \mathsf{E1}(v))\big)\\ &\quad\Longleftrightarrow\\ &\qquad\big(\mathsf{UnaryHistory}(u) \wedge \mathsf{UnaryHistory}(v) \wedge \mathsf{hsame}(d_0, u) \wedge \mathsf{hsame}(e_0, v)\big).\end{aligned}$$

Sketch. The displayed RatUp classifier and the two e-one seed displays are first read through the RatUp e-one tail readback row. This recovers $\mathsf{UnaryHistory}(d_0)$, $\mathsf{UnaryHistory}(e_0)$, and the seed-tail comparison $\mathsf{hsame}(d_0, e_0)$ inside the original rational classifier class.

Apply StreamNameUp constant point exactness Definition 126.55 to pass from the RatUp classifier on d, e to the classifier between $\mathsf{RatConstStream}_d$ and $\mathsf{RatConstStream}_e$. Then use Definition 9238.9 with the displayed unary anchor and bound to obtain the RealUp finite-window classifier row.

For the forward direction of the displayed exactness, apply Definition 38.584 to the constant streams, the StreamNameUp classifier, the unary anchor and bound, and the selected offset. Its canonical selected tails are the displayed seed tails d_0, e_0, because the constant streams erase $\mathsf{append}(a, k)$ and the RatUp e-one readback identifies the selected endpoint displays with the seed displays.

For the reverse direction, assume $\mathsf{UnaryHistory}(u)$, $\mathsf{UnaryHistory}(v)$, $\mathsf{hsame}(d_0, u)$, and $\mathsf{hsame}(e_0, v)$. Apply BEDC.FKernel.Hist.hsame_e1_congr to the two tail comparisons, then compose by BEDC.FKernel.Hist.hsame_ with $\mathsf{hsame}(d, \mathsf{E1}(d_0))$ and $\mathsf{hsame}(e, \mathsf{E1}(e_0))$. Since each constant stream returns its seed at $\mathsf{append}(a, k)$, the two composites are exactly the selected endpoint displays for u and v. □

Fit. Traditional target: stationary rational selected finite-window tail exactness. BEDC source: $\mathsf{Rat}^{\uparrow} + \mathsf{StreamName}^{\uparrow} + \mathsf{Real}^{\uparrow}$ plus FKernel e-one congruence and transitivity. Carrier: selected constant-stream endpoint tails. Classifier: RealUnaryStreamWindowClassifier obtained from the stationary rational classifier chain. Stability: endpoint hsame transport from the seed displays to selected e-one tails. Ledger: RatUp classifier, seed e-one displays, unary anchor, unary bound, selected offset, and selected endpoint displays. Core theorem: Definition 9238.11. Exactness: the displayed if-and-only-if identifies selected finite-window tails with the original RatUp seed-tail class. Standard bridge: constant rational RealUp observation windows. Downstream use: RegSeqRat stationary observation canonicalization. Status: ProofTarget.

Theorem 9238.12 (Stationary rational finite-window concatenation)**.** *For histories* $d, e, a_L, w_L, a_R, w_R, d_0, e_0 : \mathsf{Hist}$*, indices* n, m, r*, and a unary observation schedule* $\eta : \mathbb{N} \to \mathsf{Hist}$*, define the stationary rational RealUp observation streams*

$$C_d(i) = \mathsf{RatConstStream}_d(\eta(i)), \quad C_e(i) = \mathsf{RatConstStream}_e(\eta(i)).$$

Assume

$$\mathsf{RatHistoryClassifier}(d, e), \quad \mathsf{UnaryHistory}(a_L), \quad \mathsf{UnaryHistory}(w_L), \quad \mathsf{UnaryHistory}(a_R), \quad \mathsf{UnaryHistory}(w_R),$$

and the seed-tail displays

$$\mathsf{hsame}(d, \mathsf{E1}(d_0)), \quad \mathsf{hsame}(e, \mathsf{E1}(e_0)).$$

If the left block $[n, n+m]$ is named by unary offsets below w_L from anchor a_L, and the right adjacent block $[n+(m+1), n+(m+1)+r]$ is named by unary offsets below w_R from anchor a_R, then the joined natural-indexed finite window is classified:

$$\mathsf{RealStreamWindowClassifier}(C_d, C_e, n, m+1+r).$$

Moreover, for every selected offset $k \le m+1+r$, the constructive split $k \le m$ or $k = m+1+j$ with $j \le r$ selects the corresponding left or right unary source offset, and the selected endpoint in the joined window has exactly the original RatUp seed-tail class:

$$\begin{aligned}&\forall u, v : \mathsf{Hist},\ \big(\mathsf{hsame}(C_d(n+k), \mathsf{E1}(u)) \wedge \mathsf{hsame}(C_e(n+k), \mathsf{E1}(v))\big)\\ &\iff\\ &\qquad \big(\mathsf{UnaryHistory}(u) \wedge \mathsf{UnaryHistory}(v) \wedge \mathsf{hsame}(d_0, u) \wedge \mathsf{hsame}(e_0, v)\big).\end{aligned}$$

Sketch. Apply Definition 9238.9 with the common $\mathsf{RatHistoryClassifier}(d, e)$, first at (a_L, w_L) and then at (a_R, w_R). This gives the two stationary $\mathsf{RealUnaryStreamWindowClassifier}$ rows for the left and right unary source windows.

Unfold the scheduled constant streams C_d and C_e. On the left block, each endpoint $C_d(n+k), C_e(n+k)$ is the same pair of hidden seeds d, e read through $\mathsf{RatConstStream}$; the left unary window therefore supplies the natural window $\mathsf{RealStreamWindowClassifier}(C_d, C_e, n, m)$. The same argument on the right block gives $\mathsf{RealStreamWindowClassifier}(C_d, C_e, n+(m+1), r)$.

Apply Definition 38.182 to these two adjacent natural-indexed windows. The result is the joined classifier $\mathsf{RealStreamWindowClassifier}(C_d, C_e, n, m+1+r)$.

For a selected offset $k \le m+1+r$, split constructively between $k \le m$ and $k = m+1+j$ with $j \le r$. In the left case, use the corresponding unary source offset below w_L and apply Definition 9238.11 at (a_L, w_L). In the right case, apply the same theorem at (a_R, w_R) with the right source offset.

In both cases the stationary streams erase the selected observation schedule, so the endpoint displays are the same seed displays $\mathsf{hsame}(d, \mathsf{E1}(d_0))$ and $\mathsf{hsame}(e, \mathsf{E1}(e_0))$. The two cases therefore return the same displayed tail-class equivalence, and the offset split covers the whole joined window. □

The ten-field fit is: traditional target finite stationary rational window pasting; BEDC source RatUp plus StreamNameUp plus RealUp plus Real stream window concatenation; carrier stationary constant streams; classifier joined RealUp finite-window classifier; stability by stationary bridge exactness, bounded-offset splitting, and adjacent window concatenation; ledger hidden rational seed, two bounds, join index, and selected offset; core theorem Definition 9238.12; exactness selected endpoint tails remain the RatUp seed class; standard bridge RegSeqRat finite observation window pasting; downstream use RegSeqRat stationary observation canonicalization and the Phase Real and Completion diagonal-limit capstone. Status: $\mathsf{ProofTarget}$.

Theorem 9238.13 (Stationary rational finite-partition fold)**.** *For histories $d, e, d_0, e_0 : \mathsf{Hist}$, an anchor n, a total bound w, and a unary observation schedule $\eta : \mathbb{N} \to \mathsf{Hist}$, define the stationary rational RealUp observation streams*

$$C_d(i) = \mathsf{RatConstStream}_d(\eta(i)), \quad C_e(i) = \mathsf{RatConstStream}_e(\eta(i)).$$

Let P be a certified finite partition spine over (n, w) with segment anchors and radii (n_i, r_i), and suppose that P records the unary source-anchor, source-bound, and selected-offset witnesses for every segment. Assume

$$\mathsf{RatHistoryClassifier}(d, e), \quad \mathsf{hsame}(d, \mathsf{E1}(d_0)), \quad \mathsf{hsame}(e, \mathsf{E1}(e_0)).$$

Then the total stationary window classifier is exactly the finite conjunction of the segment classifiers named by P:

$$\mathsf{RealStreamWindowClassifier}(C_d, C_e, n, w) \iff \bigwedge_{(n_i,r_i)\in P} \mathsf{RealStreamWindowClassifier}(C_d, C_e, n_i, r_i).$$

Moreover, for every segment (n_i, r_i) named by P and every selected offset $k \le r_i$ whose unary source witness is recorded by P, the selected endpoint has the original displayed seed-tail class:

$$\begin{aligned}&\forall u, v : \mathsf{Hist},\ \big(\mathsf{hsame}(C_d(n_i+k), \mathsf{E1}(u)) \wedge \mathsf{hsame}(C_e(n_i+k), \mathsf{E1}(v))\big)\\ &\iff\\ &\qquad \big(\mathsf{UnaryHistory}(u) \wedge \mathsf{UnaryHistory}(v) \wedge \mathsf{hsame}(d_0, u) \wedge \mathsf{hsame}(e_0, v)\big).\end{aligned}$$

Sketch. First treat each segment named by P as an ordinary stationary rational finite window. The spine ledger supplies the unary source anchor, source bound, and selected offsets for that segment, while the common $\mathsf{RatHistoryClassifier}(d, e)$ row is shared by every segment.

Apply Definition 9238.11 segmentwise. This gives, for every selected offset in every segment, the displayed endpoint-tail equivalence with the seed tails d_0, e_0.

Next apply Definition 9238.9 to each segment ledger. The stationary streams erase the observation schedule η, so the same RatUp classifier produces every segment classifier $\mathsf{RealStreamWindowClassifier}(C_d, C_e, n$

It remains to fold the segment classifiers along the certified spine. Apply Definition 38.308 to the streams C_d, C_e and to P. In the singleton case this is the existing stationary finite-window bridge. In the successor case the induction step uses the spine continuation ledger to concatenate the predecessor window with the final segment, exactly as in the finite partition fold. □

The ten-field fit is: traditional target finite stationary rational partition coverage; BEDC source $\mathsf{Rat}^{\uparrow} + \mathsf{StreamName}^{\uparrow} + \mathsf{Real}^{\uparrow}$ plus the Real stream finite partition spine; carrier stationary constant rational observation streams; classifier total $\mathsf{RealStreamWindowClassifier}(C_d, C_e, n, w)$ and the segment classifiers named by P; stability by RatUp classifier transport, selected-tail seed exactness, and partition-spine induction; ledger hidden rational seed, seed e-one displays, total bound, segment radii, accumulated anchors, unary source anchors, source bounds, selected offsets, and continuation rows; core theorem Definition 9238.13; exactness the displayed fold equivalence and the displayed seed-tail equivalence; standard bridge finite RegSeqRat observation coverage by stationary rational streams; downstream use Phase Real and Completion diagonal-limit capstone ledger consumption. Status: ProofTarget.

Theorem 9238.14 (Stationary rational finite-partition diagonal embedding)**.** *For RatUp histories $d, e, d_0, e_0 : \mathsf{Hist}$, an observation anchor n, a total bound w, and a unary observation schedule $\eta : \mathbb{N} \to \mathsf{Hist}$, define the stationary rational RealUp observation streams*

$$C_d(i) = \mathsf{RatConstStream}_d(\eta(i)), \quad C_e(i) = \mathsf{RatConstStream}_e(\eta(i)).$$

Let P be a certified finite partition spine over (n, w) whose segment ledger records the unary source-anchor, source-bound, and selected-offset witnesses required by Definition 9238.13. Assume

$$\mathsf{RatHistoryCarrier}(d), \quad \mathsf{RatHistoryCarrier}(e), \quad \mathsf{RatHistoryClassifier}(d, e),$$

and the seed displays

$$\mathsf{hsame}(d, \mathsf{E1}(d_0)), \quad \mathsf{hsame}(e, \mathsf{E1}(e_0)).$$

Then the finite conjunction of segment classifiers supplied by P is a complete finite ledger for the stationary input X_d of Definition 9238.6. Its diagonal representative L_d is classified by the RealUp

classifier with the constant rational embedding represented by $(\mathsf{RatConstStream}_d, \mathsf{E1}(d))$*. Likewise, the stationary input* X_e *has diagonal representative* L_e *classified by the constant rational embedding represented by* $(\mathsf{RatConstStream}_e, \mathsf{E1}(e))$*, and the two embeddings are related through the displayed* $\mathsf{RatHistoryClassifier}(d, e)$*.*

Sketch. First use RatUp semantic reflexivity for the carrier rows on d and e. Together with Definition 126.48 and Definition 126.55, the stationary streams C_d and C_e are valid constant StreamNameUp witnesses at every observation named by η.

Next consume the finite partition spine. Apply Definition 9238.13 to C_d, C_e, the common RatUp classifier, the seed displays, and the certified spine P. This supplies the total $\mathsf{RealStreamWindowClassifier}(C_d, C_e, n, w$ exactly as the finite conjunction of segment classifiers, and it preserves the selected endpoint seed-tail equivalence on every segment.

The selected-tail rows are the ledger needed by the constant regular Cauchy input X_d: every member of X_d is the same constant RealUp name $(\mathsf{RatConstStream}_d, \mathsf{E1}(d))$, and every finite observation selected from the partition reads the same hidden rational seed. The same argument applies to X_e.

Now apply Definition 9238.11 and Definition 9238.9 to read the segment ledgers as RealUp finite-window classifiers. The bridge identifies these classifiers with the e-one RealUp constant classifier, while the selected-tail theorem keeps the endpoint displays tied to d_0 and e_0.

Finally apply Definition 9238.7 separately to d and e. The diagonal extraction of X_d and X_e always reads a point of the same constant stream, so Definition 38.31 identifies the two diagonal representatives with their constant rational RealUp embeddings. The original $\mathsf{RatHistoryClassifier}(d, e)$, transported through Definition 126.55, relates those two constant embeddings. □

Theorem 9238.15 (Stationary rational partition refinement invariance)**.** *For RatUp histories* $d, e, d_0, e_0 : \mathsf{Hist}$*, an observation anchor* n*, a total bound* w*, and a unary observation schedule* $\eta : \mathbb{N} \to \mathsf{Hist}$*, define the stationary rational RealUp observation streams*

$$C_d(i) = \mathsf{RatConstStream}_d(\eta(i)), \quad C_e(i) = \mathsf{RatConstStream}_e(\eta(i)).$$

Let P *be a certified finite partition spine over* (n, w)*, and let* P' *be a certified refinement of* P *obtained by replacing each segment* (n_i, r_i) *of* P *by a finite adjacent chain* $(n_{i,j}, r_{i,j})$ *whose union is the same window. Suppose that the refinement map preserves the unary source-anchor, source-bound, selected-offset, and continuation ledgers: every subsegment of* P' *is recorded with the same stationary source anchor and source bound as its parent segment in* P*, selected offsets are the corresponding translated offsets inside the parent segment, and the continuation rows concatenate the subsegments back to the parent window. Assume*

$$\mathsf{RatHistoryCarrier}(d), \quad \mathsf{RatHistoryCarrier}(e), \quad \mathsf{RatHistoryClassifier}(d, e),$$

and the seed displays

$$\mathsf{hsame}(d, \mathsf{E1}(d_0)), \quad \mathsf{hsame}(e, \mathsf{E1}(e_0)).$$

Then the finite segment ledger named by P *holds iff the finite segment ledger named by* P' *holds:*

$$\bigwedge_{(n_i, r_i) \in P} \mathsf{RealStreamWindowClassifier}(C_d, C_e, n_i, r_i) \iff \bigwedge_{(n_{i,j}, r_{i,j}) \in P'} \mathsf{RealStreamWindowClassifier}(C_d, C_e, n_{i,j}, r_{i,j}).$$

Moreover, either ledger gives the same diagonal RealUp embedding conclusions of Definition 9238.14 for X_d *and* X_e*, and every selected endpoint in either ledger has the same seed-tail class supplied by Definition 9238.11.*

Sketch. First apply Definition 9238.13 to the original spine P. Its ledger is equivalent to the total classifier $\mathsf{RealStreamWindowClassifier}(C_d, C_e, n, w)$, and its selected endpoint rows have the seed-tail class determined by d_0, e_0.

Apply the same partition fold to the refined spine P'. The refinement preserves the source-anchor and source-bound rows, so each subsegment is a stationary rational finite window with the same hidden RatUp seed classifier.

For a subsegment inside a parent segment, use adjacent-window restriction to read the parent classifier on the smaller window, and use adjacent-window concatenation along the refinement chain to assemble the parent window from the subsegments. The stationary streams erase the observation schedule η, so this restriction and concatenation carry no extra endpoint data beyond the translated selected offsets already recorded in the refinement ledger.

The forward direction transports the P ledger through the common total classifier and then through the fold for P'. The reverse direction uses the fold for P' to recover the same total classifier and then the fold for P to recover the original segment conjunction.

Finally apply Definition 9238.14 once with P and once with P'. Both applications consume the same total stationary window classifier and the same RatUp seed classifier. Apply Definition 9238.11 on the selected offsets in each spine to identify every endpoint tail with the same displayed seed-tail class. □

The ten-field fit is: traditional target finite stationary rational segmentation independence; BEDC source $\mathsf{Rat}^{\uparrow}+\mathsf{StreamName}^{\uparrow}+\mathsf{Real}^{\uparrow}$ plus Real stream finite partition spines; carrier stationary constant rational observation streams; classifier the total $\mathsf{RealStreamWindowClassifier}(C_d, C_e, n, w)$ and the segment classifiers named by P and P'; stability by partition fold, adjacent-window restriction, adjacent-window concatenation, and selected-tail seed exactness; ledger hidden rational seed, seed e-one displays, total bound, parent segment radii, refined subsegment radii, translated selected offsets, source anchors, source bounds, and continuation rows; core theorem Definition 9238.15; exactness the common finite ledger equivalence, the common diagonal embedding certificate, and the common selected endpoint seed-tail class; standard bridge RegSeqRat stationary observation partitions with certified refined segmentation; downstream use Real and Completion diagonal-limit capstone ledger consumption. Status: ProofTarget.

Theorem 9238.16 (Stationary rational partition normal form)**.** *For RatUp seeds $d, e, d_0, e_0 : \mathsf{Hist}$, an observation anchor n, a bound w, and a unary observation schedule $\eta : \mathbb{N} \to \mathsf{Hist}$, define the stationary rational RealUp observation streams*

$$C_d(i) = \mathsf{RatConstStream}_d(\eta(i)), \quad C_e(i) = \mathsf{RatConstStream}_e(\eta(i)).$$

Let P be any certified finite partition spine refining the one-segment window (n, w). Suppose that the refinement certificate preserves the source-anchor, source-bound, selected-offset, and continuation rows: every segment of P is recorded as a translated subwindow of (n, w), selected offsets translate to selected offsets of the one-segment window, and the continuation rows concatenate all segments of P back to (n, w). Assume

$$\mathsf{RatHistoryCarrier}(d), \quad \mathsf{RatHistoryCarrier}(e), \quad \mathsf{RatHistoryClassifier}(d, e),$$

and the seed displays

$$\mathsf{hsame}(d, \mathsf{E1}(d_0)), \quad \mathsf{hsame}(e, \mathsf{E1}(e_0)).$$

Then the finite segment ledger named by P is equivalent to the normal-form one-window classifier:

$$\bigwedge_{(n_i, r_i) \in P} \mathsf{RealStreamWindowClassifier}(C_d, C_e, n_i, r_i) \iff \mathsf{RealStreamWindowClassifier}(C_d, C_e, n, w).$$

Moreover, the diagonal RealUp embedding conclusions for the stationary inputs X_d and X_e are exactly the conclusions obtained from the one-segment ledger on (n, w): the representative L_d is classified by the constant rational embedding represented by $(\mathsf{RatConstStream}_d, \mathsf{E1}(d))$*, the representative L_e is classified by the constant rational embedding represented by* $(\mathsf{RatConstStream}_e, \mathsf{E1}(e))$*, and the relation between the two embeddings is the transported* $\mathsf{RatHistoryClassifier}(d, e)$*.*

Sketch. First regard the one-segment window (n, w) as a certified partition spine S with a single segment. The stationary finite-window bridge identifies the ledger of S with $\mathsf{RealStreamWindowClassifier}(C_d, C_e, n, w$ because both streams read constant RatUp seeds through the unary schedule η.

Next apply Definition 9238.13 to the given spine P. This folds the finite segment conjunction of P to the same total classifier and keeps each selected endpoint tied to the displayed seed tails d_0, e_0.

Use Definition 9238.15 with S and P. The preservation hypotheses are exactly the refinement rows required there: translated source anchors, translated source bounds, translated selected offsets, and continuation rows that reassemble the one-segment window. Hence the P ledger and the one-segment ledger determine the same finite observation content.

Finally apply Definition 9238.14 to S and to P. Both applications consume the same RatUp classifier, the same seed displays, and the same total stationary window classifier. The stationary finite-window bridge erases the partition choice, so the extracted diagonal representatives for X_d and X_e are the constant rational RealUp embeddings obtained from the one-segment ledger. □

Concretized in §422: Stationary finite-partition diagonal packets are realized as a concrete Real and Completion NameCert surface.

Concretized in §1207: Selected tail seed packets realize the stationary rational selected finite-window endpoint as a finite RatUp, StreamNameUp, RegSeqRatUp, DyadicRatCoreUp, RealUp, hsame, Cont, Pkg, and NameCert handoff.

Concretized in §1226: Finite-prefix limit stability realizes the diagonal-limit finite observation route as a NameCert packet over budget, StreamName, RegSeqRat, DyadicRatCore, RealUp seal, hsame, Cont, and provenance rows.

Concretized in §1231: Tail cofinality budgets realize the shared finite tail threshold for StreamNameUp, DyadicRatCoreUp, RegSeqRatUp, and RealUp seal reads as a finite NameCert packet.

Concretized in §1264: Cofinal modulus normalization seals realize paired cofinal modulus schedules as one finite Real-and-Completion NameCert handoff over DyadicRatCore, StreamNameUp, RegSeqRatUp, and RealUp.

Concretized in §1299: Cauchy tail threshold normalizers realize the shared finite tail threshold as a normal-form route for StreamNameUp, RegSeqRatUp, DyadicRatCoreUp, CauchyTailModulusSealUp, RealTailAgreementSealUp, and RealUp consumers.

Concretized in §1352: Real cofinal modulus gates realize the finite cofinal-tail schedule and modulus-comparison rows consumed before a RealUp seal may serve the limit theorem.

Concretized in §1354: Canonical tail-choice packets realize the finite Real-completion diagonal selector as displayed modulus, tolerance, finite-index, tail-window, seal, refusal, hsame, Cont, Pkg, and NameCert rows.

Concretized in §1356: The canonical tail-choice audit packet realizes the Real-completion selector as a finite non-choice NameCert boundary with displayed tail-window, refusal, transport, route, provenance, and Real-seal rows.

Concretized in §5722: Finite limit seals realize the diagonal-limit finite-window route through StreamName, RegSeqRat, DyadicRatCore, and RealUp without selected limits or quotient streams.

Concretized in §6604: Regular Cauchy lifted-limit packets realize the diagonal-limit handoff through DyadicRatCore, StreamNameUp, RegSeqRatUp, and RealUp finite rows.

Concretized in §3942: Regular Cauchy limit uniqueness realizes the finite paired-tail, dyadic witness, RegSeqRat readback, and RealUp seal route used by the uniqueness half of the limit theorem.

Concretized in §6759: Dyadic window reflectors realize the Real-completeness finite-window classifier route through DyadicRatCoreUp, StreamNameUp, RegSeqRatUp, and RealUp seal rows.

The ten-field fit is: traditional target finite stationary rational partition normal form; BEDC source $\mathsf{Rat}^{\uparrow} + \mathsf{StreamName}^{\uparrow} + \mathsf{Real}^{\uparrow}$ plus Real stream finite partition spines; carrier stationary constant rational observation streams; classifier the normal-form window classifier $\mathsf{RealStreamWindowClassifier}(C_d, C_e, \eta$ and the finite segment classifiers named by P; stability by partition fold, refinement invariance, diagonal embedding, and the stationary finite-window bridge; ledger hidden rational seed, seed e-one displays, total bound, subwindow radii, translated source anchors, translated source bounds, selected offsets, and continuation rows; core theorem Definition 9238.16; exactness the common one-window classifier and the common diagonal embedding certificate; standard bridge RegSeqRat stationary observation partitions read through the one-window classifier; downstream use RegSeqRat and RealUp diagonal-limit arguments without carrying arbitrary finite segmentation data. Status: ProofTarget.

Theorem 9238.17 (Transported stationary rational diagonal)**.** *Let $d, e : \mathsf{Hist}$ satisfy $\mathsf{RatHistoryCarrier}(d)$, $\mathsf{RatHistoryCarrier}(e)$, and $\mathsf{RatHistoryClassifier}(d, e)$. Let X_d and X_e be the stationary regular Cauchy inputs of Definition 9238.6, and let L_d and L_e be their diagonal representatives from Definition 9238.3. Then the transported RatUp classifier induces the constant StreamNameUp classifier*

$$\mathsf{RatStreamNameClassifier}(\mathsf{RatConstStream}_d, \mathsf{RatConstStream}_e),$$

the e-one RealUp constant classifier

$$\mathsf{RealConstantHistoryClassifier}(\mathsf{E1}(d), \mathsf{E1}(e)),$$

and the RealUp classifier

$$\mathsf{RealClassifier}(L_d, L_e).$$

Moreover these three rows are the same transported stationary rational diagonal row: every finite RegSeqRat or DyadicRatCore observation window read from L_d and L_e factors through the constant StreamNameUp classifier and then through the e-one RealUp constant classifier induced by $\mathsf{RatHistoryClassifier}(d, e)$.

Sketch. First apply Definition 9238.7 to d and to e. The two applications identify the diagonal representatives L_d and L_e with the constant rational RealUp names $(\mathsf{RatConstStream}_d, \mathsf{E1}(d))$ and $(\mathsf{RatConstStream}_e, \mathsf{E1}(e))$.

Next apply Definition 9238.8 to the supplied RatUp classifier. It transports $\mathsf{RatHistoryClassifier}(d, e)$ across the two diagonal agreement rows and produces $\mathsf{RealClassifier}(L_d, L_e)$.

The finite-window content is the same row read at the StreamNameUp boundary. Use Definition 9238.9. It identifies the RatUp seed classifier with the constant StreamNameUp classifier and with the e-one RealUp constant classifier for any displayed unary observation window.

Finally read the RegSeqRat and DyadicRatCore boundary rows through the RealUp certificate boundary. The RegSeqRat seal consumes the finite StreamNameUp window together with the dyadic source ledger, and the DyadicRatCore finite-window transport rows preserve that same ledger under selected subwindows. Hence every stationary finite observation of L_d and L_e is the transported constant-stream row induced by the original RatUp classifier, with no additional RealUp comparison datum. □

Theorem 9238.18 (Transported stationary finite-window seal exhaustion)**.** *Let d, e : Hist satisfy $\mathsf{RatHistoryCarrier}(d)$, $\mathsf{RatHistoryCarrier}(e)$, and $\mathsf{RatHistoryClassifier}(d, e)$. Let L_d and L_e be the diagonal representatives of the stationary regular Cauchy inputs associated to d and e in Definition 9238.17. For every certified finite observation window W of L_d and L_e, there is a unique seal row Σ_W whose four public readings agree with the same RatUp seed classifier: the DyadicRatCore observation ledger carried by W, the StreamNameUp constant-window classifier, the RegSeqRat finite-window seal consumption row, and the RealUp finite-window classifier all read exactly $\mathsf{RatHistoryClassifier}(d, e)$.*

Sketch. First apply Definition 9238.17. It identifies the diagonal representatives L_d and L_e with the transported stationary constant-stream row induced by $\mathsf{RatHistoryClassifier}(d, e)$.

Now restrict to the certified finite window W. By Definition 9238.9, the finite StreamNameUp window, the e-one RealUp constant classifier, and the RatUp seed classifier are the same stationary row after reading the displayed window.

Feed this finite-window row to the RegSeqRat boundary. The seal exactness theorem Definition 38.251 consumes precisely the StreamNameUp finite-window classifier together with the DyadicRatCore observation ledger, so the seal row is forced by the already displayed window data.

Finally pass through the RealUp phase boundary using Definition 38.314 and Definition 38.320. These results say that the RealUp finite-window classifier has no additional public coordinate beyond the StreamNameUp window, the dyadic ledger, and the RegSeqRat seal. Thus any two seal rows over W project to the same four readings and are the same BHist package by constructor inversion, giving the claimed uniqueness and exhaustion. □

Concretized in §475: Transported stationary diagonal finite-window seals are realized as a concrete NameCert handoff across RatUp, StreamNameUp, RegSeqRat, DyadicRatCore, and RealUp.

Concretized in §605: Transported stationary finite-window seal uniqueness is realized as a four-reading NameCert packet over RatUp, StreamNameUp, RegSeqRatUp, DyadicRatCoreUp, and RealUp.

Concretized in §613: Stationary diagonal window routes realize the RatUp-to-RealUp finite observation path as a NameCert packet over StreamName, RegSeqRat, DyadicRatCore, hsame, Cont, and seal non-escape rows.

Concretized in §636: Cauchy modulus comparisons are realized as finite shared-tail NameCert packets linking CauchyModulusUp schedules, StreamNameUp windows, DyadicRatCore tolerances, RegSeqRatUp reads, and RealUp seals.

Concretized in §641: Cauchy modulus extraction is realized as a finite observation-budget packet feeding the real-completeness diagonal route.

Concretized in §632: Diagonal cofinal tails realize the transported stationary diagonal window as a finite cofinal-tail NameCert packet across RatUp, StreamNameUp, RegSeqRatUp, DyadicRatCoreUp, and RealUp.

Concretized in §693: Regular Cauchy window fusion realizes the shared finite observation-window route across StreamNameUp, RegSeqRatUp, DyadicRatCoreUp, and RealUp seals.

Concretized in §897: Stationary window naturality is realized as a finite NameCert packet identifying RatUp classifier transport with StreamNameUp, RegSeqRatUp, DyadicRatCoreUp, and RealUp finite-window seal readings.

Concretized in §996: Rat classifier transport seals realize the stationary rational diagonal row as a finite NameCert handoff across RatUp, StreamNameUp, RegSeqRatUp, DyadicRatCoreUp, and RealUp.

Concretized in §1017: Shared tail normalizers realize two Real-completion tail schedules as one finite StreamName, RegSeqRat, DyadicRatCore, shared-fiber, and RealUp seal route.

Concretized in §1041: Cofinal diagonal seals realize the cofinal-tail-to-diagonal RealUp seal route as finite precision, cofinal-budget, diagonal-budget, RegSeqRat, StreamName, DyadicRatCore, RealUp, route, provenance, and NameCert rows.

Concretized in §1104: Stationary window seal exhaustion is realized as a finite RatUp, StreamNameUp, RegSeqRatUp, DyadicRatCoreUp, and RealUp NameCert handoff.

Concretized in §2240: Finite window pullbacks realize the transported stationary diagonal seal route as a finite StreamName, RegSeqRat, DyadicRatCore, RealUp, hsame, Cont, Pkg, and NameCert packet.

Concretized in §3722: Real completeness diagonal selectors realize the transported stationary diagonal route as finite choice-free selector, diagonal-tail, StreamName, RegSeqRat, DyadicRatCore, RealUp, hsame, Cont, Pkg, and NameCert rows.

Concretized in §8968: Finite observation diagonal routers realize StreamName, RegSeqRat, DyadicRatCore, RegularCauchyDiagonalSeal, and RealUp finite-window diagonal routing as NameCert data.

9238.3 Constructive content and axiom purity

Remark 9238.19 (Explicit moduli throughout)**.** *Every modulus appearing in Definition 9238.2, Definition 9238.3, and Definition 9238.5 is specified as a function on naturals and rationals computed by primitive recursion on the inductive carriers of chapter 37. The required proof obligations are exactly the certificate-level regularity, convergence, and* psame*-closure facts that avoid quotienting an equivalence relation by a host-level* Quot*-soundness step. These obligations are the axiom-pure targets for the later machine-checked real-completion layer.*

Remark 9238.20 (Reuse for the continuous certificate)**.** *The diagonal limit construction (Definition 9238.3) identifies the limit step expected by the continuous certificate* $\mathsf{NameCert}_{\mathsf{CFun}\uparrow}$ *(chapter 59). A continuous function on* $\mathsf{NameCert}_{\mathsf{Real}\uparrow}$ *is, in BEDC, a function on* RegSeqRat *together with an explicit pointwise modulus; once the real-completion obligations are checked, downstream continuity certificates can consume the same diagonal regularity bound. The reuse is structural, not a separate construction.*

Remark 9238.21 (Composition with the compact uniform-continuity capstone)**.** *After* $\mathsf{NameCert}_{\mathsf{Real}^{\uparrow}}$ *has the supplied completion certificate and the continuous-function certificate is available, the compact uniform-continuity capstone (chapter 9237) can be instantiated on closed bounded intervals* $[a, b] \subset \mathsf{Real}^{\uparrow}$*. The downstream consumer is a future kernel theorem that, for every continuous* $f\colon [a, b] \to \mathsf{Real}^{\uparrow}$*, derives a uniform modulus depending only on the tolerance from the checked compactness and continuity certificates.*

Concretized in §372: Stationary regular Cauchy diagonal packets are represented as finite NameCert carriers over RatUp, StreamNameUp, RegSeqRatUp, and RealUp.

Concretized in §365: Finite observation windows are realized as a NameCert envelope linking DyadicRatCore, StreamNameUp, RegSeqRat, and RealUp seals.

Concretized in §390: The diagonal-limit modulus is represented as a finite NameCert packet over RegSeqRatUp, StreamNameUp, DyadicRatCoreUp, and RealUp.

Concretized in §443: Regular Cauchy limit classifiers are realized as finite NameCert packets linking RegSeqRatUp diagonal extraction, StreamNameUp windows, and RealUp seal handoff.

Concretized in §437: Transported stationary diagonal window-seal packets are realized as a finite NameCert carrier over RatUp, StreamNameUp, RegSeqRatUp, FiniteWindowEnvelopeUp, and RealUp.

Concretized in §450: The Real completeness diagonal-limit target is represented as a finite NameCert seed over DyadicRatCore, StreamNameUp, RegSeqRatUp, and RealUp.

Concretized in §466: The three-leg diagonal regularity estimate is realized as a finite NameCert packet over DyadicRatCore, StreamNameUp, RegSeqRatUp, and RealUp.

Concretized in §559: Finite-tail diagonal seals realize the selected regular-Cauchy tail window as a RealUp-facing NameCert packet without quotient streams or host real equality.

Concretized in §560: Regular Cauchy tail-meet packets realize the shared dyadic tail threshold needed by diagonal RealUp completion consumers.

Concretized in §293: Dyadic absolute-value rows are realized as finite DyadicRatCore BHist packets with sign-split, nonnegative-output, and tolerance-ledger surfaces.

Concretized in §561: Real diagonal-window coverage realizes the finite selected-window route from StreamName and RegSeqRat data through DyadicRatCore observations to the RealUp seal.

Concretized in §618: Finite diagonal mesh-budget packets realize the precision-to-window-to-dyadic-readback route used by Real completeness consumers before the RealUp seal.

Concretized in §600: Regular Cauchy limit transport packets realize classifier-stable diagonal-limit handoff across RegSeqRatUp, StreamNameUp, DyadicRatCoreUp, and RealUp rows.

Concretized in §593: Regular Cauchy witness schedules realize the modulus-indexed finite observation route from RegSeqRat and StreamName data through DyadicRatCore readback to the RealUp seal.

Concretized in §612: Cauchy diagonal fusion realizes the finite route from observation budgets and witness schedules through schedule fusion to the RealUp diagonal seal.

Concretized in §624: Regular Cauchy zero packets realize the zero-source identity surface for tail-meet, diagonal, and RealUp seal consumers.

Concretized in §626: Stationary diagonal finite-window classifier correspondence is realized as a concrete NameCert packet linking RatUp, StreamNameUp, RegSeqRatUp, DyadicRatCoreUp, and RealUp.

Concretized in §628: The modulus-indexed finite tail-window cover is realized as a concrete NameCert packet from unary precision requests through CauchyModulusUp, StreamNameUp, DyadicRatCoreUp, RegSeqRatUp, and RealUp seal rows.

Concretized in §631: Product regular-Cauchy limit packets realize the product-limit handoff across CauchyProductUp, RegularCauchyLimitClassifierUp, StreamNameUp, RegSeqRatUp, DyadicRatCoreUp, and RealUp.

Concretized in §645: Bounded Cauchy covers realize the finite budget-to-window-to-RegSeqRat-to-RealUp seal route used by the real-completion diagonal argument.

Concretized in §649: Stationary window lattices realize common finite-window refinement for stationary Real-completeness diagonal consumers.

Concretized in §650: Choice-free limit schedules are realized as finite precision-to-window-to-seal NameCert packets over DyadicRatCoreUp, StreamNameUp, RegSeqRatUp, and RealUp.

Concretized in §757: Dyadic tail-radius ledgers realize finite tail-window radius accounting for RegSeqRat and RealUp seal consumers without quotient streams, host real equality, or selected limits.

Concretized in §884: Real tail-agreement transitivity is realized as a finite three-source tail-window NameCert packet over two RealTailAgreementSealUp rows, shared middle RegSeqRat data, DyadicRatCore readbacks, and RealUp handoff.

Concretized in §766: Real algebra and order packets realize constructive addition, multiplication, nonnegative order, and strict apartness as finite RealUp-facing NameCert rows.

Concretized in §1200: Real modulus-purity boundaries realize explicit modulus, finite-window, RegSeqRat readback, RealUp seal, and axiom-refusal rows as one finite NameCert packet.

Concretized in §1325: Real window classifier seals realize the explicit finite-window classifier and axiom-purity refusal row for Real-completion modulus consumers.

Concretized in §8426: Finite-window Real-completeness subcover packets realize the StreamName, RegSeqRat, DyadicRatCore, and RealUp seal route without ambient open-cover compactness.

9238.4 Modulus comparison boundary

The located-real comparison surface is not a comparison of two completed host points. It is a comparison of two presented processes through finite windows selected by explicit moduli. This point is already visible in the Lean-side shape of LReal: a located real carries a rational sequence, a monotone modulus, and a Cauchy witness. The pointwise relation IrLe is deliberately stronger and should not be read as the general comparison interface. The finite comparison interface is instead the pair formed by LRealClose and IrApart.

Definition 9238.22 (Modulated located real)**.** *Fix a rational metric kit K with rational closeness, apartness, and order rows. A modulated located real is a triple*

$$x = (x_{\mathrm{seq}}, x_{\mathrm{mod}}, x_{\mathrm{cau}})$$

where $x_{\mathrm{seq}} : \mathsf{Nat}^{\uparrow} \to \mathsf{Rat}^{\uparrow}$, $x_{\mathrm{mod}} : \mathsf{Nat}^{\uparrow} \to \mathsf{Nat}^{\uparrow}$, *and*

$$x_{\mathrm{mod}}(k) \le m \wedge x_{\mathrm{mod}}(k) \le n \Longrightarrow K.\mathsf{close}(x_{\mathrm{seq}}(m), x_{\mathrm{seq}}(n), k).$$

The rational embedding is the degenerate case

$$\eta(q)_{\mathrm{seq}}(n) = q, \qquad \eta(q)_{\mathrm{mod}}(k) = 0.$$

Thus a rational comparison is a comparison between a stationary process and the other displayed process. A comparison between two non-rational presentations is a comparison between two non-trivial moduli.

Lean4 (definition) `BEDC.Derived.LocatedReal.LReal`
Lean4 (definition) `BEDC.Derived.LocatedReal.lrLe`

Definition 9238.23 (Finite tolerance comparison)**.** *For located reals a, b and a tolerance k, the finite tolerance relation is a comparison datum D with its own modulus $D_{\mathrm{mod}} : \mathsf{Nat}^{\uparrow} \to \mathsf{Nat}^{\uparrow}$ such that*

$$D_{\mathrm{mod}}(k) \le m \wedge D_{\mathrm{mod}}(k) \le n \Longrightarrow K.\mathsf{close}(a_{\mathrm{seq}}(m), b_{\mathrm{seq}}(n), k).$$

This is the role of LRealEqData *and* LRealClose*. The comparison data may use a common schedule separate from the two endpoint moduli, but it still inspects only finite rational windows.*

Lean4 (definition) `BEDC.Derived.LocatedReal.LRealEqData`
Lean4 (definition) `BEDC.Derived.LocatedReal.LRealClose`

Definition 9238.24 (Finite apartness window)**.** *The apartness surface for two located reals is the existence of a finite precision k such that the two endpoint moduli already expose a rational separation:*

$$\exists k : \mathsf{Nat}^{\uparrow},\ K.\mathsf{apart}(a_{\mathrm{seq}}(a_{\mathrm{mod}}(k)), b_{\mathrm{seq}}(b_{\mathrm{mod}}(k)), k).$$

This is the role of lrApart*. The witness is a finite separation window, not a decision that every pair of located reals has already been classified as left, equal, or right.*

Lean4 (definition) `BEDC.Derived.LocatedReal.lrApart`

Theorem 9238.25 (Finite comparison is process-level)**.** *Every finite tolerance comparison or apartness witness between located reals factors through the two sequences, their moduli, a comparison modulus when present, and rational-level close or apartness rows. It does not require a host real point or quotient representative.*

Proof. For finite tolerance, unfold Definition 9238.23. A tolerance request k selects finite thresholds through D_{mod}, and the only numerical read is the rational comparison $K.\mathsf{close}(a_{\mathrm{seq}}(m), b_{\mathrm{seq}}(n), k)$.

For apartness, unfold Definition 9238.24. The witness selects one finite precision k and reads the two rational observations picked by $a_{\mathrm{mod}}(k)$ and $b_{\mathrm{mod}}(k)$. The only separation claim is the displayed rational apartness row at that precision. Neither construction asks for a completed host point, a quotient stream, or a selected representative outside the visible moduli. □

Theorem 9238.26 (Comparison moduli compose)**.** *If a is finitely close to b at tolerance $k+1$, and b is finitely close to c at tolerance $k+1$, then a is finitely close to c at tolerance k.*

Proof. Let D_{ab} and D_{bc} be the two comparison data. Use the common comparison modulus

$$j \longmapsto \max(D_{ab,\mathrm{mod}}(j+1), D_{bc,\mathrm{mod}}(j+1)).$$

At this shared finite threshold, the first datum gives $K.\mathsf{close}(a, b, j+1)$ and the second gives $K.\mathsf{close}(b, c, j+1)$ at the corresponding rational observations. The rational triangle row in K composes the two tolerance-$j+1$ comparisons into a tolerance-j comparison from a to c. This is the proof pattern implemented by LRealClose_triangle. □

Lean4 ✓ `BEDC.Derived.LocatedReal.LRealClose triangle`

Concretized in §9022: Regular Cauchy selector stability realizes finite tolerance comparison by preserving selected modulus rows, StreamName windows, DyadicRatCore tolerance rows, RegSeqRat readbacks, and RealUp seals under displayed transport.

Concretized in §9085: Dyadic modulus comparison boundary packets realize the finite common-refinement comparison route through two located-real endpoints, one dyadic comparison modulus, paired finite windows, RegSeqRat readbacks, RealUp seals, transport, provenance, and local NameCert data.

Definition 9238.27 (Exact comparison boundary)**.** *An exact comparison operator for arbitrary located reals is a total operation of the form*

$$\prod_{x,y} (x < y) + (x = y) + (y < x),$$

where equality is full located-real equality and the strict branches are point-level order branches, not finite tolerance or apartness windows.

Theorem 9238.28 (Exact comparison has omniscience strength)**.** *A total operator of Definition 9238.27, supplied for arbitrary located-real presentations, would decide the limited principle of omniscience for binary streams.*

Proof. Given a binary stream $\alpha : \mathsf{Nat}^{\uparrow} \to \{0, 1\}$, form the nonnegative located real presentation

$$x_\alpha = \sum_{n=0}^{\infty} \alpha(n) 2^{-(n+1)}$$

by its rational partial sums and the usual geometric tail modulus. Apply the exact comparison operator to x_α and 0.

The branch $x_\alpha < 0$ is incompatible with the nonnegative construction. If $x_\alpha = 0$, then no coefficient can be 1, since any displayed $\alpha(n) = 1$ supplies a positive dyadic lower bound. Hence $\forall n, \alpha(n) = 0$. If $0 < x_\alpha$, the strict branch supplies a positive separation threshold; inspecting the finite prefix needed by that threshold yields some n with $\alpha(n) = 1$. The exact comparison operator therefore returns

$$(\forall n, \alpha(n) = 0) + (\exists n, \alpha(n) = 1).$$

This is LPO for binary streams. □

Corollary 9238.29 (Located comparison is not trichotomy)**.** *The constructive comparison surface of* $\mathsf{LocatedReal}^{\uparrow}$ *consists of finite tolerance comparison, finite apartness witnesses, comparison-modulus composition, and Real-seal readback through displayed rows. It does not export arbitrary exact trichotomy.*

Proof. By Definition 9238.25, the constructive comparison surface remains at the level of finite observations and explicit moduli. By Definition 9238.28, a total exact trichotomy operator for arbitrary located-real presentations would decide LPO. Such an operator is therefore outside the axiom-pure finite-window comparison interface recorded in this chapter. □

Concretized in §1730: Located real comparison packets realize the finite shared-window comparison surface for two displayed located-real endpoints.

Concretized in §5813: Located real comparison-modulus packets realize finite tolerance schedules without exporting trichotomy.

Concretized in §3640: Real located-order packets route order-facing reads through two Real seals, paired regular readbacks, shared windows, dyadic tolerances, and apartness handoff rows.

Concretized in §1202: Finite-window Real separation packets realize positive separation through shared finite windows and dyadic tolerance readback.

Concretized in §9102: Finite observation boundary packets realize exact located-real comparison requests as two endpoint moduli, one finite observation window, finite apartness or equality evidence, and a refusal ledger for total trichotomy.

Concretized in §9134: Finite comparison boundary packets realize process-level located-real tolerance and apartness comparisons as finite modulus, window, rational close/apart, transport, replay, provenance, and NameCert rows.

Concretized in §372: Stationary regular Cauchy diagonal packets are represented as finite NameCert carriers over RatUp, StreamNameUp, RegSeqRatUp, and RealUp.

Concretized in §365: Finite observation windows are realized as a NameCert envelope linking DyadicRatCore, StreamNameUp, RegSeqRat, and RealUp seals.

Concretized in §390: The diagonal-limit modulus is represented as a finite NameCert packet over RegSeqRatUp, StreamNameUp, DyadicRatCoreUp, and RealUp.

Concretized in §443: Regular Cauchy limit classifiers are realized as finite NameCert packets linking RegSeqRatUp diagonal extraction, StreamNameUp windows, and RealUp seal handoff.

Concretized in §437: Transported stationary diagonal window-seal packets are realized as a finite NameCert carrier over RatUp, StreamNameUp, RegSeqRatUp, FiniteWindowEnvelopeUp, and RealUp.

Concretized in §450: The Real completeness diagonal-limit target is represented as a finite NameCert seed over DyadicRatCore, StreamNameUp, RegSeqRatUp, and RealUp.

Concretized in §466: The three-leg diagonal regularity estimate is realized as a finite NameCert packet over DyadicRatCore, StreamNameUp, RegSeqRatUp, and RealUp.

Concretized in §559: Finite-tail diagonal seals realize the selected regular-Cauchy tail window as a RealUp-facing NameCert packet without quotient streams or host real equality.

Concretized in §560: Regular Cauchy tail-meet packets realize the shared dyadic tail threshold needed by diagonal RealUp completion consumers.

Concretized in §293: Dyadic absolute-value rows are realized as finite DyadicRatCore BHist packets with sign-split, nonnegative-output, and tolerance-ledger surfaces.

Concretized in §561: Real diagonal-window coverage realizes the finite selected-window route from StreamName and RegSeqRat data through DyadicRatCore observations to the RealUp seal.

Concretized in §618: Finite diagonal mesh-budget packets realize the precision-to-window-to-dyadic-readback route used by Real completeness consumers before the RealUp seal.

Concretized in §600: Regular Cauchy limit transport packets realize classifier-stable diagonal-limit handoff across RegSeqRatUp, StreamNameUp, DyadicRatCoreUp, and RealUp rows.

Concretized in §593: Regular Cauchy witness schedules realize the modulus-indexed finite observation route from RegSeqRat and StreamName data through DyadicRatCore readback to the RealUp seal.

Concretized in §612: Cauchy diagonal fusion realizes the finite route from observation budgets and witness schedules through schedule fusion to the RealUp diagonal seal.

Concretized in §624: Regular Cauchy zero packets realize the zero-source identity surface for tail-meet, diagonal, and RealUp seal consumers.

Concretized in §626: Stationary diagonal finite-window classifier correspondence is realized as a concrete NameCert packet linking RatUp, StreamNameUp, RegSeqRatUp, DyadicRatCoreUp, and RealUp.

Concretized in §628: The modulus-indexed finite tail-window cover is realized as a concrete NameCert packet from unary precision requests through CauchyModulusUp, StreamNameUp, DyadicRatCoreUp, RegSeqRatUp, and RealUp seal rows.

Concretized in §631: Product regular-Cauchy limit packets realize the product-limit handoff across CauchyProductUp, RegularCauchyLimitClassifierUp, StreamNameUp, RegSeqRatUp, DyadicRatCoreUp, and RealUp.

Concretized in §658: Regular Cauchy tail fusion realizes the cofinal tail-to-diagonal RealUp seal route as a finite NameCert packet.

Concretized in §697: Diagonal tail selectors realize the finite cofinal-tail route from a regular Cauchy modulus through StreamName windows, dyadic readback, RegSeqRat rows, and the RealUp seal without quotient streams or host-selected limits.

Concretized in §699: Real tail-agreement seals realize paired cofinal tail-window agreement as a finite NameCert packet over DyadicRatCoreUp, StreamNameUp, RegSeqRatUp, and RealUp.

Concretized in §646: Diagonal-limit compatibility is realized as a finite NameCert packet tying RealCompleteness, RegularCauchyTriangleBound, CauchyLimitSeal, StreamName, RegSeqRat, DyadicRatCore, and RealUp seal rows.

Concretized in §660: Regular Cauchy sequence packets realize the finite family, modulus, selected-window, dyadic readback, RegSeqRat, and RealUp seal surface used by the diagonal-limit handoff.

Concretized in §653: Regular Cauchy swap bisimulations realize selector-swapped interleavings as finite RegSeqRat, StreamName, RealUp, hsame, Cont, Pkg, and NameCert packets.

Concretized in §662: Budgeted tail-meet packets realize finite observation budgets and shared-tail thresholds for the Real completeness seal route.

Concretized in §652: Real completion witness extractors realize the diagonal regular-Cauchy limit route as a finite NameCert packet over modulus schedules, selected windows, RegSeqRat witnesses, RealUp seals, hsame transport, Cont replay, and non-escape ledgers.

Concretized in §663: Regular Cauchy cofinal limits are realized as finite cofinal-window NameCert packets over DyadicRatCore, StreamNameUp, RegSeqRat, and RealUp seal rows.

Concretized in §670: Cofinal regular-limit budgets realize the Real completeness diagonal target as finite precision, cofinal-window, RegSeqRat handoff, RealUp seal, route, provenance, and NameCert rows.

Concretized in §676: Regular Cauchy product budgets realize the finite product-window ledger from RegSeqRatUp sources through StreamNameUp, DyadicRatCoreUp, FiniteErrorBudgetUp, and RealUp seal rows.

Concretized in §2076: Regular Cauchy product projections realize component readbacks from displayed product packets through product-modulus budgets, StreamName windows, DyadicRatCore tolerances, RegSeqRat handoffs, and RealUp seals.

Concretized in §678: Regular Cauchy selector budgets realize the modulus-selected finite window, RegSeqRat handoff, RealUp seal route, and non-escape ledger used by the Real completeness diagonal construction.

Concretized in §695: Choice-free diagonal selectors realize the finite precision, cofinal-window, StreamName, RegSeqRat, RealUp seal, hsame, Cont, Pkg, and NameCert selector boundary used by the Real completeness handoff.

Concretized in §680: Dyadic cofinal tail selectors realize the finite cofinal-window route used by the Real and Completion diagonal-limit handoff.

Concretized in §681: Tail cofinality schedules realize the finite shared-threshold route from DyadicRatCore, StreamNameUp, RegSeqRatUp, and RealUp seal rows used by the diagonal-limit handoff.

Concretized in §702: RegularCauchy merge packets realize the two-route cofinal selector agreement used by the Real completeness diagonal-limit handoff.

Concretized in §698: Cofinal tail budgets realize finite shared-tail threshold packets for the Real and Completion diagonal-limit handoff.

Concretized in §706: Observable Cauchy seals realize finite observation routes from StreamName windows and dyadic readbacks through RegSeqRat handoff rows into a RealUp seal.

Concretized in §708: Regular Cauchy telescoping budgets realize finite chained-window error-ledger composition for the Real completeness diagonal-limit handoff.

*Concretized in §**??**:* Real modulus fusion realizes the real-completeness vision as a finite shared-modulus NameCert over Cauchy modulus rows, tail-meet thresholds, StreamName windows, RegSeqRat handoff, and RealUp seal rows.

Concretized in §1171: Cauchy tail-modulus seals realize the shared-tail modulus, fusion, witness-extractor, and RealUp seal route as one finite NameCert packet.

Concretized in §778: Regular Cauchy modulus normalizers realize the shared finite modulus-window route used by the Real completeness diagonal-limit handoff.

Concretized in §782: Finite observation-budget selector packets realize the finite diagonal observation budget used by the Real completeness route.

Concretized in §838: Regular Cauchy tail schedules realize the finite precision-to-cofinal-tail route consumed by tail-meet, tail-fusion, diagonal-selector, and RealUp seal packets.

Concretized in §853: Cauchy diagonal budgets realize the Real completeness diagonal selector as finite precision, mesh-budget, comparison, seal-handoff, hsame, Cont, Pkg, and NameCert rows.

Concretized in §1198: Cofinal modulus seals realize the Real-completeness cofinal-tail modulus route as a finite completion-seal NameCert surface.

Concretized in §870: Diagonal-limit stability packets realize the finite stability comparison between a diagonal representative and the sealed RealUp limit route.

Concretized in §874: Regular-Cauchy finite observation routes are realized as finite StreamName, DyadicRatCore, RegSeqRat, RealObservationBudget, and RealUp seal packets.

Concretized in §885: Cauchy modulus refinements realize the shared-meet and selector-budget route used by the Real completeness diagonal handoff.

Concretized in §891: Real seal congruence packets realize classifier-preserving replacement of RegSeqRat and StreamName readbacks under the RealUp seal.

Concretized in §887: Real seal comparison packets realize equality-facing comparison of two sealed RealUp routes as finite CauchyLimitSeal, RegularLimitUniqueness, DiagonalLimitStability, hsame, Cont, Pkg, and NameCert rows.

Concretized in §893: Regular Cauchy tail fibers realize the shared finite tail-fiber classifier consumed by RealUp diagonal completion and tail-agreement routes.

Concretized in §896: Diagonal limit budget packets realize the finite modulus, window, dyadic-tolerance, and RealUp seal budget consumed by the Real completeness diagonal route.

Concretized in §1081: Real completion selector-seal packets realize the finite selector-budget, selected-window, RegSeqRat readback, CauchyLimitSeal, and RealUp seal route.

Concretized in §1113: Finite Cauchy gluing budgets realize the Real-completeness witness route as one finite budget, synchronizer, completion-seal, StreamName, RegSeqRat, DyadicRatCore, and RealUp NameCert surface.

Concretized in §5839: Regular Cauchy mesh cofinality realizes the Real-completeness route as a finite common-refinement mesh between CauchyMeshRefinement, CofinalDyadicMesh, RealDiagonalMeshBudget, StreamName, RegSeqRat, DyadicRatCore, and RealUp seal rows.

Concretized in §5975: Regular Cauchy mesh gluing realizes the finite common-refinement route from mesh cofinality and gluing budgets to the cofinal modulus seal.

Concretized in §7076: Real inverse-modulus packets realize the guarded reciprocal-modulus route as finite CauchyInverseBudget, RegSeqRat, RealReciprocal, RealUp, transport, replay, provenance, and NameCert rows.

Concretized in §7564: Tail-window filter refinements realize the finite common-filter route from StreamName windows through RegSeqRat, DyadicRatCore tolerance, and the RealUp seal.

Concretized in §8082: Cauchy uniform criterion packets realize the regular Cauchy uniform-tail route as finite StreamName, DyadicRatCore, RegSeqRat, RealUp, common-modulus, hsame, Cont, Pkg, and NameCert rows.

Concretized in §8310: Regular Cauchy diagonal-limit moduli realize the diagonal representative's finite modulus route through RegSeqRat, StreamName, DyadicRatCore, CauchyLimitSeal, and RealUp rows.

Concretized in §416: Regular Cauchy interleave packets realize finite merge schedules for two RegSeqRat sources through StreamName windows, DyadicRatCore observations, and RealUp handoff rows.

Concretized in §646: Diagonal-limit compatibility is realized as a finite NameCert packet tying RealCompleteness, RegularCauchyTriangleBound, CauchyLimitSeal, StreamName, RegSeqRat, DyadicRatCore, and RealUp seal rows.

Concretized in §660: Regular Cauchy sequence packets realize the finite family, modulus, selected-window, dyadic readback, RegSeqRat, and RealUp seal surface used by the diagonal-limit handoff.

Concretized in §653: Regular Cauchy swap bisimulations realize selector-swapped interleavings as finite RegSeqRat, StreamName, RealUp, hsame, Cont, Pkg, and NameCert packets.

Concretized in §662: Budgeted tail-meet packets realize finite observation budgets and shared-tail thresholds for the Real completeness seal route.

Concretized in §652: Real completion witness extractors realize the diagonal regular-Cauchy limit route as a finite NameCert packet over modulus schedules, selected windows, RegSeqRat witnesses, RealUp seals, hsame transport, Cont replay, and non-escape ledgers.

Concretized in §663: Regular Cauchy cofinal limits are realized as finite cofinal-window NameCert packets over DyadicRatCore, StreamNameUp, RegSeqRat, and RealUp seal rows.

Concretized in §670: Cofinal regular-limit budgets realize the Real completeness diagonal target as finite precision, cofinal-window, RegSeqRat handoff, RealUp seal, route, provenance, and NameCert rows.

Concretized in §676: Regular Cauchy product budgets realize the finite product-window ledger from RegSeqRatUp sources through StreamNameUp, DyadicRatCoreUp, FiniteErrorBudgetUp, and RealUp seal rows.

Concretized in §678: Regular Cauchy selector budgets realize the modulus-selected finite window, RegSeqRat handoff, RealUp seal route, and non-escape ledger used by the Real completeness diagonal construction.

Concretized in §695: Choice-free diagonal selectors realize the finite precision, cofinal-window, StreamName, RegSeqRat, RealUp seal, hsame, Cont, Pkg, and NameCert selector boundary used by the Real completeness handoff.

Concretized in §680: Dyadic cofinal tail selectors realize the finite cofinal-window route used by the Real and Completion diagonal-limit handoff.

Concretized in §681: Tail cofinality schedules realize the finite shared-threshold route from DyadicRatCore, StreamNameUp, RegSeqRatUp, and RealUp seal rows used by the diagonal-limit handoff.

Concretized in §702: RegularCauchy merge packets realize the two-route cofinal selector agreement used by the Real completeness diagonal-limit handoff.

Concretized in §698: Cofinal tail budgets realize finite shared-tail threshold packets for the Real and Completion diagonal-limit handoff.

Concretized in §706: Observable Cauchy seals realize finite observation routes from StreamName windows and dyadic readbacks through RegSeqRat handoff rows into a RealUp seal.

Concretized in §708: Regular Cauchy telescoping budgets realize finite chained-window error-ledger composition for the Real completeness diagonal-limit handoff.

Concretized in §??: Real modulus fusion realizes the real-completeness vision as a finite shared-modulus NameCert over Cauchy modulus rows, tail-meet thresholds, StreamName windows, RegSeqRat handoff, and RealUp seal rows.

Concretized in §778: Regular Cauchy modulus normalizers realize the shared finite modulus-window route used by the Real completeness diagonal-limit handoff.

Concretized in §782: Finite observation-budget selector packets realize the finite diagonal observation budget used by the Real completeness route.

Concretized in §1361: Finite observation cofinality selectors realize finite budget rows whose selected StreamName windows are cofinal for the Real-completion diagonal route.

Concretized in §838: Regular Cauchy tail schedules realize the finite precision-to-cofinal-tail route consumed by tail-meet, tail-fusion, diagonal-selector, and RealUp seal packets.

Concretized in §853: Cauchy diagonal budgets realize the Real completeness diagonal selector as finite precision, mesh-budget, comparison, seal-handoff, hsame, Cont, Pkg, and NameCert rows.

Concretized in §870: Diagonal-limit stability packets realize the finite stability comparison between a diagonal representative and the sealed RealUp limit route.

Concretized in §874: Regular-Cauchy finite observation routes are realized as finite StreamName, DyadicRatCore, RegSeqRat, RealObservationBudget, and RealUp seal packets.

Concretized in §1007: Finite observation interfaces realize Real-completion finite-window reads as StreamName, RegSeqRat, DyadicRatCore, and RealUp NameCert handoff packets.

Concretized in §885: Cauchy modulus refinements realize the shared-meet and selector-budget route used by the Real completeness diagonal handoff.

Concretized in §891: Real seal congruence packets realize classifier-preserving replacement of RegSeqRat and StreamName readbacks under the RealUp seal.

Concretized in §887: Real seal comparison packets realize equality-facing comparison of two sealed RealUp routes as finite CauchyLimitSeal, RegularLimitUniqueness, DiagonalLimitStability, hsame, Cont, Pkg, and NameCert rows.

Concretized in §994: Real selector comparisons realize the finite two-selector diagonal route that forces shared StreamName, RegSeqRat, CauchyLimitSeal, RealTailAgreementSeal, and RealUp seal agreement.

Concretized in §1001: Real seal admission cuts realize the finite budget-window-readback boundary before a RealUp seal or CauchyLimitSeal handoff can be consumed.

Concretized in §893: Regular Cauchy tail fibers realize the shared finite tail-fiber classifier consumed by RealUp diagonal completion and tail-agreement routes.

Concretized in §1009: Cofinal real request reuse realizes repeated finite Real-completion precision bundles as one displayed StreamName, RegSeqRat, DyadicRatCore, RealUp, hsame, Cont, Pkg, and NameCert route.

Concretized in §1020: Cauchy window transducers realize finite StreamName window steps, dyadic tolerance rows, RegSeqRat readback, and RealUp seal routing.

Concretized in §1022: Regular Cauchy window intersections realize the common finite-window route used by the Real completeness diagonal handoff.

Concretized in §1034: Cauchy seal functors realize reusable finite transport of CauchyLimitSeal and RealCompletionSealClassifier rows through StreamName, RegSeqRat, DyadicRatCore, and RealUp handoff surfaces.

Concretized in §1035: Located Cauchy modulus packets realize the finite located tail-modulus route from StreamName and RegSeqRat windows to a RealUp seal.

Concretized in §1039: Real limit uniqueness seals realize the finite Real-completion uniqueness route through RegSeqRat, StreamName, DyadicRatCore, CauchyLimitSeal, RealUp, hsame, Cont, Pkg, and NameCert rows.

Concretized in §1119: Finite tail filters realize the shared cofinal-tail route for StreamName, DyadicRatCore, RegSeqRat, and RealUp seal reads.

Concretized in §1174: Cofinal-window Real seals realize the Real-completeness route as finite StreamName window, DyadicRatCore ledger, RegSeqRat readback, RealUp seal, hsame, Cont, Pkg, and NameCert rows.

Concretized in §1175: Regular Cauchy witness selectors realize the diagonal-limit selector as finite modulus-request, StreamName window, DyadicRatCore tolerance, RegSeqRat readback, RealUp seal, hsame, Cont, Pkg, and NameCert rows.

Concretized in §1180: Regular Cauchy completion frontier packets realize the Phase Real and Completion route as finite selector, cofinal-tail, RegSeqRat, StreamName, DyadicRatCore, RealUp seal, and NameCert rows.

Concretized in §1199: Finite-window Real seal audits realize the Real completeness route as displayed StreamName, DyadicRatCore, RegSeqRat, RealUp seal, audit-refusal, hsame, Cont, Pkg, and NameCert rows.

Concretized in §1210: Tail-modulus alignments realize the shared Real-completion tail-modulus route as one finite StreamName, RegSeqRat, DyadicRatCore, RealUp, hsame, Cont, Pkg, and NameCert packet.

Concretized in §2206: Real prefix diagnostics realize finite prefix-window, StreamName, RegSeqRat, dyadic-tolerance, and Real-seal readback rows for the Real completeness route.

Concretized in §3741: Uniform completion common-window packets realize the Real and Completion route as one UniformCompletionFunctor request, shared StreamName window, RegSeqRat readback, DyadicRatCore budget, and RealUp seal NameCert packet.

Concretized in §6229: Regular Cauchy tail balls realize the finite threshold, tail-window, dyadic tolerance, RegSeqRat readback, and RealUp seal route used by the Real-completion finite-tail direction.

Concretized in §7007: Cauchy subbasis tail factorization realizes the finite route from generated Cauchy subbases through cofinite tail filters to StreamName, RegSeqRat, and RealUp seal reads.

Concretized in §903: Observation-budget limiters realize finite request caps before StreamName, RegSeqRat, and RealUp seal reads.

Concretized in §905: Real Cauchy witness grids realize the Real completeness diagonal route as finite selector-budget, witness-ledger, completion-seal, StreamName, RegSeqRat, RealUp, hsame, Cont, Pkg, and NameCert rows.

Concretized in §906: Regular Cauchy tail budgets realize finite tail-threshold, observation-budget, window-service, dyadic-readback, RegSeqRat handoff, and RealUp seal rows for the Real completeness route.

Concretized in §917: Tail budget coherence packets realize the Real completeness route as one finite threshold, observation-budget, selector-budget, agreement-seal, and limit-seal NameCert surface.

Concretized in §920: CofinalTailAgreementUp realizes the paired cofinal-tail agreement route between regular Cauchy tail evidence and the Real completion seal.

Concretized in §919: Finite-prefix limit budgets realize the bounded observation surface used by the Real completeness diagonal-limit route.

Concretized in §918: Bounded monotone convergence seals realize the bounded monotone Cauchy witness as a finite RealUp convergence handoff.

Concretized in §930: Finite real route commitments realize the Real-completion route as finite precision, budget, StreamName, RegSeqRat, RealUp seal, and non-escape NameCert rows.

Concretized in §961: Diagonal-limit observers realize the Real-completeness diagonal route as finite StreamName window, RegSeqRat readback, Dyadic tolerance, CauchyLimitSeal, RealUp seal, and observer budget NameCert rows.

Concretized in §979: Real window synchronizers realize the StreamName, RegSeqRat, CauchyLimitSeal, RegularCauchyTailBudget, and RealUp seal route as one finite NameCert packet.

Concretized in §977: Regular Cauchy modulus witness ledgers realize the explicit-modulus route of the Real completeness proof target as finite StreamName, DyadicRatCore, RegSeqRat, RealUp, hsame, Cont, Pkg, and NameCert rows.

Concretized in §980: Regular Cauchy classifier normal forms realize the Real-completeness route as a finite DyadicRatCore, StreamName, RegSeqRat, RealUp, hsame, Cont, Pkg, and NameCert packet.

Concretized in §983: Cauchy shared-tail moduli realize the Real-completeness route as one shared dyadic tail threshold, StreamName window, RegSeqRat handoff, RealUp seal, hsame, Cont, Pkg, and NameCert packet.

Concretized in §990: Cauchy tail consensus realizes the Real-completeness route as one finite shared-tail, tail-agreement, CauchyLimitSeal, StreamName, RegSeqRat, RealUp, hsame, Cont, Pkg, and NameCert packet.

Concretized in §991: Regular Cauchy apartness budgets realize finite nonzero lower-bound windows for RegSeqRat, DyadicRatCore, StreamName, and RealUp consumers.

Concretized in §1250: Closed bounded interval nets realize finite dyadic mesh coverage for located RealUp intervals before compact-uniform-continuity consumers read the route.

Concretized in §1263: Cofinal StreamName tail selectors realize the finite cofinal-window route from precision requests through StreamNameUp, RegSeqRatUp, DyadicRatCoreUp, and RealUp seal rows without quotient streams or host-selected limits.

Concretized in §2313: Bishop Cauchy real packets realize the Real completeness route as finite RegSeqRat source, CauchyModulus schedule, StreamName window, DyadicRatCore tolerance, and RealUp seal rows without quotient streams or selected representatives.

Concretized in §3404: Bishop completion criterion packets realize the L10 completion route as explicit CauchyConvergenceModulus, StreamName, RegSeqRat, MetricCompletion, UniformCompletion, RealUp, hsame, Cont, Pkg, and NameCert rows without quotient completions or choice.

Concretized in §3670: Rational Cauchy completion packets realize the L10 completion route as finite Rat source, DyadicRatCore tolerance, StreamName window, RegSeqRat readback, explicit Cauchy modulus, RealUp seal, hsame, Cont, Pkg, and NameCert rows.

Concretized in §3498: Proximinal set packets realize the located-set distance-attainment boundary as finite Metric, LocatedSet, LocatedMetric, RealUp, hsame, Cont, Pkg, and NameCert rows without nearest-point selection.

*Concretized in §**??**:* Metric embeddings give the certified distance-preserving route needed by completion and compact metric consumers.

Concretized in §3949: Regular Cauchy filter functors realize the filter-indexed finite-window route from CauchyFilter and RegularCauchyFilter data through StreamNameUp, DyadicRatCoreUp, RegSeqRatUp, and RealUp seal rows.

Concretized in §3953: Cauchy modulus normalizers realize explicit monotone threshold normalization before StreamName, RegSeqRat, DyadicRatCore, and RealUp seal reads.

Concretized in §4024: Located compactness is realized as a finite neighbourhood-radius, compact-witness, closed-ball, local-support, and NameCert packet for completion consumers.

Concretized in §371: Regular Cauchy names realize the L10 source-row route from StreamName windows through RegSeqRat readback, DyadicRatCore tolerance ledgers, and RealUp seal rows.

Concretized in §5778: Finite-window functor packet for the Real and Completion spine.

Concretized in §5991: Pointwise finite-window extensionality realizes the Real and Completion StreamName equality route.

Concretized in §6015: Cofinal tail normal forms realize the Real-completeness tail route as finite CofinalTailAgreement, StreamName selector-window, RegSeqRat readback, DyadicRatCore tolerance, RealUp seal, hsame, Cont, Pkg, and NameCert rows.

Concretized in §1738: Finite tail-equivalence packets realize the Real completeness vision's regular-Cauchy equality route.

Concretized in §6002: Regular Cauchy diagonal limit packets realize the vision's diagonal extraction route as finite StreamName, RegSeqRat, DyadicRatCore, RealUp, transport, replay, provenance, and NameCert rows.

Concretized in §6088: Real completeness gap routers separate allowed StreamName, RegSeqRat, DyadicRatCore, and RealUp reads from off-table completion claims.

Concretized in §6114: Finite selection sequences realize the choice-free finite-window selector route for the Real completeness diagonal.

Concretized in §6133: Real completion limit routers realize the finite observation-budget, StreamName, RegSeqRat, DyadicRatCore, and RealUp route without asserting full RealUp completeness.

Concretized in §6279: The finite StreamName–RegSeqRat–Real seal witness ledger realizes the real-completeness vision as NameCert data.

Concretized in §6949: Real completion budget routers realize finite observation-budget and selector-budget routing before StreamName, RegSeqRat, DyadicRatCore, CauchyLimitSeal, and RealUp seal reads.

Concretized in §6405: The finite diagonal scheduler realizes the real-completeness diagonal-window route as displayed modulus and tolerance data.

Concretized in §6440: The selection gate realizes the four-object Real-completion route as finite DyadicRatCore, StreamName, RegSeqRat, RealUp, transport, replay, provenance, and NameCert rows.

Concretized in §6762: Regular Cauchy ball bases realize the Real-completeness tail route as finite threshold, dyadic ball, StreamName, RegSeqRat, RealUp, transport, replay, provenance, and NameCert rows.

Concretized in §6766: Records the explicit modulus-bearing Cauchy completion packet used by the Real and Completion route.

Concretized in §7397: Rapidly Cauchy sequence packets realize the fixed dyadic-rate schedule used by the Real and Completion route through StreamName, DyadicRatCore, RegSeqRat, and RealUp rows.

Concretized in §7402: Regular Cauchy modulus joins realize the finite shared-tail route through paired StreamName windows, DyadicRatCore tolerance, RegSeqRat readback, and the RealUp seal.

Concretized in §7612: Diagonal-limit uniqueness witnesses realize the paired diagonal-representative comparison route as finite StreamName, RegSeqRat, DyadicRatCore, CauchyLimitSeal, RealUp, hsame, Cont, Pkg, and NameCert rows.

Concretized in §7983: Located real spread packets realize the Real-completeness diagonal route as finite located-window, dyadic-tail, RegSeqRat readback, StreamName, RealUp, hsame, Cont, Pkg, and NameCert rows.

Concretized in §8218: Real completeness density windows realize explicit dyadic approximation windows before RegSeqRat and RealUp seal reads.

Concretized in §8426: Finite-window subcovers realize the Real-completeness route through explicit StreamName windows, RegSeqRat readbacks, DyadicRatCore tolerances, and RealUp seal rows.

Concretized in §774: Finite Bairstow root-window packets realize polynomial coefficient windows, quadratic-factor updates, residual budgets, dyadic brackets, RegSeqRat readback, BisectionRootCauchySeal, and RealUp handoff rows.

Concretized in §8663: Real completion diagonal routers realize the finite precision-window route from StreamName and RegSeqRat data through DyadicRatCore readback to the RealUp seal.

Concretized in §9042: Real prefix diagonal packets realize the finite prefix-window diagonal route through StreamName, RegSeqRat, DyadicRatCore, and RealUp seal rows.

Concretized in §9172: Real tail-budget handoffs realize the Real-completeness route as finite precision-request, explicit-modulus, tail-budget, StreamName, DyadicRatCore, RegSeqRat, RealUp, hsame, Cont, Pkg, and NameCert rows.

Chapter 9239

The Riemann Hypothesis as a BEDC Conjecture

This capstone formally states the Riemann Hypothesis inside BEDC's distinction-foundationalist framework, using only the naming certificates and operations licensed in the dependency chain spanning LEVEL 1 (the arithmetic certificates $\mathsf{NameCert}_{\mathsf{Nat}^\uparrow}$, $\mathsf{NameCert}_{\mathsf{Int}^\uparrow}$, $\mathsf{NameCert}_{\mathsf{Rat}^\uparrow}$, $\mathsf{NameCert}_{\mathsf{Prime}^\uparrow}$), LEVEL 2 (the analytic certificates $\mathsf{NameCert}_{\mathsf{Real}^\uparrow}$, $\mathsf{NameCert}_{\mathsf{CFun}^\uparrow}$, $\mathsf{NameCert}_{\mathsf{Met}^\uparrow}$ together with the regular Cauchy completion of chapter 9238), LEVEL 3 (the complex-analytic limit and convergence-radius certificates $\mathsf{NameCert}_{\mathsf{CplxLim}^\uparrow}$ and $\mathsf{NameCert}_{\mathsf{ConvRad}^\uparrow}$), LEVEL 4 (the holomorphy package $\mathsf{NameCert}_{\mathsf{CplxDiff}^\uparrow}$, $\mathsf{NameCert}_{\mathsf{Holomorphic}^\uparrow}$, $\mathsf{NameCert}_{\mathsf{Contour}^\uparrow}$, $\mathsf{NameCert}_{\mathsf{AnaCont}^\uparrow}$), and LEVEL 5 (the Dirichlet and zeta package $\mathsf{NameCert}_{\mathsf{CplxSer}^\uparrow}$, $\mathsf{NameCert}_{\mathsf{Dirichlet}^\uparrow}$, $\mathsf{NameCert}_{\mathsf{ZetaBasic}^\uparrow}$, $\mathsf{NameCert}_{\mathsf{ZetaCont}^\uparrow}$, $\mathsf{NameCert}_{\mathsf{CritStrip}^\uparrow}$, $\mathsf{NameCert}_{\mathsf{ZetaZeros}^\uparrow}$). The chapter does not prove the Riemann Hypothesis. Its purpose is fivefold. First, it makes the conjecture precise as a single BEDC statement-level Lean target. Second, it traces the LEVEL 1 through LEVEL 5 dependency chain explicitly so that the chain of constructive obligations is visible at a glance. Third, it catalogs the witness types that any constructive proof inside BEDC would have to produce. Fourth, it discusses axiom-purity considerations: any RH proof would have to remain inside the BEDC fragment that uses no Classical.choice, no Quot.sound, and no propext, or else expose explicitly the points at which it leaves the framework. Fifth, it connects the conjecture to existing partial BEDC results. A constructive proof of RH is, by Curry-Howard, a function that takes any complex history s in the critical strip with $\zeta(s) = 0$ and produces an explicit witness that $\Re(s) = 1/2$; equivalently, a constructive disproof would produce an explicit s realizing $\mathsf{ZetaZero}(s)$ and $\mathsf{InCritStrip}(s)$ and $\neg\mathsf{OnCritLine}(s)$ as distinct concrete histories. Whether RH is provable inside this fragment is itself an open question, and articulating that open question precisely is the only contribution this capstone makes.

9239.1 LEVEL 1–5 dependency chain

The dependency chain of the conjecture is laid out explicitly here, level by level, because the constructive content of the statement depends on every layer above it. Each level is given as a remark naming the supporting certificates, the responsible chapters, the current closure status (closed ✓, pending □, scaffold-only ∘), and the specific contribution of each chapter to the RH statement.

Remark 9239.1 (LEVEL 1: arithmetic foundation, status ✓/□)**.** *The naming certificates* $\mathsf{NameCert}_{\mathsf{Nat}^\uparrow}$ *(chapter 28),* $\mathsf{NameCert}_{\mathsf{Int}^\uparrow}$*, and* $\mathsf{NameCert}_{\mathsf{Rat}^\uparrow}$ *(chapter 37) form the checked arithmetic base.*

They supply the generators on which every later layer is built: $\mathsf{Nat}^\uparrow$ *provides indexing for series,* $\mathsf{Int}^\uparrow$ *provides signed exponents, and* $\mathsf{Rat}^\uparrow$ *provides the dense subfield needed for the regular Cauchy completion of* $\mathsf{Real}^\uparrow$*. The certificate* $\mathsf{NameCert}_{\mathsf{Prime}^\uparrow}$ *(chapter 64) remains an open arithmetic certificate until its semantic naming certificate carries* $\mathsf{TheoryGate}(\mathsf{Prime}^\uparrow, \mathsf{scopedClosed})$ *at* $\mathsf{FormalStatus}(\mathsf{Prime}^\uparrow, \mathsf{theoremChecked})$*; once both axes hold, it supplies the index set of the Euler product* $\zeta(s) = \prod_p (1 - p^{-s})^{-1}$*.*

Remark 9239.2 (LEVEL 2: real analysis, status □)**.** *The certificate* $\mathsf{NameCert}_{\mathsf{Real}^\uparrow}$ *(chapter 38) is in place pointwise; its completion to a regular Cauchy carrier is the subject of chapter 9238 and remains a pending capstone. The certificates* $\mathsf{NameCert}_{\mathsf{CFun}^\uparrow}$ *and* $\mathsf{NameCert}_{\mathsf{Met}^\uparrow}$ *depend on* $\mathsf{Real}^\uparrow$ *for their distance and convergence structure. RH inherits the constructive content of the real completion: every* $\zeta(s)$ *value inside the critical strip is, ultimately, a regular Cauchy sequence over* $\mathsf{Rat}^\uparrow$ *with an explicit modulus.*

Remark 9239.3 (LEVEL 3: complex limit and radius, status ○)**.** *The certificates* $\mathsf{NameCert}_{\mathsf{CplxLim}^\uparrow}$ *(chapter 65) and* $\mathsf{NameCert}_{\mathsf{ConvRad}^\uparrow}$ *(chapter 66) are scaffolds awaiting elaboration. They lift the regular Cauchy machinery from* $\mathsf{Real}^\uparrow$ *to* $\mathsf{Complex}^\uparrow$*, and they fix what it means for a complex power series to converge with an explicit modulus. RH needs both: zeta-as-Dirichlet-series converges in* $\Re(s) > 1$*, and the analytic continuation past* $\Re(s) = 1$ *requires a complex-limit notion that is constructively well-behaved in the critical strip.*

Remark 9239.4 (LEVEL 4: holomorphy, status ○)**.** *The certificates* $\mathsf{NameCert}_{\mathsf{CplxDiff}^\uparrow}$ *(chapter 67, packaging the Cauchy-Riemann equations as a constructive predicate),* $\mathsf{NameCert}_{\mathsf{Holomorphic}^\uparrow}$ *(chapter 68, packaging holomorphy as a uniform-on-compacts version of complex differentiability),* $\mathsf{NameCert}_{\mathsf{Contour}^\uparrow}$ *(the contour-integral operation), and* $\mathsf{NameCert}_{\mathsf{AnaCont}^\uparrow}$ *(the analytic-continuation operation) are scaffolds. RH lives inside this layer:* ζ *is holomorphic on* $\mathsf{Complex}^\uparrow \setminus \{1\}$*, its zero set is invariant under contour deformation, and the critical strip is the natural domain of analytic continuation from* $\Re(s) > 1$*.*

Remark 9239.5 (LEVEL 5: Dirichlet series and zeta, status ○)**.** *The certificates* $\mathsf{NameCert}_{\mathsf{CplxSer}^\uparrow}$ *(chapter 69),* $\mathsf{NameCert}_{\mathsf{Dirichlet}^\uparrow}$ *(chapter 70),* $\mathsf{NameCert}_{\mathsf{ZetaBasic}^\uparrow}$ *(chapter 71), the* $\mathsf{NameCert}_{\mathsf{ZetaCont}^\uparrow}$ *application (chapter 9342),* $\mathsf{NameCert}_{\mathsf{CritStrip}^\uparrow}$ *(chapter 72), and* $\mathsf{NameCert}_{\mathsf{ZetaZeros}^\uparrow}$ *(chapter 73) are scaffolds. They specialize the LEVEL 4 holomorphy package to the specific function* ζ *and to the specific predicates* $\mathsf{InCritStrip}$, $\mathsf{ZetaZero}$, $\mathsf{OnCritLine}$ *that appear in the conjecture. The RH statement of Definition 9239.7 is a single quantification over the histories carried by* $\mathsf{NameCert}_{\mathsf{ZetaZeros}^\uparrow}$*.*

Concretized in §72: The critical-strip dependency in the RH formulation is realized as the finite $\mathsf{CritStrip}^\uparrow$ NameCert surface.

Remark 9239.6 (Reading the chain)**.** *Each level depends only on the levels strictly below it. The dependency is acyclic; the order in which a constructive RH proof must be assembled is exactly the order of Definition 9239.1 through Definition 9239.5. No level can be skipped. The closure status column makes visible the current obligation: LEVEL 1 has a closed* $\mathsf{Nat}^\uparrow/\mathsf{Int}^\uparrow/\mathsf{Rat}^\uparrow$ *base with* $\mathsf{Prime}^\uparrow$ *still pending, LEVEL 2 is one capstone away from closure, and LEVELs 3 through 5 are scaffolds whose elaboration is the bulk of the work between this capstone and a finished RH statement.*

9239.2 Formal statement of RH in BEDC

Definition 9239.7 (RH predicate)**.** *The Riemann Hypothesis* RH *is the proposition that for every complex history* s *carried by* $\mathsf{NameCert}_{\mathsf{Complex}^\uparrow}$ *such that* $\mathsf{InCritStrip}(s)$ *holds (chapter 72:* $0 <$

$\Re(s) < 1$, *presented as a constructive predicate on the regular Cauchy representative of* $\Re(s)$*) and such that* $\mathsf{ZetaZero}(s)$ *holds (chapter 73: the regular Cauchy representative of* $\zeta(s)$ *is* hsame *to the zero history of* $\mathsf{NameCert}_{\mathsf{Complex}^\uparrow}$*), the predicate* $\mathsf{OnCritLine}(s)$ *holds, where* $\mathsf{OnCritLine}(s)$ *is the constructive predicate stating that the regular Cauchy representative of* $\Re(s)$ *is* hsame *to the rational history* $1/2$*. The predicate* RH *is a* Π*-statement over the carrier of* $\mathsf{NameCert}_{\mathsf{ZetaZeros}^\uparrow}$ *restricted by* $\mathsf{NameCert}_{\mathsf{CritStrip}^\uparrow}$.

Proposition 9239.8 (Constructive form: zero-by-zero certificate)**.** *A constructive proof of* RH *is, by Curry-Howard, a total function* $\Phi : \{\, s \mid \mathsf{ZetaZero}(s) \wedge \mathsf{InCritStrip}(s) \,\} \to \{\, \textit{witness of } \mathsf{OnCritLine}(s) \,\}$ *that takes any zero of* ζ *in the critical strip and produces an explicit* hsame*-witness identifying the regular Cauchy representative of* $\Re(s)$ *with the rational history* $1/2$*. Equivalently, a constructive disproof of* RH *is an explicit complex history* s *together with three concrete witnesses* $\mathsf{ZetaZero}(s)$*,* $\mathsf{InCritStrip}(s)$*, and* $\neg\mathsf{OnCritLine}(s)$*, the last being a positive lower bound on the distance from the regular Cauchy representative of* $\Re(s)$ *to* $1/2$*.*

Remark 9239.9 (Why the constructive form is strictly stronger)**.** *A classical proof of* RH *that proceeds by contradiction (assume a zero off the critical line, derive a contradiction) does not, on its own, supply the function* Φ *of Definition 9239.8. Inside BEDC the constructive form is the only form available: by chapter 9458, the framework simulates classical reasoning by contradiction but does not entail it on existential conclusions. Any RH proof landing inside the BEDC fragment therefore has to produce* Φ *explicitly, or expose precisely where it appeals to a meta-closure move outside the fragment.*

9239.3 Carrier-stack reading

Definition 9239.10 (Top-down BEDC-RH stack)**.** *The top-down BEDC reading of the conjecture starts with the carrier containment*

$$\mathbb{Z}_\zeta \subseteq \mathbb{H}_\zeta$$

of Definition 9246.3. The ambient carrier is the pre-RH recovered zeta carrier $\mathbb{G}^0_\zeta$*, whose rows are the Dirichlet projection, Euler projection, analytic-continuation row, archimedean-completion row, functional-equation row, pole ledger, zero ledger, and branch-transport ledger of Definition 9254.13. The fixed-half subcarrier then admits the equivalent readouts*

$$\Re(s) = 1/2, \qquad J(s) = s, \qquad \forall p \in \mathsf{Prime}^\uparrow,\ |p^{1/2-s}|\mathsf{hsame1},$$

$$\delta = 0, \qquad \textit{no } e^{\delta x} \textit{ Laplace bias}, \qquad \mathsf{OnCritLine}(s),$$

as recorded in Definition 9254.10. Below these readouts sit the prime-coordinate and exponential-kernel rows, the prime-fingerprint separation row, the local finite prime-window defect rows, and the Axis-Zeckendorf finite-window laboratory used only as a bridge prototype.

Principle 9239.11 (Stack order is not proof order collapse)**.** *The stack of Definition 9239.10 is an ordering of interfaces, not a proof of* RH*. The upper containment*

$$\mathbb{Z}_\zeta \subseteq \mathbb{H}_\zeta$$

is the same target as Definition 9239.7 by Definition 9246.7. The mirror, prime-unitary, information-channel, and Laplace readings give equivalent fixed-half surfaces, but none of them proves that a zero ledger must factor through that surface. The finite Window-six and Zeckendorf layers provide auditable models of no-adjacent geometry and residual-return discipline; by Definition 9349.9, they do not construct the missing zeta-to-residual bridge by themselves.

Theorem 9239.12 (Defect incompatibility is the remaining stack hinge)**.** *Assume the located real-bias readout, the finite prime-window defect formula, source compatibility into the completed carrier, and the carrier-level row Definition 9246.13. Then the top-down stack of Definition 9239.10 supplies the BEDC-RH witness target.*

Proof. The finite prime-window defect formula turns a positive off-fixed witness into a positive finite prime-window radial defect. Source compatibility and completion place that defect in the same completed zeta carrier row as the zero ledger. Applying Definition 9246.13 yields $\mathsf{Apart}_0(\zeta(s))$. This is the local-global zero exclusion output assembled in Definition 9246.20. Its contradiction with a zero-ledger witness gives the fixed-half section target, hence the BEDC-RH witness target by Definition 9254.4. □

9239.4 Witness types a proof would produce

A constructive proof of RH exposes constructive content beyond the bare conjunction. The witness types below catalog this content as Lean statement-level targets that any RH proof would have to discharge or supply. Each is a refinement or corollary of Definition 9239.8.

Theorem 9239.13 (Modulus from zero-on-strip to half)**.** *A constructive proof of* RH *supplies, for every* s *with* $\mathsf{ZetaZero}(s) \wedge \mathsf{InCritStrip}(s)$*, an explicit modulus function* $\mu_s : \mathsf{Nat}^{\uparrow} \to \mathsf{Nat}^{\uparrow}$ *such that for every* n*, the rational representative* q_n *of* $\Re(s)$ *at depth* $\mu_s(n)$ *satisfies* $|q_n - 1/2| < 2^{-n}$ *as a* $\mathsf{Rat}^{\uparrow}$*-level inequality. The function* μ_s *is the constructive content of the* hsame*-witness for* $\Re(s) = 1/2$*.*

Concretized in §548: Critical-line witness packets realize the RH constructive witness type as finite rows over $\mathsf{ZetaZeros}^{\uparrow}$, $\mathsf{CritStrip}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{Rat}^{\uparrow}$, hsame, Cont, Pkg, and $\mathsf{NameCert}$.

Theorem 9239.14 (Approach-rate bound near the critical line)**.** *A compact-window strengthening of a constructive* RH *route may expose a height-local bound*

$$\beta : \mathsf{Nat}^{\uparrow} \times \mathsf{Nat}^{\uparrow} \to \mathsf{Rat}^{\uparrow}$$

with $\beta(n, T) > 0$ *such that every complex history* s *in the critical strip with* $|\Im(s)| \leq T$ *and* $|\Re(s) - 1/2| > 2^{-n}$ *has a constructive lower bound*

$$|\zeta(s)| \geq \beta(n, T).$$

The height parameter is part of the statement: compactness applies to the displayed window only. A height-uniform global $\beta(n)$ *would be an additional analytic barrier stronger than the bare RH witness and is not treated here as an ordinary output of a proof of* RH*.*

Concretized in §705: Critical-strip barrier packets realize the RH approach-rate witness as finite zero-localization, rational lower-bound, transport, route, package, and NameCert rows.

Theorem 9239.15 (Riemann-von Mangoldt zero count, prerequisite ledger)**.** *An unconditional analytic prerequisite ledger may provide an explicit zero-counting function* $N : \mathsf{Nat}^{\uparrow} \to \mathsf{Nat}^{\uparrow}$ *together with a witness, for every imaginary height* $T \in \mathsf{Nat}^{\uparrow}$*, of a* Unary *upper bound on the cardinality of* $\{\, s \mid \mathsf{ZetaZero}(s) \wedge \mathsf{InCritStrip}(s) \wedge |\Im(s)| \leq T \,\}$ *that agrees, up to an explicit constructive error term, with the Riemann-von Mangoldt formula* $N(T) \approx (T/2\pi)\log(T/2\pi) - T/2\pi$*. This belongs to a complete zeta formalization, not to the Curry-Howard witness for* RH *itself.*

Concretized in §573: Riemann zero-count ledgers realize the unconditional height-window, zero-list, unary-count, error-ledger, and NameCert rows supporting a complete zeta formalization.

Theorem 9239.16 (Trivial-zero classifier, supporting chapter)**.** *The trivial-zero classifier is an unconditional support row: the negative even integers $-2, -4, -6, \ldots$ are classified through the functional equation and the arithmetic of negative even integer inputs, independently of* RH*. The classifier takes the form of a* psame*-respecting predicate on* $\mathsf{NameCert}_{\mathsf{ZetaZeros}^\uparrow}$ *such that the trivial-zero subset is exactly the image of the negative-even-integer carrier under the embedding* $\mathsf{Int}^\uparrow \hookrightarrow \mathsf{Complex}^\uparrow$*. The RH predicate then consumes the non-trivial zero interface after this separation is already in place.*

Concretized in §999: Trivial-zero classifiers are realized as unconditional finite negative-even-integer, zeta-zero, real-part, rational-comparison, hsame, Cont, Pkg, and NameCert rows.

Theorem 9239.17 (Critical-line restriction of the zero set)**.** *A constructive proof of* RH *supplies a* psame*-isomorphism between the carrier of* $\{\, s \mid \mathsf{ZetaZero}(s) \wedge \mathsf{InCritStrip}(s) \,\}$ *and the carrier of* $\{\, t \in \mathsf{Real}^\uparrow \mid \mathsf{ZetaZero}(1/2 + it) \,\}$*, exhibiting that every non-trivial zero is determined by its imaginary part alone. The isomorphism is the conjunction of* Φ *from Definition 9239.8 with the projection to imaginary part.*

9239.5 Axiom-purity considerations

The supporting chapters of LEVELs 1 through 5 are required to remain axiom-pure in the BEDC sense: no use of Classical.choice, no use of Quot.sound, no use of propext. Any RH statement-level target sits on top of this entire stack, so the same gate applies to it transitively. Three outcomes are mathematically meaningful, and the RH roadmap distinguishes them as the only three things a constructive engagement with the conjecture can land on.

Remark 9239.18 (Outcome (i): RH is provable in the fragment)**.** *A construction* Φ *of Definition 9239.8 is exhibited inside BEDC and the entire dependency chain runs under* check-axioms.py *and* bedc_ci.py axiom-purity --strict *without flagging any stdlib axiom. This is the strongest possible outcome and would constitute a genuine constructive proof of RH.*

Remark 9239.19 (Outcome (ii): independence inside the fragment)**.** *A meta-theorem is exhibited stating that neither* RH *nor* $\neg$RH *is provable in the BEDC fragment. This outcome would not require the supporting chapters to leave axiom-purity but would require a meta-level layer above the kernel. By chapter 9461, that meta layer is structurally available, and the independence statement would be a meta-level* `leanstmt` *record, not a closure of* RH *at the kernel level. This is the "schema-only horizon" outcome: BEDC exposes the conjecture as an interface that codifies the constructive content but admits no closed witness inside the framework.*

Remark 9239.20 (Outcome (iii): explicit constructive counterexample)**.** *A specific complex history* s_0 *is exhibited together with explicit witnesses* $\mathsf{ZetaZero}(s_0)$*,* $\mathsf{InCritStrip}(s_0)$*, and a positive* $\mathsf{Rat}^\uparrow$*-level lower bound on* $|\Re(s_0) - 1/2|$*. By Definition 9239.8, this is the constructive disproof. It would settle RH negatively, and unlike a classical disproof it would carry the actual offending zero as data.*

Remark 9239.21 (The fragment may not decide which outcome)**.** *The BEDC fragment is constructive and axiom-pure; it is not, in general, complete. By Definition 9461.18, the open meta loop of the framework guarantees that some statements over BEDC primitives are formally undecidable inside the fragment. Whether* RH *is one such statement is itself open. Articulating this open question is the purpose of the present capstone.*

9239.6 Connection to existing BEDC content

Remark 9239.22 (Reasoning by contradiction in RH)**.** *chapter 9458 establishes that BEDC reasoning by contradiction has a boundary: refutation of a false existence claim by exhibited counterexample stays inside the closed ground loop and is accepted, but proof of an existence statement by contradiction is not. The classical literature on RH is full of contradiction arguments. A BEDC translation of any such argument has to respect this boundary: refutational content stays, but any existence conclusion has to be replaced by an explicit witness or recategorized as a meta-closure move that exits the fragment.*

Remark 9239.23 (Reflection and limits)**.** *chapter 9461 fixes the level structure: the BEDC kernel lives at the ground, the meta layer describes the kernel from above, and Tarski undefinability prevents the meta layer from closing. The conjecture* RH *lives at the kernel level. Any proof of* RH *is a kernel-level theorem. Any meta-theorem about the provability of* RH *inside the fragment (Definition 9239.19) lives at the meta level. The two are different artifacts and do not collapse into one another; conflating them would be a Tarski-undefinability move and is forbidden by the framework.*

Remark 9239.24 (Real completeness dependency)**.** *chapter 9238 is the immediate prerequisite of LEVEL 2 closure. Every $\zeta(s)$ value inside the critical strip is, ultimately, a regular Cauchy sequence over* $\mathsf{Rat}^{\uparrow}$*, and the closure of chapter 38 into a complete carrier through that capstone is what licenses talking about ζ-values and zeros at all in the constructive sense. RH inherits the constructive content of the real completion: until the regular Cauchy completion of* $\mathsf{Real}^{\uparrow}$ *closes, the RH statement of Definition 9239.7 type-checks but is not yet inhabitable in any nontrivial way.*

Remark 9239.25 (Curry-Howard placement)**.** *The constructive form of Definition 9239.8 is what Curry-Howard buys at the BEDC fragment level:* RH *as a Π-type, a proof as a function, a disproof as a sigma-type witness. This is the same Curry-Howard discipline applied in every other concrete-instance certificate of LEVELs 1 through 5. RH is special only in that the inhabiting function or sigma-witness is conjectured but not yet supplied; the typing is identical to every other constructive statement in the manuscript.*

9239.7 Roadmap and scope

This capstone is a roadmap, not a proof. The conjecture RH has been stated as Definition 9239.7 and refined to its constructive form as Definition 9239.8; the witness types of Definition 9239.13 through Definition 9239.17 catalog the constructive content any proof would expose; the dependency chain of section 9239.1 fixes the order in which the supporting concrete-instance chapters must close before the RH statement can be inhabited; and section 9239.5 fixes the three mathematically meaningful outcomes inside the BEDC fragment. The supporting LEVEL 3 through LEVEL 5 chapters are scaffolds awaiting codex pipeline elaboration. A rough scale estimate: twelve concrete-instance chapters across LEVELs 3, 4, and 5, each carrying eight to twelve Lean targets, totaling on the order of one hundred and twenty new theorems plus the RH statement-level targets of the present capstone. Even when the entire scaffold is closed and the chain is fully formalized, the Riemann Hypothesis remains the foundation for a future research program rather than a finished result; the roadmap clarifies what such a program would have to produce, in what order, and under what axiom-purity constraints. The chapter uses no Classical.choice, no Quot.sound, and no propext; whether RH itself is provable inside this fragment is part of what this roadmap is intended to clarify.

Concretized in §550: Critical-strip zeta-zero witness packets realize the RH capstone as a finite NameCert obligation surface.

Concretized in §659: Non-trivial zero classifiers are realized as finite ZetaZerosUp/CritStripUp boundary packets separating critical-strip zero witnesses from trivial-zero rows without host zero-set quotients.

Concretized in §521: Contour-integral operation packets realize the RH holomorphy dependency as piecewise-linear contour rows, Riemann-sum ledgers, operation-law rows, hsame transport, Cont replay, Pkg provenance, and NameCert data.

Chapter 9240

Three Boundaries for RH

chapter 9239 states RH as a constructive function from certified critical-strip zero packets to OnCritLine witnesses. The nearby RH chapters also use the functional-equation mirror, prime-unitary channels, finite prime windows, and route-closure boundaries. The present chapter fixes the separation between three objects that should not be conflated: the geometric critical line, an exact zero decision operator, and the global rigidity statement called RH.

Definition 9240.1 (Mirror fixed surface)**.** *The functional-equation mirror is*

$$J(s) := 1 - \overline{s}.$$

The geometric boundary is the fixed surface

$$\mathsf{GeomBoundary}_\zeta := \mathrm{Fix}(J) := \sum_s J(s) \sim s.$$

Equivalently, the pointwise predicate $\mathsf{CritLine}(s)$ *is* $J(s) \sim s$*.*

Lean4 (definition) `BEDC.Derived.RHRoute.FunctionalEquationSymmetry.reflectJ`
Lean4 (definition) `BEDC.Derived.RHRoute.FunctionalEquationSymmetry.JFixed`
Lean4 (definition) `BEDC.Derived.RHRoute.FunctionalEquationSymmetry.CriticalLine`

Lemma 9240.2 (The mirror fixed surface is the critical line)**.** *For every complex history* s*,*

$$J(s) \sim s \quad \Longleftrightarrow \quad \Re(s) \sim_{\mathsf{Real}^\uparrow} 1/2.$$

Proof. Write $s = \sigma + it$. Then

$$J(s) = 1 - \overline{s} = 1 - \sigma + it.$$

Thus $J(s) \sim s$ is equivalent to equality of real parts

$$1 - \sigma \sim \sigma,$$

which is equivalent to $\sigma \sim 1/2$. The imaginary component is unchanged by the calculation. This is the same fixed-point computation used in Definition 9241.12. □

Lean4 ✓ `BEDC.Derived.RHRoute.FunctionalEquationSymmetry.J fixed iff re half`

Definition 9240.3 (Certified zero predicate and exact zero decider)**.** *The certified zeta-zero predicate is the packet*

$$\mathsf{ZetaZero}(s) := \sum_z \big(\mathsf{ZetaVal}(s,z) \times z \sim_{\mathsf{Complex}^\uparrow} 0\big),$$

read through the recovered zeta carrier and its continuation, branch, transport, and zero-ledger rows. The exact zero decision operator is the stronger object

$$\mathsf{ZeroDecider}_\zeta := \prod_s \mathsf{Decidable}\big(\mathsf{ZetaZero}(s)\big).$$

The first object is a certificate-bearing predicate; the second is a total decision procedure for that predicate on all complex histories.

Definition 9240.4 (Rigidity boundary)**.** *The rigidity boundary is the RH proposition*

$$\mathsf{RigidityBoundary}_\zeta := \prod_s \big(\mathsf{ZetaZero}(s) \times \mathsf{InCritStrip}(s) \to \mathsf{OnCritLine}(s)\big).$$

Equivalently, it asserts that the support of the certified non-trivial zero predicate factors through $\mathrm{Fix}(J)$*.*

Theorem 9240.5 (Three-boundary separation)**.** *The geometric boundary* $\mathrm{Fix}(J)$*, the exact zero decision operator* $\mathsf{ZeroDecider}_\zeta$*, and the rigidity boundary* $\mathsf{RigidityBoundary}_\zeta$ *are distinct kinds of data.*

Proof. The geometric boundary is defined only from the mirror map J and the complex-history structure. By Definition 9240.2, it is the critical line, and it does not mention $\mathsf{ZetaZero}$.

The exact zero decision operator has type

$$\prod_s \mathsf{Decidable}\big(\mathsf{ZetaZero}(s)\big).$$

It must decide, for every complex history, whether a certified zero packet exists. This is stronger than the certified zero predicate itself, which only records evidence when a zero packet is supplied.

The rigidity boundary has type

$$\prod_s \big(\mathsf{ZetaZero}(s) \times \mathsf{InCritStrip}(s) \to \mathsf{OnCritLine}(s)\big).$$

It does not decide whether arbitrary histories are zeros. It consumes an already certified critical-strip zero packet and returns a fixed-surface witness. Hence the three objects have different inputs, outputs, and proof obligations. □

Corollary 9240.6 (The critical line is the target fixed surface)**.** *The critical line is available before the RH proposition is stated. RH is the assertion that the certified non-trivial zero support lands in that fixed surface:*

$$\mathrm{Supp}(\mathsf{ZetaZero} \times \mathsf{InCritStrip}) \subseteq \mathrm{Fix}(J).$$

Proof. The fixed surface is defined in Definition 9240.1. The RH predicate of Definition 9239.7 is the map from a certified critical-strip zero packet to $\mathsf{OnCritLine}(s)$, and Definition 9240.2 identifies that output with membership in $\mathrm{Fix}(J)$. □

Definition 9240.7 (Prime-unitary readout boundary)**.** *For $a > 1$, define the centered channel*

$$U_a(s) := a^{1/2-s}.$$

For displayed prime rows, the prime-unitary readout is

$$\mathsf{PrimeUnitary}(s) := \prod_{p:\mathsf{Prime}^{\uparrow}} (|U_p(s)|\mathsf{hsame1}).$$

Theorem 9240.8 (Prime-unitary balance is a critical-line readout)**.** *For every displayed $a > 1$,*

$$|a^{1/2-s}| = 1 \quad \Longleftrightarrow \quad \Re(s) = 1/2.$$

Consequently, $\mathsf{PrimeUnitary}(s)$ *is equivalent to* $\mathsf{OnCritLine}(s)$ *on the displayed prime packet.*

Proof. Write $s = \sigma + it$. Then

$$a^{1/2-s} = a^{1/2-\sigma-it} = a^{1/2-\sigma}a^{-it}.$$

The factor a^{-it} has modulus one, so

$$|a^{1/2-s}| = a^{1/2-\sigma}.$$

For $a > 1$, this modulus is one exactly when $1/2 - \sigma = 0$, namely $\Re(s) = 1/2$. The prime-indexed version is Definition 9243.7. □

Principle 9240.9 (Prime-unitary balance is not the RH mechanism)**.** *Prime-unitary balance is an exact readout of the critical line, not by itself a proof mechanism for RH. The calculation of Definition 9240.8 works for every displayed $a > 1$ and therefore does not use zero ledgers, Euler-product support, finite-window residual control, or any incompatibility between an off-line zero packet and the recovered zeta carrier. It becomes RH-facing only when connected to certified non-trivial zero packets by additional bridge data.*

Definition 9240.10 (Finite prime imbalance bridge)**.** *A finite prime imbalance certificate*

$$\mathsf{FinitePrimeImbalanceCert}(s, W)$$

records that a finite prime window W constructively observes a nonzero deviation of s from the fixed-half surface. A tail bound

$$\mathsf{TailBound}(W, s)$$

records that the prime or zeta residual outside W is controlled by an explicit modulus and cannot hide a cancellation of the finite defect.

An RH bridge is the displayed equivalence

$$\mathsf{RHBridge} := \prod_s \left(\mathsf{OffLineZeroCert}(s) \simeq \sum_W (\mathsf{FinitePrimeImbalanceCert}(s, W) \times \mathsf{TailBound}(W, s)) \right),$$

where

$$\mathsf{OffLineZeroCert}(s) := \mathsf{ZetaZero}(s) \times \mathsf{InCritStrip}(s) \times \neg\mathsf{OnCritLine}(s).$$

Theorem 9240.11 (Finite imbalance bridge gives the contradiction route)**.** *Assume* RHBridge*, a finite-window incompatibility row*

$$\prod_{s,W} (\mathsf{ZetaZero}(s) \times \mathsf{FinitePrimeImbalanceCert}(s, W) \times \mathsf{TailBound}(W, s) \to \bot),$$

and a located critical-line classifier

$$\prod_{s} (\mathsf{OnCritLine}(s) + \neg\mathsf{OnCritLine}(s)).$$

Then the BEDC RH predicate is inhabited.

Proof. Fix s with

$$\mathsf{ZetaZero}(s) \times \mathsf{InCritStrip}(s).$$

Apply the located critical-line classifier. If it gives $\mathsf{OnCritLine}(s)$, the required witness is present. Otherwise the zero packet, critical-strip packet, and non-line witness form $\mathsf{OffLineZeroCert}(s)$. By RHBridge, this yields a finite window W with

$$\mathsf{FinitePrimeImbalanceCert}(s, W) \times \mathsf{TailBound}(W, s).$$

Together with $\mathsf{ZetaZero}(s)$, the finite-window incompatibility row gives $\bot$. Hence the non-line branch is impossible, and the surviving branch supplies $\mathsf{OnCritLine}(s)$. □

Principle 9240.12 (Axiom footprint is not a necessity lower bound)**.** *A Lean axiom printout for one implementation path records that path's dependency footprint. It does not quantify over all possible implementations and therefore does not show that zeta, zero predicates, or RH carry a mathematical need for* Classical.choice*,* Quot.sound*, or* propext*. In the BEDC discipline, any use of those constants is an exposed implementation dependency, while the RH target remains the axiom-pure construction of a uniform witness*

$$\Phi : \{\, s \mid \mathsf{ZetaZero}(s) \wedge \mathsf{InCritStrip}(s) \,\} \to \{\, \mathsf{OnCritLine}(s) \ \textit{witness} \,\}.$$

Concretized in §8864: The geometric critical-line surface, certified zero predicate, and RH rigidity boundary are separated as finite NameCert rows.

Concretized in §8868: finite critical-strip window certificate separating mirror geometry from exact zero decision and global RH rigidity

Chapter 9241

The RH Zero–Skew EventFlow Target

chapter 9239 states the Riemann Hypothesis as a constructive Π-statement: a proof consumes a critical-strip zeta-zero witness and returns an $\mathsf{OnCritLine}$ witness. The present chapter records the same obligation at the compiler-facing event-flow layer. It does not add a proof of RH. It identifies which rows are already recoverable from the zeta-continuation and functional-equation ledgers, which rows are supplied by the critical-strip zero witness packet, and which row is still the missing RH witness.

9241.1 Zero and skew packets

Definition 9241.1 (RH zero code)**.** *An* RH zero code *for a complex history s is a finite packet containing the displayed rows*

$$s, \quad \mathsf{ZetaCont}(s), \quad \mathsf{hsame}(\mathsf{ZetaCont}(s), 0_{\mathbb{C}}), \quad \mathsf{InCritStrip}(s),$$
$$H, \quad C, \quad P, \quad N.$$

The rows H, C, P, N record componentwise transport, continuation replay, package provenance, and local naming. The packet is not a host-side element of a zero set. It is a finite BEDC read of a zeta-zero premise through the $\mathsf{ZetaCont}^{\uparrow}$, $\mathsf{ZetaZeros}^{\uparrow}$, and $\mathsf{CritStrip}^{\uparrow}$ surfaces.

Definition 9241.2 (RH skew-zero code)**.** *For the same complex history s, the associated* RH skew-zero code *is a finite packet containing*

$$s, \quad \Re(s), \quad 1/2, \quad \delta(s) = \Re(s) - 1/2, \quad 0_{\mathbb{R}},$$
$$\mathsf{hsame}(\delta(s), 0_{\mathbb{R}}), \quad H, \quad C, \quad P, \quad N.$$

Thus the skew-zero packet is the critical-line witness written as a real offset from the line rather than as a direct equality $\Re(s) = 1/2$.

Proposition 9241.3 (Zero–skew form of RH)**.** *The BEDC statement RH of Definition 9239.7 is equivalent to the existence of a total transformer*

$$\Phi_{\mathsf{RH}} : \prod_{s} \mathsf{ZeroCode}_{\mathsf{RH}}(s) \to \mathsf{SkewZeroCode}_{\mathsf{RH}}(s).$$

Proof. By Definition 9239.7, the premise of RH is exactly the displayed conjunction $\mathsf{ZetaZero}(s) \wedge \mathsf{InCritStrip}(s)$, read through the zeta-zero and critical-strip packets. This is the semantic content of $\mathsf{ZeroCode}_{\mathsf{RH}}(s)$. The conclusion $\mathsf{OnCritLine}(s)$ says that the real component of s is hsame to

the rational half. Equivalently, the skew $\delta(s) = \Re(s) - 1/2$ is hsame to $0_{\mathbb{R}}$, which is precisely the additional row carried by $\mathsf{SkewZeroCode}_{\mathsf{RH}}(s)$. Under the Curry–Howard reading, an inhabitant of RH is therefore exactly a total function from the first packet type to the second packet type, uniformly in s. □

9241.2 EventFlow reading

Definition 9241.4 (RH zero event flow)**.** *An* RH zero event flow *for s is an event flow $S_0(s)$ together with a generated recognizer flow R_0 such that the judgment*

$$\mathsf{RecognizesZeroCode}(R_0, S_0(s), s)$$

holds. The recognized roles of $S_0(s)$ include a complex-history row for s, a recovered $\mathsf{ZetaCont}^{\uparrow}$ value row, an evaluation route for $\mathsf{ZetaCont}(s)$, a complex-zero row, an hsame row identifying the value with $0_{\mathbb{C}}$, an $\mathsf{InCritStrip}(s)$ row, and the H, C, P, N provenance rows.

Lean isolates the skew substrate with
Lean4 (definition) `BEDC.Derived.RHRoute.EventflowCertificate.SkewBalanceRow`
,
Lean4 (definition) `BEDC.Derived.RHRoute.EventflowCertificate.zero skew`
, and
Lean4 (definition) `BEDC.Derived.RHRoute.EventflowCertificate.zero skew eventflow`
. The finite-balance zero case is checked by
Lean4 ✓ `BEDC.Derived.RHRoute.EventflowCertificate.zero skew nil`
.

Definition 9241.5 (RH skew event flow)**.** *An* RH skew event flow *for s is an event flow $S_{\mathrm{skew}}(s)$ together with a generated recognizer flow R_{skew} such that*

$$\mathsf{RecognizesSkewZero}(R_{\mathrm{skew}}, S_{\mathrm{skew}}(s), s)$$

holds. The recognized roles include the real-part extraction row, the rational half row, the skew row $\delta(s) = \Re(s) - 1/2$, the real-zero row, the $\mathsf{hsame}(\delta(s), 0_{\mathbb{R}})$ row, and the same H, C, P, N support rows.

9241.3 Channel and recognition boundary

Proposition 9241.6 (Terminators are not zero records)**.** *The channel glyph pair* 11 *is only the event terminator of Definition 9208.2. It is not a complex zero, not a real zero, not a zeta zero, and not a proof row.*

Proof. By Definition 9208.3, a raw event w is encoded as

$$\mathsf{Ev}(w) = \zeta(w)\,11.$$

By Definition 9208.6, the body $\zeta(w)$ contains no adjacent 11, so the decoder reads the first adjacent 11 only as the end of the current raw event. The empty raw event already satisfies $\mathsf{Ev}(\epsilon) = 11$, which shows that the glyph pair alone cannot carry a zeta-zero reading. A zero reading requires a decoded event flow together with a generated recognizer judgment such as $\mathsf{RecognizesZeroCode}(R_0, S_0(s), s)$. □

Corollary 9241.7 (Terminator count is event count)**.** *If an RH zero event flow contains n raw events, then its legal channel encoding contains n event terminators. This count is a count of encoded event boundaries, not a count of zeta zeros.*

Proof. The flow encoding of Definition 9208.9 appends one terminator to each raw event and no terminator outside the event encodings. Thus the number of terminators is the number of raw events in the decoded flow. The zeta-zero reading is attached only to the whole recognized packet, not to each terminator. □

Proposition 9241.8 (Channel decodability is not self-reference)**.** *The bijection*

$$\mathsf{EventFlow} \cong \mathsf{LegalZStream}$$

of Definition 9208.19 is a unique-decodability result, not a self-reference principle.

Proof. The round-trip theorem

$$\mathsf{Decode}(\mathsf{Compile}(S)) = \mathsf{some}(S)$$

asserts that event boundaries can be recovered from a legal channel stream. It does not assert that the stream recognizes, compiles, proves, or interprets itself. Self-reference would require a semantic judgment at the recognizer or compiler layer, for example a recognized compiler flow whose behavior is related to its own event-flow code. The terminator 11 supplies only channel-level punctuation. □

Proposition 9241.9 (Display glyphs are not mathematical zeros)**.** *The displayed glyph* 0 *in the GroundCompiler alphabet is not* $0_{\mathbb{C}}$*, not* $0_{\mathbb{R}}$*, not a natural-number zero, and not a zeta-zero assertion.*

Proof. Definition 9207.1 fixes 0 and 1 as presentation glyphs for the two raw marks. The display convention does not interpret a glyph as a number, truth value, theorem, or analytic value. A complex-zero row or real-zero row appears only after a source-level recognizer assigns that role to an event flow and the corresponding certificate rows are accepted. Therefore the RH target is not a glyph-level implication $0 \to 0$; it is the recognized semantic implication from a complex-value zero row to a real-skew zero row. □
